More than one grouping variable can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if Smoker is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array \{Gender, Smoker\}
divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: \{Gender, Smoker\}

\section*{Data Types}
single | double | logical | cell | char

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: fitdist(x,'Kernel', 'Kernel', 'triangle') fits a kernel distribution object to the data in x using a triangular kernel function.

\section*{'Censoring' - Logical flag for censored data}

0 (default) | vector of logical values
Logical flag for censored data, specified as the comma-separated pair consisting of 'Censoring' and a vector of logical values that is the same size as input vector x . The value is 1 when the corresponding element in \(x\) is a right-censored observation and 0 when the corresponding elements is an exact observation. The default is a vector of 0 s , indicating that all observations are exact.
fitdist ignores any NaN values in this censoring vector. Additionally, any NaN values in X or the frequency vector causes fitdist to ignore the corresponding values in the censoring vector.

\section*{Data Types}
logical

\section*{'Frequency' - Observation frequency}

1 (default) | vector of nonnegative integer values
Observation frequency, specified as the comma-separated pair consisting of 'Frequency ' and a vector of nonnegative integer values

\section*{fitdist}
that is the same size as input vector \(x\). Each element of the frequency vector specifies the frequencies for the corresponding elements in \(x\). The default is a vector of 1 s , indicating that each value in X only appears once.
fitdist ignores any NaN values in this frequency vector are ignored by the fitting calculations. Additionally, any NaN values in X or the censoring vector causes fitdist to ignore the corresponding values in the frequency vector.

\section*{Data Types}
logical

\section*{'Options' - Control parameters}
structure
Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of 'Options' and a structure you create using statset.

\section*{Data Types \\ struct}

\section*{'NTrials' - Number of trials}
positive integer value
Number of trials for the binomial distribution, specified as the comma-separated pair consisting of 'NTrials' and a positive integer value. You must specify distname as 'Binomial' to use this option.

\section*{Data Types \\ single | double}

\section*{'Theta' - Threshold parameter}

\section*{0 (default) | scalar value}

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of 'Theta' and a scalar value. You must specify distname as 'GeneralizedPareto' to use this option.
```

Data Types
single | double

```

\section*{'Kernel' - Kernel smoother type}
```

'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

```

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following:
- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

You must specify distname as 'Kernel' to use this option.

\section*{'Support' - Kernel density support}
'unbounded' (default) | 'positive' | two-element vector
Kernel density support, specified as the comma-separated pair consisting of 'Support' and a string or two-element vector. The string must be one of the following.
\begin{tabular}{ll} 
'unbounded' & \begin{tabular}{l} 
Density can extend over the whole real \\
line.
\end{tabular} \\
'positive' & Density is restricted to positive values.
\end{tabular}

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify distname as 'Kernel' to use this option.
Data Types
single | double
'Width' - Bandwidth of kernel smoothing window
scalar value

\section*{fitdist}

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by fitdist is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify distname as 'Kernel' to use this option.

\section*{Data Types}
single | double

\section*{Output Arguments}

\section*{pd - Probability distribution}
probability distribution object
Probability distribution, returned as a probability distribution object. The distribution specified by distname determines the class type of the returned probability distribution object.

\section*{pdca - Probability distribution objects}
cell array
Probability distribution objects of the type specified by distname, returned as a cell array.

\section*{gn-Group labels}
cell array of strings
Group labels, returned as a cell array of strings.

\section*{gl - Grouping variable levels}
cell array of strings
Grouping variable levels, returned as a cell array of strings containing one column for each grouping variable.

\section*{Examples Fit a Normal Distribution to Data}

Load the sample data. Create a vector containing the patients' weight data.
```

load hospital;
x = hospital.Weight;

```

Create a normal distribution object by fitting it to the data.
```

pd = fitdist(x,'Normal')
pd =

```

NormalDistribution
```

    Normal distribution
        mu = 154 [148.728, 159.272]
        sigma = 26.5714 [23.3299, 30.8674]
    ```

Plot the pdf of the distribution.
x_values = 50:1:250;
pdf = pdf(pd,x_values);
plot(x_values,pdf,'LineWidth', 2)

\section*{fitdist}

\section*{Fit a Kernel Distribution to Data}

Load the sample data. Create a vector containing the patients' weight data.
load hospital;
x = hospital.Weight;
Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.
```

pd = fitdist(x,'Kernel','Kernel','epanechnikov')
pd =
KernelDistribution
Kernel = epanechnikov
Bandwidth = 14.3792
Support = unbounded

```
Plot the pdf of the distribution.
x_values = 50:1:250;
pdf = pdf(pd,x_values);
plot(x_values,pdf)

\section*{fitdist}

\section*{Fit Normal Distributions to Grouped Data}

Load the sample data. Create a vector containing the patients' weight data.
load hospital;
x = hospital.Weight;
Create normal distribution objects by fitting them to the data, grouped by patient gender.
```

gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)
pdca =
Column 1
[1x1 prob.NormalDistribution]
Column 2
[1x1 prob.NormalDistribution]
gn =
'Female'
'Male'
gl =
'Female'
'Male'

```

The cell array pdca contains two probability distribution objects, one for each gender group. The cell array gn contains two strings of the group labels. The cell array gl contains two strings of the group levels.

View each distribution in the cell array pdca to compare the mean, mu, and the standard deviation, sigma, grouped by patient gender.
```

female = pdca{1} % distribution for females
female =

```

NormalDistribution

\section*{fitdist}
```

    Normal distribution
        mu = 130.472 [128.183, 132.76]
    sigma = 8.30339 [6.96947, 10.2736]
    male = pdca{2} % distribution for males
male =

```
    NormalDistribution
```

Normal distribution
mu = 180.532 [177.833, 183.231]
sigma = 9.19322 [7.63933, 11.5466]

```

Compute the pdf of each distribution.
```

x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);

```

Plot the pdfs for a visual comparison of weight distribution by gender.
```

figure;
plot(x_values,femalepdf,'LineWidth',2)
hold on;
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gn,'Location','NorthEast');
hold off;

```

\section*{Fit Kernel Distributions to Grouped Data}

Load the sample data. Create a vector containing the patients' weight data.
load hospital;
x = hospital.Weight;
Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

\section*{fitdist}
```

gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');

```

View each distribution in the cell array pdca to see the kernel distributions for each gender.
```

female = pdca{1} % distribution for females
female =

```
    KernelDistribution
    Kernel = triangle
    Bandwidth = 4.25894
    Support = unbounded
male \(=\operatorname{pdca}\{2\}\) \% distribution for males
male =

\section*{KernelDistribution}

Kernel = triangle
Bandwidth = 5.08961
Support = unbounded
Compute the pdf of each distribution.
```

x values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);

```

Plot the pdfs for a visual comparison of weight distribution by gender.
figure;
plot(x_values,femalepdf,'LineWidth', 2)
hold on;
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
```

legend(gn,'Location','NorthEast');
hold off;

```

\section*{Algorithms}

The fitdist function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.
- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.

\section*{fitdist}
- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

\section*{Alternative Functionality}

\section*{App}
dfittool opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object.

\section*{See Also \\ makedist | dfittool}

\section*{fitensemble}

\section*{Purpose Fitted ensemble for classification or regression}
```

Syntax ens = fitensemble(X,Y,method, nlearn, learners)
ens = fitensemble(X,Y,method,nlearn,learners,Name,Value)

```

Description

Tips
- If X has categorical predictors with many levels, use 'GentleBoost' or 'LogitBoost' for binary classification. Using other algorithms in this case would likely cause long training times and can exhaust memory.

\section*{X}

Matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

\section*{Y}

For classification, Y is a categorical variable, character array, or cell array of strings. Each row of \(Y\) represents the classification of the corresponding row of \(X\).

For regression, \(Y\) is a numeric column vector with the same number of rows as \(X\). Each entry in \(Y\) is the response to the data in the corresponding row of \(X\).
method
Case-insensitive string consisting of one of the following.
- For classification with two classes:

\section*{fitensemble}
- 'AdaBoostM1'
- 'LogitBoost'
- 'GentleBoost'
- 'RobustBoost' (requires an Optimization Toolbox license)
- 'LPBoost' (requires an Optimization Toolbox license)
- 'TotalBoost' (requires an Optimization Toolbox license)
- 'RUSBoost'
- 'Subspace'
- 'Bag'
- For classification with three or more classes:
- 'AdaBoostM2'
- 'LPBoost' (requires an Optimization Toolbox license)
- 'TotalBoost' (requires an Optimization Toolbox license)
- 'RUSBoost'
- 'Subspace'
- 'Bag'
- For regression:
- 'LSBoost'
- 'Bag'
'Bag' applies to all methods. So when you use 'Bag', indicate whether you want a classifier or regressor with the type name-value pair set to 'classification' or 'regression'.

\section*{nlearn}

Number of ensemble learning cycles, a positive integer (or the string 'AllPredictorCombinations', see the next paragraph). At every training cycle, fitensemble loops over all learner templates in
learners and trains one weak learner for every template. The total number of trained learners in ens is nlearn*numel(learners).
If you set method to 'Subspace', you can set nlearn to 'AllPredictorCombinations'. With this setting, fitensemble constructs learners for all possible combinations of predictors taken NPredToSample at a time. This gives a total of nchoosek (size (X,2), NPredToSample) learners in the ensemble. You can use only one learner template for this setting.
nlearn for ensembles can vary from a few dozen to a few thousand. Usually, an ensemble with a good predictive power needs from a few hundred to a few thousand weak learners. You do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and, if necessary, train more weak learners using the resume method of the ensemble.

\section*{learners}

One of the following:
- A string with the name of a weak learner:
- 'Discriminant' (applies only to 'Subspace')
- 'KNN' (applies only to 'Subspace')
- 'tree' (applies to all methods except 'Subspace')
- A single weak learner template you create with ClassificationTree.template, RegressionTree.template, ClassificationKNN.template, or ClassificationDiscriminant.template.
- A cell array of weak learner templates. Usually you should supply only one weak learner template.
Ensemble performance depends on the parameters of the weak learners, and you can get poor performance using weak learners with default parameters. Specify the parameters for the weak learners in the template. Specify parameters for the ensemble in the fitensemble name-value pairs.

\section*{fitensemble}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{All Ensembles:}

\section*{'CategoricalPredictors'}

List of categorical predictors. Pass CategoricalPredictors as one of:
- A numeric vector with indices from 1 to \(p\), where \(p\) is the number of columns of \(X\).
- A logical vector of length \(p\), where a true entry means that the corresponding column of X is a categorical variable.
- 'all', meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the PredictorNames property.
- A character matrix, where each row of the matrix is the name of a predictor variable. The names must match entries in the PredictorNames property. Pad the names with extra blanks so each row of the character matrix has the same length.

You can set CategoricalPredictors for these learners:
- 'Tree'
- 'KNN ', when all predictors are categorical

Default: []

\section*{'crossval'}

If 'on', grows a cross-validated learner with 10 folds. You can use 'kfold', 'holdout', 'leaveout', or 'cvpartition' parameters to

\section*{fitensemble}
override this cross-validation setting. You can only use one of these four parameters ('kfold', 'holdout', 'leaveout', or 'cvpartition') at a time when creating a cross-validated learner.

Default: 'off'

\section*{'cvpartition'}

Partition created with cvpartition to use in a cross-validated learner. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

\section*{'fresample'}

Fraction of the training set to be selected by resampling for every weak learner. A numeric scalar from 0 to 1. This parameter has no effect unless you grow an ensemble by bagging or set 'resample' to 'on'. The default setting is the one used most often for an ensemble grown by resampling.

\section*{Default: 1}

\section*{'holdout'}

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated learner: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

\section*{'kfold \({ }^{\prime}\)}

Number of folds to use in a cross-validated learner, a positive integer. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

Default: 10

\section*{'leaveout'}

\section*{fitensemble}

Use leave-one-out cross validation by setting to 'on '. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

\section*{'NPredToSample'}

Number of predictors in each random subspace learner, a positive integer from 1 to size (X,2).

Default: 1

\section*{'nprint'}

Printout frequency, a positive integer scalar. Set to 'off' for no printout. Use this parameter to track how many weak learners have been trained so far. This is useful when you train ensembles with many learners on large datasets. If you use one of the cross-validation options, this parameter defines the printout frequency per number of cross-validation folds.

\section*{Default: 'off'}

\section*{'PredictorNames'}

Cell array of names for the predictor variables, in the order in which they appear in \(X\).

Default: \{'x1','x2',...\}

\section*{'replace'}
'on' or 'off'. If 'on', sample with replacement. If 'off', sample without replacement. This parameter has no effect unless you grow an ensemble by bagging or set resample to 'on'. If you set resample to 'on' and replace to 'off', fitensemble samples training observations assuming uniform weights, and boosts by reweighting observations.

Default: 'on'

\section*{fitensemble}

\section*{'resample'}
'on' or 'off'. If 'on', grow an ensemble by resampling, with the resampling fraction given by fresample, and sampling with or without replacement given by replace.
- Boosting - When 'off', the boosting algorithm reweights observations at every learning iteration. When 'on ', the algorithm samples training observations using updated weights as the multinomial sampling probabilities.
- Bagging - You can use only the default value of this parameter ('on').

Default: 'off' for boosting, 'on' for bagging

\section*{'ResponseName'}

Name of the response variable Y , a string.
Default: ' \(Y\) '

\section*{'type'}

String, either 'classification' or 'regression'. Specify type when the method is 'bag'.

\section*{'weights'}

Vector of observation weights. The length of weights is the number of rows in X .

Default: ones(size (X, 1), 1)

\section*{Classification Ensembles:}

\section*{'classnames'}

Array of class names. Specify a data type the same as exists in Y.

\section*{fitensemble}

Default: Class names that exist in \(Y\)

\section*{'cost'}

Square matrix C, where \(C(i, j)\) is the cost of classifying a point into class \(j\) if its true class is i. Alternatively, cost can be a structure S having two fields: S.ClassNames containing the group names as a categorical variable, character array, or cell array of strings; and S.ClassificationCosts containing the cost matrix C.

Default: C(i,j) = 1 if \(i \sim=j\), and \(C(i, j)=0\) if \(i=j\)

\section*{'prior'}

Prior probabilities for each class. Specify as one of:
- A string:
- 'empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, they are used to compute the class probabilities.
- 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure S with two fields:
- S.ClassNames containing the class names as a categorical variable, character array, or cell array of strings
- S.ClassProbs containing a vector of corresponding probabilities

If you set values for both weights and prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Default: 'empirical'

\section*{AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, RUSBoost, and LSBoost:}

\section*{fitensemble}

\section*{'LearnRate'}

Learning rate for shrinkage, a numeric scalar from 0 to 1 . If you set the learning rate to less than 1 , the ensemble requires more learning iterations but often achieves a better accuracy. 0.1 is a popular choice for an ensemble grown with shrinkage.

Default: 1

\section*{RUSBoost:}

\section*{'RatioToSmallest'}

Either a numeric scalar or vector with \(K\) elements when there are \(K\) classes. Every element of this vector is the sampling proportion for this class with respect to the class with fewest observations in Y. If you pass a scalar, fitensemble uses this sampling proportion for all classes. For example, suppose you have class A with 100 observations and class B with 10 observations. If you pass [2 1] for 'RatioToSmallest', every learner in the ensemble is trained on 20 observations of class A and 10 observations of class B. If you pass 2 or [2 2], every learner is trained on 20 observations of class A and 20 observations of class B. If you pass 'ClassNames', fitensemble matches elements in the array of class names to elements in this vector.

Default: ones (K,1)

\section*{LPBoost and TotalBoost:}

\section*{'MarginPrecision'}

Margin precision, a numeric scalar between 0 and 1. MarginPrecision affects the number of boosting iterations required for conversion. Use a small value to grow an ensemble with many learners, and use a large value to grow an ensemble with few learners.

Default: 0.01

\section*{fitensemble}

\section*{RobustBoost:}

\section*{'RobustErrorGoal'}

Target classification error for RobustBoost, a numeric scalar from 0 to 1. Usually there is an optimal range for this parameter for your training data. If you set the error goal too low or too high, RobustBoost can produce a model with poor classification accuracy.

Default: 0.1

\section*{'RobustMarginSigma'}

Spread of the distribution of classification margins over the training set for RobustBoost, a numeric positive scalar. You should consult literature on RobustBoost before setting this parameter

Default: 0.1

\section*{'RobustMaxMargin'}

Maximal classification margin for RobustBoost in the training set, a nonnegative numeric scalar. RobustBoost minimizes the number of observations in the training set with classification margins below RobustMaxMargin.

\section*{Default: 0}

\section*{Output} Arguments

\section*{ens}

Ensemble object for predicting characteristics. The class of ens depends on settings. In the following table, cross-validation names are crossval, kfold, holdout, leaveout, and cvpartition.
\begin{tabular}{l|l}
\hline Settings & Class \\
\hline \begin{tabular}{l} 
resample name-value pair is 'off', and you \\
don't set a cross-validation name-value pair.
\end{tabular} & ClassificationEnsemble \\
\hline \begin{tabular}{l} 
resample name-value pair is 'off', and you \\
don't set a cross-validation name-value pair.
\end{tabular} & RegressionEnsemble \\
\hline \begin{tabular}{l} 
resample name-value pair is 'on', type \\
is 'classification', and you don't set a \\
cross-validation name-value pair.
\end{tabular} & ClassificationBaggedEnsemble \\
\hline \begin{tabular}{l} 
resample name-value pair is 'on ', type \\
is 'regression', and you don't set a \\
cross-validation name-value pair.
\end{tabular} & RegressionBaggedEnsemble \\
\hline \begin{tabular}{l} 
method is a classification method, and you \\
set a cross-validation name-value pair.
\end{tabular} & ClassificationPartitionedEnsemble \\
\hline \begin{tabular}{l} 
method is a regression method, and you set \\
a cross-validation name-value pair.
\end{tabular} & RegressionPartitionedEnsemble \\
\hline
\end{tabular}

Examples Train a boosting ensemble, and inspect the resubstitution loss:
```

load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
plot(resubLoss(ada,'mode','cumulative'));
xlabel('Number of decision trees');
ylabel('Resubstitution error');

```

\section*{fitensemble}

Train a regression ensemble to predict car mileage based on the number of cylinders, engine displacement, horsepower, and weight. Predict the mileage for a four-cylinder car with a 200 cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

\section*{fitensemble}
```

load carsmall
X = [Cylinders,Displacement,Horsepower,Weight];
xnames = {'Cylinders','Displacement','Horsepower','Weight'};
t = RegressionTree.template('Surrogate','on');
rens = fitensemble(X,MPG,'LSBoost',100,t,'PredictorNames',xnames)
rens =
classreg.learning.regr.RegressionEnsemble:
PredictorNames: {'Cylinders' 'Displacement' 'Horsepower' 'Weight'}
CategoricalPredictors: []
ResponseName: 'Y'
ResponseTransform: 'none'
NObservations: 94
NTrained: 100
Method: 'LSBoost'
LearnerNames: {'Tree'}
ReasonForTermination: [1x77 char]
FitInfo: [100x1 double]
FitInfoDescription: [2x83 char]
Regularization: []
predict(rens,[4 200 150 3000])
ans =
20.4982

```

Train and estimate the generalization error on a holdout sample:
```

load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
'holdout',0.5);
plot(kfoldLoss(ada,'mode','cumulative'));
xlabel('Number of decision trees');
ylabel('Holdout error');

```

Purpose Flip categorical array along specified dimension

\section*{Syntax \\ \(B=\) flipdim(A,dim)}

Description \(\quad B=\) flipdim (A, dim) returns the categorical array A with dimension dim flipped.

See Also fliplr | flipud | permute | rot90
Purpose Flip categorical matrix in left/right direction
Syntax

\[
B=f l i p l r(A)
\]
Description \(B=f l i p l r(A)\) returns the \(2-D\) categorical matrix \(A\) with rows preserved and columns flipped in the left/right direction.
See Also flipdim | flipud | permute | rot90

\section*{categorical.flipud}

Purpose Flip categorical matrix in up/down direction

\section*{Syntax \\ \(B\) = flipud(A)}

Description \(\quad B=\) flipud \((A)\) returns the 2-D categorical matrix \(A\) with rows preserved and columns flipped in the up/down direction.

See Also flipdim | fliplr | permute | rot90

\section*{Purpose}
\(F\) probability density function

\section*{Syntax \\ \(Y=f p d f(X, V 1, V 2)\)}
\(Y=\operatorname{fpdf}(X, V 1, V 2)\) computes the \(F\) pdf at each of the values in \(X\) using the corresponding numerator degrees of freedom V1 and denominator degrees of freedom V2. X, V1, and V2 can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. V1 and V2 parameters must contain real positive values, and the values in X must lie on the interval \([0 \infty\) ).

The probability density function for the \(F\) distribution is
\[
y=f\left(x \mid v_{1}, v_{2}\right)=\frac{\Gamma\left[\frac{\left(v_{1}+v_{2}\right)}{2}\right]}{\Gamma\left(\frac{v_{1}}{2}\right) \Gamma\left(\frac{v_{2}}{2}\right)}\left(\frac{v_{1}}{v_{2}}\right)^{\frac{v_{1}}{2}} \frac{x^{\frac{v_{1}-2}{2}}}{\left[1+\left(\frac{v_{1}}{v_{2}}\right) x\right]^{\frac{v_{1}+v_{2}}{2}}}
\]

\section*{Examples}
```

y = fpdf(1:6,2,2)
y =
0.2500}00.1111 0.0625 0.0400 0.0278 0.0204
z = fpdf(3,5:10,5:10)
z =
0.0689 0.0659

```

How To
- "F Distribution" on page B-38

Purpose Fractional factorial design
Syntax \(\quad X=\) fracfact \((\) gen \()\)
[X,conf] = fracfact(gen)
[X,conf] = fracfact(gen,Name,Value)

\section*{Description}

Input
Arguments
\(X=\) fracfact (gen) creates the two-level fractional factorial design defined by the generator string gen.
[ \(\mathrm{X}, \mathrm{conf}\) ] = fracfact (gen) returns a cell array of strings containing the confounding pattern for the design.
[X,conf] = fracfact(gen, Name, Value) creates a fractional factorial designs with additional options specified by one or more Name, Value pair arguments.

\section*{gen}

Either a cell array of strings where each cell contains one "word," or a string consisting of "words" separated by spaces. "Words" consist of case-sensitive letters or groups of letters, where 'a' represents string 1, 'b' represents string \(2, \ldots\), 'A' represents string \(27, \ldots\), 'Z' represents string 52.
Each word defines how the corresponding factor's levels are defined as products of generators from a \(2^{\wedge} \mathrm{K}\) full-factorial design. K is the number of letters of the alphabet in gen.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'FactorNames'}

Cell array specifying the name for each factor.

Default: \{'X1','X2', ...\}

\section*{'MaxInt'}

Positive integer setting the maximum level of interaction to include in the confounding output.

\section*{Default: 2}

\section*{Output} Arguments

\section*{X}

The two-level fractional factorial design. X is a matrix of size N -by- P , where
- \(N=2^{\wedge} K\), where \(K\) is the number of letters of the alphabet in gen.
- \(P\) is the number of words in gen.

Because \(X\) is a two-level design, the components of \(X\) are -1 . For the meaning of \(X\), see "Fractional Factorial Designs" on page 17-5.

\section*{conf}

Cell array of strings containing the confounding pattern for the design.
Examples Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:
```

x = fracfact('a b c abc')
x =

| -1 | -1 | -1 | -1 |
| ---: | ---: | ---: | ---: |
| -1 | -1 | 1 | 1 |
| -1 | 1 | -1 | 1 |
| -1 | 1 | 1 | -1 |
| 1 | -1 | -1 | 1 |
| 1 | -1 | 1 | -1 |
| 1 | 1 | -1 | -1 |
| 1 | 1 | 1 | 1 |

```

Find generators for a six-factor design that uses four factors and achieves resolution IV using fracfactgen. Use the result to specify the design:
```

generators = fracfactgen('a b c d e f',4, ... % 4 factors
4) % resolution 4
generators =
'a'
'b'
'c'
'd'
'bcd'
' acd'
x = fracfact(generators)
X =

| -1 | -1 | -1 | -1 | -1 | -1 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| -1 | -1 | -1 | 1 | 1 | 1 |
| -1 | -1 | 1 | -1 | 1 | 1 |
| -1 | -1 | 1 | 1 | -1 | -1 |
| -1 | 1 | -1 | -1 | 1 | -1 |
| -1 | 1 | -1 | 1 | -1 | 1 |
| -1 | 1 | 1 | -1 | -1 | 1 |
| -1 | 1 | 1 | 1 | 1 | -1 |
| 1 | -1 | -1 | -1 | -1 | 1 |
| 1 | -1 | -1 | 1 | 1 | -1 |
| 1 | -1 | 1 | -1 | 1 | -1 |
| 1 | -1 | 1 | 1 | -1 | 1 |
| 1 | 1 | -1 | -1 | 1 | 1 |
| 1 | 1 | -1 | 1 | -1 | -1 |
| 1 | 1 | 1 | -1 | -1 | -1 |
| 1 | 1 | 1 | 1 | 1 | 1 |

```

How To - "Fractional Factorial Designs" on page 17-5

Fractional factorial design generators
```

generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)

```
generators \(=\) fracfactgen(terms) uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by terms. terms is a string consisting of words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a'-'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, terms \(=\) 'a b c ab ac'. Single-character words indicate main effects to be estimated; multiple-character words indicate interactions. Alternatively, terms is an \(m\)-by- \(n\) matrix of 0 s and 1 s where \(m\) is the number of model terms to be estimated and \(n\) is the number of factors. For example, if terms contains rows [ \(\left.\begin{array}{llll}0 & 1 & 0 & 0\end{array}\right]\) and [ \(\left.\begin{array}{llll}1 & 0 & 0 & 1\end{array}\right]\), then the factor \(b\) and the interaction between factors \(a\) and d are included in the model. generators is a cell array of strings with one generator per cell. Pass generators to fracfact to produce the fractional-factorial design and corresponding confounding pattern.
generators = fracfactgen(terms,k) returns generators for a two-level fractional-factorial design with \(2^{k}\)-runs, if possible. If \(k\) is [ ], fracfactgen finds the smallest design.
generators \(=\) fracfactgen(terms, \(k, R\) ) finds a design with resolution \(R\), if possible. The default resolution is 3 .

A design of resolution \(R\) is one in which no \(n\)-factor interaction is confounded with any other effect containing less than \(R-n\) factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If fracfactgen is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model.

If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.
generators \(=\) fracfactgen(terms, \(k, R\), basic) also accepts a vector basic specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in terms.

\section*{Examples}

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require \(2^{4}=16\) runs. The fracfactgen function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only \(2^{3}=8\) runs:
```

generators = fracfactgen('a b c d',3,4)
generators =
'a'
'b'
'c'
'abc'

```

The more economical design and the corresponding confounding pattern are returned by fracfact:
```

[dfF,confounding] = fracfact(generators)
dfF =
-1
-1
-1
-1
1
1 -1
1 1-1
1 1 1 1 1 1
confounding =
'Term' 'Generator' 'Confounding'
'X1' 'a' 'X1'
'X2' 'b' 'X2'

```

\section*{fracfactgen}
\begin{tabular}{|c|c|c|}
\hline ' X3' & 'c' & ' X3' \\
\hline ' \(\mathrm{X} 4{ }^{\prime}\) & 'abc' & 'X4' \\
\hline ' X 1 * \(\mathrm{X}^{\prime}{ }^{\prime}\) & 'ab' & \({ }^{\prime} \mathrm{X} 1 * \mathrm{X} 2+\mathrm{X} 3^{*} \mathrm{X} 4{ }^{\prime}\) \\
\hline ' X 1 * \(\times 3{ }^{\prime}\) & 'ac' & \({ }^{\prime} \mathrm{X} 1^{*} \mathrm{X} 3+\mathrm{X} 2^{*} \mathrm{X} 4{ }^{\prime}\) \\
\hline ' X 1 * \(\mathrm{X4}^{\prime}\) & 'bc' & \({ }^{\prime} \mathrm{X} 1\) * \(\mathrm{X} 4+\mathrm{X} 2^{*} \mathrm{X} 3^{\prime}\) \\
\hline ' X 2 * \(\times 3{ }^{\prime}\) & 'bc' & \({ }^{\prime} \mathrm{X} 1 * \mathrm{X} 4+\mathrm{X} 2 * \mathrm{X}{ }^{\prime}\) \\
\hline ' \(\mathrm{X} 2 * \times 4{ }^{\prime}\) & 'ac' & \({ }^{\prime} \mathrm{X} 1 * \mathrm{X} 3+\mathrm{X} 2 * \mathrm{X} 4{ }^{\prime}\) \\
\hline ' X 3 * X4 \({ }^{\prime}\) & 'ab' & ' \(\mathrm{X} 1{ }^{*} \mathrm{X} 2\) + \(\mathrm{X} 3 * \mathrm{X} 4{ }^{\prime}\) \\
\hline
\end{tabular}

The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

How To . "Fractional Factorial Designs" on page 17-5

\section*{Purpose Friedman's test}
Syntax \(\quad\)\begin{tabular}{l}
\(p=\) friedman \((X\), reps \()\) \\
\\
\(p=\) friedman \((X\), reps, displayopt \()\) \\
\\
\\
\\
{\([p\), table \(]=\) friedman \((\ldots)\)} \\
\end{tabular}

\section*{Description}
\(p\) = friedman(X, reps) performs the nonparametric Friedman's test to compare column effects in a two-way layout. Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of \(X\) represent changes in a factor \(A\). The different rows represent changes in a blocking factor \(B\). If there is more than one observation for each combination of factors, input reps indicates the number of replicates in each "cell," which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (reps=2). The subscripts indicate row, column, and replicate, respectively.
\(\left[\begin{array}{lll}x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232}\end{array}\right]\)

Friedman's test assumes a model of the form
\[
x_{i j k}=\mu+\alpha_{i}+\beta_{j}+\varepsilon_{i j k}
\]
where \(\mu\) is an overall location parameter, \(\alpha_{i}\) represents the column effect, \(\beta_{j}\) represents the row effect, and \(\varepsilon_{i j k}\) represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The p that friedman returns is the \(p\) value for the null hypothesis that \(\alpha_{i}=0\). If the \(p\) value is near zero, this casts doubt on the null hypothesis. A sufficiently small \(p\) value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical \(p\) value to determine whether a result is "statistically significant" is left to the researcher. It is common to declare a result significant if the \(p\) value is less than 0.05 or 0.01 .
friedman also displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:
- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if reps is greater than its default value of 1 )
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:
- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the \(p\) value for the chi-square statistic.
\(\mathrm{p}=\mathrm{friedman}(\mathrm{X}, \mathrm{reps}\), displayopt) enables the ANOVA table display when displayopt is 'on' (default) and suppresses the display when displayopt is 'off'.
[p,table] = friedman(...) returns the ANOVA table (including column and row labels) in cell array table. (You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the Edit menu.
[p,table,stats] = friedman(...) returns a stats structure that you can use to perform a follow-up multiple comparison test. The friedman test evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. Sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the multcompare function to perform such tests by supplying the stats structure as input.

\section*{Assumptions}

Friedman's test makes the following assumptions about the data in X :
- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

\section*{Examples}

Let's repeat the example from the anova2 function, this time applying Friedman's test. Recall that the data below come from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix popcorn are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.
```

load popcorn
popcorn
popcorn =
5.5000 4.5000 3.5000
5.5000 4.5000 4.0000

```

\section*{friedman}

The small \(p\) value of 0.001 indicates the popcorn brand affects the yield of popcorn. This is consistent with the results from anova2.

Purpose \(F\) random numbers
Syntax \(\mathrm{R}=\mathrm{frnd}(\mathrm{V} 1, \mathrm{~V} 2)\)

R = frnd(V1,V2,m,n,...)

\(R=f r n d(V 1, V 2,[m, n, \ldots])\)
Description\(\mathrm{R}=\mathrm{frnd}(\mathrm{V} 1, \mathrm{~V} 2)\) generates random numbers from the \(F\) distributionwith numerator degrees of freedom V1 and denominator degrees offreedom V2. V1 and V2 can be vectors, matrices, or multidimensionalarrays that all have the same size. A scalar input for V1 or V2 isexpanded to a constant array with the same dimensions as the otherinput.
\(R=f r n d(V 1, V 2, m, n, \ldots)\) or \(R=f r n d(V 1, V 2,[m, n, \ldots])\) generates
an m-by-n-by-... array containing random numbers from the \(F\)
distribution with parameters V1 and V2. V1 and V2 can each be scalars
or arrays of the same size as \(R\).

\section*{Examples}
```

n1 = frnd(1:6,1:6)
n1 =
0.0022 0.3121 3.0528

```
n2 \(=\) frnd (2,2,[23])
n2 =
    \(0.3186 \quad 0.9727 \quad 3.0268\)
    \(0.2052148 .5816 \quad 0.2191\)
n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 \(=\)
    \(\begin{array}{lll}0.6233 & 0.2322 & 31.5458\end{array}\)
    \(2.5848 \quad 0.2121 \quad 4.4955\)

How To . "F Distribution" on page B-38

Purpose \(\quad F\) mean and variance

\section*{Syntax \(\quad[M, V]=\operatorname{fstat}(V 1, V 2)\)}

Description
\([\mathrm{M}, \mathrm{V}]=\mathrm{fstat}(\mathrm{V} 1, \mathrm{~V} 2)\) returns the mean of and variance for the \(F\) distribution with numerator degrees of freedom V1 and denominator degrees of freedom V2. V1 and V2 can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V . A scalar input for V 1 or V 2 is expanded to a constant arrays with the same dimensions as the other input.

The mean of the \(F\) distribution for values of \(v_{2}\) greater than 2 is
\[
\frac{v_{2}}{v_{2}-2}
\]

The variance of the \(F\) distribution for values of \(v_{2}\) greater than 4 is
\[
\frac{2 v_{2}^{2}\left(v_{1}+v_{2}-2\right)}{v_{1}\left(v_{2}-2\right)^{2}\left(v_{2}-4\right)}
\]

The mean of the \(F\) distribution is undefined if \(v_{2}\) is less than 3. The variance is undefined for \(v_{2}\) less than 5 .

\section*{Examples fstat returns \(N a N\) when the mean and variance are undefined.}
```

[m,v] = fstat(1:5,1:5)
m =
NaN NaN 3.0000 2.0000 1.6667
v =
NaN NaN NaN NaN 8.8889

```

How To - "F Distribution" on page B-38

\section*{Purpose}

Interactive contour plot

\section*{Syntax}

Description

\section*{Examples}
```

fsurfht(fun,xlims,ylims)
fsurfht(fun,xlims,ylims,p1, p2,p3,p4,p5)

```
fsurfht(fun, xlims, ylims) is an interactive contour plot of the function specified by the text variable fun. The \(x\)-axis limits are specified by xlims in the form [xmin xmax], and the \(y\)-axis limits are specified by ylims in the form [ymin ymax].
fsurfht(fun, xlims, ylims, p1, p2, p3, p4, p5) allows for five optional parameters that you can supply to the function fun.

The intersection of the vertical and horizontal reference lines on the plot defines the current \(x\) value and \(y\) value. You can drag these reference lines and watch the calculated \(z\)-values (at the top of the plot) update simultaneously. Alternatively, you can type the \(x\) value and \(y\) value into editable text fields on the \(x\)-axis and \(y\)-axis.

Plot the Gaussian likelihood function for the gas.mat data.
```

load gas

```

Create a function containing the following commands, and name it gauslike.m.
```

function z = gauslike(mu,sigma,p1)
n = length(p1);
z = ones(size(mu));
for i = 1:n
z = z .* (normpdf(p1(i),mu,sigma));
end

```

The gauslike function calls normpdf, treating the data sample as fixed and the parameters \(\mu\) and \(\sigma\) as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.
```

fsurfht('gauslike',[112 118],[3 5],price1)

```

\section*{fsurfht}

The sample mean is the \(x\) value at the maximum, but the sample standard deviation is not the \(y\) value at the maximum.
```

mumax = mean(price1)
mumax =
115.1500
sigmamax = std(price1)*sqrt(19/20)
sigmamax =
3.7719

```
Purpose Full factorial design
Syntax dFF = fullfact(levels)
Description dFF = fullfact(levels) gives factor settings dFF for a full factorialdesign with \(n\) factors, where the number of levels for each factor is givenby the vector levels of length \(n\). dFF is \(m\)-by- \(n\), where \(m\) is the numberof treatments in the full-factorial design. Each row of dFF correspondsto a single treatment. Each column contains the settings for a singlefactor, with integer values from one to the number of levels.
Examples The following generates an eight-run full-factorial design with twolevels in the first factor and four levels in the second factor:

dFF = fullfact([24])

\(\mathrm{dFF}=\)

    \(1 \quad 1\)

Gage repeatability and reproducibility study
```

gagerr(y,{part,operator})
gagerr(y,GROUP)
gagerr(y,part)
gagerr(...,param1,val1,param2,val2,...)
[TABLE, stats] = gagerr(...)

```
gagerr(y,\{part,operator\}) performs a gage repeatability and reproducibility study on measurements in y collected by operator on part. y is a column vector containing the measurements on different parts. part and operator are categorical variables, numeric vectors, character matrices, or cell arrays of strings. The number of elements in part and operator should be the same as in \(y\).
gagerr prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R\&R of total variations (PRR).
gagerr also plots a bar graph showing the percentage of different components of variations. Gage \(R \& R\), repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.
To determine the capability of a measurement system using NDC, use the following guidelines:
- If NDC \(>5\), the measurement system is capable.
- If NDC \(<2\), the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:
- If \(\operatorname{PRR}<10 \%\), the measurement system is capable.
- If PRR \(>30 \%\), the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
gagerr (y, GROUP) performs a gage R\&R study on measurements in \(y\) with part and operator represented in GROUP. GROUP is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in GROUP should be the same as the number of elements in \(y\).
gagerr(y, part) performs a gage R\&R study on measurements in y without operator information. The assumption is that all variability is contributed by part.
gagerr(..., param1,val1, param2,val2,...) performs a gage \(R \& R\) study using one or more of the following parameter name/value pairs:
- 'spec' - A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:
- If PTR \(<0.1\), the measurement system is capable.
- If PTR \(>0.3\), the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
- 'printtable' - A string with a value 'on' or 'off' that indicates whether the tabular output should be printed in the command window or not. The default value is 'on'.
- 'printgraph' - A string with a value 'on' or 'off' that indicates whether the bar graph should be plotted or not. The default value is 'on'.
- 'randomoperator' - A logical value, true or false, that indicates whether the effect of operator is random or not. The default value is true.
- 'model' - The model to use, specified by one of:
- 'linear' - Main effects only (default)
- 'interaction' - Main effects plus two-factor interactions
- 'nested' - Nest operator in part

The default value is 'linear'.
[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage \(R \& R\), repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:
- ndc - Number of distinct categories
- prr - Percentage of gage R\&R of total variations
- ptr - Precision-to-tolerance ratio. The value is NaN if the parameter 'spec ' is not given.

\section*{Examples}

Conduct a gage R\&R study for a simulated measurement system using a mixed ANOVA model without interactions:
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multicolumn{3}{|l|}{\(y=\operatorname{randn}(100,1)\);} & \multicolumn{3}{|l|}{\% measurements} \\
\hline \multicolumn{3}{|l|}{part \(=\) ceil (3*rand (100,1));} & \multicolumn{2}{|l|}{\% parts} & \\
\hline \multicolumn{3}{|l|}{operator \(=\operatorname{ceil}(4 *\) rand (100,1)) ;} & \multicolumn{2}{|l|}{\% operators} & \\
\hline \multicolumn{6}{|l|}{gagerr(y, \{part, operator\},'randomoperator',true) \% analysis} \\
\hline Source & Variance & \% Variance & sigma & 5.15*sigma & \% 5.15*sigma \\
\hline Gage R\&R & 0.77 & 100.00 & 0.88 & 4.51 & 100.00 \\
\hline Repeatability & 0.76 & 99.08 & 0.87 & 4.49 & 99.54 \\
\hline Reproducibility & 0.01 & 0.92 & 0.08 & 0.43 & 9.61 \\
\hline Operator & 0.01 & 0.92 & 0.08 & 0.43 & 9.61 \\
\hline Part & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\
\hline
\end{tabular}
Total
0.77
100.00
0.88
4.51

Number of distinct categories (NDC): 0
\% of Gage R\&R of total variations (PRR): 100.00

Note: The last column of the above table does not have to sum to \(100 \%\)

How To . "Grouping Variables" on page 2-51

Purpose Gamma cumulative distribution function
```

Syntax gamcdf(X,A,B)
[P,PLO,PUP] = gamcdf(X,A,B,pcov,alpha)

```

\section*{Description}
gamcdf \((X, A, B)\) computes the gamma cdf at each of the values in \(X\) using the corresponding shape parameters in \(A\) and scale parameters in \(B\). \(X, A\), and \(B\) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in \(A\) and \(B\) must be positive.

The gamma cdf is
\[
p=F(x \mid a, b)=\frac{1}{b^{a} \Gamma(a)} \int_{0}^{x} t^{a-1} e^{\frac{-t}{b}} d t
\]

The result, \(p\), is the probability that a single observation from a gamma distribution with parameters \(a\) and \(b\) will fall in the interval \([0 x]\).
[P,PLO,PUP] = gamcdf(X,A,B,pcov,alpha) produces confidence bounds for \(P\) when the input parameters \(A\) and \(B\) are estimates. pcov is a 2-by- 2 matrix containing the covariance matrix of the estimated parameters. alpha has a default value of 0.05 , and specifies \(100(1\)-alpha) \(\%\) confidence bounds. PLO and PUP are arrays of the same size as P containing the lower and upper confidence bounds.
gammainc is the gamma distribution with \(b\) fixed at 1 .

\section*{Examples}
```

a = 1:6;
b = 5:10;
prob = gamcdf(a.*b,a,b)
prob =
0.6321}00.5940 0.5768 0.5665 0.5595 0.5543

```

The mean of the gamma distribution is the product of the parameters, \(a b\). In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

\section*{Purpose Gamma parameter estimates}
```

Syntax phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)

```

\section*{Description}

\section*{Examples}
phat \(=\) gamfit(data) returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector data.
[phat,pci] = gamfit(data) returns MLEs and 95\% percent confidence intervals. The first row of pci is the lower bound of the confidence intervals; the last row is the upper bound.
[phat,pci] = gamfit(data,alpha) returns 100(1-alpha)\% confidence intervals. For example, alpha \(=0.01\) yields \(99 \%\) confidence intervals.
[...] = gamfit(data, alpha, censoring) accepts a Boolean vector of the same size as data that is 1 for observations that are right-censored and 0 for observations that are observed exactly.
[...] = gamfit(data,alpha, censoring,freq) accepts a frequency vector of the same size as data. freq typically contains integer frequencies for the corresponding elements in data, but may contain any nonnegative values.
[...] = gamfit(data, alpha, censoring,freq,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an options structure which can be created using the function statset. Enter statset('gamfit') to see the names and default values of the parameters that gamfit accepts in the options structure.

Fit a gamma distribution to random data generated from a specified gamma distribution:
```

a = 2; b = 4;
data = gamrnd(a,b,100,1);
[p,ci] = gamfit(data)
p =
2.1990 3.7426
ci =
1.6840 2.8298
2.7141 4.6554

```

\section*{prob.GammaDistribution}

Superclasses ToolboxFittableParametricDistribution

\section*{Purpose Gamma probability distribution object}

Description prob.GammaDistribution is an object consisting of parameters, a model description, and sample data for a gamma probability distribution.
Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd = makedist('Gamma') creates a gamma probability distribution object using the default parameter values.
pd = makedist('Gamma','a',a,'b',b) creates a gamma probability distribution object using the specified parameter values.

\section*{Input Arguments}

\section*{a-Shape parameter}

\section*{1 (default) | positive scalar value}

Shape parameter for the gamma distribution, specified as a positive scalar value.
```

Data Types
single | double
b - Scale parameter

```
1 (default) | nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

\section*{Data Types}
single | double

\section*{Properties}

\section*{a}

Shape parameter for the gamma distribution, stored as a positive scalar value.
```

Data Types
single | double
b

```

Scale parameter for the gamma distribution, stored as a nonnegative scalar value.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types}
char

\section*{InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

\section*{Data Types}
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{prob.GammaDistribution}

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\author{
Data Types \\ single | double

\section*{Definitions Gamma Distribution}

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline a & Shape parameter & \(a>0\) \\
\hline b & Scale parameter & \(b \geq 0\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid a, b)=\frac{1}{b^{a} \Gamma(a)} x^{a-1} e^{\frac{-x}{b}} \quad ; \quad x>0
\]
where \(\Gamma(\cdot)\) is the Gamma function.

\section*{Purpose \\ Gamma inverse cumulative distribution function}

Syntax
\(X=\operatorname{gaminv}(P, A, B)\)
[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)

\section*{Algorithms}

Examples
\(X=\) gaminv \((P, A, B)\) computes the inverse of the gamma cdf with shape parameters in \(A\) and scale parameters in \(B\) for the corresponding probabilities in P. P, A, and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in A and B must all be positive, and the values in \(P\) must lie on the interval [01].

The gamma inverse function in terms of the gamma cdf is
\[
x=F^{-1}(p \mid a, b)=\{x: F(x \mid a, b)=p\}
\]
where
\[
p=F(x \mid a, b)=\frac{1}{b^{a} \Gamma(a)} \int_{0}^{x} t^{a-1} e^{\frac{-t}{b}} d t
\]
[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha) produces confidence bounds for \(P\) when the input parameters \(A\) and \(B\) are estimates. pcov is a 2 -by- 2 matrix containing the covariance matrix of the estimated parameters. alpha has a default value of 0.05 , and specifies \(100(1\)-alpha) \% confidence bounds. PLO and PUP are arrays of the same size as P containing the lower and upper confidence bounds.

There is no known analytical solution to the integral equation above. gaminv uses an iterative approach (Newton's method) to converge on the solution.

This example shows the relationship between the gamma cdf and its inverse function.
```

a = 1:5;
b = 6:10;
x = gaminv(gamcdf(1:5,a,b),a,b)
x =
1.0000 2.0000 3.0000 4.0000 5.0000

```
See Also icdf | gamcdf | gampdf | gamstat | gamfit | gamlike | gamrnd
How To - "Gamma Distribution" on page B-40

\section*{Purpose Gamma negative log-likelihood}

Syntax

Description

\section*{Examples}
```

nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)

```
nlogL = gamlike(params, data) returns the negative of the gamma log-likelihood of the parameters, params, given data. params (1)=A, shape parameters, and params (2) \(=B\), scale parameters.
[nlogL,AVAR] = gamlike(params,data) also returns AVAR, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in params are the maximum likelihood estimates. AVAR is the inverse of Fisher's information matrix. The diagonal elements of AVAR are the asymptotic variances of their respective parameters.
[...] = gamlike(params,data, censoring) accepts a Boolean vector of the same size as data that is 1 for observations that are right-censored and 0 for observations that are observed exactly.
[...] = gamfit(params,data, censoring,freq) accepts a frequency vector of the same size as data. freq typically contains integer frequencies for the corresponding elements in data, but may contain any non-negative values.
gamlike is a utility function for maximum likelihood estimation of the gamma distribution. Since gamlike returns the negative gamma log-likelihood function, minimizing gamlike using fminsearch is the same as maximizing the likelihood.

Compute the negative log-likelihood of parameter estimates computed by the gamfit function:
```

a = 2; b = 3;
$r=\operatorname{gamrnd}(a, b, 100,1) ;$
[nlogL,AVAR] = gamlike(gamfit(r), r)
nlogL =
267.5648
AVAR $=$

```

How To - "Gamma Distribution" on page B-40

Purpose Gamma mean and variance

\section*{Syntax \\ [M, V] = gamstat(A, B)}
\([M, V]=\operatorname{gamstat}(A, B)\) returns the mean of and variance for the gamma distribution with shape parameters in \(A\) and scale parameters in \(B\). A and B can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of \(M\) and \(V\). A scalar input for \(A\) or \(B\) is expanded to a constant array with the same dimensions as the other input.

The mean of the gamma distribution with parameters \(a\) and \(b\) is \(a b\). The variance is \(a b^{2}\).

\section*{Examples}
\([\mathrm{m}, \mathrm{v}]=\operatorname{gamstat}(1: 5,1: 5)\)
\(\mathrm{m}=\)
\(\begin{array}{lllll}1 & 4 & 9 & 16 & 25\end{array}\)

gampdf | gamcdf | gaminv | gamfit | gamlike | gamrnd
How To . "Gamma Distribution" on page B-40

\section*{Purpose Greater than or equal relation for handles}

\section*{Syntax \\ h1 >= h2}

Description h1 >= h2 performs element-wise comparisons between handle arrays h 1 and h2. h 1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise \(>=\) result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.
\(\mathrm{tf}=\mathrm{ge}(\mathrm{h} 1, \mathrm{~h} 2)\) stores the result in a logical array of the same dimensions.

\section*{Definitions}

\section*{Generalized Extreme Value Distribution}

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:
- Type 1 - Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 - Distributions whose tails decrease as a polynomial, such as Student's \(t\) distribution
- Type 3 - Distributions whose tails are finite, such as the beta distribution

The generalized extreme value distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline k & Shape parameter & \(-\infty \leq k \leq \infty\) \\
\hline sigma & Scale parameter & \(\sigma \geq 0\) \\
\hline mu & Location parameter & \(-\infty \leq \mu \leq \infty\) \\
\hline
\end{tabular}

\section*{prob.GeneralizedExtremeValueDistribution}

The probability density function (pdf) for a Type 1 distribution, where shape parameter \(k=0\), is
\[
f(x \mid 0, \mu, \sigma)=\left(\frac{1}{\sigma}\right) \exp \left(-\exp \left(-\frac{(x-\mu)}{\sigma}\right)-\frac{(x-\mu)}{\sigma}\right) ;-\infty<x<\infty .
\]

When \(k \neq 0\), the pdf is
\[
f(x \mid k, \mu, \sigma)=\left(\frac{1}{\sigma}\right) \exp \left(-\left(1+k \frac{(x-\mu)}{\sigma}\right)^{-\frac{1}{k}}\right)\left(1+k \frac{(x-\mu)}{\sigma}\right)^{-1-\frac{1}{k}}
\]
for
\[
1+k \frac{(x-\mu)}{\sigma}>0
\]

For the Type 2 case, \(k>0\) and \(x \geq \mu-\frac{\sigma}{k}\). For the Type 3 case, \(k<0\) and \(x<\mu-\frac{\sigma}{k}\).

\section*{GeneralizedLinearModel}
Purpose Generalized linear regression model class
DescriptionAn object comprising training data, model description, diagnosticinformation, and fitted coefficients for a generalized linear regression.Predict model responses with the predict or feval methods.
Construction
mdl = GeneralizedLinearModel.fit(ds) or mdl =
GeneralizedLinearModel.fit(X,y) creates a generalizedlinear model of a dataset array ds, or of the responses y to a data matrixX. For details, see GeneralizedLinearModel.fit.
mdl = GeneralizedLinearModel.stepwise(ds) or mdl =
GeneralizedLinearModel.stepwise(X,y) creates a generalized
linear model of a dataset array ds, or of the responses \(y\) to a data
matrix X, with unimportant predictors excluded. For details, see
GeneralizedLinearModel.stepwise.

\section*{Input Arguments}

\section*{ds}
Dataset array, where by default the last column is the response variable, and all other columns are the predictors. Predictors can be numeric, or can be any grouping variable type, such as logical or categorical (see "Grouping Variables" on page 2-51). The response must be numeric or logical.
To set a different column as the response variable, use the ResponseVar name-value pair. To use a subset of the columns as predictors, use the PredictorVars name-value pair.

\section*{X}
Matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

\section*{y}
Vector of response values with the same number of rows as X . Each entry in \(y\) is the response to the data in the corresponding row of X.

\section*{GeneralizedLinearModel}

\section*{Properties}

\section*{CoefficientCovariance}

Covariance matrix of coefficient estimates.

\section*{CoefficientNames}

Cell array of strings containing a label for each coefficient.

\section*{Coefficients}

Table of coefficient values in a dataset array. Coefficients has one row for each coefficient and these columns:
- Estimate - Estimated coefficient value
- SE - Standard error of the estimate
- tStat - \(t\) statistic for a test that the coefficient is zero
- pValue - \(p\)-value for the \(t\) statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in mdl the estimated coefficient vector is
beta \(=\) mdl.Coefficients.Estimate

Use coefTest to perform other tests on the coefficients.

\section*{Deviance}

Deviance of the fit, equal to -2*LogLikelihood.
Deviance is useful for comparing two models when one is a special case of the other. The difference \(D\) between the deviance of the two models is -2 times the log of the likelihood ratio. Asymptotically, \(D\) has a chi-square distribution with degrees of freedom \(V\) equal to the number of parameters that are estimated in one model but fixed (typically at 0 ) in the other. The \(p\)-value for this test is 1 - chi2cdf( \(\mathrm{D}, \mathrm{V}\) ).

\section*{DFE}

\section*{GeneralizedLinearModel}

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

\section*{Diagnostics}

Dataset array with diagnostics helpful in finding outliers and influential observations. The structure contains the following fields:
\begin{tabular}{l|l|l}
\hline Field & Meaning & Utility \\
\hline Leverage & \begin{tabular}{l} 
Diagonal elements of \\
HatMatrix
\end{tabular} & \begin{tabular}{l} 
Leverage indicates to what extent the predicted \\
value for an observation is determined by \\
the observed value for that observation. A \\
value close to 1 indicates that the prediction is \\
largely determined by that observation, with \\
little contribution from the other observations. \\
A value close to 0 indicates the fit is largely \\
determined by the other observations. For a \\
model with P coefficients and N observations, the \\
average value of Leverage is P/N. An observation \\
with Leverage larger than 2*P/N can be an \\
outlier.
\end{tabular} \\
\hline CooksDistance & \begin{tabular}{l} 
Cook's measure of \\
scaled change in \\
fitted values
\end{tabular} & \begin{tabular}{l} 
CooksDistance is a measure of scaled \\
change in fitted values. An observation with \\
CooksDistance larger than three times the \\
mean Cook's distance can be an outlier.
\end{tabular} \\
\hline HatMatrix & \begin{tabular}{l} 
Projection matrix to \\
compute fitted from \\
observed responses
\end{tabular} & \begin{tabular}{l} 
HatMatrix is an N-by-N matrix such that \\
Fitted = HatMatrix*Y, where Y is the response \\
vector and Fitted is the vector of fitted response \\
values.
\end{tabular} \\
\hline
\end{tabular}

All of these quantities are computed on the scale of the linear predictor. So, for example, in the equation that defines the hat matrix,

Yfit = glm.Fitted.LinearPredictor
Y = glm.Fitted.LinearPredictor + glm.Residuals.LinearPredictor

\section*{GeneralizedLinearModel}

\section*{Dispersion}

Scale factor of the variance of the response. Dispersion multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is \(p(1-p) / n\), where \(p\) is the probability parameter and \(n\) is the sample size parameter. If Dispersion is near 1 , the variance of the data appears to agree with the theoretical variance of the binomial distribution. If Dispersion is larger than 1, the data are "overdispersed" relative to the binomial distribution.

\section*{DispersionEstimated}

Logical value indicating whether GeneralizedLinearModel.fit used the Dispersion property to compute standard errors for the coefficients in Coefficients.SE. If DispersionEstimated is false, GeneralizedLinearModel.fit used the theoretical value of the variance.
- DispersionEstimated can be false only for 'binomial' or 'poisson' distributions.
- Set DispersionEstimated by setting the DispersionFlag name-value pair in GeneralizedLinearModel.fit.

\section*{Distribution}

Structure with the following fields relating to the generalized distribution:

\section*{GeneralizedLinearModel}
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Name & \begin{tabular}{l} 
Name of the distribution, one of 'normal ', 'binomial', \\
'poisson', 'gamma', or 'inverse gamma'.
\end{tabular} \\
\hline DevianceFunction & \begin{tabular}{l} 
Function that computes the components of the deviance as a \\
function of the fitted parameter values and the response values.
\end{tabular} \\
\hline VarianceFunction & \begin{tabular}{l} 
Function that computes the theoretical variance for the \\
distribution as a function of the fitted parameter values. When \\
DispersionEstimated is true, Dispersion multiplies the \\
variance function in the computation of the coefficient standard \\
errors.
\end{tabular} \\
\hline
\end{tabular}

Fitted
Table of predicted (fitted) values based on the training data, a dataset array with one row for each observation and the following columns.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Response & Predicted values on the scale of the response. \\
\hline LinearPredictor & \begin{tabular}{l} 
Predicted values on the scale of the linear predictor. These are the \\
same as the link function applied to the Response fitted values.
\end{tabular} \\
\hline Probability & \begin{tabular}{l} 
Fitted probabilities (this column is included only with the \\
binomial distribution).
\end{tabular} \\
\hline
\end{tabular}

To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model mdl, the vector \(f\) of fitted values on the response scale is
f = mdl.Fitted.Response
Use predict to compute predictions for other predictor values, or to compute confidence bounds on Fitted.

\section*{Formula}

Object containing information about the model.

\section*{GeneralizedLinearModel}

\section*{Link}

Structure with fields relating to the link function. The link is a function \(f\) that links the distribution parameter \(\mu\) to the fitted linear combination \(X b\) of the predictors:
\[
f(\mu)=X b .
\]

The structure has the following fields.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Name & \begin{tabular}{l} 
Name of the link function, or ' ' if you specified the link as a \\
function handle rather than a string.
\end{tabular} \\
\hline LinkFunction & The function that defines \(f\), a function handle. \\
\hline DevianceFunction & Derivative of \(f\), a function handle. \\
\hline VarianceFunction & Inverse of \(f\), a function handle. \\
\hline
\end{tabular}

\section*{LogLikelihood}

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

\section*{ModelCriterion}

AIC and other information criteria for comparing models. A structure with fields:
- AIC - Akaike information criterion
- AICc - Akaike information criterion corrected for sample size
- BIC - Bayesian information criterion
- CAIC - Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model mdl, the AIC value aic is:

\section*{GeneralizedLinearModel}
aic \(=\) mdl.ModelCriterion.AIC

\section*{NumCoefficients}

Number of coefficients in the model, a positive integer. NumCoefficients includes coefficients that are set to zero when the model terms are rank deficient.

\section*{NumEstimatedCoefficients}

Number of estimated coefficients in the model, a positive integer. NumEstimatedCoefficients does not include coefficients that are set to zero when the model terms are rank deficient. NumEstimatedCoefficients is the degrees of freedom for regression.

\section*{NumObservations}

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original dataset or matrix, minus any excluded rows (set with the Excluded name-value pair) or rows with missing values.

\section*{NumPredictors}

Number of variables LinearModel.fit used as predictors for fitting.

\section*{NumVariables}

Number of variables in the data. NumVariables is the number of variables in the original dataset when the fit is based on a dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

\section*{ObservationInfo}

Dataset with the same number of rows as the input data (ds or X).

\section*{GeneralizedLinearModel}
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Weights & Observation weights. Default is all 1. \\
\hline Excluded & \begin{tabular}{l} 
Logical value, 1 indicates an observation that \\
you excluded from the fit with the Exclude \\
name-value pair.
\end{tabular} \\
\hline Missing & \begin{tabular}{l} 
Logical value, 1 indicates a missing value in \\
the input. Missing values are not used in the \\
fit.
\end{tabular} \\
\hline Subset & \begin{tabular}{l} 
Logical value, 1 indicates the observation is \\
not excluded or missing, so is used in the fit.
\end{tabular} \\
\hline
\end{tabular}

\section*{ObservationNames}

Cell array of strings containing the names of the observations used in the fit.
- If the fit is based on a dataset containing observation names, ObservationNames uses those names.
- Otherwise, ObservationNames is an empty cell array

\section*{Offset}

Vector with the same length as the number of rows in the data, passed from GeneralizedLinearModel.fit or GeneralizedLinearModel.stepwise in the Offset name-value pair. The fitting function used Offset as a predictor variable, but with the coefficient set to exactly 1 . In other words, the formula for fitting was
```

~ Offset + (terms involving real predictors)

```
with the Offset predictor having coefficient 1.
For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by

\section*{GeneralizedLinearModel}
specifying \(\log (A)\) as an offset, you can force the model to satisfy this theoretical constraint.

\section*{PredictorNames}

Cell array of strings, the names of the predictors used in fitting the model.

\section*{Residuals}

Dataset array containing a table of residuals, with one row for each observation and these variables.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Raw & Observed minus fitted values. \\
\hline LinearPredictorResiduals on the linear predictor scale, equal \\
to the adjusted response value minus the \\
fitted linear combination of the predictors.
\end{tabular}, \begin{tabular}{l} 
Raw residuals divided by the estimated \\
standard deviation of the response.
\end{tabular}

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model mdl, the ordinary raw residual vector \(r\) is:
\(r=\) mdl.Residuals.Raw
Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain NaN values.

Rows not used in the fit because of excluded values (in ObservationInfo.Excluded) contain NaN values, with the following exceptions:

\section*{GeneralizedLinearModel}
- raw contains the difference between the observed and predicted values.
- standardized is the residual, standardized in the usual way.
- studentized matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

\section*{ResponseName}

String giving naming the response variable.

\section*{Rsquared}

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:
\[
\text { Rsquared }=\text { SSR/SST }=1 \text { - SSE/SST. }
\]

Rsquared is a structure with two fields:
- Ordinary - Ordinary (unadjusted) R-squared
- Adjusted - R-squared adjusted for the number of coefficients

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted \(R\)-squared value in mdl is
r2 = mdl.Rsquared.Adjusted

\section*{SSE}

Sum of squared errors (residuals).
The Pythagorean theorem implies
SST = SSE + SSR.

\section*{GeneralizedLinearModel}

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
SST = SSE + SSR.

\section*{SST}

Total sum of squares, the sum of squared deviations of \(y\) from mean(y).

The Pythagorean theorem implies
SST = SSE + SSR.

\section*{Steps}

Structure that is empty unless LinearModel.stepwise constructed the model.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Start & Formula representing the starting model \\
\hline Lower & \begin{tabular}{l} 
Formula representing the lower bound model, \\
these terms that must remain in the model
\end{tabular} \\
\hline Upper & \begin{tabular}{l} 
Formula representing the upper bound model, \\
model cannot contain more terms than Upper
\end{tabular} \\
\hline Criterion & \begin{tabular}{l} 
Criterion used for the stepwise algorithm, \\
such as 'sse '
\end{tabular} \\
\hline PEnter & Value of the parameter, such as 0.05 \\
\hline PRemove & Value of the parameter, such as 0.10 \\
\hline History & Dataset representing the steps taken in the fit \\
\hline
\end{tabular}

The History dataset has one row for each step including the initial fit, and the following variables (columns).

\section*{GeneralizedLinearModel}
\begin{tabular}{|c|c|}
\hline Field & Description \\
\hline Action & \begin{tabular}{l}
Action taken during this step, one of: \\
- 'Start' - First step \\
- 'Add' - A term is added \\
- 'Remove' - A term is removed
\end{tabular} \\
\hline TermName & \begin{tabular}{l}
- 'Start' step: The starting model specification \\
- 'Add' or 'Remove' steps: The term moved in that step
\end{tabular} \\
\hline Terms & Terms matrix (see modelspec in "Input Arguments" on page 20-799 of LinearModel.fit) \\
\hline DF & Regression degrees of freedom after this step \\
\hline deldF & Change in regression degrees of freedom from previous step (negative for steps that remove a term) \\
\hline Deviance & Deviance (residual sum of squares) at that step \\
\hline FStat & \(F\) statistic that led to this step \\
\hline PValue & \(p\)-value of the \(F\) statistic \\
\hline
\end{tabular}

\section*{Variablelnfo}

Dataset array containing metadata about Variables. There is one row for each term in the model, and the following columns.

\section*{GeneralizedLinearModel}
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Class & String giving variable class, such as 'double ' \\
\hline Range & \begin{tabular}{l} 
Cell array giving variable range: \\
• Continuous variable - Two-element vector \\
[min, max ], the minimum and maximum \\
values
\end{tabular} \\
- Categorical variable - Cell array of \\
distinct variable values
\end{tabular}\(|\)\begin{tabular}{l} 
Logical vector, where true indicates the \\
variable is in the model
\end{tabular}

\section*{VariableNames}

Cell array of strings containing names of the variables in the fit.
- If the fit is based on a dataset, this property provides the names of the variables in that dataset.
- If the fit is based on a predictor matrix and response vector, VariableNames is the values in the VarNames name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

\section*{Variables}

Dataset array containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a dataset array, Variables is a copy of that dataset. Otherwise, Variables is a dataset created from the input data matrix \(X\) and response vector \(y\).

\section*{GeneralizedLinearModel}

\section*{Methods}
\begin{tabular}{|c|c|}
\hline addTerms & Add terms to generalized linear model \\
\hline coefCI & Confidence intervals of coefficient estimates of generalized linear model \\
\hline coefTest & Linear hypothesis test on generalized linear regression model coefficients \\
\hline devianceTest & Analysis of deviance \\
\hline disp & Display generalized linear regression model \\
\hline feval & Evaluate generalized linear regression model prediction \\
\hline fit & Create generalized linear regression model \\
\hline plotDiagnostics & Plot diagnostics of generalized linear regression model \\
\hline plotResiduals & Plot residuals of generalized linear regression model \\
\hline plotSlice & Plot of slices through fitted generalized linear regression surface \\
\hline predict & Predict response of generalized linear regression model \\
\hline random & Simulate responses for generalized linear regression model \\
\hline removeTerms & Remove terms from generalized linear model \\
\hline
\end{tabular}

\section*{GeneralizedLinearModel}
\[
\begin{array}{ll}
\text { step } & \begin{array}{l}
\text { Improve generalized linear } \\
\text { regression model by adding or } \\
\text { removing terms }
\end{array} \\
\text { stepwise } & \begin{array}{l}
\text { Create generalized linear } \\
\text { regression model by stepwise } \\
\text { regression }
\end{array}
\end{array}
\]

\section*{Definitions \\ Canonical Link Function}

The default link function for a generalized linear model is the canonical link function.

\section*{Canonical Link Functions for Generalized Linear Models}
\begin{tabular}{l|l|l|l}
\hline Distribution & \begin{tabular}{l} 
Link Function \\
Name
\end{tabular} & Link Function & \begin{tabular}{l} 
Mean (Inverse) \\
Function
\end{tabular} \\
\hline 'normal' & 'identity' & \(f(\mu)=\mu\) & \(\mu=X b\) \\
\hline 'binomial' & 'logit' & \(f(\mu)=\log (\mu /(1-\mu))\) & \(\mu=\exp (X b) /(1+\exp (X b))\) \\
\hline 'poisson' & 'log' & \(f(\mu)=\log (\mu)\) & \(\mu=\exp (X b)\) \\
\hline 'gamma' & -1 & \(f(\mu)=1 / \mu\) & \(\mu=1 /(X b)\) \\
\hline \begin{tabular}{l} 
'inverse \\
gaussian'
\end{tabular} & -2 & \(f(\mu)=1 / \mu^{2}\) & \(\mu=(X b)^{-1 / 2}\) \\
\hline
\end{tabular}

\section*{Hat Matrix}

The hat matrix \(H\) is defined in terms of the data matrix \(X\) and a diagonal weight matrix \(W\) :
\[
H=X\left(X^{T} W X\right)^{-1} X^{T} W^{T} .
\]
\(W\) has diagonal elements \(w_{i}\) :

\section*{GeneralizedLinearModel}
\[
w_{i}=\frac{g^{\prime}\left(\mu_{i}\right)}{\sqrt{V\left(\mu_{i}\right)}},
\]
where
- \(g\) is the link function mapping \(y_{i}\) to \(x_{i} b\).
- \(g^{\prime}\) is the derivative of the link function \(g\).
- \(V\) is the variance function.
- \(\mu_{i}\) is the \(i\) th mean.

The diagonal elements \(H_{i i}\) satisfy
\[
\begin{aligned}
& 0 \leq h_{i i} \leq 1 \\
& \sum_{i=1}^{n} h_{i i}=p
\end{aligned}
\]
where \(n\) is the number of observations (rows of \(X\) ), and \(p\) is the number of coefficients in the regression model.

\section*{Leverage}

The leverage of observation \(i\) is the value of the \(i\) th diagonal term of the hat matrix \(H_{i i}\). Because the sum of the leverage values is \(p\) (the number of coefficients in the regression model), an observation \(i\) can be considered to be an outlier if its leverage substantially exceeds \(p / n\), where \(n\) is the number of observations.

\section*{Cook's Distance}

The Cook's distance \(D_{i}\) of observation \(i\) is
\[
D_{i}=w_{i} \frac{e_{i}^{2}}{p \hat{\varphi}} \frac{h_{i i}}{\left(1-h_{i i}\right)^{2}},
\]
where

\section*{GeneralizedLinearModel}
- \(\hat{\varphi}\) is the dispersion parameter (estimated or theoretical).
- \(e_{i}\) is the linear predictor residual, \(g\left(y_{i}\right)-x_{i} \hat{\beta}\), where
- \(g\) is the link function.
- \(y_{i}\) is the observed response.
- \(x_{i}\) is the observation.
- \(\hat{\beta}\) is the estimated coefficient vector.
- \(p\) is the number of coefficients in the regression model.
- \(h_{i i}\) is the \(i\) th diagonal element of the Hat Matrix \(H\).

Copy
Semantics

\section*{Examples}

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

\section*{Fit a Generalized Linear Model}

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.
load hospital
ds = hospital; \% just to use the ds name
Specify the model using a formula that allows up to two-way interactions.
```

modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';

```

Create the generalized linear model.
```

mdl = GeneralizedLinearModel.fit(ds,...
modelspec,'Distribution','binomial')

```
md1 \(=\)

\section*{GeneralizedLinearModel}
\begin{tabular}{|c|c|c|c|c|}
\hline \multicolumn{5}{|l|}{```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```} \\
\hline \multicolumn{5}{|l|}{Estimated Coefficients:} \\
\hline & Estimate & SE & tStat & pValue \\
\hline (Intercept) & -6.0492 & 19.749 & -0.3063 & 0.75938 \\
\hline Sex_Male & -2.2859 & 12.424 & -0.18399 & 0.85402 \\
\hline Age & 0.11691 & 0.50977 & 0.22934 & 0.81861 \\
\hline Weight & 0.031109 & 0.15208 & 0.20455 & 0.83792 \\
\hline Sex_Male:Age & 0.020734 & 0.20681 & 0.10025 & 0.92014 \\
\hline Sex_Male:Weight & 0.01216 & 0.053168 & 0.22871 & 0.8191 \\
\hline Age:Weight & -0.00071959 & 0.0038964 & -0.18468 & 0.85348 \\
\hline
\end{tabular}

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value \(=0.535\)
The large \(p\)-value indicates the model might not differ statistically from a constant.

\section*{Create a Generalized Linear Model Stepwise}

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.
```

rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);

```

Fit a generalized linear model using the Poisson distribution.

\section*{GeneralizedLinearModel}
```

mdl = GeneralizedLinearModel.stepwise(X,y,···.
'constant','upper','linear','Distribution','poisson')

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094
mdl =
```
Generalized Linear regression model:
    \(\log (y) \sim 1+x 5+x 10+x 15\)
    Distribution \(=\) Poisson

Estimated Coefficients:
\begin{tabular}{lclll} 
& Estimate & SE & tStat & \multicolumn{1}{l}{ pValue } \\
(Intercept) & 1.0115 & 0.064275 & 15.737 & \(8.4217 \mathrm{e}-56\) \\
x5 & 0.39508 & 0.066665 & 5.9263 & \(3.0977 \mathrm{e}-09\) \\
x10 & 0.18863 & 0.05534 & 3.4085 & 0.0006532 \\
x15 & 0.29295 & 0.053269 & 5.4995 & \(3.8089 \mathrm{e}-08\)
\end{tabular}

100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, \(p\)-value \(=9.61 \mathrm{e}-20\)

Superclasses ToolboxFittableParametricDistribution
Purpose Generalized Pareto probability distribution object
Description prob.GeneralizedParetoDistribution is an object consisting of parameters, a model description, and sample data for a generalized Pareto probability distribution.
Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd = makedist('GeneralizedParetoDistribution') creates a generalized Pareto probability distribution object using default parameter values.
pd =
makedist('GeneralizedParetoDistribution', 'k',k,'sigma', sigma, 'theta', creates a generalized Pareto probability distribution object using the specified parameter values.

\section*{Input Arguments}

\section*{k - Shape parameter}

1 (default) | scalar value
Shape parameter for the generalized Pareto distribution, specified as a scalar value.

\section*{Data Types}
single | double

\section*{sigma-Scale parameter}

\section*{1 (default) | nonnegative scalar value}

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

\author{
Data Types \\ single | double
}

\section*{prob.GeneralizedParetoDistribution}

\section*{theta- Location parameter}

\author{
1 (default) | scalar value
}

Location parameter for the generalized Pareto distribution, specified as a scalar value.

\author{
Data Types \\ single | double
}

\section*{Properties \\ k}

Shape parameter for the generalized Pareto distribution, stored as a scalar value.

\section*{Data Types \\ single | double \\ sigma}

Scale parameter for the generalized Pareto distribution, stored as a nonnegative scalar value.
```

Data Types
single | double
theta

```

Location parameter for the generalized Pareto distribution, stored as a scalar value.

\section*{Data Types \\ single | double \\ DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types}
char

\section*{InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

\section*{Data Types}
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterCovariance}

Covariance matrix of the parameter estimates, stored as a \(p\)-by- \(p\) matrix, where \(p\) is the number of parameters in the distribution. The ( \(i, j\) ) element is the covariance between the estimates of the ith parameter and the \(j\) th parameter. The ( \(i, i\) ) element is the estimated variance of the ith parameter. If parameter \(i\) is fixed rather than estimated by fitting the distribution to data, then the ( \(i, i\) ) elements of the covariance matrix are 0 . This property is read-only.

\section*{prob.GeneralizedParetoDistribution}

\section*{Data Types \\ single | double \\ ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{Data Types}
char

\section*{ParameterlsFixed}

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

\section*{Data Types}
logical

\section*{ParameterNames}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types \\ char}

\section*{ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\section*{Data Types}
single | double

\section*{Truncation}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

\section*{Definitions Generalized Pareto Distribution}

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.
- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's \(t\), lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline k & Shape parameter & \(-\infty<k<\infty\) \\
\hline sigma & Scale parameter & \(\sigma \geq 0\) \\
\hline theta & Location parameter & \(-\infty<\theta<\infty\) \\
\hline
\end{tabular}

The probability density function (pdf) of the generalized Pareto distribution with shape parameter \(k \neq 0\) is
\[
f(x \mid k, \sigma, \theta)=\left(\frac{1}{\sigma}\right)\left(1+k \frac{(x-\theta)}{\sigma}\right)^{-1-\frac{1}{k}}
\]
for \(x>\theta\), when \(k>0\), or for \(\theta<x<-\frac{\sigma}{k}\), when \(k<0\).
For \(k=0\), the pdf is
\[
y=f(x \mid 0, \sigma, \theta)=\left(\frac{1}{\sigma}\right) \exp \left(-\frac{(x-\theta)}{\sigma}\right)
\]
for \(x>\theta\).
If \(k=0\) and \(\theta=0\), the generalized Pareto distribution is equivalent
to the exponential distribution. If \(k>0\) and \(\theta=\frac{\sigma}{k}\), the generalized Pareto distribution is equivalent to the Pareto distribution.

\section*{Examples}

\section*{Create a Generalized Pareto Distribution Object Using Default Parameters}

Create a generalized Pareto distribution object using the default parameter values.
```

pd = makedist('GeneralizedPareto')
pd =

```

GeneralizedParetoDistribution

\section*{Purpose}

Geometric cumulative distribution function

\section*{Syntax}

Description

\section*{Examples}
\(Y=\operatorname{geocdf}(X, P)\) \(X\) using the corresponding probabilities in \(P . X\) and \(P\) can be vectors, matrices, or multidimensional arrays that all have the same size. A as the other input. The parameters in P must lie on the interval [01].

The geometric cdf is
\[
y=F(x \mid p)=\sum_{i=0}^{\text {floor }(x)} p q^{i}
\]
where \(q=1-p\).
The result, \(y\), is the probability of observing up to \(x\) trials before a success, when the probability of success in any given trial is \(p\).
\(Y=\operatorname{geocdf}(X, P)\) computes the geometric cdf at each of the values in scalar input is expanded to a constant array with the same dimensions

Suppose you toss a fair coin repeatedly. If the coin lands face up (heads), that is a success. What is the probability of observing three or fewer tails before getting a heads?
```

p = geocdf(3,0.5)
p =
0.9375

```

How To - "Geometric Distribution" on page B-54

Purpose Geometric inverse cumulative distribution function
\[
\text { Syntax } \quad X=\operatorname{geoinv}(Y, P)
\]

Description

Examples

\section*{See Also}

How To
\(X=\) geoinv \((Y, P)\) returns the smallest positive integer \(X\) such that the geometric cdf evaluated at \(X\) is equal to or exceeds \(Y\). You can think of \(Y\) as the probability of observing \(X\) successes in a row in independent trials where \(P\) is the probability of success in each trial.
\(Y\) and \(P\) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for P or Y is expanded to a constant array with the same dimensions as the other input. The values in \(P\) and \(Y\) must lie on the interval [01].

The probability of correctly guessing the result of 10 coin tosses in a row is less than 0.001 (unless the coin is not fair).
```

psychic = geoinv(0.999,0.5)
psychic =
9

```

The example below shows the inverse method for generating random numbers from the geometric distribution.
```

rndgeo = geoinv(rand (2,5),0.5)
rndgeo =

| 0 | 1 | 3 | 1 | 0 |
| :--- | :--- | :--- | :--- | :--- |

    0
    ```

\section*{Purpose}

Geometric mean

\section*{Syntax}
\(m=\) geomean \((x)\)
geomean \((X\), dim \()\)
Description
\(m=\) geomean \((x)\) calculates the geometric mean of a sample. For vectors, geomean \((x)\) is the geometric mean of the elements in \(x\). For matrices, geomean \((X)\) is a row vector containing the geometric means of each column. For N-dimensional arrays, geomean operates along the first nonsingleton dimension of \(X\).
geomean ( \(\mathrm{X}, \mathrm{dim}\) ) takes the geometric mean along the dimension dim of \(X\).

The geometric mean is
\[
m=\left[\prod_{i=1}^{n} x_{i}\right]^{\frac{1}{n}}
\]

\section*{Examples}

The arithmetic mean is greater than or equal to the geometric mean.
```

x = exprnd(1,10,6);
geometric = geomean(x)
geometric =
0.7466
average = mean(x)
average =
1.3509 1.1583 0.9741 0.5319 1.0088

```
See Also mean | median | harmmean | trimmean
How To

Purpose Geometric probability density function

\section*{Syntax \(\quad Y=\operatorname{geopdf}(X, P)\)}

Description \(\quad Y=\) geopdf \((X, P)\) computes the geometric pdf at each of the values in \(X\) using the corresponding probabilities in \(P\). \(X\) and \(P\) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in P must lie on the interval [01].

The geometric pdf is
\[
y=f(x \mid p)=p q^{x} I_{(0,1, \ldots)}(x)
\]
where \(q=1-p\).

\section*{Examples \\ ```
p = geopdf(3,0.5) \\ p = \\ 0.0625
```}

Suppose you toss a fair coin repeatedly. If the coin lands face up (heads), that is a success. What is the probability of observing exactly three tails before getting a heads?

\\
\\
\\
\(\mathrm{p}=\operatorname{get}(\mathrm{A})\) \\
\(\mathrm{p}=\operatorname{get}(\mathrm{A}\), PropertyName \()\) \\
\end{tabular}
\end{tabular}

Description

\section*{Examples}
get (A) displays a list of property/value pairs for the dataset array \(A\).
\(s=\operatorname{get}(A)\) returns the values in a scalar structure \(s\) with field names given by the properties.
\(p=\operatorname{get}(A, P r o p e r t y N a m e)\) returns the value of the property specified by the string PropertyName.
\(\mathrm{p}=\operatorname{get}(\mathrm{A},\{\) PropertyName1,PropertyName2, ...\}) allows multiple property names to be specified and returns their values in a cell array.

Create a dataset array from Fisher's iris data and access the information:
```

load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
{meas,'SL','SW','PL','PW'},...
'ObsNames ',NameObs);
get(iris)
Description:
Units: {}
DimNames: {'Observations' 'Variables'}
UserData: []
ObsNames: {150x1 cell}
VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
ON = get(iris,'ObsNames');
ON(1:3)

```

\section*{dataset.get}
ans =

\section*{Purpose Access categorical array labels}

\section*{Syntax labels = getlabels(A)}

Description labels = getlabels \((A)\) returns the labels of the levels in the categorical array A as a cell array of strings labels. For ordinal A, the labels are returned in the order of the levels.

\section*{Examples}

\section*{Example 1}

Display levels in a nominal and an ordinal array:
```

standings = nominal({'Leafs','Canadiens','Bruins'});
getlabels(standings)
ans =
'Bruins' 'Canadiens' 'Leafs'
standings = ordinal(1:3,{'Leafs','Canadiens','Bruins'});
getlabels(standings)
ans =
'Leafs' 'Canadiens' 'Bruins'

```

\section*{Example 2}

Display age groups containing data in hospital.mat:
```

load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);
AgeGroup = droplevels(AgeGroup);
getlabels(AgeGroup)
ans =
'20s' '30s' '40s' '50s'

```

How To

P = gevcdf(X,k,sigma,mu)
\(P=\operatorname{gevcdf}(X, k\), sigma, mu \()\) returns the cdf of the generalized extreme value (GEV) distribution with shape parameter \(k\), scale parameter sigma, and location parameter, mu, evaluated at the values in \(X\). The size of \(P\) is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k , sigma, and mu are 0,1 , and 0 , respectively.
When \(\mathrm{k}<0\), the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If \(w\) has a Weibull distribution as computed by the wblcdf function, then -w has a type III extreme value distribution and \(1 / w\) has a type II extreme value distribution. In the limit as \(k\) approaches 0 , the GEV is the mirror image of the type I extreme value distribution as computed by the evcdf function.

The mean of the GEV distribution is not finite when \(k \geq 1\), and the variance is not finite when \(k \geq 1 / 2\). The GEV distribution has positive density only for values of X such that \(\mathrm{k}^{*}(\mathrm{X}-\mathrm{mu}) /\) sigma \(>-1\).

Purpose Generalized extreme value parameter estimates
Syntax
```

parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)

```

\section*{References}
parmhat \(=\) gevfit \((X)\) returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in X. parmhat (1) is the shape parameter, \(k\), parmhat (2) is the scale parameter, sigma, and parmhat (3) is the location parameter, mu.
[parmhat, parmci] = gevfit(X) returns \(95 \%\) confidence intervals for the parameter estimates.
[parmhat, parmci] = gevfit(X,alpha) returns 100(1-alpha)\% confidence intervals for the parameter estimates.
[...] = gevfit(X,alpha,options) specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to statset. See statset('gevfit') for parameter names and default values. Pass in [] for alpha to use the default values.

When \(\mathrm{k}<0\), the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If whas a Weibull distribution as computed by the wblfit function, then -w has a type III extreme value distribution and \(1 / w\) has a type II extreme value distribution. In the limit as \(k\) approaches 0 , the GEV is the mirror image of the type I extreme value distribution as computed by the evfit function.

The mean of the GEV distribution is not finite when \(k \geq 1\), and the variance is not finite when \(k \geq 1 / 2\). The GEV distribution is defined for \(k^{*}(X-m u) /\) sigma > -1 .

\section*{Purpose}

Generalized extreme value negative log-likelihood

\section*{Syntax}

Description

\section*{References}

See Also
How To
```

nlogL = gevlike(params,data)

```
[nlogL,ACOV] = gevlike(params,data)
nlogL = gevlike(params, data) returns the negative of the log-likelihood nlogL for the generalized extreme value (GEV) distribution, evaluated at parameters params. params(1) is the shape parameter, \(k\), params(2) is the scale parameter, sigma, and params (3) is the location parameter, mu.
[nlogL,ACOV] = gevlike(params, data) returns the inverse of Fisher's information matrix, ACOV. If the input parameter values in params are the maximum likelihood estimates, the diagonal elements of ACOV are their asymptotic variances. ACOV is based on the observed Fisher's information, not the expected information.
When \(\mathrm{k}<0\), the GEV is the type III extreme value distribution. When \(k>0\), the GEV distribution is the type II, or Frechet, extreme value distribution. If whas a Weibull distribution as computed by the wbllike function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as \(k\) approaches 0 , the GEV is the mirror image of the type I extreme value distribution as computed by the evlike function.

The mean of the GEV distribution is not finite when \(k \geq 1\), and the variance is not finite when \(k \geq 1 / 2\). The GEV distribution has positive density only for values of \(X\) such that \(k *(X-m u) /\) sigma \(>-1\).

\section*{gline}

Purpose Interactively add line to plot
```

Syntax gline(h)
gline
hline = gline(...)

```

Description
gline (h) allows you to draw a line segment in the figure with handle \(h\) by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.
gline with no input arguments defaults to \(\mathrm{h}=\) gcf and draws in the current figure.
hline = gline(...) returns the handle hline to the line.

\section*{Examples}

Use gline to connect two points in a plot:
```

x = 1:10;
y = x + randn(1,10);
scatter(x,y,25,'b','*')
lsline
mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')
hline = gline; % Connect circles
set(hline,'Color','r')

```

\section*{See Also}
refline | refcurve | lsline

\section*{glmfit}

Purpose Generalized linear model regression
```

Syntax $\quad b=\operatorname{glmfit}(X, y$, distr $)$
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)

```

\section*{Description}
\(\mathrm{b}=\operatorname{glmfit}(\mathrm{X}, \mathrm{y}\), distr) returns a \(p\)-by- 1 vector b of coefficient estimates for a generalized linear regression of the responses in y on the predictors in X , using the distribution distr. X is an \(n\)-by- \(p\) matrix of \(p\) predictors at each of \(n\) observations. distr can be any of the following strings: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, y is an \(n\)-by- 1 vector of observed responses. For the binomial distribution, y can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

Note By default, glmfit adds a first column of 1 s to X , corresponding to a constant term in the model. Do not enter a column of 1s directly into \(X\). You can change the default behavior of glmfit using the 'constant' parameter, below.
glmfit treats NaNs in either X or y as missing values, and ignores them. b = glmfit(X,y,distr,param1,val1,param2,val2,...) additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows:
\begin{tabular}{|c|c|c|}
\hline Parameter & Value & Description \\
\hline \multirow[t]{9}{*}{'link'} & 'identity ', default for the distribution 'normal' & \(\mu=X b\) \\
\hline & \(\log\) ', default for the distribution 'poisson' & \(\log (\mu)=X b\) \\

relative variance of \\
each observation
\end{tabular} & 'on' (default) \\
\hline 'constant' & \begin{tabular}{l} 
Includes a constant term in \\
the model. The coefficient of \\
the constant term is the first \\
element of b.
\end{tabular} \\
\hline & 'off' & Omit the constant term \\
\hline
\end{tabular}
[b, dev] = glmfit(...)returns dev, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test whether the model with more terms is significantly better than the model with fewer terms.
[b,dev,stats] = glmfit(...) returns dev and stats.
stats is a structure with the following fields:
- beta - Coefficient estimates b
- dfe - Degrees of freedom for error
- s-Theoretical or estimated dispersion parameter
- sfit - Estimated dispersion parameter
- se - Vector of standard errors of the coefficient estimates \(b\)
- coeffcorr - Correlation matrix for b
- covb - Estimated covariance matrix for B
- \(\mathrm{t}-t\) statistics for b
- \(\mathrm{p}-p\)-values for b
- resid - Vector of residuals
- residp - Vector of Pearson residuals
- residd - Vector of deviance residuals
- resida - Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then stats.s is set equal to stats.sfit. Also, the elements of stats.se differ by the factor stats.s from their theoretical values.

\section*{Examples}

Fit a probit regression model for \(y\) on \(x\). Each \(y(i)\) is the number of successes in \(n\) (i) trials.
```

x = [2100 2300 2500 2700 2900 3100 ...
3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 0 3 8 8 14 17 19 15 17 21]';
b = glmfit(x,[y n],'binomial','link','probit');
yfit = glmval(b, x,'probit','size', n);
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)

```

\section*{glmfit}

glmval | regress | regstats
}

Purpose Generalized linear model values
Syntax \(\quad\) yhat \(=\operatorname{glmval}(b, x\), link \()\)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)

\section*{Description}
yhat \(=\) glmval ( \(b, X, l i n k)\) computes predicted values for the
generalized linear model with link function link and predictors \(X\). Distinct predictor variables should appear in different columns of X. b is a vector of coefficient estimates as returned by the glmfit function. link can be any of the strings used as values for the link parameter in the glmfit function.

Note By default, glmval adds a first column of 1 s to \(X\), corresponding to a constant term in the model. Do not enter a column of 1 s directly into \(X\). You can change the default behavior of glmval using the 'constant' parameter, below.
[yhat,dylo,dyhi] = glmval(b,X,link,stats) also computes 95\% confidence bounds for the predicted values. When the stats structure output of the glmfit function is specified, dylo and dyhi are also returned. dylo and dyhi define a lower confidence bound of yhat-dylo, and an upper confidence bound of yhat+dyhi. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.
[...] = glmval(...,param1,val1,param2,val2,...) specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline \begin{tabular}{l} 
' confidence ' - the confidence \\
level for the confidence bounds
\end{tabular} & A scalar between 0 and 1 \\
\hline \begin{tabular}{l} 
'size' - the size parameter (N) \\
for a binomial model
\end{tabular} & \begin{tabular}{l} 
A scalar, or a vector with one \\
value for each row of X
\end{tabular} \\
\hline \begin{tabular}{l} 
'offset' - used as an additional \\
predictor variable, but with a \\
coefficient value fixed at 1.0
\end{tabular} & A vector \\
\hline 'constant' & \begin{tabular}{l} 
- 'on' - Includes a constant \\
term in the model. The \\
coefficient of the constant term \\
is the first element of b.
\end{tabular} \\
- 'off' - Omit the constant \\
term
\end{tabular}

\section*{Examples}

Fit a probit regression model for y on x . Each \(\mathrm{y}(\mathrm{i})\) is the number of successes in \(n\) (i) trials.
```

x = [l2100 2300 2500 2700 2900 3100 ···.
3300 3500 3700 3900 4100 4300]';
n = [llllllllllllllllll
y = [llllllllllllllll}
b = glmfit(x,[y n],'binomial','link','probit');
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)

```

\section*{glyphplot}

Purpose Glyph plot
```

Syntax
glyphplot(X)
glyphplot(X,'glyph','face')
glyphplot(X,'glyph','face','features',f)
glyphplot(X,...,'grid',[rows,cols])
glyphplot(X,...,'grid',[rows,cols],'page', p)
glyphplot(X,...,'centers',C)
glyphplot(X,...,'centers',C,'radius',r)
glyphplot(X,...,'obslabels',labels)
glyphplot(X,...,'standardize',method)
glyphplot(X,...,prop1,val1,...)
h = glyphplot(X,...)

```

\section*{Description}
glyphplot(X) creates a star plot from the multivariate data in the \(n\)-by- \(p\) matrix X . Rows of X correspond to observations, columns to variables. A star plot represents each observation as a "star" whose \(i\) th spoke is proportional in length to the \(i\) th coordinate of that observation. glyphplot standardizes \(X\) by shifting and scaling each column separately onto the interval \([0,1]\) before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. glyphplot treats NaNs in X as missing values, and does not plot the corresponding rows of X . glyphplot(X,'glyph', 'star') is a synonym for glyphplot(X).
glyphplot(X, 'glyph', 'face') creates a face plot from X. A face plot represents each observation as a "face," whose \(i\) th facial feature is drawn with a characteristic proportional to the \(i\) th coordinate of that observation. The features are described in "Face Features" on page 20-988Face Features.
glyphplot(X,'glyph','face','features',f) creates a face plot where the \(i\) th element of the index vector \(f\) defines which facial feature will represent the \(i\) th column of \(X\). f must contain integers from 0 to 17, where 0 indicate that the corresponding column of \(X\) should not be plotted. See "Face Features" on page 20-988 for more information.
glyphplot(X,...,'grid', [rows, cols]) organizes the glyphs into a rows-by-cols grid.
glyphplot(X,...,'grid',[rows, cols],'page', p ) organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page \(p\). If \(p\) is a vector, glyphplot displays multiple pages in succession. If \(p\) is 'all', glyphplot displays all pages. If \(p\) is 'scroll', glyphplot displays a single plot with a scrollbar.
glyphplot(X,...,'centers', C) creates a plot with each glyph centered at the locations in the \(n\)-by- 2 matrix C .
glyphplot(X,..., 'centers', C, 'radius', r) creates a plot with glyphs positioned using \(C\), and scale the glyphs so the largest has radius \(r\).
glyphplot(X, .., 'obslabels', labels) labels each glyph with the text in the character array or cell array of strings labels. By default, the glyphs are labelled \(1: \mathrm{N}\). Use ' ' for blank labels.
glyphplot(X,...,'standardize', method) standardizes X before making the plot. Choices for method are
- 'column' - Maps each column of \(X\) separately onto the interval [ 0,1\(]\). This is the default.
- 'matrix' - Maps the entire matrix \(X\) onto the interval [0,1].
- 'PCA' - Transforms \(X\) to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval \([0,1]\).
- 'off' - No standardization. Negative values in X may make a star plot uninterpretable.
glyphplot(X,..., prop1, val1, ...) sets properties to the specified property values for all line graphics objects created by glyphplot.
\(\mathrm{h}=\) glyphplot \((\mathrm{X}, \ldots)\) returns a matrix of handles to the graphics objects created by glyphplot. For a star plot, \(h(:, 1)\) and \(h(:, 2)\) contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, h(: 1 ) and h(: 2 ) contain object handles

\section*{glyphplot}
to the lines making up each face and to the pupils, respectively. \(\mathrm{h}(:, 3)\) contains handles to the text objects for the labels, if present.

\section*{Face Features}

The following table describes the correspondence between the columns of the vector \(f\), the value of the 'Features' input parameter, and the facial features of the glyph plot. If \(x\) has fewer than 17 columns, unused features are displayed at their default value.
\begin{tabular}{l|l}
\hline Column & Facial Feature \\
\hline 1 & Size of face \\
\hline 2 & Forehead/jaw relative arc length \\
\hline 3 & Shape of forehead \\
\hline 4 & Shape of jaw \\
\hline 5 & Width between eyes \\
\hline 6 & Vertical position of eyes \\
\hline 7 & Height of eyes \\
\hline 8 & Width of eyes (this also affects eyebrow width) \\
\hline 9 & Angle of eyes (this also affects eyebrow angle) \\
\hline 10 & Vertical position of eyebrows \\
\hline 11 & Width of eyebrows (relative to eyes) \\
\hline 12 & Angle of eyebrows (relative to eyes) \\
\hline 13 & Direction of pupils \\
\hline 14 & Length of nose \\
\hline 15 & Vertical position of mouth \\
\hline 16 & Shape of mouth \\
\hline 17 & Mouth arc length \\
\hline
\end{tabular}

\section*{Examples}

\section*{Copy Semantics}

\section*{Examples}

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

\section*{Fit a Gaussian Mixture Model}

Generate data from a mixture of two bivariate Gaussian distributions using the mvnrnd function. Fit the resulting data.

Generate the data using 1000 points from each distribution.
```

MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];
scatter(X(:,1),X(:,2),10,'.')
hold on

```

\section*{gmdistribution}

Fit a two-component Gaussian mixture model.
```

options = statset('Display','final');
obj = gmdistribution.fit(X,2,'Options',options);
1 8 iterations, log-likelihood = -7058.35
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);

```

Examples

\section*{Concepts}

\section*{Purpose Construct Gaussian mixture distribution}
```

Syntax obj = gmdistribution(mu,sigma,p)

```

Description

Examples
obj \(=\) gmdistribution(mu, sigma, \(p\) ) constructs an object obj of the gmdistribution class defining a Gaussian mixture distribution.
mu is a \(k\)-by- \(d\) matrix specifying the \(d\)-dimensional mean of each of the \(k\) components.
sigma specifies the covariance of each component. The size of sigma is:
- \(d\)-by- \(d\)-by- \(k\) if there are no restrictions on the form of the covariance. In this case, sigma( \(:,:, I)\) is the covariance of component I.
- 1-by- \(d\)-by- \(k\) if the covariance matrices are restricted to be diagonal, but not restricted to be same across components. In this case, sigma(:,: I) contains the diagonal elements of the covariance of component I.
- \(d\)-by- \(d\) matrix if the covariance matrices are restricted to be the same across components, but not restricted to be diagonal. In this case, sigma is the pooled estimate of covariance.
- 1-by- \(d\) if the covariance matrices are restricted to be diagonal and the same across components. In this case, sigma contains the diagonal elements of the pooled estimate of covariance.
\(p\) is an optional 1-by- \(k\) vector specifying the mixing proportions of each component. If \(p\) does not sum to 1 , gmdistribution normalizes it. The default is equal proportions.

Create a gmdistribution object defining a two-component mixture of bivariate Gaussian distributions:
```

mu = [1 2;-3 -5];
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(mu,sigma,p);

```

Purpose Generalized Pareto cumulative distribution function
Syntax \(\quad P=\operatorname{gpcdf}(X, K\), sigma, theta \()\)
Description \(\quad P=\operatorname{gpcdf}(X, K\), sigma, theta) returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter K, scale parameter sigma, and threshold (location) parameter, theta, evaluated at the values in \(X\). The size of \(P\) is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for K, sigma, and theta are 0,1 , and 0 , respectively.
When \(K=0\) and theta \(=0\), the GP is equivalent to the exponential distribution. When \(K>0\) and theta \(=\) sigma/K, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when \(\mathrm{K} \geq\) 1 , and the variance is not finite when \(K \geq 1 / 2\). When \(K \geq 0\), the GP has positive density for

X > theta, or, when
\(\mathrm{K}<0,0 \leq \frac{X-\theta}{\sigma} \leq-\frac{1}{K}\).

Purpose
Generalized Pareto parameter estimates
Syntax
parmhat = gpfit(X)
[parmhat, parmci] = gpfit(X)
[parmhat, parmci] = gpfit(X,alpha)
[...] = gpfit(X,alpha,options)
parmhat \(=\) gpfit \((X)\) returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in X . parmhat (1) is the tail index (shape) parameter, K and parmhat(2) is the scale parameter, sigma. gpfit does not fit a threshold (location) parameter.
[parmhat, parmci] = gpfit(X) returns 95\% confidence intervals for the parameter estimates.
[parmhat, parmci] = gpfit(X,alpha) returns 100(1-alpha)\% confidence intervals for the parameter estimates.
[...] = gpfit(X, alpha,options) specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to statset. See statset('gpfit') for parameter names and default values.

Other functions for the generalized Pareto, such as gpcdf allow a threshold parameter, theta. However, gpfit does not estimate theta. It is assumed to be known, and subtracted from \(X\) before calling gpfit.
When \(\mathrm{K}=0\) and theta \(=0\), the GP is equivalent to the exponential distribution. When \(K>0\) and theta \(=\) sigma/ \(K\), the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when \(K \geq\) 1 , and the variance is not finite when \(K \geq 1 / 2\). When \(K \geq 0\), the GP has positive density for

X > theta, or, when
\[
0 \leq \frac{X-\theta}{\sigma} \leq-\frac{1}{K}

\section*{Purpose Generalized Pareto negative log-likelihood}
```

Syntax nlogL = gplike(params,data)
[nlogL,ACOV] = gplike(params,data)

```

\section*{Description}
nlogL = gplike(params, data) returns the negative of the log-likelihood nlogL for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters params. params(1) is the tail index (shape) parameter, K, params (2) is the scale parameter, sigma, and params (3) is the threshold (location) parameter, mu.
[nlogL,ACOV] = gplike(params, data) returns the inverse of Fisher's information matrix, ACOV. If the input parameter values in params are the maximum likelihood estimates, the diagonal elements of ACOV are their asymptotic variances. ACOV is based on the observed Fisher's information, not the expected information.

When \(K=0\) and theta \(=0\), the GP is equivalent to the exponential distribution. When K > 0 and theta \(=\) sigma/K, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when \(\mathrm{K} \geq\) 1 , and the variance is not finite when \(K \geq 1 / 2\). When \(K \geq 0\), the GP has positive density for
\(X>\) theta, or, when
\(\mathrm{K}<0,0 \leq \frac{X-\theta}{\sigma} \leq-\frac{1}{K}\).

\section*{See Also pdf \| gpcdf | gpinv \| gpstat \| gpfit \| gplike | gprnd}

Purpose Matrix of scatter plots by group
Syntax gplotmatrix(x,y,group)
gplotmatrix(x,y,group, clr,sym,siz)
gplotmatrix(x,y,group, clr,sym, siz,doleg)
gplotmatrix(x,y,group, clr,sym, siz, doleg, dispopt)
gplotmatrix(x,y,group, clr, sym,siz, doleg,dispopt, xnam, ynam)
[h,ax,bigax] = gplotmatrix(...)

\section*{Description}
gplotmatrix ( \(\mathrm{x}, \mathrm{y}\), group) creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of \(x\) against a column of \(y\). All plots are grouped by the grouping variable group.
x and y are matrices with the same number of rows. If x has \(p\) columns and y has \(q\) columns, the figure contains a \(p\)-by- \(q\) matrix of scatter plots. If you omit \(y\) or specify it as the empty matrix, [ ], gplotmatrix creates a square matrix of scatter plots of columns of \(x\) against each other.
group is a grouping variable that can be a categorical variable, vector, string array, or cell array of strings. group must have the same number of rows as \(x\) and \(y\). Points with the same value of group are placed in the same group, and appear on the graph with the same marker and color. Alternatively, group can be a cell array containing several grouping variables (such as \(\{\mathrm{g} 1 \mathrm{~g} 2 \mathrm{~g} 3\}\) ); in that case, observations are in the same group if they have common values of all grouping variables.
gplotmatrix ( \(\mathrm{x}, \mathrm{y}\), group, clr, sym, siz) specifies the color, marker type, and size for each group. clr is a string array of colors recognized by the plot function. The default for clr is 'bgrcmyk'. sym is a string array of symbols recognized by the plot command, with the default value '.'. siz is a vector of sizes, with the default determined by the DefaultLineMarkerSize property. If you do not specify enough values for all groups, gplotmatrix cycles through the specified values as needed.
gplotmatrix(x,y,group, clr, sym,siz, doleg) controls whether a legend is displayed on the graph (doleg is 'on', the default) or not (doleg is 'off').
gplotmatrix(x,y,group, clr,sym,siz,doleg,dispopt) controls what appears along the diagonal of a plot matrix of \(y\) versus x. Allowable values are 'none', to leave the diagonals blank, 'hist', to plot histograms, or 'variable', to write the variable names. gplotmatrix displays histograms along the diagonal only when there is only one variable (i.e., gplotmatrix(x,[],[],[],[],[],'hist').
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam, ynam) specifies the names of the columns in the x and y arrays. These names are used to label the \(x\) - and \(y\)-axes. xnam and ynam must be character arrays or cell arrays of strings, with one name for each column of \(x\) and y , respectively.
[h,ax,bigax] = gplotmatrix(...) returns three arrays of handles. \(h\) is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in G. ax is a matrix of handles to the axes of the individual plots. If dispopt is 'hist', ax contains one extra row of handles to invisible axes in which the histograms are plotted. bigax is a handle to big (invisible) axes framing the entire plot matrix. bigax is fixed to point to the current axes, so a subsequent title, xlabel, or ylabel command will produce labels that are centered with respect to the entire plot matrix.

\section*{Examples}

Load the cities data. The ratings array has ratings of the cities in nine categories (category names are in the array categories). group is a code whose value is 2 for the largest cities. You can make scatter plots of the first three categories against the other four, grouped by the city size code:
```

load discrim
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group)

```

The output figure (not shown) has an array of graphs with each city group represented by a different color. The graphs are a little easier to read if you specify colors and plotting symbols, label the axes with the rating categories, and move the legend off the graphs:
```

gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...

```
```

'br','.o',[],'on','', categories(1:2,:),...
categories([4 7],:))

```

\section*{Purpose}

Train additional trees and add to ensemble
Syntax
\(B=\) growTrees ( \(B\), ntrees )
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)
Description
\(B=\) growTrees( \(B\), ntrees) grows ntrees new trees and appends them
to those trees already stored in the ensemble B .
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...) pecifies optional parameter name/value pairs:
\begin{tabular}{ll} 
'nprint' & \begin{tabular}{l} 
Specifies that a diagnostic message showing \\
training progress should display after every \\
value training cycles (grown trees). Default is \\
no diagnostic messages.
\end{tabular} \\
'options ' & \begin{tabular}{l} 
A struct that specifies options that govern \\
computation when growing the ensemble of \\
decision trees. One option requests that the \\
computation of decision trees on multiple
\end{tabular} \\
bootstrap replicates uses multiple processors, \\
if the Parallel Computing Toolbox is available. \\
Two options specify the random number streams \\
to use in selecting bootstrap replicates. You can \\
create this argument with a call to statset. You \\
can retrieve values of the individual fields with a \\
call to statget. Applicable statset parameters \\
are:
\end{tabular}
- 'UseParallel' - If true and if a matlabpool of the Parallel Computing Toolbox is open, compute decision trees drawn on separate boostrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a matlabpool is not open, computation occurs in serial mode. Default is false, or serial computation.

\section*{TreeBagger.growTrees}
- UseSubstreams - Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
- Streams - A RandStream object or cell array of such objects. If you do not specify Streams, growTrees uses the default stream or streams. If you choose to specify Streams, use a single object except in the case
- You have an open MATLAB pool
- UseParallel is true
- UseSubstreams is false

In that case, use a cell array the same size as the MATLAB pool.

\section*{See Also \\ classregtree}

\section*{Purpose Create index vector from grouping variable}

\section*{Syntax}
[G,GN]=grp2idx(S) [G,GN,GL] = grp2idx(S)
[G,GN]=grp2idx(S) creates an index vector \(G\) from the grouping variable S. S can be a categorical, numeric, or logical vector; a cell vector of strings; or a character matrix with each row representing a group label. The result \(G\) is a vector taking integer values from 1 up to the number K of distinct groups. GN is a cell array of strings representing group labels. \(G N(G)\) reproduces \(S\) (aside from any differences in type).

The order of GN depends on the grouping variable:
- For numeric and logical grouping variables, the order is the sorted order of S .
- For categorical grouping variables, the order is the order of getlabels(S).
- For string grouping variables, the order is the order of first appearance in S .
[G,GN,GL] = grp2idx(S) returns a column vector GL representing the group levels. The set of groups and their order in GL and GN are the same, except that GL has the same type as S . If S is a character matrix, GL( \(\mathrm{G}, \mathrm{:}\) ) reproduces S , otherwise \(\mathrm{GL}(\mathrm{G})\) reproduces S .
grp2idx treats NaNs (numeric or logical), empty strings (char or cell array of strings), or <undefined> values (categorical) in S as missing values and returns NaNs in the corresponding rows of G. GN and GL don't include entries for missing values.

\section*{Examples}

Load the data in hospital.mat and create a categorical grouping variable:
```

load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);

```

\section*{grp2idx}
```

ages = hospital.Age(1:5)
ages =
38
4 3
38
4 0
4 9
group = AgeGroup(1:5)
group =
30s
40s
30s
40s
40s
indices = grp2idx(group)
indices =
4
5
4
5
5

```

How To
- "Grouping Variables" on page 2-51
\begin{tabular}{l} 
Purpose \\
Syntax \\
\\
\hline \\
\\
\hline
\end{tabular}
Summary statistics organized by group
```

statarray = grpstats(ds,groupvar)
statarray = grpstats(ds,groupvar,whichstats)
statarray = grpstats(ds,groupvar,whichstats,Name,Value)
means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',
alpha)
grpstats(X,group,alpha)

```
statarray = grpstats(ds, groupvar) returns a dataset array with the means for the data groups in the dataset array ds determined by the values of the grouping variable or variables specified in groupvar.
- If there is a single grouping variable, then there is a row in statarray for each value of the grouping variable. grpstats sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If groupvar is a cell array of strings containing multiple grouping variable names, or a vector of column numbers, then there is a row in statarray for each observed unique combination of values of the grouping variables. grpstats sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in ds (other than those specified in groupvar) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, DataVars.
statarray \(=\) grpstats(ds, groupvar, whichstats) returns the group values for the summary statistics types specified in whichstats.
statarray \(=\) grpstats(ds,groupvar, whichstats, Name, Value) uses additional options specified by one or more Name, Value pair arguments.
means \(=\) grpstats \((X\), group \()\) returns a column vector or matrix with the means of the groups of the data in the matrix or vector \(X\) determined by the values of the grouping variable or variables, group. The rows of means correspond to the grouping variable values.
- If there is a single grouping variable, then there is a row in means for each value of the grouping variable. grpstats sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If group is a cell array of grouping variables, then there is a row in means for each observed unique combination of values of the grouping variables. grpstats sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If \(X\) is a matrix, then means is a matrix with the same number of columns as \(X\). Each column of means has the group means for the corresponding column of \(X\).
[stats1,...,statsN] = grpstats(X,group, whichstats) returns column vectors or arrays with group values for the summary statistic types specified in whichstats.
```

[stats1,...,statsN] =
grpstats(X,group,whichstats,'Alpha',alpha) specifies the
significance level for confidence and prediction intervals.

```
grpstats ( \(X\), group, alpha) plots the means of the groups of data in the vector or matrix \(X\) determined by the values of the grouping variable, group. The grouping variable values are on the horizontal plot axis. Each group mean has \(100 \times(1-a l p h a) \%\) confidence intervals.
- If \(X\) is a matrix, then grpstats plots the means and confidence intervals for each column of \(X\).
- If group is a cell array of grouping variables, then grpstats plots the means and confidence intervals for the groups of data in \(X\) determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

\section*{Input \\ Arguments}
ds - Input data
dataset array
Input data, specified as a dataset array. The dataset array must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for dataset array variables that have a numeric or logical data type. If any variables in ds (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument DataVars to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

\section*{groupvar - Identifiers for the grouping variables}
cell array of strings | vector of positive integers | logical vector | []
Identifiers for the grouping variables in the input dataset array, ds, specified as one of the following:

String or cell array of strings Names of the grouping variables
Positive integer or vector of Variable numbers of the grouping positive integers

Vector of logical values with number of elements equal to the number of variables in ds

\section*{[]}

Logical indicator with value true for grouping variables and false otherwise

No groups (returns summary statistics for all data)

Any variable that is identified by groupvar as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, or cell array of strings.

For example, consider an input dataset array, ds, with six variables. The fourth variable is named Gender. To be a valid grouping variable, the data type of Gender might be a cell array of strings or a nominal array, with the unique values Male and Female. To specify the variable Gender as the grouping variable, you can use any of these syntaxes:
- statarray = grpstats(ds,'Gender')
- statarray = grpstats(ds,4)
- statarray = grpstats(ds,logical([0 0001000\(])\) )

\section*{Data Types \\ double | logical | cell | char}

\section*{whichstats - Types of summary statistics}

\section*{string | function handle}

Types of summary statistics to compute, specified as a string or function handle, or a cell array of strings and function handles. Use a cell array to specify multiple types of summary statistics.
Possible string values are:
\begin{tabular}{ll} 
'mean' & Mean \\
'sem' & Standard error of the mean \\
'numel' & Count, or number, of non-NaN elements \\
'gname' & Group name
\end{tabular}
\begin{tabular}{ll} 
'std' & Standard deviation \\
'var' & Variance \\
'min' & Minimum \\
'max' & Maximum \\
'range' & Range \\
'meanci' & \(95 \%\) confidence interval for the mean \\
'predci' & \(95 \%\) prediction interval for a new observation
\end{tabular}
```

Example: [stat1,stat2] = grpstats(X,group,{'mean','sem'})

```

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, Alpha.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time grpstats calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an nuals-by- 1 column vector for descriptive statistics of length nuals (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-ncols row vector, or an nuals-by-ncols matrix, where ncols is the number of columns in the input data matrix.

Example: [stat1,stat2,stat3] =
grpstats(X,group,\{'mean','std', @skewness\})

\section*{Data Types}
char | function_handle

\section*{alpha-Significance level}
scalar value in the range \((0,1)\)
Significance level, specified as a scalar value in the range \((0,1)\).
- When you specify 'meanci' or 'predci' in whichstats, you can use alpha to specify the significance level for the confidence or prediction
intervals. If you specify alpha, then grpstats returns \(100 \times(1-\) alpha) \(\%\) confidence or prediction intervals. If you do not specify alpha, then grpstats returns \(95 \%\) intervals (alpha \(=0.05\) ).
- Use alpha with the grpstats (X, group, alpha) syntax to plot group means and corresponding \(100 \times(1-\) alpha \() \%\) confidence intervals.

\section*{Data Types}
double

\section*{X - Input data}
vector | matrix
Input data, specified as a vector or a matrix. If \(x\) is a matrix, then grpstats returns summary statistics for each column of \(X\).

\section*{Data Types}
double | single

\section*{group - Grouping variable}
categorical array | logical or numeric vector | cell array of strings | [ ]
Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group. grpstats groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data X. Observations (rows) with the same value of the grouping variable are in the same group. Use [ ] to compute summary statistics for all data, without using groups.

For example, if Gender is a cell array of strings with values 'Male ' and 'Female', you can use Gender as a grouping variable to summarize your data by gender.
You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if Smoker is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array \{Gender, Smoker\} divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. grpstats returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'DataVars', [1, 3, 4],'Alpha', 0.01 specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with \(99 \%\) confidence intervals.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).
When you include 'meanci' or 'predci' in whichstats, you can use Alpha to specify the significance level for confidence or prediction intervals. If you specify the value \(\alpha\), then grpstats returns \(100 \times(1-\) \(a) \%\) confidence or prediction intervals.
If you do not specify a value for Alpha, then grpstats returns \(95 \%\) intervals ( \(\alpha=0.05\) ).

Example: 'Alpha', 0.1
Data Types
double
'DataVars' - Variable names or columns
cell array of strings | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input dataset array you want to compute summary statistics for, specified as the comma-separated pair consisting of 'DataVars ' and a cell array of strings, vector of positive integers, or a logical vector. Use a string to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (true if you want to compute summary statistics, false otherwise).

You must specify DataVars if there are any variables in ds (other than the grouping variables specified in groupvar) that are not numeric or logical arrays. Summary statistics can only be calculated for dataset array variables that have a numeric or logical data type.
Example: 'DataVars', \{'Height', 'Weight'\}
```

Data Types
double | cell | char

```

\section*{'VarNames' - Variable names for output dataset array cell array of strings}

Variable names for the output dataset array, statarray, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings. By default, grpstats constructs output variable names by appending a prefix to the variable names from the input dataset array, ds. This prefix corresponds to the summary statistic name.
```

Example: 'VarNames',{'MaleMean','FemaleMean'}

```

\section*{Data Types}
cell

\section*{Output Arguments}

\section*{statarray - Group summary statistics}
dataset array
Group summary statistics, returned as a dataset array. statarray contains summary statistic values for the groups of data in the dataset array ds determined by the levels of the grouping variables specified by groupvar. There is a row in statarray for each observed value
or combination of values in the variables specified by groupvar. The dataset array, statarray, contains:
- All grouping variables specified by groupvar.
- The variable GroupCount, containing the number of observations in each group.
- Group summary statistic values for all variables in ds (other than those specified by groupvar), or for only the variables specified using DataVars.

The total number of variables in statarray is ngroupvars \(+1+\) ndatavars \(\times\) nstats, where ngroupvars is the number of variables in groupvar, ndatavars is the number of variables for which summary statistics are computed, and nstats is the number of summary statistic types specified in whichstats.
grpstats assigns default names to the variables in statarray, unless you specify variable names using the name-value pair argument VarNames.

\section*{means - Group means}
column vector | array
Group means for the groups of data in the vector or matrix \(X\) determined by the levels of group, returned as an ngroups-by-ncols array. Here, ngroups is the number of unique values in the grouping variable, and ncols is the number of columns in X . If X is a vector, then means is a column vector.

\section*{stats \(1, \ldots\), stats \(\mathbf{N}\) - Group summary statistics}
column vectors | arrays
Group summary statistics for the groups of data in the vector or matrix X determined by the levels of group, returned as ngroups-by-ncols arrays. Here, ngroups is the number of unique values in the grouping variable, and ncols is the number of columns in \(X\). You must specify an output argument for each type of summary statistic specified in whichstats.

If a summary statistic type in whichstats returns a value of length nuals (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an ngroups-by-ncols-by-nvals array.

\section*{Examples}

\section*{Dataset Array Summary Statistics Organized by Group}

Load the sample data.
```

load('hospital')

```

The dataset array, hospital, has 100 observations and 7 variables.
Create a dataset array with only the variables Sex, Age, Weight, and Smoker.
```

ds = hospital(:,{'Sex','Age','Weight','Smoker'});

```

Sex is a nominal array, with levels Male and Female. The variables Age and Weight have numeric values, and Smoker has logical values.

Compute the mean for the numeric and logical arrays, Age, Weight, and Smoker, grouped by the levels in Sex.
```

statarray = grpstats(ds,'Sex')

```
statarray =
\begin{tabular}{lllll} 
& Sex & GroupCount & mean_Age & mean_Weight \\
Female & Female & 53 & 37.717 & 130.47 \\
Male & Male & 47 & 38.915 & 180.53
\end{tabular}
statarray is a dataset array with two rows, corresponding to the levels in Sex. GroupCount is the number of observations in each group. The means of Age, Weight, and Smoker, grouped by Sex, are given in mean_Age, mean_Weight, and mean_Smoker.

Compute the mean for Age and Weight, grouped by the values in Smoker.
```

statarray = grpstats(ds,'Smoker','mean','DataVars',{'Age','Weight'})
statarray =

|  | Smoker | GroupCount | mean_Age | mean_Weight |
| :--- | :--- | :--- | :---: | :--- |
| 0 | false | 66 | 37.97 | 149.91 |
| 1 | true | 34 | 38.882 | 161.94 |

```

In this case, not all variables in ds (excluding the grouping variable, Smoker) are numeric or logical arrays; the variable Sex is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using DataVars.

Compute the minimum and maximum weight, grouped by the combinations of values in Sex and Smoker.
```

statarray = grpstats(ds,{'Sex','Smoker'},{'min','max'},...
'DataVars','Weight')
statarray =

```
\begin{tabular}{llllll} 
& Sex & Smoker & GroupCount & min_Weight & max_ \\
Female_0 & Female & false & 40 & 111 & 147 \\
Female_1 & Female & true & 13 & 115 & 146 \\
Male_0 & Male & false & 26 & 158 & 194 \\
Male_1 & Male & true & 21 & 164 & 202
\end{tabular}

There are two unique values in Smoker and two levels in Sex, for a total of four possible combinations of values: Female Nonsmoker (Female_0), Female Smoker (Female_1), Male Nonsmoker (Male_0), and Male Smoker (Male_1).

\section*{Summary Statistics for a Dataset Array Without Grouping}

Load the sample data.
```

load('hospital')

```

The dataset array, hospital, has 100 observations and 7 variables.
Create a dataset array with only the variables Age, Weight, and Smoker.
```

ds = hospital(:,{'Age','Weight','Smoker'});

```

The variables Age and Weight have numeric values, and Smoker has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, Age, Weight, and Smoker, with no grouping.
```

statarray = grpstats(ds,[],{'mean','min','max'})
statarray =

|  | GroupCount | mean_Age | min_Age | max_Age | mean_Weight |
| :--- | :--- | :--- | :--- | :--- | :--- |
| All | 100 | 38.28 | 25 | 50 | 154 |

```
min_Weight max_Weight mean_Smoker min_Smoker \(\begin{array}{llll}\text { All } 111 & 202 & 0.34 & f a l s e\end{array}\)

The observation name All indicates that all observations in ds were used to compute the summary statistics.

\section*{Group Means for a Matrix Using One or More Grouping Variables}

Load the sample data.
```

load('carsmall')

```

All variables are measured for 100 cars. Origin is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). Cylinders has three unique values, 4,6 , and 8 , indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.
```

means = grpstats(Acceleration,Origin)
means =

```
    18.0500
    16.3778
    15.5000
    15.8867
    16.6000
    14.4377
means is a 6-by- 1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.
```

means = grpstats(Acceleration,{Origin,Cylinders})

```
means =
18.0500
16.3375
16.7000
15.5000
15.9143
15.5000
16.6000
17.0818
16.5267
11.6406

There are 18 possible combinations of grouping variable values because Origin has 6 unique values and Cylinders has 3 unique values. Only 10 of the possible combinations appear in the data, so means is a 10 -by- 1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.
```

[means,grps] = grpstats(Acceleration,{Origin,Cylinders},...
{'mean','gname'})
means =
17.0818
16.5267
11.6406
18.0500
15.9143
15.5000
16.3375
16.7000
16.6000
15.5000

```
grps =
\begin{tabular}{|c|}
\hline ' USA ' \\
\hline 'USA' \\
\hline 'USA' \\
\hline France' \\
\hline 'Japan' \\
\hline 'Japan' \\
\hline 'Germany ' \\
\hline 'Germany ' \\
\hline 'Sweden' \\
\hline Italy ' \\
\hline
\end{tabular}

The output grps shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4 -cylinder cars made in France is 18.05.

\section*{Multiple Summary Statistics for a Matrix Organized by Group}

Load the sample data.
load('carsmall')
The variable Acceleration was measured for 100 cars. The variable Origin is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum, median, and maximum acceleration, grouped by country of origin.
[grpMin, grpMed, grpMax, grp] \(=\)
\(\quad\) grpstats(Acceleration, Origin, \(\ldots\),
grpMin =
8.0000
15.3000
13.9000
12.2000
15.7000
15.5000
grpMed =
14.7000
17.5000
15.7000
15.3000
16.6000
15.5000
grpMax =
```

22.2000
21.9000
18.2000
24.6000
17.5000
15.5000
' USA'
' France
'Japan
Germany
Sweden
Italy'

```
grp \(=\)

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

\section*{Plot Prediction Intervals for a New Observation in Each Group}

Load the sample data.
load('carsmall')

The variable Weight was measured for 100 cars. The variable Model_Year has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and \(90 \%\) prediction intervals for each model year.
```

[means,pred,grp] = grpstats(Weight,Model_Year,...
{'mean','predci','gname'},'Alpha',0.1);

```

Plot error bars showing the mean weight and \(90 \%\) prediction intervals, grouped by model year. Label the horizontal axis with the group names.
```

ngrps = length(grp); % Number of groups

```
```

figure()

```
errorbar((1:ngrps)', means, pred(:,2)-means)
set(gca, 'xtick',1:ngrps,'xticklabel',grp)
title('90\% Prediction Intervals for Weight by Year')

\section*{Plot Group Means and Confidence Intervals}

Load the sample data.
```

load('carsmall')

```

The variables Acceleration and Weight are the acceleration and weight values measured for 100 cars. The variable Cylinders is the number of cylinders in each car. The variable Model_Year has three unique values, 70,76 , and 82 , which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by Cylinders, with \(95 \%\) confidence intervals.
grpstats(Acceleration, Cylinders, 0.05)

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by Cylinders, and \(95 \%\) confidence intervals. Scale the Weight values by 1000 so the means of Weight and Acceleration are the same order of magnitude.
grpstats([Acceleration, Weight/1000],Cylinders,0.05)

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both Cylinders and Model_Year. Specify \(95 \%\) confidence intervals.
```

grpstats(Acceleration,{Cylinders,Model_Year},0.05)

```

There are nine possible combinations of grouping variable values because there are three unique values in Cylinders and three unique values in Model_Year. The plot does not show 8 -cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8 -cylinder cars made in 1970.

\section*{Algorithms}
- grpstats treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- grpstats ignores empty group names.

See Also dataset I
Related - "Summary Statistics Grouped by Category" on page 2-37Examples- "Test Differences Between Category Means" on page 2-28

Concepts • "Dataset Arrays" on page 2-135
- "Grouping Variables" on page 2-51
- "Categorical Arrays" on page 2-41

\section*{Purpose Scatter plot by group}
```

Syntax gscatter(x,y,group)
gscatter(x,y,group,clr,sym,siz)
gscatter(x,y,group,clr,sym,siz,doleg)
gscatter(x,y,group,clr,sym,siz,doleg,xnam, ynam)
h = gscatter(...)

```

\section*{Description}
gscatter ( \(x, y\), group) creates a scatter plot of \(x\) and \(y\), grouped by group. \(x\) and \(y\) are vectors of the same size. group is a grouping variable in the form of a categorical variable, vector, string array, or cell array of strings. Alternatively, group can be a cell array containing several grouping variables (such as \{g1 g2 g3\}), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group and appear on the graph with the same marker and color.
gscatter ( \(\mathrm{x}, \mathrm{y}\), group, clr, sym, siz) specifies the color, marker type, and size for each group. clr is a string array of colors recognized by the plot function. The default for clr is 'bgrcmyk'. sym is a string array of symbols recognized by the plot command, with the default value '.'. siz is a vector of sizes, with the default determined by the 'DefaultLineMarkerSize' property. If you do not specify enough values for all groups, gscatter cycles through the specified values as needed.
gscatter( \(\mathrm{x}, \mathrm{y}\), group, clr,sym,siz,doleg) controls whether a legend is displayed on the graph (doleg is 'on', the default) or not (doleg is 'off').
gscatter( \(\mathrm{x}, \mathrm{y}\), group, clr, sym, siz,doleg, xnam, ynam) specifies the name to use for the \(x\)-axis and \(y\)-axis labels. If the x and y inputs are simple variable names and xnam and ynam are omitted, gscatter labels the axes with the variable names.
\(\mathrm{h}=\) gscatter (...) returns an array of handles to the lines on the graph.

Examples
Load the cities data and look at the relationship between the ratings for climate (first column) and housing (second column) grouped by city size. We'll also specify the colors and plotting symbols.
load discrim
gscatter(ratings(:,1), ratings(: , 2), group,'br','xo')

How To
- "Grouping Variables" on page 2-51

\section*{Purpose Greater than relation for handles}

\section*{Syntax \\ h1 > h2}

Description \(\quad \mathrm{h} 1>\mathrm{h} 2\) performs element-wise comparisons between handle arrays h 1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise > result.

If one of h 1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.
\(\mathrm{tf}=\mathrm{gt}(\mathrm{h} 1, \mathrm{~h} 2)\) stores the result in a logical array of the same dimensions.

- "Quasi-Random Point Sets" on page 6-16

\section*{haltonset}

\section*{Examples}

\section*{Purpose Construct Halton quasi-random point set}
```

Syntax
p = haltonset(d)
p = haltonset(d,prop1,val1,prop2,val2,...)
p = haltonset(d,prop1,val1,prop2,val2,...)

```

\section*{Description \\ Syntax}
\(p=\) haltonset \((d)\) constructs a d-dimensional point set \(p\) of the
haltonset class, with default property settings.
p = haltonset(d,prop1,val1,prop2,val2,...) specifies property name/value pairs used to construct \(p\).

The object \(p\) returned by haltonset encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the Skip and Leap properties and by limits on the size of point set indices (maximum value of \(2^{53}\) ). Values of the point set are not generated and stored in memory until you access p using net or parenthesis indexing.

Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:
```

p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
Halton point set in 3 dimensions (8.918019e+013 points)
Properties:
Skip : 1000
Leap : 100
ScrambleMethod : none

```

Use scramble to apply reverse-radix scrambling:
p = scramble( \(\mathrm{p}, \mathrm{CR}^{\prime}\) R2')
p =
Halton point set in 3 dimensions (8.918019e+013 points) Properties:

Skip : 1000
Leap : 100
ScrambleMethod : RR2

Use net to generate the first four points:
```

XO = net(p,4)
XO =
0.0928 0.6950 0.0029
0.6958 0.2958 0.8269
0.3013 0.6497 0.4141
0.9087 0.7883 0.2166

```

Use parenthesis indexing to generate every third point, up to the 11th point:
```

X = p(1:3:11,:)
X =
0.0928 0.6950 0.0029
0.9087 0.7883 0.2166
0.3843 0.9840 0.9878
0.6831 0.7357 0.7923

```

\section*{References}

\section*{harmmean}

Purpose Harmonic mean

\section*{Syntax \\ \(\mathrm{m}=\) harmmean \((\mathrm{X})\) harmmean(X,dim)}

Description
\(m=\) harmmean \((X)\) calculates the harmonic mean of a sample. For vectors, harmmean \((x)\) is the harmonic mean of the elements in \(x\). For matrices, harmmean \((X)\) is a row vector containing the harmonic means of each column. For \(N\)-dimensional arrays, harmmean operates along the first nonsingleton dimension of X .
harmmean ( \(\mathrm{X}, \mathrm{dim}\) ) takes the harmonic mean along dimension dim of X .
The harmonic mean is
\[
m=\frac{n}{\sum_{i=1}^{n} \frac{1}{x_{i}}}
\]

Examples The arithmetic mean is greater than or equal to the harmonic mean.
```

x = exprnd(1,10,6);
harmonic = harmmean(x)
harmonic =
0.3382 0.3200 0.3710 0.0540 0.4936 0.0907
average = mean(x)
average =
1.3509 1.1583 0.9741 0.5319 1.0088 0.8122

```

\section*{See Also mean | median | geomean \| trimmean}

Purpose
Syntax
Description
Bivariate histogram
```

hist3(X)
hist3(X,nbins)
hist3(X,ctrs)
hist3(X,'Edges',edges)
N = hist3(X,...)
[N,C] = hist3(X,...)
hist3(...,param1,val1,param2,val2,...)

```
hist3(X) bins the elements of the \(m\)-by- 2 matrix \(X\) into a 10 -by- 10 grid of equally spaced containers, and plots a histogram. Each column of \(\mathbf{X}\) corresponds to one dimension in the bin grid.
hist3(X, nbins) plots a histogram using an nbins(1)-by-nbins (2) grid of bins. hist3( \(X\), 'Nbins', nbins) is equivalent to hist3( \(X\), nbins).
hist3 ( \(\mathrm{X}, \mathrm{ctrs}\) ), where ctrs is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2 -D grid of bins centered on \(\operatorname{ctrs}\{1\}\) in the first dimension and on \(\operatorname{ctrs}\{2\}\) in the second. hist3 assigns rows of \(X\) falling outside the range of that grid to the bins along the outer edges of the grid, and ignores rows of \(X\) containing NaNs. hist3 ( X, ' Ctrs', ctrs) is equivalent to hist3(X, ctrs).
hist3( \(X\), 'Edges ', edges), where edges is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins with edges at edges \(\{1\}\) in the first dimension and at edges \(\{2\}\) in the second. The \((i, j)\) th bin includes the value \(X(k,:)\) if
```

edges{1}(i) <= X(k,1) < edges{1}(i+1)
edges{2}(j) <= X(k,2) < edges{2}(j+1)

```

Rows of \(X\) that fall on the upper edges of the grid, edges \(\{1\}\) (end) or edges \(\{2\}\) (end), are counted in the ( \(I, j\) )th or ( \(i, J\) ) th bins, where I and \(J\) are the lengths of edges \(\{1\}\) and edges \(\{2\}\). hist 3 does not count rows of \(X\) falling outside the range of the grid. Use - Inf and Inf in edges to include all non- NaN values.
\(N=\) hist3(X,...) returns a matrix containing the number of elements of \(X\) that fall in each bin of the grid, and does not plot the histogram.
\([N, C]=\) hist \(3(X, \ldots)\) returns the positions of the bin centers in a 1 -by-2 cell array of numeric vectors, and does not plot the histogram. hist3(ax, \(x, \ldots\) ) plots onto an axes with handle ax instead of the current axes. See the axes reference page for more information about handles to plots.
hist3(...,param1, val1,param2, val2,...) allows you to specify graphics parameter name/value pairs to fine-tune the plot.

\section*{Examples}

\section*{Example 1}

Make a 3-D figure using a histogram with a density plot underneath:
```

load seamount
dat = [-y,x]; % Grid corrected for negative y-values
hold on
hist3(dat) % Draw histogram in 2D
n = hist3(dat); % Extract histogram data;
% default to 10x10 bins
n1 = n';
n1( size(n,1) + 1 , size(n,2) + 1 ) = 0;

```

Generate grid for 2-D projected view of intensities:
```

xb = linspace(min(dat(:,1)),max(dat(:,1)),size(n,1)+1);
yb = linspace(min(dat(:,2)),max(dat(:,2)),size(n,1)+1);

```

Make a pseudocolor plot:
h = pcolor(xb,yb,n1);
Set the z-level and colormap of the displayed grid:
```

set(h, 'zdata', ones(size(n1)) * -max(max(n)))
colormap(hot) % heat map
title('Seamount: ...

```

\section*{Data Point Density Histogram and Intensity Map'); grid on}

Display the default 3-D perspective view:
view(3);

Seamount: Data Point Density Histogram and Intensity Map

\section*{Example 2}

Use the car data to make a histogram on a 7 -by- 7 grid of bins.
load carbig
X = [MPG,Weight];
hist3(X,[7 7]);
xlabel('MPG'); ylabel('Weight');

Make a histogram with semi-transparent bars:
hist3(X,[7 7],'FaceAlpha',.65);
xlabel('MPG'); ylabel('Weight');
set(gcf,'renderer','opengl');

Specify bin centers, different in each direction; get back counts, but don't make the plot.
```

cnt = hist3(X, {0:10:50 2000:500:5000});

```

\section*{Example 3}

Make a histogram with bars colored according to height.
```

load carbig
X = [MPG,Weight];
hist3(X,[7 7]);
xlabel('MPG'); ylabel('Weight');
set(gcf,'renderer','opengl');
set(get(gca,'child'),'FaceColor','interp','CDataMode',...
'auto');

```

See Also accumarray | bar | bar3 | hist | histc

\section*{Purpose Plot histogram of categorical data}

Syntax
```

hist(Y)
hist(Y,X)
hist(ax,...)
N = hist(...)
[N,X] = hist(...)

```

Description
hist ( Y ) plots a histogram bar plot of the counts for each level of the categorical vector \(Y\). If \(Y\) is an \(m\)-by- \(n\) categorical matrix, hist computes counts for each column of \(Y\), and plots a group of \(n\) bars for each categorical level.
hist \((\mathrm{Y}, \mathrm{X})\) plots bars only for the levels specified in \(\mathrm{X} . \mathrm{X}\) is a categorical vector or a cell array of level names as strings.
hist ( \(\mathrm{ax}, \ldots\) ) plots into the axes with handle ax instead of gca.
\(N=\) hist (...) returns the counts for each categorical level. If \(Y\) is a matrix, hist works down the columns of \(Y\) and returns a matrix of counts with one column for each coluimn of \(Y\) and one row for each cetegorical level.
\([\mathrm{N}, \mathrm{X}]=\) hist (...) returns the categorical levels corresponding to each count in \(N\), or corresponding to each column of \(N\) if \(Y\) is a matrix.

\section*{Examples \\ Create a histogram of age groups from the hospital.mat dataset:}
```

load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);
AgeGroup = droplevels(AgeGroup);
hist(AgeGroup)

```

See Also
hist | categorical.levelcounts | categorical.getlevels

\section*{Purpose Histogram with a distribution fit}

Syntax
```

histfit(data)
histfit(data,nbins)
histfit(data,nbins,dist)
h = histfit(___)

```

Description

\section*{Input} Arguments
histfit(data) plots a histogram of values in data using the number of bins equal to the square root of the number of elements in data and fits a normal density function.
histfit(data, nbins) plots a histogram using nbins bins and fits a normal density function.
histfit(data, nbins, dist) plots a histogram with nbins bins and fits a density function from the distribution specified by dist.
h = histfit( \(\qquad\) ) returns a vector of handles h , where \(\mathrm{h}(1)\) is the handle to the histogram and \(\mathrm{h}(2)\) is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

\section*{data- Input data}
vector
Input data, specified as a vector.
Example: data \(=\left[\begin{array}{lll}1.5 & 2.5 & 4.6 \\ 1.2 & 3.4\end{array}\right]\)
Example: data \(=\left[\begin{array}{llll}1.5 & 2.5 & 4.6 & 1.2 \\ 3.4\end{array}\right]\)

\section*{Data Types}
double | single
nbins - Number of bins
positive integer | []

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in data, rounded up. Use [ ] for the default number of bins when fitting a distribution.

Example: y \(=\) histfit( \(x, 8\) )
Example: y = histfit(x,10,'gamma')
Example: y = histfit(x, [ ],'weibull')

\section*{Data Types}
double | single

\section*{dist - Distribution to fit}
'normal' (default) | string
Distribution to fit to the histogram, specified as a string. The following table shows the supported distributions.
\begin{tabular}{l|l}
\hline dist & Description \\
\hline 'beta' & Beta \\
\hline 'birnbaumsaunders' & Birnbaum-Saunders \\
\hline 'burr' & Burr Type XII \\

\section*{hmmdecode}

\author{
Purpose \\ \section*{Syntax} \\ \section*{Description}
}

Hidden Markov model posterior state probabilities

PSTATES = hmmdecode(seq,TRANS, EMIS)
[PSTATES,logpseq] = hmmdecode(...)
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)
hmmdecode(..., 'Symbols', SYMBOLS)
PSTATES = hmmdecode(seq,TRANS,EMIS) calculates the posterior state probabilities, PSTATES, of the sequence seq, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state \(k\) at step \(i\), given the observed sequence of symbols, sym. You specify the model by a transition probability matrix, TRANS, and an emissions probability matrix, EMIS. TRANS \((i, j)\) is the probability of transition from state \(i\) to state \(j\). EMIS ( \(k\), seq) is the probability that symbol seq is emitted from state \(k\).

PSTATES is an array with the same length as seq and one row for each state in the model. The \((i, j)\) th element of PSTATES gives the probability that the model is in state \(i\) at the \(j\) th step, given the sequence seq.

Note The function hmmdecode begins with the model in state 1 at step 0 , prior to the first emission. hmmdecode computes the probabilities in PSTATES based on the fact that the model begins in state 1 .
[PSTATES,logpseq] = hmmdecode(...) returns logpseq, the logarithm of the probability of sequence seq, given transition matrix TRANS and emission matrix EMIS.
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...) returns the forward and backward probabilities of the sequence scaled by \(S\).
hmmdecode(..., 'Symbols', SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through \(N\), where \(N\) is the number of possible emissions.

\section*{hmmestimate}

Purpose
Syntax

Description

Hidden Markov model parameter estimates from emissions and states
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions', PSEUDOE)
hmmestimate(...,'Pseudotransitions', PSEUDOTR)
[TRANS,EMIS] = hmmestimate(seq,states) calculates the maximum likelihood estimate of the transition, TRANS, and emission, EMIS, probabilities of a hidden Markov model for sequence, seq, with known states, states.
hmmestimate(...,'Symbols', SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N , where N is the number of possible emissions.
hmmestimate(...,'Statenames', STATENAMES) specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through \(M\), where M is the number of states.
hmmestimate(...,'Pseudoemissions', PSEUDOE) specifies pseudocount emission values in the matrix PSEUDO. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size \(m\)-by- \(n\), where \(m\) is the number of states in the hidden Markov model and \(n\) is the number of possible emissions. If the \(i \rightarrow k\) emission does not occur in seq, you can set \(\operatorname{PSEUDOE}(i, k)\) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.
hmmestimate(...,'Pseudotransitions',PSEUDOTR) specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size \(m\)-by- \(m\), where \(m\) is the number of states in the hidden

Markov model. If the \(i \rightarrow j\) transition does not occur in states, you can set PSEUDOTR ( \(i, j\) ) to be a positive number representing an estimate of the expected number of such transitions in the sequence states.

\section*{Pseudotransitions and Pseudoemissions}

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence states, or the emission might never occur in the sequence seq. In either case, the algorithm returns a probability of 0 for the given transition or emission in TRANS or EMIS. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of PSEUDO or
PSEUDOTR to 1. For example, if the transition \(i \rightarrow j\) does not occur in states, set PSEUOTR \((i, j)=1\). This forces \(\operatorname{TRANS}(i, j)\) to be positive.

If you have an estimate for the expected number of transitions \(i \rightarrow j\) in a sequence of the same length as states, and the actual number of transitions \(i \rightarrow j\) that occur in seq is substantially less than what you expect, you can set \(\operatorname{PSEUOTR}(i, j)\) to the expected number. This increases the value of \(\operatorname{TRANS}(i, j)\). For transitions that do occur in states with the frequency you expect, set the corresponding entry of PSEUDOTR to 0 , which does not increase the corresponding entry of TRANS.
If you do not know the sequence of states, use hmmtrain to estimate the model parameters.

\section*{hmmgenerate}

\section*{Purpose Hidden Markov model states and emissions}

Syntax

Description
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames', STATENAMES)
[seq, states] = hmmgenerate(len, TRANS,EMIS) takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate
- A random sequence seq of emission symbols
- A random sequence states of states

The length of both seq and states is len. TRANS \((i, j)\) is the probability of transition from state \(i\) to state \(j\). EMIS \((k, l)\) is the probability that symbol \(l\) is emitted from state \(k\).

Note The function hmmgenerate begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state \(\mathrm{i}_{1}\), with probability \(T_{1 i}\), and generates an emission \(a_{k_{I}}\) with probability \(E_{i, k_{l} .}\). hmmgenerate returns \(\mathrm{i}_{1}\) as the first entry of states, and \(a_{k_{1}}\) as the first entry of seq.
hmmgenerate(..., 'Symbols', SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through \(N\), where \(N\) is the number of possible emissions.
hmmgenerate(...,'Statenames', STATENAMES) specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through \(M\), where \(M\) is the number of states.

Since the model always begins at state 1 , whose transition probabilities are in the first row of TRANS, in the following example, the first entry of

\section*{hmmgenerate}
the output states is be 1 with probability 0.95 and 2 with probability 0.05 .
```

Examples
trans = [0.95,0.05;
0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
1/10 1/10 1/10 1/10 1/10 1/2];
[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
'Symbols',{'one','two','three','four','five','six'},...
'Statenames',{'fair';'loaded'})

```

\author{

}

Purpose
Hidden Markov model parameter estimates from emissions

\section*{Syntax}

\section*{Description}
```

[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose', true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS) estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. seq can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. TRGUESS and EMITGUESS are initial estimates of the transition and emission probability matrices. \(\operatorname{TRGUESS}(i, j)\) is the estimated probability of transition from state \(i\) to state \(j\). EMITGUESS ( \(i, k\) ) is the estimated probability that symbol \(k\) is emitted from state i.
hmmtrain(...,'Algorithm', algorithm) specifies the training algorithm. algorithm can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.
hmmtrain(...,'Symbols', SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through \(N\), where \(N\) is the number of possible emissions.
hmmtrain(...,'Tolerance', tol) specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is 1e-4.
hmmtrain(...,'Maxiterations', maxiter) specifies the maximum number of iterations for the estimation process. The default maximum is 100 .

\section*{hmmtrain}
hmmtrain(..., 'Verbose', true) returns the status of the algorithm at each iteration.
hmmtrain(..., 'Pseudoemissions', PSEUDOE) specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size \(m\)-by- \(n\), where \(m\) is the number of states in the hidden Markov model and \(n\) is the number of possible emissions. If the \(i \rightarrow k\) emission does not occur in seq, you can set PSEUDOE ( \(\mathrm{i}, \mathrm{k}\) ) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.
hmmtrain(..., 'Pseudotransitions', PSEUDOTR) specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size \(m\)-by- \(m\), where \(m\) is the number of states in the hidden Markov model. If the \(i \rightarrow j\) transition does not occur in states, you can set PSEUDOTR ( \(i, j\) ) to be a positive number representing an estimate of the expected number of such transitions in the sequence states.

If you know the states corresponding to the sequences, use hmmestimate to estimate the model parameters.

\section*{Tolerance}

The input argument 'tolerance' controls how many steps the hmmtrain algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for tolerance:
- The log likelihood that the input sequence seq is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of 'tolerance' is .0001. Increasing the tolerance decreases the number of steps the hmmtrain algorithm executes before it terminates.

\section*{maxiterations}

The maximum number of iterations, 'maxiterations ', controls the maximum number of steps the algorithm executes before it terminates. If the algorithm executes maxiter iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of 'maxiterations' to make the algorithm reach the desired tolerance before terminating.

Purpose Horizontal concatenation for categorical arrays
```

Syntax $\quad C=\operatorname{horzcat}(\operatorname{dim}, A, B, \ldots)$
$C=\operatorname{horzcat}(A, B)$

```

Description \(\quad C=\) horzcat (dim, \(A, B, \ldots\) ) horizontally concatenates the categorical arrays A, B, .. . For matrices, all inputs must have the same number of rows. For n-D arrays, all inputs must have the same sizes except in the second dimension. The set of categorical levels for C is the sorted union of the sets of levels of the inputs, as determined by their labels. \(C=\) horzcat \((A, B)\) is called for the syntax [A B].

\section*{See Also \\ cat | vertcat}

\section*{Purpose Horizontal concatenation for dataset arrays}

Syntax ds = horzcat(ds1, ds2, ...)
Description ds = horzcat(ds1, ds2, ...) horizontally concatenates the dataset arrays ds1, ds2, ... . You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and horzcat includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. horzcat concatenates by matching observation names when present, or by position for datasets that do not have observation names.

\(Y=\) hygepdf( \(X, M, K, N\) ) computes the hypergeometric pdf at each of the values in \(X\) using the corresponding size of the population, \(M\), number of items with the desired characteristic in the population, K , or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in \(M, K\), and \(N\) must all be positive integers, with \(N \leq M\).

The hypergeometric pdf is
\[
y=f(x \mid M, K, N)=\frac{\binom{K}{x}\binom{M-K}{N-x}}{\binom{M}{N}}
\]

The result, \(y\), is the probability of drawing exactly \(x\) of a possible \(K\) items in \(n\) drawings without replacement from a group of \(M\) objects. floppy disks if you select 10 at random?
```

p = hygepdf(0:5,100,20,10)
p =
0.0951 0.2679

```
pdf | hygecdf | hygeinv | hygestat | hygernd
and number of samples drawn, \(N . X, M, K\), and \(N\) can be vectors, matrices, The values in \(X\) must be less than or equal to all the parameter values.

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective

Purpose Hypergeometric random numbers
Syntax \(\quad \begin{aligned} R & =\operatorname{hygernd}(M, K, N) \\ R & =\operatorname{hygernd}(M, K, N, m, n, \ldots) \\ R & =\operatorname{hygernd}(M, K, N,[m, n, \ldots])\end{aligned}\)
\(R=\) hygernd \((M, K, N)\) generates random numbers from the hypergeometric distribution with corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. M, K, and N can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of R. A scalar input for \(M, K\), or \(N\) is expanded to a constant array with the same dimensions as the other inputs.
\(R=\) hygernd ( \(M, K, N, m, n, \ldots\) ) or \(R=\) hygernd ( \(M, K, N,[m, n, \ldots]\) ) generates an m-by-n-by-... array. The M, K, N parameters can each be scalars or arrays of the same size as \(R\).

Examples numbers \(=\) hygernd \((1000,40,50)\) numbers \(=\)

\section*{Purpose}

Hypergeometric mean and variance

\section*{Syntax}
[MN, V] = hygestat (M, K, N)
[MN, V] = hygestat ( \(M, K, N\) ) returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, M , number of items with the desired characteristic in the population, K , and number of samples drawn, \(N\). Vector or matrix inputs for M, K, and N must have the same size, which is also the size of MN and V. A scalar input for \(\mathrm{M}, \mathrm{K}\), or N is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters \(\mathrm{M}, \mathrm{K}\), and \(N\) is \(N K / M\), and the variance is \(N K(M-K)(M-N) /\left[M^{\wedge} 2(M-1)\right]\).

\section*{Examples}

The hypergeometric distribution approaches the binomial distribution, where \(p=K / M\), as \(M\) goes to infinity.
```

[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
m =
0.9000}00.9000 0.9000 0.9000
v =
0.0900}00.7445 0.8035 0.8094
[m,v] = binostat(9,0.1)
m =
0.9000
v =
0.8100

```

Purpose Inverse cumulative distribution functions
Syntax \(\quad \begin{aligned} Y & =\operatorname{icdf}(\text { name }, X, A) \\ Y & =\operatorname{icdf}(\text { name }, X, A, B) \\ Y & =\operatorname{icdf}(\text { name }, X, A, B, C)\end{aligned}\)

\section*{Description}
\(Y=\operatorname{icdf}(\) name \(, X, A)\) computes the inverse cumulative distribution function for the one-parameter family of distributions specified by name. Parameter values for the distribution are given in A. The inverse cumulative distribution function is evaluated at the values in \(X\) and its values are returned in Y .

If \(X\) and \(A\) are arrays, they must be the same size. If \(X\) is a scalar, it is expanded to a constant matrix the same size as \(A\). If \(A\) is a scalar, it is expanded to a constant matrix the same size as \(X\).
\(Y\) is the common size of \(X\) and \(A\) after any necessary scalar expansion.
\(Y=\operatorname{icdf}(\) name \(, X, A, B)\) computes the inverse cumulative distribution function for two-parameter families of distributions, where parameter values are given in \(A\) and \(B\).

If \(X, A\), and \(B\) are arrays, they must be the same size. If \(X\) is a scalar, it is expanded to a constant matrix the same size as A and B. If either A or B are scalars, they are expanded to constant matrices the same size as \(X\).
\(Y\) is the common size of \(X, A\), and \(B\) after any necessary scalar expansion.
\(Y=\operatorname{icdf}(\) name \(, X, A, B, C)\) computes the inverse cumulative distribution function for three-parameter families of distributions, where parameter values are given in \(A, B\), and \(C\).

If \(X, A, B\), and \(C\) are arrays, they must be the same size. If \(X\) is a scalar, it is expanded to a constant matrix the same size as \(A, B\), and \(C\). If any of \(A, B\) or \(C\) are scalars, they are expanded to constant matrices the same size as \(X\).
\(Y\) is the common size of \(X, A, B\) and \(C\) after any necessary scalar expansion.

\section*{Examples}

Compute the icdf of the normal distribution with mean 0 and standard deviation 1 at inputs \(0.1,0.3, \ldots, 0.9\) :
```

x1 = icdf('Normal',0.1:0.2:0.9,0,1)
x1 =
-1.2816 -0.5244 0

```

The order of the parameters is the same as for norminv.
Compute the icdfs of Poisson distributions with rate parameters \(0,1, \ldots\), 4 at inputs \(0.1,0.3, \ldots, 0.9\), respectively:
x2 \(=\) icdf('Poisson', 0.1:0.2:0.9, 0:4)
\(\mathrm{x} 2=\)
\(\begin{array}{lllll}\mathrm{NaN} & 0 & 2 & 4 & 7\end{array}\)

The order of the parameters is the same as for poissinv.

Probability Outside Limits is 0.05

See Also
makedist | fitdist | cdf | pdf | normspec | dfittool

\section*{Purpose Inconsistency coefficient}

Syntax \(\quad Y=\) inconsistent \((Z)\)
Y = inconsistent(Z,d)
Description \(\quad Y=\) inconsistent \((Z)\) computes the inconsistency coefficient for each link of the hierarchical cluster tree \(\mathbf{Z}\), where \(\mathbf{Z}\) is an ( \(m-1\) )-by-3 matrix generated by the linkage function. The inconsistency coefficient characterizes each link in a cluster tree by comparing its height with the average height of other links at the same level of the hierarchy. The higher the value of this coefficient, the less similar the objects connected by the link.
\(Y=\) inconsistent ( \(Z, d\) ) computes the inconsistency coefficient for each link in the hierarchical cluster tree \(Z\) to depth \(d\), where \(d\) is an integer denoting the number of levels of the cluster tree that are included in the calculation. By default, \(\mathrm{d}=2\).

The output, Y , is an ( \(m-1\) )-by- 4 matrix formatted as follows.
\begin{tabular}{l|l}
\hline Column & Description \\
\hline 1 & \begin{tabular}{l} 
Mean of the heights of all the links included in the \\
calculation.
\end{tabular} \\
\hline 2 & \begin{tabular}{l} 
Standard deviation of the heights of all the links included \\
in the calculation.
\end{tabular} \\
\hline 3 & Number of links included in the calculation. \\
\hline 4 & Inconsistency coefficient. \\
\hline
\end{tabular}

For each link, \(k\), the inconsistency coefficient is calculated as:
\[
Y(k, 4)=(z(k, 3)-Y(k, 1)) / Y(k, 2)
\]

For leaf nodes, nodes that have no further nodes under them, the inconsistency coefficient is set to 0 .

\section*{ProbDist.InputData property}

\section*{Purpose Read-only structure containing information about input data to ProbDist object}

\author{
Description
}

InputData is a read-only property of the ProbDist class. InputData is a structure containing information about input data to a ProbDist object. It includes the following fields:
- data
- cens
- freq

\section*{Values}

Possible values for the three fields in the structure are any data supplied to the fitdist function:
- data - Data passed to the fitdist function when creating the ProbDist object. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam. ProbDistUnivParam constructor.
- cens - The vector supplied with the 'censoring' parameter when creating the ProbDist object using the fitdist function. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam. ProbDistUnivParam constructor.
- freq - The vector supplied with the 'frequency ' parameter when creating the ProbDist object using the fitdist function. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam. ProbDistUnivParam constructor.

Use this information to view and compare the data supplied to create distributions.
Purpose Convert categorical array to signed 8-bit integer array
Syntax ..... B = int8(A)
Description \(B=\) int8(A) converts the categorical array \(A\) to a signed 8-bit integerarray. Each element of B contains the internal categorical level code forthe corresponding element of \(A\).Undefined elements of A are assigned the value 0 in B. If A containsmore than intmax ('int8') levels, the internal codes will saturate tointmax('int8') when cast to int8.

How To - "Integers"

Purpose Convert categorical array to signed 64-bit integer array

\section*{Syntax \\ \(B=i n t 64(A)\)}

Description \(\quad B=\) int64 (A) converts the categorical array A to a signed 64-bit integer array. Each element of \(B\) contains the internal categorical level code for the corresponding element of A.
Undefined elements of A are assigned the value 0 in B.
See Also double | uint64
How To . "Integers"

\section*{Purpose Interaction plot for grouped data}
```

Syntax
interactionplot(Y,GROUP)
interactionplot(Y,GROUP,'varnames',VARNAMES)
[h,AX,bigax] = interactionplot(...)

```

\section*{Description}

Examples
Display interaction plots for data with four 3-level factors named 'A', 'B','C', and 'D':
y = randn(1000,1); \% response

\section*{interactionplot}
```

group = ceil(3*rand(1000,4)); % four 3-level factors
interactionplot(y,group,'varnames',{'A','B','C','D'})

```

\(\begin{array}{ll}\text { See Also } & \text { maineffectsplot | multivarichart } \\ \text { How To } & \text { - "Grouping Variables" on page 2-51 }\end{array}\)

\section*{Purpose Set intersection for categorical arrays}

Note In a future release, the behavior of categorical.intersect will change to be consistent with the MATLAB function intersect. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for intersect.

Syntax
\(C=\) intersect \((A, B)\)
[C,IA,IB] = intersect(A, B)
[...] = intersect(A,B,'rows')
[...] = intersect(...,'R2012a')
[...] = intersect(...,'legacy')
[...] = intersect(A,B, setOrder)
[...] = intersect(A,B,'rows',setOrder)

\section*{Description}
\(C=\) intersect \((A, B)\) for categorical vectors \(A\) and \(B\), returns a categorical vector \(C\) containing the values common to the two vectors with no repetitions. The result C is sorted. The set of categorical levels for \(C\) is the sorted union of the sets of levels of the inputs.
[C,IA,IB] = intersect(A,B) also returns index vectors IA and IB such that \(C=A(I A)\) and \(C=B(I B)\). If there are repeated common values in \(A\) or \(B\), then the index of the last occurrence of each repeated value is returned.
\([\ldots]=\) intersect \((A, B\), 'rows') for categorical matrices \(A\) and \(B\) with the same number of columns, returns the rows common to the two matrices. The rows of the matrix C are sorted. The set of categorical levels for C is the sorted union of the sets of levels of the inputs. The optional outputs IA and IB are index vectors such that \(C=A(I A,:)\) and \(C=B(I B,:)\).
[...] = intersect(...,'R2012a') adopts the future behavior of intersect. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.
[...] = intersect(...,'legacy') preserves the current behavior of intersect. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.
[...] = intersect(A,B,setOrder) and [...] = intersect ( \(\mathrm{A}, \mathrm{B}\), 'rows', setOrder) returns the observations of \(C\) in a specific order. setOrder='sorted ' returns the values or rows of \(C\) in sorted order. setOrder='stable' returns the values or rows of \(C\) in the same order as \(A\). If A and B are row vectors, then \(C\) is also a row vector. Otherwise, \(C\) is a column vector. IA and IB are column vectors. If there are repeated common values in \(A\) or \(B\), then the index of the first occurrence of each repeated value is returned.

See Also
ismember | setdiff | setxor | union | unique

\section*{Purpose \\ Syntax \\ Description}

Set intersection for dataset array observations
\(C=\) intersect \((A, B)\)
\(C=\) intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( __ )

\section*{Input Arguments}
\(C=\) intersect \((A, B)\) for dataset arrays \(A\) and \(B\) returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array C are in sorted order.
\(C=\) intersect \((A, B\), vars \()\) returns the set of common observations from the two arrays, considering only the variables specified in vars, with repetitions removed. The observations in the dataset array \(C\) are sorted by those variables.

The values for variables not specified in vars for each observation in \(C\) are taken from the corresponding observations in \(A\). If there are multiple observations in A that correspond to an observation in C , then those values are taken from the first occurrence.
\(C=\) intersect (A, B, vars, setOrder) returns the observations in \(C\) in the order specified by setOrder.
\([\mathrm{C}, \mathrm{iA}, \mathrm{iB}]=\) intersect (__) also returns index vectors iA and \(i B\) such that \(C=A(i A,:)\) and \(C=B(i B,:)\). If there are repeated observations in \(A\) or \(B\), then intersect returns the index of the first occurrence. You can use any of the previous input arguments.

\section*{A,B}

Input dataset arrays.

\section*{vars}

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in \(A\) and \(B\) that intersect considers.

Specify vars as [] to use its default value of all variables.

\section*{dataset.intersect}

\section*{setOrder}

Flag indicating the sorting order for the observations in C . The possible values of setOrder are:
\begin{tabular}{ll} 
'sorted' & \begin{tabular}{l} 
Observations in \(C\) are in sorted order \\
(default).
\end{tabular} \\
'stable' & \begin{tabular}{l} 
Observations in \(C\) are in the same order that \\
they appear in \(A\).
\end{tabular}
\end{tabular}

\section*{Output Arguments}

\section*{Examples}

\section*{Intersection of Two Dataset Arrays}

Load sample data.
```

A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);

```

Return the intersection and index vectors.

\section*{prob.InverseGaussianDistribution}

Superclasses ToolboxFittableParametricDistribution
Purpose Inverse Gaussian probability distribution object
Description prob.InverseGaussianDistribution is an object consisting of parameters, a model description, and sample data for an inverse Gaussian probability distribution.
Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd = makedist('InverseGaussian') creates an inverse Gaussian probability distribution object using the default parameter values.
pd = makedist('InverseGaussian','mu',mu,'lambda',lambda) creates an inverse Gaussian probability distribution object using the specified parameter values.

\section*{Input Arguments}

\section*{mu - Scale parameter}

1 (default) | positive scalar value
Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

\section*{Data Types \\ single | double}

\section*{lambda - Shape parameter}

1 (default) | positive scalar value
Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

\author{
Data Types \\ single | double
}

\section*{Properties}
mu
Scale parameter for the inverse Gaussian distribution, stored as a positive scalar value.

\section*{Data Types}
single | double

\section*{lambda}

Shape parameter for the inverse Gaussian distribution, stored as a positive scalar value.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types}
char

\section*{InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

\section*{Data Types}
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated.

\section*{prob.InverseGaussianDistribution}

If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types \\ single | double}

\section*{ParameterCovariance}

Covariance matrix of the parameter estimates, stored as a \(p\)-by- \(p\) matrix, where \(p\) is the number of parameters in the distribution. The ( \(\mathrm{i}, \mathrm{j}\) ) element is the covariance between the estimates of the \(i\) th parameter and the \(j\) th parameter. The ( \(i, i\) ) element is the estimated variance of the ith parameter. If parameter \(i\) is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{Data Types \\ char}

\section*{Parameterlsfixed}

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

\section*{Data Types}
logical

\section*{ParameterNames}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types}
char

\section*{ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\section*{Data Types}
single | double

\section*{Truncation}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

\section*{Data Types}
single | double

\section*{Definitions Inverse Gaussian Distribution}

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline mu & Scale parameter & \(\mu>0\) \\
\hline lambda & Shape parameter & \(\lambda>0\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid \mu, \lambda)=\sqrt{\frac{\lambda}{2 \pi x^{3}}} \exp \left\{-\frac{\lambda}{2 \mu^{2} x}(x-\mu)^{2}\right\} \quad ; \quad x>0 .
\]

\section*{Examples Create an Inverse Gaussian Distribution Object Using Default Parameters}

Create an inverse Gaussian distribution object using the default parameter values.
```

pd = makedist('InverseGaussian')
pd =

Syntax
XO = invpred(X,Y,YO)
[XO,DXLO,DXUP] = invpred(X,Y,YO)
[XO,DXLO, DXUP] = invpred(X,Y,YO,name1,val1,name2,val2,...)

\section*{Description}
\(X 0=\) invpred \((X, Y, Y O)\) accepts vectors \(X\) and \(Y\) of the same length, fits a simple regression, and returns the estimated value \(X 0\) for which the height of the line is equal to YO . The output, XO , has the same size as Y 0 , and \(Y 0\) can be an array of any size.
[XO,DXLO,DXUP] = invpred (X,Y,YO) also computes \(95 \%\) inverse prediction intervals. DXLO and DXUP define intervals with lower bound XO DXLO and upper bound XO+DXUP. Both DXLO and DXUP have the same size as YO.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to - Inf or +Inf, and some may extend over the entire real line.
[XO,DXLO,DXUP] = invpred(X,Y,YO,name1,val1,name2,val2,...) specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.
\begin{tabular}{l|l}
\hline Name & Value \\
\hline 'alpha' & \begin{tabular}{l} 
A value between 0 and 1 specifying a \\
confidence level of 100*(1-alpha)\%. Default \\
is alpha=0.05 for 95\% confidence.
\end{tabular} \\
\hline 'predopt' & \begin{tabular}{l} 
Either 'observation ', the default value to \\
compute the intervals for X0 at which a new \\
observation could equal Y0, or 'curve' to \\
compute intervals for the XO value at which \\
the curve is equal to YO.
\end{tabular} \\
\hline
\end{tabular}
```

Examples $\quad x=4 *$ rand $(25,1)$;
$y=10+5 * x+r a n d n(s i z e(x)) ;$
scatter( $\mathrm{x}, \mathrm{y}$ )
$x 0=\operatorname{invpred}(x, y, 20)$

```

\title{
Purpose Inverse permute dimensions of categorical array
}
\[
\text { Syntax } \quad A=\text { ipermute }(B, \text { order })
\]

Description
\(A=\) ipermute \((B\), order \()\) is the inverse of permute. ipermute rearranges the dimensions of the categorical array B so that permute (A, order) will produce B. The array produced has the same values of A but the order of the subscripts needed to access any particular element are rearranged as specified by order. The elements of order must be a rearrangement of the numbers from 1 to n .

\author{
See Also permute
}
Purpose Interquartile range
Syntax \(\mathrm{y}=\mathrm{iqr}(\mathrm{X})\)
iqr(X, dim)
Description \(y=i q r(X)\) returns the interquartile range of the values in \(X\). For vectorinput, y is the difference between the 75 th and the 25 th percentilesof the sample in \(X\). For matrix input, \(y\) is a row vector containing theinterquartile range of each column of \(X\). For \(N\)-dimensional arrays, iqroperates along the first nonsingleton dimension of \(X\).
iqr( \(\mathrm{X}, \mathrm{dim}\) ) calculates the interquartile range along the dimension dim of \(X\).
Tips
Examples This Monte Carlo simulation shows the relative efficiency of the IQR to the sample standard deviation for normal data.
```

x = normrnd(0,1,100,100);
s = std(x);
s_IQR = 0.7413*iqr(x);
efficiency = (norm(s-1)./norm(s_IQR-1)).^2
efficiency =
0.3297

```
See Also std \| mad \| range

\section*{ProbDistUnivKernel.iqr}

\section*{Purpose}

Return interquartile range (IQR) for ProbDistUnivKernel object

\section*{Syntax}

Description
\(Y=\operatorname{iqr}(P D)\) returns \(Y\), the interquartile range for the ProbDistUnivKernel object PD. The interquartile range is the distance between the 75 th and 25 th percentiles.

\section*{Input \\ Arguments \\ Output \(Y\) Arguments}

See Also iqr | ProbDistUnivKernel.icdf

\section*{ProbDistUnivParam.iqr}

Purpose Return interquartile range (IQR) for ProbDistUnivParam object
Syntax
\(Y=i q r(P D)\)

Description
\(Y=\) iqr ( \(P D\) ) returns \(Y\), the interquartile range for the ProbDistUnivParam object \(P D\). The interquartile range is the distance between the 75 th and 25 th percentiles.

\section*{Input \\ \(P D\) \\ Arguments \\ Output \(Y\) \\ Arguments}

See Also iqr | ProbDistUnivParam.icdf

\section*{Purpose Interquartile range of probability distribution object}
Syntax
\(r=i q r(p d)\)

Description

Input
Arguments
\(r=i q r(p d)\) returns the interquartile range \(r\) of the probability distribution pd.

\author{
pd - Probability distribution
}
probability distribution object
Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using fitdist or dfittool.

\section*{Output r-Interquartile range \\ Arguments}

\section*{Examples}

\section*{Interquartile Range of a Fitted Distribution}

Load the sample data. Create a vector containing the first column of students' exam grade data.
load examgrades;
\(x=\operatorname{grades}(:, 1) ;\)
x = grades(:,1);
Crete a normal distribution object by fitting it to the data.
```

pd = fitdist(x,'Normal')
pd =

```

NormalDistribution

\section*{prob.TruncatableDistribution.iqr}
```

Normal distribution
mu = 75.0083 [73.4321, 76.5846]
sigma = 8.7202 [7.7391, 9.98843]

```

Compute the interquartile range of the fitted distribution.
```

r = iqr(pd)

```
\(r=\)
11.7634

The returned result indicates that the difference between the 75 th and 25 th percentile of the students' grades is 11.7634 .

Use icdf to determine the 75 th and 25 th percentiles of the students' grades.
```

y = icdf(pd,[0.25,0.75])
y =
69.1266 80.8900

```

Calculate the difference between the 75 th and 25 th percentiles. This yields the same result as iqr.
```

y(2)-y(1)
ans =
11.7634

```

Use boxplot to visualize the interquartile range.
```

boxplot(x)

```

The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

\section*{classregtree.isbranch}

Purpose Test node for branch
Syntax \(\quad \begin{aligned} \text { ib } & =\text { isbranch }(t) \\ \text { ib } & =\text { isbranch }(t, \text { nodes })\end{aligned}\)
Description
ib \(=\) isbranch( t\()\) returns an \(n\)-element logical vector ib that is true for each branch node and false for each leaf node.
ib = isbranch(t, nodes) takes a vector nodes of node numbers and returns a vector of logical values for the specified nodes.

\section*{Examples Create a classification tree for Fisher's iris data:}
```

load fisheriris;
t = classregtree(meas,species,...
'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
class = setosa
if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
class = virginica
if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
class = virginica
class = versicolor
class = virginica
view(t)

```
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline & & & & & & & & - \\
\hline Click to display: & Identity & \(\checkmark\) & Magnification: & 100\% & \(\checkmark\) & Pruning level: & 0 of 4 &  \\
\hline
\end{tabular}

```

ib = isbranch(t)
ib =
1

Purpose True for empty categorical array
Syntax

TF = isempty (A)

Description \(\quad \begin{aligned} & \text { TF }=\text { isempty }(A) \text { returns true (1) if } A \text { is an empty categorical array } \\ & \text { and false (0) otherwise. An empty array has no elements, that is } \\ & \text { numel }(A)==0 .\end{aligned}\)
See Also numel | size

\section*{dataset.isempty}

Purpose True for empty dataset array

\section*{Syntax \(\quad\) tf \(=\) isempty \((A)\)}

Description \(\quad t f=\) isempty \((A)\) returns true (1) if \(A\) is an empty dataset and false ( 0 ) otherwise. An empty array has no elements, that is \(\operatorname{prod}(\operatorname{size}(A))==0\).

See Also size

\section*{Purpose True if categorical arrays are equal}

\section*{Syntax}

TF = isequal(A,B)
TF = isequal \((A, B, C, \ldots)\)
Description \(\quad\) TF \(=\) isequal \((A, B)\) is true (1) if the categorical arrays \(A\) and \(B\) are the same class, have the same size and the same sets of levels, and contain the same values, and false (0) otherwise.

TF = isequal ( \(\mathrm{A}, \mathrm{B}, \mathrm{C}, \ldots\) ) is true (1) if all the input arguments are equal.

Elements with undefined levels are not considered equal to each other.

\section*{See Also \\ getlabels}

\section*{Purpose Test for levels}

\section*{Syntax \\ I = islevel(levels,A)}

Description
I = islevel(levels, A) returns a logical array I the same size as the string, cell array of strings, or 2-D character matrix levels. I is true (1) where the corresponding element of levels is the label of a level in the categorical array A, even if the level contains no elements. I is false ( 0 ) otherwise.

Examples
Display age levels in the data in hospitl.mat, before and after dropping occupied levels:
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','\%d'),\{'s'\});
disp(labels')
'Os' '10s' '20s' '30s' '40s' '50s' '60s' '70s' '80s' '90s'
AgeGroup = ordinal(hospital.Age,labels,[],edges);
I = islevel(labels,AgeGroup);
disp(I')
\(\begin{array}{llllllllll}1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1\end{array}\)
AgeGroup = droplevels(AgeGroup);
I = islevel(labels, AgeGroup);
disp(I')
\(\begin{array}{llllllllll}0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0\end{array}\)

\author{
See Also ismember \| isundefined
}
\begin{tabular}{ll} 
Purpose & Test for membership \\
Syntax & \(I=\) ismember (A, levels) \\
& {\([I, I D X]=\) ismember (A, levels) }
\end{tabular}

Description I = ismember (A, levels) returns a logical array I the same size as the categorical array A. I is true (1) where the corresponding element of A is one of the levels specified by the labels in the categorical array, cell array of strings, or 2-D character array levels. I is false (0) otherwise.
[I,IDX] = ismember(A,levels) also returns an array of indices IDX containing the highest absolute index in levels for each element in A whose level is a member of levels, and 0 if there is no such index.

\section*{Examples Example 1}

For nominal data:
```

load hospital
sex = hospital.Sex; % Nominal
smokers = hospital.Smoker; % Logical
I = ismember(sex(smokers),'Female');
I(1:5)
ans =
0
1
0
0
O

```

The use of ismember above is equivalent to:
I = (sex(smokers) == 'Female');

\section*{Example 2}

For ordinal data:
load hospital
edges = 0:10:100;

\section*{ordinal.ismember}
```

labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);
I = ismember(AgeGroup(1:5),{'20s','30s'})
I =
1
0
1
0
0

```

See Also islevel | isundefined

\section*{Purpose \\ True for elements of categorical array in set}

Note In a future release, the behavior of categorical.ismember will change to be consistent with the MATLAB function ismember. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for ismember.

Syntax \(\quad\) TF \(=\) ismember \((A, B)\)
[TF,LOCB] = ismember(A,B)
[...] = ismember(A,B,'rows')
[...] = intersect(...,'R2012a')
[...] = intersect(...,'legacy')
Description
TF = ismember \((A, B)\) for categorical arrays \(A\) and \(B\), returns a logical array the same size as A, containing true (1) where the elements of A are in B, and false (0) otherwise. B can also be a cell array of strings or two-dimensional character array containing level labels.
[TF,LOCB] = ismember(A,B) also returns an index array LOCB containing the highest absolute index in \(B\) for each element in \(A\) which is a member of B , and 0 if there is no such index.
[...] = ismember (A, B, 'rows'), for categorical matrices \(A\) and \(B\) with the same number of columns, returns a logical vector containing true (1) where the rows of A are also rows of \(B\), and false ( 0 ) otherwise. The optional output LOCB is an index vector containing the highest absolute index in \(B\) for each row in \(A\) which is a member of \(B\) and 0 if there is no such index.
[...] = intersect(...,'R2012a') adopts the future behavior of ismember. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.

\section*{categorical.ismember}
[...] = intersect(...,'legacy') preserves the current behavior of ismember. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.

See Also intersect | islevel | setdiff | setxor | union | unique

\section*{Purpose}

Dataset array elements that are members of set
Syntax
LiA = ismember(A,B)
LiA = ismember(A,B,vars)
[LiA,LocB] = ismember( \(\qquad\)
\(\operatorname{LiA}=\) ismember \((A, B)\) for dataset arrays \(A\) and \(B\) returns a vector of logical values the same length as \(A\). The output vector, LiA, has value 1 (true) in the elements that correspond to observations in \(A\) that are also present in \(B\), and 0 (false) otherwise.

LiA = ismember ( \(A, B\), vars) returns a vector of logical values the same length as A. The output vector, LiA, has value 1 (true) in the elements that correspond to observations in \(A\) that are also present in \(B\) for the variables specified in vars only, and 0 (false) otherwise.
[LiA, LocB] = ismember (__ ) also returns a vector the same length as \(A\) containing the index to the first observation in \(B\) that corresponds to each observation in \(A\), or 0 if there is no such observation. You can use any of the previous input arguments.

\section*{Input Arguments}

A
Query dataset array, containing the observations to be found in B.

\section*{B}

Set dataset array. When an observation in A is found in B, for all variables or only those variables specified in vars, the corresponding element of LiA is 1 .

\section*{vars}

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating which variables to match observations on in A and B.

\section*{dataset.ismember}

\section*{Output \\ LiA}

Arguments
Vector of logical values the same length as A. LiA has value 1 (true) when the corresponding observation in \(A\) is present in \(B\). Otherwise, LiA has value 0 (false).

If you specify vars, LiA has value 1 when the corresponding observation in \(A\) is present in \(B\) for the variables in vars only.

LocB
Vector the same length as A containing the index to the first observation in \(B\) that corresponds to each observation in \(A\), for all variables or only those variables specified in vars.

\section*{Examples Find Observations That Are Members of a Dataset Array}

Load sample data.
load('hospital')
B = hospital(1:50,1:5);
This set dataset array, B, has 50 observations on 5 variables.
Specify a query dataset array.
```

rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
A =

```
\begin{tabular}{llllll}

}

\section*{Purpose \\ Find dataset array elements with missing values}

Syntax
I = ismissing(ds)
I = ismissing(ds,Name,Value)

Description

\section*{Input Arguments}

I = ismissing(ds) returns a logical array that indicates which elements in the dataset array, ds, contain a missing value. By default, ismissing recognizes NaN as a missing value in numeric variables, as a missing value in string variables, and <undefined> as a missing value in categorical arrays.
- ds2 = ds(~any(I,2),:) creates a new dataset array containing only the complete observations in ds.
- ds2 = ds(:, ~any (I,1)) creates a new dataset array containing only the variables from ds with no missing values.

I = ismissing(ds,Name, Value) returns missing value indices with additional options specified by one or more Name, Value pair arguments.

\section*{ds}
dataset array

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'NumericTreatAsMissing'}

\section*{dataset.ismissing}
r of numeric values to treat as missing value indicators in floating point ds variables. ismissing always treats a NaN value as a missing value.

\section*{'StringTreatAsMissing'}

String or cell array of strings to treat as missing value indicators in string ds variables. ismissing always treats the empty string ' ' as a missing value.

\section*{Output Arguments \\ I}

Logical array indicating which elements in ds contain a missing value. I is the same size as ds, with value 1 for elements that contain a missing value.

\section*{See Also \\ dataset | isempty | isnanisundefined | replaceWithMissing |}

Purpose True if categorical array is scalar
Syntax TF = isscalar(A)
Description TF = isscalar(A) returns true (1) if the categorical array A is a 1-by-1 matrix, and false (0) otherwise.
See Also ..... isempty | isvector | size

Purpose Test for undefined elements
Syntax I = isundefined (A)
Description I = isundefined (A) returns a logical array I the same size as the categorical array A. I is true (1) where the corresponding element of A is not assigned to any level. I is false (0) where the corresponding element of A is assigned to a level.

Examples Create and display undefined levels in an ordinal array:
```

A = ordinal([[1 2 3 2 1],{'lo','med','hi'})
A =
lo med hi med lo
A = droplevels(A,{'med','hi'})
Warning: OLDLEVELS contains categorical levels that
were present in A, caused some array elements to
have undefined levels.
A =
lo <undefined> <undefined> <undefined> lo
I = isundefined(A)
I =
0

```

See Also islevel | ismember

\section*{Purpose Test handle validity}

\section*{Syntax tf = isvalid(h)}

Description \(\quad \mathrm{tf}=\) isvalid( h ) performs an element-wise check for validity on the handle elements of \(h\). The result is a logical array of the same dimensions as h , where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

See Also delete | qrandstream
Purpose True if categorical array is vector

\section*{Syntax \\ TF = isvector(A)}

Description TF = isvector (A) returns true (1) if the categorical array \(A\) is a 1-by- \(n\) or \(n\)-by- 1 vector, where \(n>=0\), and false ( 0 ) otherwise.

See Also isempty | isscalar | size

Purpose Number of iterations
Description The number of iterations of the algorithm.

Note This property applies only to gmdistribution objects constructed with fit.

\section*{iwishrnd}

Purpose Inverse Wishart random numbers
\begin{tabular}{ll} 
Syntax & W \(=\) iwishrnd \((T a u, d f)\) \\
& W \(=\) iwishrnd (Tau, df, DI) \\
{\([W, D I]=\) iwishrnd(Tau,df) }
\end{tabular}

Description

See Also
wishrnd
How To . "Inverse Wishart Distribution" on page B-59
\begin{tabular}{|c|c|}
\hline Purpose & Jackknife sampling \\
\hline Syntax & ```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
``` \\
\hline Description & jackstat = jackknife(jackfun, X) draws jackknife data samples from the \(n\)-by-p data array \(X\), computes statistics on each sample using the function jackfun, and returns the results in the matrix jackstat. jackknife regards each row of \(X\) as one data sample, so there are \(n\) data samples. Each of the \(n\) rows of \(j\) ackstat contains the results of applying jackfun to one jackknife sample. jackfun is a function handle specified with @. Row i of jackstat contains the results for the sample consisting of \(X\) with the ith row omitted:
```

s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);

``` \\
\hline & \begin{tabular}{l}
If jackfun returns a matrix or array, then this output is converted to a row vector for storage in jackstat. If X is a row vector, it is converted to a column vector. \\
jackstat \(=\) jackknife(jackfun, X,Y,...) accepts additional arguments to be supplied as inputs to jackfun. They may be scalars, column vectors, or matrices. jackknife creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to jackfun unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments. \\
jackstat = jackknife(jackfun,...,'Options',option) provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set 'Options ' as a structure you create with statset. jackknife uses the following field in the structure:
\end{tabular} \\
\hline
\end{tabular}

\title{
'UseParallel' If true and if a matlabpool of the Parallel Computing Toolbox is open, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, or a matlabpool is not open, computation occurs in serial mode. Default is false, or serial computation.
}

\section*{Examples}

Estimate the bias of the MLE variance estimator of random samples taken from the vector y using jackknife. The bias has a known formula in this problem, so you can compare the jackknife value to this formula.
```

sigma = 5;

```
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y, 1);
n = length(y);
bias = -sigma^2 / n \% known bias formula
jbias \(=(n-1) *(m e a n(m)-\operatorname{var}(y, 1)) \%\) jackknife bias estimate
bias =
    -0.2500
jbias =
    -0.3378

bootstrp | random | randsample | hist | ksdensity
Tutorials - "Jackknife" on page 3-19

Purpose
Jarque-Bera test
Syntax
h = jbtest(x)
h = jbtest(x,alpha)
[h,p] = jbtest(...)
[h,p,jbstat] = jbtest(...)
[h, p,jbstat,critval] = jbtest(...)
[h,p,...] = jbtest(x,alpha,mctol)

\section*{Description}
\(\mathrm{h}=\mathrm{jbtest}(\mathrm{x})\) performs a Jarque-Bera test of the null hypothesis that the sample in vector \(x\) comes from a normal distribution with unknown mean and variance, against the alternative that it does not come from a normal distribution. The test is specifically designed for alternatives in "Generating Data Using the Pearson System" on page \(6-26\) of distributions. The test returns the value \(h=1\) if it rejects the null hypothesis at the \(5 \%\) significance level, and \(h=0\) if it cannot. The test treats NaN values in x as missing values, and ignores them.

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully-specified null distribution is unknown and its parameters must be estimated. The test statistic is
\[
J B=\frac{n}{6}\left(s^{2}+\frac{(k-3)^{2}}{4}\right)
\]
where \(n\) is the sample size, \(s\) is the sample skewness, and \(k\) is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see lillietest) for small samples. jbtest, by contrast, uses a table of critical values computed using Monte-Carlo simulation for sample sizes less than 2000 and significance levels between 0.001 and 0.50 . Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.
\(\mathrm{h}=\mathrm{jbtest}(\mathrm{x}, \mathrm{alpha})\) performs the test at significance level alpha. alpha is a scalar in the range [0.001, 0.50]. To perform the test at a significance level outside of this range, use the motol input argument.
\([\mathrm{h}, \mathrm{p}]=\mathrm{jbtest}(\ldots)\) returns the \(p\) value p , computed using inverse interpolation into the table of critical values. Small values of \(p\) cast doubt on the validity of the null hypothesis. jbtest warns when \(p\) is not found within the tabulated range of [0.001, 0.50], and returns either the smallest or largest tabulated value. In this case, you can use the mctol input argument to compute a more accurate \(p\) value.
[h, p,jbstat] \(=\) jbtest(...) returns the test statistic jbstat.
[h,p,jbstat,critval] = jbtest(...) returns the critical value critval for the test. When jbstat > critval, the null hypothesis is rejected at significance level alpha.
[h,p,...] = jbtest(x,alpha,mctol) computes a Monte-Carlo approximation for \(p\) directly, rather than interpolating into the table of pre-computed values. This is useful when alpha or \(p\) lie outside the range of the table. jbtest chooses the number of Monte Carlo replications, mcreps, large enough to make the Monte Carlo standard error for \(p\), \(\operatorname{sqrt}\left(p^{*}(1-p) / m c r e p s\right)\), less than mctol.

\section*{Examples Use jbtest to determine if car mileage, in miles per gallon (MPG),} follows a normal distribution across different makes of cars:
```

load carbig
[h,p] = jbtest(MPG)
h =
1
p =
0.0022

```

The \(p\) value is below the default significance level of \(5 \%\), and the test rejects the null hypothesis that the distribution is normal.

With a log transformation, the distribution becomes closer to normal, but the \(p\) value is still well below \(5 \%\) :
```

[h, p] = jbtest(log(MPG))
h =
1
p =
0.0078

```

Decreasing the significance level makes it harder to reject the null hypothesis:
```

[h, p] = jbtest(log(MPG),0.0075)
$\mathrm{h}=$
0
$\mathrm{p}=$
0.0078

```

This paper proposed a Monte Carlo simulation for determining the distribution of the test statistic. The results of this function are based on an independent Monte Carlo simulation, not the results in this paper.

Purpose Johnson system random numbers
Syntax \(\quad \begin{aligned} & r=\text { johnsrnd(quantiles, } m, n) \\ & r=\text { johnsrnd(quantiles) } \\ & \\ & {[r, \text { type }]=j \text { johnsrnd }(\ldots)} \\ & \\ & {[r, \text { type }, \text { coefs }]=\text { johnsrnd }(\ldots)}\end{aligned}\)

\section*{Description}
\(r=j o h n s r n d(q u a n t i l e s, m, n)\) returns an \(m\)-by-n matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by quantiles. quantiles is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles [ \(-1.5-0.50 .51 .5]\). In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities [0.067 0.309 0.691 0.933]. quantiles may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

Note Because \(r\) is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.
\(r=\) johnsrnd(quantiles) returns a scalar value.
\(r=\) johnsrnd(quantiles, \(m, n, \ldots\) ) or \(r=\)
johnsrnd(quantiles, \(m, n, \ldots]\) ) returns an \(m\)-by-n-by-... array.
[ \(r\), type] \(=\) johnsrnd (...) returns the type of the specified distribution within the Johnson system. type is 'SN', 'SL', 'SB', or 'SU'. Set \(m\) and \(n\) to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:
- 'SN ' - Identity transformation (normal distribution)
- 'SL' - Exponential transformation (lognormal distribution)
- 'SB' - Logistic transformation (bounded)
- 'SU' - Hyperbolic sine transformation (unbounded)
[r,type,coefs] = johnsrnd(...) returns coefficients coefs of the transformation that defines the distribution. coefs is [gamma, eta, epsilon, lambda]. If \(z\) is a standard normal random variable and \(h\) is one of the transformations defined above, \(r=\) lambda*h( \(z\)-gamma)/eta) +epsilon is a random variate from the distribution type corresponding to \(h\).

\section*{Examples}

Generate random values with longer tails than a standard normal:
```

r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
qqplot(r);

```

Generate random values skewed to the right:
\(r=j o h n s r n d([-1.3-.5\). 5 1.7],1000,1); qqplot(r);

Generate random values that match some sample data well in the right-hand tail:
```

load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]
ans =
16.7000 18.2086 19.5376 21.7263
16.8190 18.2474 19.4492 22.4156

```

Determine the distribution type and the coefficients:
```

[r,type,coefs] = johnsrnd([qnorm;q],0)
r =
[]
type =
SU
coefs =
1.0920 0.5829 18.4382 1.4494

```

How To . "Johnson System" on page B-61

Purpose
Syntax
Description

Merge observations
```

$C=j 0 i n(A, B)$
$C=j o i n(A, B, k e y s)$
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A, B, 'Type', TYPE,...)
C = join(A, B,'Type',TYPE,'MergeKeys',true,...)
[C,IA, IB] = join(A, B, 'Type',TYPE,...)

```
\(C=j o i n(A, B)\) creates a dataset array C by merging observations from the two dataset arrays \(A\) and \(B\). join performs the merge by first finding key variables, that is, pairs of dataset variables, one in A and one in B, that share the same name. Each observation in B must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from A. join then uses these key variables to define a many-to-one correspondence between observations in A and those in B. join uses this correspondence to replicate the observations in B and combine them with the observations in \(A\) to create \(C\).
\(C=j o i n(A, B, k e y s)\) performs the merge using the variables specified by keys as the key variables in both \(A\) and \(B\). keys is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

C contains one observation for each observation in A. Variables in C include all of the variables from \(A\), as well as one variable corresponding to each variable in B (except for the keys from B). If A and B contain variables with identical names, join adds the suffix '_left' and '_right' to the corresponding variables in C.
\(C=j o i n(A, B, p a r a m 1, v a l 1, p a r a m 2, v a l 2, \ldots)\) specifies optional parameter name/value pairs to control how the dataset variables in A and \(B\) are used in the merge. Parameters are:
- 'Keys' - Specifies the variables to use as keys in both A and B.
- 'LeftKeys' - Specifies the variables to use as keys in A.
- 'RightKeys ' - Specifies the variables to use as keys in B.

You may provide either the 'Keys ' parameter, or both the 'LeftKeys' and 'RightKeys' parameters. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing variable names, or a logical vector. 'LeftKeys' or 'RightKeys ' must both specify the same number of key variables, and join pairs the left and right keys in the order specified.
- 'LeftVars' - Specifies which variables from A to include in C. By default, join includes all variables from A.
- 'RightVars' - Specifies which variables from B to include in C. By default, join includes all variables from B except the key variables.

You can use 'LeftVars' or 'RightVars' to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.
[C,IB] = join(...) returns an index vector IB, where join constructs \(C\) by horizontally concatenating A(: LeftVars) and B(IB,RightVars). join can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between A and B , and allow unmatched observations in either A or B.
\(C=\) join(A, B,'Type',TYPE,...) performs the join operation specified by TYPE. TYPE is one of 'inner', 'leftouter', 'rightouter', 'fullouter', or 'outer' (which is a synonym for 'fullouter'). For an inner join, \(C\) only contains observations corresponding to a combination of key values that occurred in both A and B. For a left (or right) outer join, \(C\) also contains observations corresponding to keys in \(A(\) or \(B)\) that did not match any in B (or A). Variables in C taken from A (or B) contain null values in those observations. A full outer join is equivalent to a left and right outer join. C contains variables corresponding to the key variables from both A and B, and join sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. join sorts the observations in the result C by the key values.

C = join(A, B,'Type', TYPE,'MergeKeys',true,...) includes a single variable in \(C\) for each key variable pair from \(A\) and \(B\), rather than including two separate variables. For outer joins, join creates the single variable by merging the key values from A and B, taking values from \(A\) where a corresponding observation exists in \(A\), and from \(B\) otherwise. Setting the 'MergeKeys' parameter to true overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to false is equivalent to not passing in the 'MergeKeys' parameter.
[C,IA,IB] = join(A, B,'Type',TYPE,...) returns index vectors IA and IB indicating the correspondence between observations in \(C\) and those in A and B. For an inner join, join constructs \(C\) by horizontally concatenating A(IA,LeftVars) and B(IB,RightVars). For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

\section*{Examples}

Create a dataset array from Fisher's iris data:
```

load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
{meas,'SL','SW','PL','PW'},...
'ObsNames',NameObs);

```

Create a separate dataset array with the diploid chromosome counts for each species of iris:
```

snames = nominal({'setosa';'versicolor';'virginica'});
CC = dataset({snames,'species'},{[38;108;70],'cc'})
CC =
species cc

```
```

setosa
38
versicolor 108
virginica 70

```

Broadcast the data in CC to the rows of iris using the key variable species in each dataset:
```

iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =

|  | species | SL | SW | PL | PW | CC |
| :--- | :--- | :--- | :--- | :--- | :--- | ---: |
| Obs1 | setosa | 5.1 | 3.5 | 1.4 | 0.2 | 38 |
| Obs2 | setosa | 4.9 | 3 | 1.4 | 0.2 | 38 |
| Obs51 | versicolor | 7 | 3.2 | 4.7 | 1.4 | 108 |
| Obs52 | versicolor | 6.4 | 3.2 | 4.5 | 1.5 | 108 |
| Obs101 | virginica | 6.3 | 3.3 | 6 | 2.5 | 70 |
| Obs102 | virginica | 5.8 | 2.7 | 5.1 | 1.9 | 70 |

```

Create two datasets and join them using the 'MergeKeys' flag:
\% Create two data sets that both contain the key variable \% 'Key1'. The two arrays contain observations with common \% values of Key1, but each array also contains observations \% with values of Key1 not present in the other. a = dataset(\{'a' 'b' 'c' 'e' 'h'\}',[10 2311 17]',...
'VarNames',\{'Key1' 'Var1'\}) b = dataset(\{'a' 'b' 'd' 'e'\}',[4 5 6 7]',...
'VarNames',\{'Key1' 'Var2'\})
\% Combine a and b with an outer join, which matches up \% observations with common key values, but also retains \% observations whose key values don't have a match. \% Keep the key values as separate variables in the result. couter = join(a,b,'key','Key1','Type','outer')
```

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
'MergeKeys',true)
% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
'MergeKeys',true)
a =

| Key1 | Var1 |
| :--- | ---: |
| 'a' | 1 |
| 'b' | 2 |
| 'c' | 3 |
| 'e' | 11 |
| 'h' | 17 |

b =

| Key1 | Var2 |
| :--- | :--- |
| 'a' | 4 |
| 'b' | 5 |
| 'd' | 6 |
| 'e' | 7 |

couter =

| Key1_left | Var1 | Key1_right | Var2 |
| :--- | :---: | :--- | ---: |
| 'a' | 1 | 'a' | 4 |
| 'b' | 2 | 'b' | 5 |
| 'c' | 3 | $' '$ | NaN |
| '' | NaN | 'd' | 6 |
| 'e' | 11 | 'e' | 7 |

```
\begin{tabular}{cccc} 
'h' & NaN \\
coutermerge \(=\) & & \\
Key1 & Var1 & Var2 \\
'a' & 1 & 4 \\
'b' & 2 & 5 \\
'c' & 3 & NaN \\
'd' & NaN & 6 \\
'e' & 11 & 7 \\
'h' & 17 & NaN \\
& & \\
cinner \(=\) & & \\
Key1 & Var1 & Var2 \\
'a' & 1 & 4

\section*{KDTreeSearcher}
Superclasses NeighborSearcher
Purpose Nearest neighbors search using \(k d\)-tree
Description A KDTreeSearcher object represents \(k \mathrm{NN}\) ( \(k\)-nearest neighbor) searchusing a \(k\) d-tree. Search objects store information about the data used,the distance metric and parameters, and the maximal number of datapoints in each leaf node. You cannot create this object for sparseinput data. The search performance for this object, compared with theExhaustiveSearcher object, tends to be better for smaller dimensions(10 or fewer) and worse for larger dimensions. For more information onsearch objects, see "What Are Search Objects?" on page 15-17.
ConstructionNS = KDTreeSearcher(X,'Name', Value) constructs a \(k\) d-tree based on\(X\) and saves the information in a KDTreeSearcher object where rows ofX correspond to observations and columns correspond to variables. Youcan use this tree to find neighbors in \(X\) nearest to the query points. Seethe following section for optional name/value pairs.
NS = createns(X,'NSMethod','kdtree','Name', Value) creates a
\(k d\)-tree based on \(X\) using createns and saves the information in a
KDTreeSearcher object where rows of \(X\) correspond to observations and
columns correspond to variables. You can use this tree to find neighbors
in \(X\) nearest to the query points. See the following section for optional
name/value pairs.

\section*{Name-Value Pair Arguments}
KDTreeSearcher and createns accept one or more of the following optional name/value pairs as input:

\section*{'Distance'}
A string specifying the default distance metric used when you call the knnsearch method.
- 'euclidean' - Euclidean distance (default).
- 'cityblock' - City block distance.

\section*{KDTreeSearcher}
- 'chebychev' - Chebychev distance (maximum coordinate difference).
- 'minkowski' - Minkowski distance.

For more information on these distance metrics, see "Distance Metrics" on page 15-9.

\section*{'P'}

A positive scalar indicating the exponent of the Minkowski distance. This parameter is only valid when Distance is 'minkowski'. Default is 2.

\section*{'BucketSize'}

A positive integer, indicating the maximum number of data points in each leaf node of the \(k\) d-tree. Default is 50 .

\section*{Properties \\ X}

A matrix used to create the object

\section*{Distance}

A string specifying a built-in distance metric that you provide when you create the object. This property is the default distance metric used when you call the knnsearch method to find nearest neighbors for future query points.

\section*{DistParameter}

Specifies the additional parameter for the chosen distance metric. The value is:
- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance.
- Otherwise: Empty.
```

Methods
knnsearch
rangesearch
Find k-nearest neighbors using KDTreeSearcher object
Find all neighbors within specified distance using object
Examples Create a KDTreeSearcher object using the constructor:

```
```

load fisheriris

```
load fisheriris
x = meas(:,3:4);
x = meas(:,3:4);
kdtreeobj = KDTreeSearcher(x,'distance','minkowski')
kdtreeobj =
kdtreeobj =
    KDTreeSearcher
    KDTreeSearcher
    Properties:
    Properties:
        BucketSize: 50
        BucketSize: 50
            X: [150x2 double]
            X: [150x2 double]
            Distance: 'minkowski'
            Distance: 'minkowski'
        DistParameter: 2
```

        DistParameter: 2
    ```

Create a KDTreeSearcher object using createns:
```

load fisheriris
x = meas(:,3:4);
kdtreeobj = createns(x,'NsMethod','kdtree',...
'distance','minkowski')
kdtreeobj =
KDTreeSearcher
Properties:
BucketSize: 50

```

\section*{KDTreeSearcher}
```

    X: [150x2 double]
    Distance: 'minkowski'
    DistParameter: 2

```

For more in-depth examples using the knnsearch method, see the method reference page or see "Example: Classifying Query Data Using knnsearch" on page 15-18.

\section*{prob.KernelDistribution}

Superclasses TruncatableDistribution

\section*{Purpose Kernel probability distribution object}

Description prob.KernelDistribution is an object consisting of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution. Create a prob.KernelDistribution object using fitdist or dfittool.

Construction
pd = fitdist(x, 'Kernel') creates a probability distribution object by fitting a kernel-smoothing distribution to the data in \(x\).
pd = fitdist( x, 'Kernel', Name, Value) creates a probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can change the kernel function or specify the kernel bandwidth.

\section*{Input Arguments}

\section*{x - Input data}
column vector
Input data to fit with a kernel-smoothing distribution, specified as a column vector of scalar values. fitdist ignores \(N a N\) values in \(x\).
```

Data Types
single | double

```

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{Kernel - Kernel smoother type}
'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following kernel smoothing function types:
- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

\section*{Support - Kernel density support}
'unbounded' (default) | 'positive' | two-element vector
Kernel density support, specified as the comma-separated pair consisting of 'Support' and a string or two-element vector. The string must be one of the following.
\begin{tabular}{ll} 
'unbounded' & \begin{tabular}{l} 
Density can extend over the whole \\
real line.
\end{tabular} \\
'positive' & \begin{tabular}{l} 
Density is restricted to positive \\
values.
\end{tabular}
\end{tabular}

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

\section*{Data Types}
single | double

\section*{Width - Bandwidth of kernel smoothing window}
scalar value
Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by fitdist is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

\section*{prob.KernelDistribution}

\author{
Data Types \\ single | double
}

\section*{Properties \\ Kernel}

Kernel function type, stored as a valid kernel function type name.

\section*{BandWidth}

Bandwidth of the kernel smoothing window, stored as a positive scalar value.

\end{tabular}

\section*{Definitions \\ Kernel Distribution}

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.
\begin{tabular}{l|l|l}
\hline Option & Description & Possible Values \\
\hline Kernel & Kernel function type & \begin{tabular}{l} 
normal, box, triangle, \\
epanechnikov
\end{tabular} \\
\hline BandWidth & \begin{tabular}{l} 
Kernel smoothing \\
parameter
\end{tabular} & BandWidth >0 \\
\hline
\end{tabular}

The kernel density estimator is
\[
\hat{f}_{h}(x)=\frac{1}{n h} \sum_{i=1}^{n} K\left(\frac{x-x_{i}}{h}\right) \quad ; \quad-\infty<x<\infty,
\]
where \(K(\square)\) is the kernel function and \(h\) is the bandwidth.

\section*{Examples}

\section*{Fit a Kernel Distribution Object to Data}

Load the sample data. Visualize the patient weight data using a histogram.
```

load hospital;
hist(hospital.Weight)

```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.
```

pd = fitdist(hospital.Weight,'Kernel')
pd =

```

\section*{prob.KernelDistribution}

KernelDistribution
Kernel = normal
Bandwidth = 14.3792
Support = unbounded
For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.
pd_normal = fitdist(hospital.Weight,'Normal')
pd_normal =
NormalDistribution

Normal distribution
\(\mathrm{mu}=154 \quad[148.728,159.272]\)
sigma \(=26.5714 \quad[23.3299,30.8674]\)

Define the x values and compute the pdf of each distribution.
```

x = 50:1:250;
pdf_kernel = pdf(pd_kernel,x);
pdf_normal = pdf(pd_normal,x);

```

Plot the pdf of each distribution.
```

plot(x,pdf_kernel,'Color','r','LineStyle',':','LineWidth',2);
hold on;
plot(x,pdf_normal,'Color','b','LineWidth',2);
legend('Kernel Distribution','Normal Distribution','Location','SouthEast'
hold off;

```

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

\hline & 'mode' \\
\hline
\end{tabular}

\section*{'mode'}

\section*{ClassificationPartitionedEnsemble.kfoldEdge}

String representing the meaning of the output edge:
- 'average ' - edge is a scalar value, the average over all folds.
- 'individual' - edge is a vector of length ens.KFold with one element per fold.
- 'cumulative' - edge is a vector of length min(ens.NTrainedPerFold) in which element \(J\) is obtained by averaging values across all folds for weak learners \(1: J\) in each fold.

Default: 'average'

\section*{Output E \\ Arguments}

\section*{Definitions}

\section*{Edge}

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in obj. Prior.

\section*{Margin}

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix obj. x .

\section*{Score (ensemble)}

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

\section*{ClassificationPartitionedEnsemble.kfoldEdge}
- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
- Bag scores range from 0 to 1.
```

Examples Compute the k -fold edge for an ensemble trained on the Fisher iris data:
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree'); cvens = crossval(ens);
E = kfoldEdge(cvens)
E =
3.2078

```

See Also kfoldPredict | kfoldLoss | kfoldMargin | kfoldfun | crossval

\section*{ClassificationPartitionedModel.kfoldEdge}
\begin{tabular}{|c|c|}
\hline Purpose & Classification edge for observations not used for training \\
\hline Syntax & ```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
``` \\
\hline Description & \begin{tabular}{l}
E = kfoldEdge(obj) returns classification edge (average classification margin) obtained by cross-validated classification model obj. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations. \\
E = kfoldEdge(obj,Name, Value) calculates edge with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, , NameN, ValueN.
\end{tabular} \\
\hline Input Arguments & obi Object of class ClassificationPartitionedModel. \\
\hline & Name-Value Pair Arguments \\

\hline & 'folds' \\
\hline
\end{tabular}

Indices of folds ranging from 1 to obj. KFold. Use only these folds for predictions.

Default: 1:obj.KFold

\section*{'mode'}

String representing the meaning of the output edge:
- 'average ' - edge is a scalar value, the average over all folds.

\section*{ClassificationPartitionedModel.kfoldEdge}
- 'individual' - edge is a vector of length obj. KFold with one element per fold.

Default: 'average'

\section*{Output \\ Arguments \\ E}

\section*{Definitions}

The average classification margin. E is a scalar or vector, depending on the setting of the mode name-value pair.

\section*{Edge}

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in obj. Prior. If you supply weights in the weights name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

\section*{Margin}

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix obj. X . A high value of margin indicates a more reliable prediction than a low value.

\section*{Score (discriminant analysis)}

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 14-7.

\section*{Score (tree)}

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

\section*{ClassificationPartitionedModel.kfoldEdge}

For example, consider classifying a predictor X as true when \(\mathrm{X}<0.15\) or \(X>0.95\), and \(X\) is false otherwise.

1
Generate 100 random points and classify them:
rng(0,'twister') \% for reproducibility
\(X=\operatorname{rand}(100,1)\);
\(\mathrm{Y}=(\mathrm{abs}(\mathrm{X}-.55) \mathrm{>} .4)\);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')

2
Prune the tree:
```

tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')

```

\section*{ClassificationPartitionedModel.kfoldEdge}

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than . 15 should be about \(.05 / .85=.06\) for true, and about \(.8 / .85=.94\) for false.

3
Compute the prediction scores for the first 10 rows of X :
[~,score] = predict(tree1, X(1:10));
[score X(1:10,:)]
```

ans =

| 0.9059 | 0.0941 | 0.8147 |
| ---: | ---: | ---: |
| 0.9059 | 0.0941 | 0.9058 |
| 0 | 1.0000 | 0.1270 |
| 0.9059 | 0.0941 | 0.9134 |
| 0.9059 | 0.0941 | 0.6324 |
| 0 | 1.0000 | 0.0975 |

```

\section*{ClassificationPartitionedModel.kfoldEdge}
\begin{tabular}{lll}
0.9059 & 0.0941 & 0.5469 \\
0.9059 & 0.0941 & 0.9575 \\
0.9059 & 0.0941 & 0.9649
\end{tabular}

Indeed, every value of \(X\) (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1 , while the other values of \(X\) have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in \(X\) in the range (.95,1) instead of the expected 5 observations.

\section*{Examples Compute the k -fold edge for a model trained on the Fisher iris data:}
```

load fisheriris
tree = ClassificationTree.fit(meas,species);
cvtree = crossval(tree);
E = kfoldEdge(cvtree)
E =
0.8711

```
See Also \begin{tabular}{l}

| crossval | ClassificationPartitionedEnsemble | \\
ClassificationPartitionedModel
\end{tabular}

\section*{ClassificationPartitionedModel.kfoldfun}

Purpose Cross validate function
Syntax \(\quad\) vals \(=\) kfoldfun (obj, fun \()\)

Description

Input Arguments
vals \(=\) kfoldfun(obj,fun) cross validates the function fun by applying fun to the data stored in the cross-validated model obj. You must pass fun as a function handle.
obi
Object of class ClassificationPartitionedModel or ClassificationPartitionedEnsemble.

\section*{fun}

A function handle for a cross-validation function. fun has the syntax
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
- CMP is a compact model stored in one element of the obj.Trained property.
- Xtrain is the training matrix of predictor values.
- Ytrain is the training array of response values.
- Wtrain are the training weights for observations.
- Xtest and Ytest are the test data, with associated weights Wtest.
- The returned value testvals must have the same size across all folds.

\section*{Output vals}

Arguments

The arrays of testvals output, concatenated vertically over all folds. For example, if testvals from every fold is a numeric vector of length N , kfoldfun returns a KFold-by-N numeric matrix with one row per fold.
```

Examples Cross validate a classification tree, and obtain the classification error
(see kfoldLoss):
load fisheriris
t = ClassificationTree.fit(meas,species);
rng(0,'twister') % for reproducibility
cv = crossval(t);
L = kfoldLoss(cv)
L =
0.0467

```

Examine the result when the error of misclassifying a flower as 'versicolor' is 10 , and any other error is 1 :

1 Write a function file that gives a cost of 1 for misclassification, but 10 for misclassifying a flower as versicolor.
```

function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % index of bad decisions
cost = sum(misclassified) + ...
9*sum(misclassified \& classifiedAsVersicolor); % total differences
averageCost = cost/numel(Ytest); % average error

```

2 Save the file as noversicolor.m on your MATLAB path.
3 Compute the mean misclassification error with the noversicolor cost:
mean(kfoldfun(cv,@noversicolor))
ans =
0.1667

\section*{ClassificationPartitionedEnsemble.kfoldLoss}

\section*{Purpose}

Classification loss for observations not used for training
Syntax

L = kfoldLoss(ens)
L = kfoldLoss(ens,Name, Value)

Description

Input
Arguments
\(\mathrm{L}=\) kfoldLoss(ens) returns loss obtained by cross-validated classification model ens. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

L = kfoldLoss(ens,Name, Value) calculates loss with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, , NameN, ValueN.

\section*{ens}

Object of class ClassificationPartitionedEnsemble. Create ens with fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create ens from a classification ensemble with crossval.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'folds'}

Indices of folds ranging from 1 to ens. KFold. Use only these folds for predictions.

Default: 1:ens.KFold

\section*{'lossfun'}

\section*{ClassificationPartitionedEnsemble.kfoldLoss}

Function handle or string representing a loss function. Built-in loss functions:
- 'binodeviance' - See "Loss Functions" on page 20-1190
- 'classiferror' - Fraction of misclassified data
- 'exponential' - See "Loss Functions" on page 20-1190

You can write your own loss function in the syntax described in "Loss Functions" on page 20-1190.

Default: 'classiferror'

\section*{'mode'}

A string for determining the output of kfoldLoss:
- 'average ' - L is a scalar, the loss averaged over all folds.
- 'individual' - L is a vector of length ens.KFold, where each entry is the loss for a fold.
- 'cumulative' - \(L\) is a vector in which element \(J\) is obtained by using learners \(1: J\) from the input list of learners.

Default: 'average'

\section*{Output Arguments}

\section*{Definitions}

L
Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

\section*{Loss Functions}

The built-in loss functions are:

\section*{ClassificationPartitionedEnsemble.kfoldLoss}
- 'binodeviance' - For binary classification, assume the classes \(y_{n}\) are -1 and 1 . With weight vector \(w\) normalized to have sum 1 , and predictions of row \(n\) of data \(X\) as \(f\left(X_{n}\right)\), the binomial deviance is
\[
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
\]
- 'classiferror' - Fraction of misclassified data, weighted by \(w\).
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is
\[
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
\]

To write your own loss function, create a function file of the form
```

function loss = lossfun(C,S,W,COST)

```
- \(N\) is the number of rows of ens. \(X\).
- \(K\) is the number of classes in ens, represented in ens.ClassNames.
- \(C\) is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in tree.ClassNames.
- \(S\) is an \(N\)-by-K numeric matrix. \(S\) is a matrix of posterior probabilities for classes with one row per observation, similar to the score output from predict.
- W is a numeric vector with \(N\) elements, the observation weights.
- COST is a K-by-K numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

\section*{ClassificationPartitionedEnsemble.kfoldLoss}
```

Examples Find the average cross-validated classification error for an ensemble model of the ionosphere data:
load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)
L =
0.0826

```

\section*{ClassificationPartitionedModel.kfoldLoss}
- 'binodeviance ' - See "Loss Functions" on page 20-1195.
- 'classiferror' - Fraction of misclassified observations. See "Loss Functions" on page 20-1195.
- 'exponential' - See "Loss Functions" on page 20-1195.
- 'mincost' - Smallest misclassification cost as given by the obj . Cost matrix. See "Loss Functions" on page 20-1195.

You can write your own loss function in the syntax described in "Loss Functions" on page 20-1195.

Default: 'mincost'

\section*{'mode'}

A string for determining the output of kfoldLoss:
- 'average' - L is a scalar, the loss averaged over all folds.
- 'individual' - L is a vector of length obj. KFold, where each entry is the loss for a fold.

Default: 'average'

\section*{Output L}

\section*{Definitions}

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

\section*{Classification Error}

The default classification error is the fraction of the data \(X\) that obj misclassifies, where \(Y\) are the true classifications.

Weighted classification error is the sum of weight \(i\) times the Boolean value that is 1 when obj misclassifies the \(i\) th row of \(X\), divided by the sum of the weights.

\section*{ClassificationPartitionedModel.kfoldLoss}

\section*{Loss Functions}

The built-in loss functions are:
- 'binodeviance' - For binary classification, assume the classes \(y_{n}\) are -1 and 1 . With weight vector \(w\) normalized to have sum 1, and predictions of row \(n\) of data \(X\) as \(f\left(X_{n}\right)\), the binomial deviance is
\[
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
\]
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is
\[
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
\]
- 'classiferror' - Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' - Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the Cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:
```

function loss = lossfun(C,S,W,COST)

```
- \(N\) is the number of rows of \(X\).
- \(K\) is the number of classes in the classifier, represented in the ClassNames property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.
- \(S\) is an N -by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.

\section*{ClassificationPartitionedModel.kfoldLoss}
- \(W\) is a numeric vector with \(N\) elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use COST \(=\) ones \((K)\) - eye (K), which means a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.
```

Examples Find the average cross-validated classification error for a model of the
ionosphere data:
load ionosphere
tree = ClassificationTree.fit(X,Y);
cvtree = crossval(tree);
L = kfoldLoss(cvtree)
L =
0.1197

How To

- "Examine the Quality of a KNN Classifier" on page 15-26

```

\section*{RegressionPartitionedEnsemble.kfoldLoss}

\section*{Purpose}

Cross-validation loss of partitioned regression ensemble
Syntax

L = kfoldLoss(cvens)
L = kfoldLoss(cvens,Name, Value)

Description

\section*{Input Arguments}
\(\mathrm{L}=\mathrm{kfold}\) Loss(cvens) returns the cross-validation loss of cvens.
L = kfoldLoss(cvens, Name, Value) returns cross-validation loss with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

\section*{cvens}

Object of class RegressionPartitionedEnsemble. Create
obj with fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create obj from a regression ensemble with crossval.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'folds'}

Indices of folds ranging from 1 to cvens.KFold. Use only these folds for predictions.

Default: 1:cvens.KFold

\section*{'lossfun'}

\section*{RegressionPartitionedEnsemble.kfoldLoss}

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle fun, loss calls it as
fun(Y,Yfit,w)
where \(\mathrm{Y}, \mathrm{Yfit}\), and W are numeric vectors of the same length.
- Y is the observed response.
- Yfit is the predicted response.
- \(W\) is the observation weights.

The returned value fun(Y,Yfit, W) should be a scalar.
Default: 'mse'

\section*{'mode'}

String representing the meaning of the output L:
- 'ensemble' - L is a scalar value, the loss for the entire ensemble.
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - \(L\) is a vector in which element \(J\) is obtained by using learners \(1: J\) from the input list of learners.

Default: 'ensemble'

\section*{Output L}

Arguments
The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. L can be a vector, and can mean different things, depending on the name-value pair settings.

\section*{RegressionPartitionedEnsemble.kfoldLoss}
```

Examples Find the cross-validation loss for a regression ensemble of the carsmall
data:
load carsmall
X = [Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSboost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
L =
25.6935

```

See Also RegressionPartitionedEnsemble | loss | kfoldPredict

\section*{RegressionPartitionedModel.kfoldLoss}
Purpose Cross-validation loss of partitioned regression model
Syntax

L = kfoldLoss(cvmodel)

L = kfoldLoss(cvmodel,Name, Value)Description

\section*{Input} Arguments
\(\mathrm{L}=\mathrm{kfoldLoss}(\) cvmodel) returns the cross-validation loss of cvmodel.
L = kfoldLoss(cvmodel, Name, Value) returns cross-validation loss with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

\section*{cvmodel}

Object of class RegressionPartitionedModel. Create obj with RegressionTree.fit along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create obj from a regression tree with crossval.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\footnotetext{
'folds' for predictions.

Default: 1:obj.KFold

\section*{'lossfun'}
}

Indices of folds ranging from 1 to obj. KFold. Use only these folds

\section*{RegressionPartitionedModel.kfoldLoss}

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle fun, kfoldLoss calls it as
fun(Y,Yfit,w)
where \(Y\), \(Y\) fit, and \(W\) are numeric vectors of the same length.
- Y is the observed response.
- Yfit is the predicted response.
- W is the observation weights.

The returned value fun(Y,Yfit,W) should be a scalar.
Default: 'mse'

\section*{'mode'}

One of the following strings:
- 'average ' - L is the average loss over all folds.
- 'individual' - L is a vector of the individual losses of in-fold observations trained on out-of-fold data.

Default: 'average'

\section*{Output L}

Arguments

\section*{Examples}

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If mode is 'individual', \(L\) is a vector of the losses. If mode is 'average ', \(L\) is the average loss.

Construct a partitioned regression model, and examine the cross-validation losses for the folds:
load carsmall

\section*{RegressionPartitionedModel.kfoldLoss}
```

XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = RegressionTree.fit(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')
L =
44.9635
11.8525
18.2046
9.2965
29.4329
54.8659
24.6446
8.2085
19.7593
16.7394

```

\title{
Alternatives You can avoid constructing a cross-validated tree model by calling cvLoss instead of kfoldLoss. The cross-validated tree can save time if you are going to examine it more than once.
}

\section*{See Also \\ loss | kfoldPredict}

\section*{ClassificationPartitionedModel.kfoldMargin}

\section*{Purpose}

Classification margins for observations not used for training

\section*{Syntax}

Description

\section*{Input Arguments}

\section*{Output \\ M}

Arguments

\section*{Definitions}

M = kfoldMargin(obj)
M = kfoldMargin(obj) returns classification margins obtained by cross-validated classification model obj. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.

\section*{obj}

A partitioned classification model of type ClassificationPartitionedModel or ClassificationPartitionedEnsemble.

The classification margin.

\section*{Margin}

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix obj. x . A high value of margin indicates a more reliable prediction than a low value.

\section*{Score (discriminant analysis)}

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 14-7.

\section*{Score (ensemble)}

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

\section*{ClassificationPartitionedModel.kfoldMargin}

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:
- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
- Bag scores range from 0 to 1 .

\section*{Score (tree)}

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor \(X\) as true when \(X<0.15\) or \(X>0.95\), and \(X\) is false otherwise.

1
Generate 100 random points and classify them:
```

rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')

```

\section*{ClassificationPartitionedModel.kfoldMargin}

2
Prune the tree:
tree1 = prune(tree, 'level', 1 );
view(tree1,'mode','graph')

\section*{ClassificationPartitionedModel.kfoldMargin}

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than .15 should be about \(.05 / .85=.06\) for true, and about \(.8 / .85=.94\) for false.

3
Compute the prediction scores for the first 10 rows of X :
[~,score] = predict(tree1, X(1:10));
[score X(1:10,:)]
```

ans =

| 0.9059 | 0.0941 | 0.8147 |
| ---: | ---: | ---: |
| 0.9059 | 0.0941 | 0.9058 |
| 0 | 1.0000 | 0.1270 |
| 0.9059 | 0.0941 | 0.9134 |
| 0.9059 | 0.0941 | 0.6324 |
| 0 | 1.0000 | 0.0975 |

```

\section*{ClassificationPartitionedModel.kfoldMargin}
\begin{tabular}{lll}
0.9059 & 0.0941 & 0.5469 \\
0.9059 & 0.0941 & 0.9575 \\
0.9059 & 0.0941 & 0.9649
\end{tabular}

Indeed, every value of \(X\) (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of \(X\) have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in \(X\) in the range (. 95,1 ) instead of the expected 5 observations.

\section*{Examples}

Find the k-fold margins for an ensemble that classifies the ionosphere data:
```

load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
cvens = crossval(ens);
M = kfoldMargin(cvens);
[min(M) mean(M) max(M)]
ans =
-7.6394 7.3469 22.4833

```

\section*{ClassificationPartitionedModel.kfoldPredict}

Description

Input
Arguments

\section*{Output \\ Arguments}
```

Purpose Predict response for observations not used for training
Syntax label = kfoldPredict(obj)
[label,score] = kfoldPredict(obj)
[label,score,cost] = kfoldPredict(obj)
Predict response for observations not used for training
label = kfoldPredict(obj) [label,score] = kfoldPredict(obj)
[label,score, cost] = kfoldPredict(obj)

```
label \(=\) kfoldPredict(obj) returns class labels predicted by obj, a cross-validated classification. For every fold, kfoldPredict predicts class labels for in-fold observations using a model trained on out-of-fold observations.
[label,score] = kfoldPredict(obj) returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.
[label, score, cost] = kfoldPredict(obj) returns misclassification costs.
obj
Object of class ClassificationPartitionedModel or ClassificationPartitionedEnsemble.

\section*{label}

Vector of class labels of the same type as the response data used in training obj. Each entry of label corresponds to a predicted class label for the corresponding row of X .

\section*{score}

Numeric matrix of size N -by-K, where N is the number of observations (rows) in obj. X , and K is the number of classes (in obj.ClassNames). score( \(i, j\) ) represents the confidence that row i of obj. X is of class j . For details, see "Definitions" on page 20-1209.

\section*{cost}

\section*{ClassificationPartitionedModel.kfoldPredict}

\section*{Definitions}

\section*{Cost (discriminant analysis)}

The average misclassification cost is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in "Cost" on page 14-8.

\section*{Score (discriminant analysis)}

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 14-7.

\section*{Score (ensemble)}

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:
- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
- Bag scores range from 0 to 1.

\section*{Score (tree)}

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.
For example, consider classifying a predictor \(X\) as true when \(X<0.15\) or \(X>0.95\), and \(X\) is false otherwise.

\section*{ClassificationPartitionedModel.kfoldPredict}

1
Generate 100 random points and classify them:
rng(0,'twister') \% for reproducibility
\(X=\operatorname{rand}(100,1)\);
\(Y=(a b s(X-.55)>.4) ;\)
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
\begin{tabular}{|l|l|l|l|l|}
\hline Click to display: Identity & Magnification: \(100 \%\) & \(\vee\) & Pruning level: 0 of 2 \\
\hline
\end{tabular}

2
Prune the tree:
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')

\section*{ClassificationPartitionedModel.kfoldPredict}

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than . 15 should be about \(.05 / .85=.06\) for true, and about \(.8 / .85=.94\) for false.

\section*{3}

Compute the prediction scores for the first 10 rows of X :
```

[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
ans =

| 0.9059 | 0.0941 | 0.8147 |
| ---: | ---: | ---: |
| 0.9059 | 0.0941 | 0.9058 |
| 0 | 1.0000 | 0.1270 |
| 0.9059 | 0.0941 | 0.9134 |
| 0.9059 | 0.0941 | 0.6324 |
| 0 | 1.0000 | 0.0975 |
| 0.9059 | 0.0941 | 0.2785 |

```

\section*{ClassificationPartitionedModel.kfoldPredict}
\begin{tabular}{lll}
0.9059 & 0.0941 & 0.5469 \\
0.9059 & 0.0941 & 0.9575 \\
0.9059 & 0.0941 & 0.9649
\end{tabular}

Indeed, every value of \(X\) (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1 , while the other values of \(X\) have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in \(X\) in the range (.95,1) instead of the expected 5 observations.
```

Examples Find the cross-validation predictions for a model based on the Fisher
iris data:
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
[elabel escore] = kfoldPredict(cvens);
max(escore)
ans =
$9.3634 \quad 8.5624 \quad 9.3981$
min(escore)
ans $=$
$0.0017 \quad 3.7518 \quad 0.8911$

\section*{RegressionPartitionedModel.kfoldPredict}

Purpose
Predict response for observations not used for training.

Syntax
Description

\section*{Input \\ Arguments}

Output yfit
Arguments

\section*{Examples}

\section*{obi}
yfit = kfoldPredict(obj)
yfit \(=k f o l d P r e d i c t(o b j)\) returns the predicted values for the responses of the training data based on obj, an object trained on out-of-fold observations.

Object of class RegressionPartitionedModel. Create obj with RegressionTree.fit or fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create obj from a regression tree or regression ensemble with crossval.

A vector of predicted values for the response data based on a model trained on out-of-fold observations.

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between yfit and the true response data:
```

load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = RegressionTree.fit(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
L =
26.5271
yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )

```

\section*{RegressionPartitionedModel.kfoldPredict}
\[
\begin{aligned}
& \text { ans }= \\
& 26.5271
\end{aligned}
\]

}
```

Purpose K
Syntax IDX = kmeans(X,k)
[IDX,C] = kmeans(X,k)
[IDX,C,sumd] = kmeans(X,k)
[IDX,C,sumd,D] = kmeans(X,k)
[...] = kmeans(...,param1,val1,param2,val2,...)

```

Description
IDX \(=\) kmeans \((X, k)\) partitions the points in the \(n\)-by- \(p\) data matrix \(X\) into k clusters. This iterative partitioning minimizes the sum, over all clusters, of the within-cluster sums of point-to-cluster-centroid distances. Rows of \(X\) correspond to points, columns correspond to variables. kmeans returns an \(n\)-by- 1 vector IDX containing the cluster indices of each point. By default, kmeans uses squared Euclidean distances. When X is a vector, kmeans treats it as an \(n\)-by- 1 data matrix, regardless of its orientation.
[IDX,C] = kmeans(X,k) returns the \(k\) cluster centroid locations in the k -by-p matrix C .
[IDX,C,sumd] = kmeans(X,k) returns the within-cluster sums of point-to-centroid distances in the 1 -by-k vector sumd.
[IDX, C, sumd, D] = kmeans ( \(\mathrm{X}, \mathrm{k}\) ) returns distances from each point to every centroid in the \(n\)-by- \(k\) matrix \(D\).
[...] = kmeans(...,param1,val1,param2,val2,...) enables you to specify optional parameter/value pairs to control the iterative algorithm used by kmeans. Valid parameter strings are listed in the following table.
\begin{tabular}{l|l|l}
\hline Parameter & Value \\
\hline 'distance' & \begin{tabular}{l} 
Distance measure, in p-dimensional space. kmeans \\
minimizes with respect to this parameter. kmeans \\
computes centroid clusters differently for the \\
different supported distance measures.
\end{tabular} \\
\hline & 'sqEuclidean' & \begin{tabular}{l} 
Squared Euclidean distance \\
(default). Each centroid is the \\
mean of the points in that cluster.
\end{tabular} \\
\hline & 'cityblock' & \begin{tabular}{l} 
Sum of absolute differences, i.e., \\
the L1 distance. Each centroid \\
is the component-wise median of \\
the points in that cluster.
\end{tabular} \\
\hline & 'cosine' & \begin{tabular}{l} 
One minus the cosine of the \\
included angle between points \\
(treated as vectors). Each \\
centroid is the mean of the points \\
in that cluster, after normalizing \\
those points to unit Euclidean \\
length.
\end{tabular} \\
\hline & 'correlation' & \begin{tabular}{l} 
One minus the sample correlation \\
between points (treated as \\
sequences of values). Each \\
centroid is the component-wise \\
mean of the points in that cluster, \\
after centering and normalizing \\
those points to zero mean and \\
unit standard deviation.
\end{tabular} \\
\hline & 'Hamming' & \begin{tabular}{l} 
Percentage of bits that differ (only \\
suitable for binary data). Each \\
centroid is the component-wise \\
median of points in that cluster.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{l|l|l}
\hline Parameter & \multicolumn{1}{|l}{ Value } \\
\hline \multirow{5}{*}{ 'emptyaction' } & \multicolumn{1}{|l}{\begin{tabular}{l} 
Action to take if a cluster loses all its member \\
observations.
\end{tabular}} \\
\cline { 2 - 4 } & 'error' & \begin{tabular}{l} 
Treat an empty cluster as an \\
error (default).
\end{tabular} \\
\cline { 2 - 4 } & 'drop' & \begin{tabular}{l} 
Remove any clusters that \\
become empty. kmeans sets the \\
corresponding return values in C \\
and D to NaN.
\end{tabular} \\
\hline \multirow{5}{*}{ 'onlinephase ' } & \begin{tabular}{l} 
Flag indicating whether kmeans should perform an \\
online update phase in addition to a batch update \\
phase. The online phase can be time consuming \\
for large data sets, but guarantees a solution that \\
is a local minimum of the distance criterion, that \\
is, a partition of the data where moving any single \\
point to a different cluster increases the total sum \\
of distances.
\end{tabular} \\
\cline { 2 - 3 } & \begin{tabular}{l} 
Create a new cluster consisting \\
of the one point furthest from its \\
centroid.
\end{tabular} \\
\hline & 'on' & Perform online update (default). \\
\hline & 'off' & Do not perform online update. \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter & \multicolumn{2}{|l|}{Value} \\
\hline \multirow[t]{6}{*}{'options'} & \multicolumn{2}{|l|}{Structure specifying options for the iterative algorithm used to minimize the fitting criteria. Create the options structure with statset. Applicable statset parameters are:} \\
\hline & Display & Level of display output. Choices are `off'(default), `iter', and 'final'. \\
\hline & MaxIter & Maximum number of iterations allowed. The default is 100 . \\
\hline & UseParallel & If true and if a matlabpool of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a matlabpool is not open, computation occurs in serial mode. Default is default, meaning serial computation. \\
\hline & UseSubstreams & Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a' \\
\hline & Streams & \begin{tabular}{l}
A RandStream object or cell array of such objects. If you do not specify Streams, kmeans uses the default stream or streams. If you choose to specify Streams, use a single object except in the case: \\
- You have an open MATLAB pool
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter & \multicolumn{2}{|l|}{Value} \\
\hline & & \begin{tabular}{l}
- UseParallel is true \\
- UseSubstreams is false \\
In that case, use a cell array the same size as the MATLAB pool. If a MATLAB pool is not open, then Streams must supply a single random number stream.
\end{tabular} \\
\hline 'replicates' & \multicolumn{2}{|l|}{Number of times to repeat the clustering, each with a new set of initial cluster centroid positions. kmeans returns the solution with the lowest value for sumd. You can supply 'replicates' implicitly by supplying a 3D array as the value for the 'start' parameter.} \\
\hline \multirow[t]{5}{*}{'start'} & \multicolumn{2}{|l|}{Method used to choose the initial cluster centroid positions, sometimes known as seeds.} \\
\hline & 'sample' & Select k observations from \(X\) at random (default). \\
\hline & 'uniform' & Select k points uniformly at random from the range of \(X\). Not valid with Hamming distance. \\
\hline & 'cluster' & Perform a preliminary clustering phase on a random \(10 \%\) subsample of \(x\). This preliminary phase is itself initialized using 'sample'. \\
\hline & Matrix & k-by-p matrix of centroid starting locations. In this case, you can pass in [] for \(k\), and kmeans infers \(k\) from the first dimension of the matrix. You can also supply a 3-D array, implying a value for the \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Parameter & Value \\
& \\
\hline
\end{tabular}

\section*{Algorithms}

\section*{References}
kmeans uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all \(k\) clusters:

1 The first phase uses batch updates, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum, that is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.

2 The second phase uses online updates, where points are individually reassigned if doing so will reduce the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during the second phase consists of one pass though all the points. The second phase will converge to a local minimum, although there may be other local minima with lower total sum of distances. The problem of finding the global minimum can only be solved in general by an exhaustive (or clever, or lucky) choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

\section*{ExhaustiveSearcher.knnsearch}

\section*{Purpose}

Find \(k\)-nearest neighbors using ExhaustiveSearcher object

\section*{Syntax}

IDX = knnsearch(NS, Y)
[IDX, D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y,'Name', Value)

Name-Value Pair Arguments Arguments

A positive integer, \(k\), specifying the number of nearest neighbors in NS.X for each point in Y. Default is 1. IDX and D are \(n y\)-by- \(k\) matrices. D sorts the distances in each row in ascending order. Each row in IDX contains the indices of the \(k\) closest neighbors in NS. X corresponding to the \(k\) smallest distances in D.

\section*{'IncludeTies'}

A logical value indicating whether knnsearch includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, knnsearch includes all these neighbors. In this case, IDX and D are ny-by- 1 cell arrays. Each

\section*{ExhaustiveSearcher.knnsearch}
row in IDX and \(D\) contains a vector with at least \(K\) numeric numbers. \(D\) sorts the distances in each vector in ascending order. Each row in IDX contains the indices of the closest neighbors corresponding to these smallest distances in \(D\).

Default: false

\section*{'Distance'}
- 'euclidean' - Euclidean distance (default).
- 'seuclidean' - Standardized Euclidean distance. Each coordinate difference between \(X\) and each query point is scaled by dividing by a scale value S . The default value of S is NS.DistParameter if NS.Distance is 'seuclidean', otherwise the default is the standard deviation computed from X, S=nanstd (X). To specify another value for S, use the 'Scale' argument.
- 'cityblock' - City block distance.
- 'chebychev' - Chebychev distance (maximum coordinate difference).
- 'minkowski' - Minkowski distance.
- 'mahalanobis' - Mahalanobis distance, which is computed using a positive definite covariance matrix C . The default value of \(C\) is nancov \((X)\). To change the value of \(C\), use the Cov parameter.
- 'cosine ' - One minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' - One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' - One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming ' - Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' - One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function - A distance function specified using @ (for example, @distfun). A distance function must be of the form function D2 = distfun(ZI, ZJ), taking as arguments a 1-by- \(n\) vector ZI containing a single row of from X or from the query points Y , an \(m 2\)-by- \(n\) matrix ZJ containing multiple rows of \(X\) or \(Y\), and returning an \(m 2\)-by- 1 vector of distances D2, whose \(j\) th element is the distance between the observations \(Z I\) and \(Z J(j,:)\).

Default is NS.Distance. For more information on these distance metrics, see "Distance Metrics" on page 15-9.
' \(\mathbf{P}\) '
A positive scalar, \(p\), indicating the exponent of the Minkowski distance. This parameter is only valid if knnsearch uses the 'minkowski' distance metric. Default is NS. DistParameter if NS.Distance is 'minkowski' and 2 otherwise.

\section*{'Cov'}

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when knnsearch uses the 'mahalanobis' distance metric. Default is NS.DistParameter if NS.Distance is 'mahalanobis', or nancov (X) otherwise.

\section*{'Scale'}

A vector \(S\) with the length equal to the number of columns in X. Each coordinate of \(X\) and each query point is scaled by the corresponding element of \(S\) when computing the standardized Euclidean distance. This parameter is only valid when Distance is 'seuclidean'. Default is nanstd ( X ).

\section*{ExhaustiveSearcher.knnsearch}

Examples
Create an ExhaustiveSearcher object specifying 'cosine' as the distance metric. Perform a \(k\)-nearest neighbors search on the object using the mahalanobis metric and compare the results:
```

load fisheriris
x = meas(:,3:4);
exhaustiveobj = ExhaustiveSearcher(x,'Distance','cosine')
exhaustiveobj =
ExhaustiveSearcher
Properties:
X: [150x2 double]
Distance: 'cosine'
DistParameter: []
% Perform a knnsearch between x and a query point, using
% first cosine then mahalanobis distance metrics:
newpoint = [5 1.45];
[n,d]=knnsearch(exhaustiveobj, newpoint, 'k',10);
[nmah,dmah] = knnsearch(exhaustiveobj,newpoint,'k',10,···
'distance','mahalanobis');
% Visualize the results of the two different nearest
% neighbors searches:
% First plot the training data:
gscatter(x(:,1),x(:,2),species)
% Plot an X for the query point:
line(newpoint(1),newpoint(2),'marker','x','color','k', ...
'markersize',10,'linewidth',2,'linestyle','none')
% Use circles to denote the cosine nearest neighbors:
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
'linestyle','none','markersize',10)
% Use pentagrams to denote the mahalanobis nearest neighbors:
line(x(nmah,1),x(nmah,2),'color',[.5 .5 .5],'marker','p',...

```
```

\section*{ExhaustiveSearcher.knnsearch}
- "Distance Metrics" on page 15-9

\section*{Purpose}

Find \(k\)-nearest neighbors using KDTreeSearcher object

IDX = knnsearch(NS, Y)
[IDX, D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y,'Name', Value)

Description

\section*{Input Arguments}

IDX \(=\) knnsearch ( \(N S, Y\) ) finds the nearest neighbor (closest point) in NS. X for each point in Y. Rows of \(Y\) correspond to observations and columns correspond to features. Y must have the same number of columns as NS.X. IDX is a column vector with ny rows, where \(n y\) is the number of rows in Y. Each row in IDX contains the index of observation in NS. X which has the smallest distance to the corresponding observation in \(Y\).
[IDX, D] = knnsearch(NS,Y) returns a column vector D containing the distances between each observation in \(Y\) and the corresponding closest observation in NS.X. That is, \(D(i)\) is the distance between NS. X(IDX(i),:) and Y(i,:).
[IDX, D] = knnsearch(NS, Y, 'Name', Value) accepts one or more comma-separated name/value pairs. Specify Name inside single quotes.

\section*{Name-Value Pair Arguments}

\section*{' \(\mathbf{K}^{\prime}\)}

A positive integer, \(k\), specifying the number of nearest neighbors in NS.X for each point in Y. Default is 1. IDX and D are \(n y\)-by- \(k\) matrices. D sorts the distances in each row in ascending order. Each row in IDX contains the indices of the \(k\) closest neighbors in NS. X corresponding to the \(k\) smallest distances in D.

\section*{'Distance'}

Select one of the following distance algorithms.
- 'euclidean' - Euclidean distance (default).
- 'cityblock' - City block distance.

\section*{KDTreeSearcher.knnsearch}
- 'chebychev' - Chebychev distance (maximum coordinate difference).
- 'minkowski' - Minkowski distance.

Default is NS.Distance. For more information on these distance metrics, see "Distance Metrics" on page 15-9.

\section*{'IncludeTies'}

A logical value indicating whether knnsearch includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, knnsearch includes all these neighbors. In this case, IDX and D are \(n y\)-by- 1 cell arrays. Each row in IDX and \(D\) contains a vector with at least \(K\) numeric numbers. \(D\) sorts the distances in each vector in ascending order. Each row in IDX contains the indices of the closest neighbors corresponding to these smallest distances in \(D\).

Default: false

\section*{'P'}

A positive scalar, \(p\), indicating the exponent of the Minkowski distance. This parameter is only valid whenthe Distance is 'minkowski'. Default is NS.DistParameter if NS. Distance is 'minkowski' and 2 otherwise.

\section*{Examples}

Create a KDTreeSearcher object specifying 'minkowski' as the distance metric with an exponent of 5 . Perform a \(k\)-nearest neighbors search on the object using the chebychev metric and compare the results:
```

load fisheriris
x = meas(:,3:4);
kdtreeNS = KDTreeSearcher(x,'Distance','minkowski','P',5)
kdtreeNS =
KDTreeSearcher

```
```

Properties:
BucketSize: 50
X: [150x2 double]
Distance: 'minkowski'
DistParameter: 5
% Perform a knnsearch between X and a query point, using
% first Minkowski then Chebychev distance metrics:
newpoint = [5 1.45];
[n,d]=knnsearch(kdtreeNS,newpoint,'k',10);
[ncb,dcb] = knnsearch(kdtreeNS,newpoint,'k',10,...
'distance','chebychev');
% Visualize the results of the two different nearest
% neighbors searches:
% First plot the training data:
gscatter(x(:,1),x(:,2),species)
% Zoom in on the points of interest:
set(gca,'xlim',[4.5 5.5],'ylim',[1 2]); axis square
% Plot an X for the query point:
line(newpoint(1),newpoint(2),'marker','x','color','k',...
'markersize',10,'linewidth',2,'linestyle','none')
% Use circles to denote the Minkowski nearest neighbors:
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
'linestyle','none','markersize',10)
% Use pentagrams to denote the Chebychev nearest neighbors:
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...
'linestyle','none','markersize',10)
legend('setosa','versicolor','virginica','query point',...
'minkowski','chebychev')
set(legend,'location','best')

```

- "Distance Metrics" on page 15-9

Purpose
Find \(k\)-nearest neighbors using data

\section*{Syntax}

IDX = knnsearch (X,Y)
[IDX,D] = knnsearch(X,Y)
[IDX, D] = knnsearch(X,Y,'Name', Value)

\section*{Input Arguments}

IDX \(=\operatorname{knnsearch}(X, Y)\) finds the nearest neighbor in \(X\) for each point nearest neighbor in \(X\) for the corresponding row in \(Y\). observation in \(X\). That is, \(D(i)\) is the distance between \(X(\operatorname{IDX}(i),:)\) and \(Y(i,:)\).
[IDX, D] = knnsearch(X,Y, 'Name', Value) accepts one or more quotes.
knnsearch does not save a search object. To create a search object, use createns. of each point in \(Y\).

\section*{Name-Value Pair Arguments}
in \(Y\). \(X\) is an \(m x\)-by- \(n\) matrix and \(Y\) is an \(m y\)-by- \(n\) matrix. Rows of \(X\) and Y correspond to observations and columns correspond to variables. IDX is a column vector with \(m y\) rows. Each row in IDX contains the index of
[IDX, D] = knnsearch ( \(\mathrm{X}, \mathrm{Y}\) ) returns an \(m y\)-by-1 vector D containing the distances between each observation in \(Y\) and the corresponding closest optional comma-separated name/value pairs. Specify Name inside single
- For a fixed positive integer K, knnsearch finds the \(K\) points in \(X\) that are nearest each point in \(Y\). In contrast, for a fixed positive real value \(r\), rangesearch finds all the points in \(X\) that are within a distance \(r\)

\section*{'K'}

Positive integer specifying the number of nearest neighbors in \(X\) for each point in Y. Default is 1. IDX and D are \(m y\)-by-K matrices. D sorts the distances in each row in ascending order. Each row in IDX contains the indices of the \(K\) closest neighbors in \(X\) corresponding to the \(K\) smallest distances in \(D\).

\section*{'IncludeTies'}

A logical value indicating whether knnsearch includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, knnsearch includes all these neighbors. In this case, IDX and D are \(m y\)-by- 1 cell arrays. Each row in IDX and D contains a vector with at least \(K\) numeric numbers. \(D\) sorts the distances in each vector in ascending order. Each row in IDX contains the indices of the closest neighbors corresponding to these smallest distances in D.

Default: false

\section*{'NSMethod'}

Nearest neighbors search method. Value is either:
- 'kdtree' - Creates and uses a Kd-tree to find nearest neighbors. This is the default value when the number of columns of X is less than \(10, \mathrm{X}\) is not sparse, and the distance measure is one of the following measures. 'kdtree' is only valid when the distance measure is one of the following:
- 'euclidean'
- 'cityblock'
- 'minkowski'
- 'chebychev'
- 'exhaustive' - Uses the exhaustive search algorithm by computing the distance values from all the points in \(X\) to each point in \(Y\) to find nearest neighbors.

\section*{'Distance'}

A string or a function handle specifying the distance metric. The value can be one of the following:
- 'euclidean' - Euclidean distance (default).
- 'seuclidean' - Standardized Euclidean distance. Each coordinate difference between rows in \(X\) and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from X, S=nanstd (X). To specify another value for S, use the Scale argument.
- 'cityblock' - City block distance.
- 'chebychev' - Chebychev distance (maximum coordinate difference).
- 'minkowski' - Minkowski distance. The default exponent is 2 . To specify a different exponent, use the ' \(P\) ' argument.
- 'mahalanobis' - Mahalanobis distance, computed using a positive definite covariance matrix \(C\). The default value of \(C\) is nancov ( \(X\) ). To change the value of C , use the Cov parameter.
- 'cosine' - 1 minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' - One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman ' - One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' - Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' - One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function - A distance function specified using @ (for example, @distfun). A distance function must be of the form function D2 \(=\) distfun(ZI, ZJ), taking as arguments a 1-by-n vector \(Z I\) containing a single row of \(X\) or \(Y\), an \(m 2\)-by- \(n\) matrix \(Z J\) containing multiple rows of \(X\) or Y , and returning an \(m 2\)-by- 1 vector of distances D2, whose \(j\) th element is the distance between the observations ZI and ZJ(j,:).
For more information on these distance metrics, see "Distance Metrics" on page 15-9.

\section*{'P'}

A positive scalar, \(p\), indicating the exponent of the Minkowski distance. This parameter is only valid if the Distance is 'minkowski'. Default is 2 .

\section*{'Cov'}

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when Distance is 'mahalanobis'. Default is nancov ( X ).

\section*{'Scale'}

A vector \(S\) containing nonnegative values, with length equal to the number of columns in \(X\). Each coordinate of \(X\) and each query point is scaled by the corresponding element of \(S\) when computing the standardized Euclidean distance. This argument is only valid when Distance is 'seuclidean'. Default is nanstd ( X ).

\section*{'BucketSize'}

The maximum number of data points in the leaf node of the \(k \mathrm{~d}\)-tree. This argument is only meaningful when using the \(k\) d-tree search method. Default is 50 .

\section*{Examples}

Find the 10 nearest neighbors in \(x\) to each point in \(y\) using first the 'minkowski' distance metric with a p value of 5 , and then using the 'chebychev' distance metric. Visually compare the results:
```

load fisheriris
x = meas(:,3:4);
y = [5 1.45;6 2;2.75 .75];
% Perform a knnsearch between x and the query points in y,
% using first Minkowski then Chebychev distance metrics.
[n,d]=knnsearch(x,y,'k',10,'distance','minkowski','p',5);
[ncb,dcb] = knnsearch(x,y,'k',10,...
'distance','chebychev');

```
```

% Visualize the results of the two different nearest
% neighbors searches.
% First plot the training data.
gscatter(x(:,1),x(:,2),species)
% Plot an X for the query points.
line(y(:,1),y(:,2),'marker','x','color','k',...
'markersize',10,'linewidth',2,'linestyle','none')
% Use circles to denote the Minkowski nearest neighbors.
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
'linestyle','none','markersize',10)
% Use pentagrams to denote the Chebychev nearest neighbors.
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...
'linestyle','none','markersize',10)
legend('setosa','versicolor','virginica','query point',...
'minkowski','chebychev')
set(legend,'location','best')

```

\section*{kruskalwallis}
Purpose Kruskal-Wallis test
\begin{tabular}{|c|c|}
\hline Syntax & \(\mathrm{p}=\) kruskalwallis(X) \\
\hline & \(\mathrm{p}=\) kruskalwallis(X, group) \\
\hline & \(\mathrm{p}=\) kruskalwallis(X,group,displayopt) \\
\hline & [ p ,table] = kruskalwallis(...) \\
\hline & [p,table,stats] = kruskalwallis( \\
\hline
\end{tabular}

\section*{Description}
p = kruskalwallis(X) performs a Kruskal-Wallis test to compare samples from two or more groups. Each column of the \(m\)-by- \(n\) matrix X represents an independent sample containing \(m\) mutually independent observations. The function compares the medians of the samples in X , and returns the \(p\)-value for the null hypothesis that all samples are drawn from the same population (or equivalently, from different populations with the same distribution). Note that the Kruskal-Wallis test is a nonparametric version of the classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups.

If the \(p\)-value is near zero, this casts doubt on the null hypothesis and suggests that at least one sample median is significantly different from the others. The choice of a critical \(p\)-value to determine whether the result is judged statistically significant is left to the researcher. It is common to declare a result significant if the \(p\)-value is less than 0.05 or 0.01.

The kruskalwallis function displays two figures. The first figure is a standard ANOVA table, calculated using the ranks of the data rather than their numeric values. Ranks are found by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. For example, the following table shows the ranks for a small sample.
\begin{tabular}{l|l|l|l|l|l|l|l}
\hline X value & 1.4 & 2.7 & 1.6 & 1.6 & 3.3 & 0.9 & 1.1 \\
\hline Rank & 3 & 6 & 4.5 & 4.5 & 7 & 1 & 2 \\
\hline
\end{tabular}

The entries in the ANOVA table are the usual sums of squares, degrees of freedom, and other quantities calculated on the ranks. The usual \(F\) statistic is replaced by a chi-square statistic. The \(p\)-value measures the significance of the chi-square statistic.
The second figure displays box plots of each column of \(X\) (not the ranks of \(X\) ).
\(\mathrm{p}=\) kruskalwallis( X , group) uses the values in group (a character array or cell array) as labels for the box plot of the samples in \(X\), when \(X\) is a matrix. Each row of group contains the label for the data in the corresponding column of \(X\), so group must have length equal to the number of columns in \(X\).

When \(X\) is a vector, kruskalwallis performs a Kruskal-Wallis test on the samples contained in \(X\), as indexed by input group (a categorical variable, vector, character array, or cell array). Each element in group identifies the group (i.e., sample) to which the corresponding element in vector \(X\) belongs, so group must have the same length as \(X\). The labels contained in group are also used to annotate the box plot.

It is not necessary to label samples sequentially (1, 2, 3, ...). For example, if \(X\) contains measurements taken at three different temperatures, \(-27^{\circ}, 65^{\circ}\), and \(110^{\circ}\), you could use these numbers as the sample labels in group. If a row of group contains an empty cell or empty string, that row and the corresponding observation in \(X\) are disregarded. NaNs in either input are similarly ignored.
\(\mathrm{p}=\) kruskalwallis(X,group,displayopt) enables the table and box plot displays when displayopt is 'on' (default) and suppresses the displays when displayopt is 'off'.
[ \(p\),table] = kruskalwallis(...) returns the ANOVA table (including column and row labels) in cell array table.
[p,table,stats] = kruskalwallis(...) returns a stats structure that you can use to perform a follow-up multiple comparison test. The kruskalwallis test evaluates the hypothesis that all samples come from populations that have the same median, against the alternative that the medians are not all the same. Sometimes it is preferable to

\section*{kruskalwallis}
perform a test to determine which pairs are significantly different, and which are not. You can use the multcompare function to perform such tests by supplying the stats structure as input.

\section*{Assumptions}

The Kruskal-Wallis test makes the following assumptions about the data in \(X\) :
- All samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects.
- All observations are mutually independent.

The classical one-way ANOVA test replaces the first assumption with the stronger assumption that the populations have normal distributions.

\section*{Examples}

This example compares the material strength study used with the anova1 function, to see if the nonparametric Kruskal-Wallis procedure leads to the same conclusion. The example studies the strength of beams made from three alloys:
```

strength = [82 86 79 83 84 85 86 87 74 82 ...
78 75 76 77 79 79 77 78 82 79];
alloy = {'st','st','st','st','st','st','st','st',...
'al1','al1','al1','al1','al1','al1',...
'al2','al2','al2','al2','al2','al2'};

```

This example uses both classical and Kruskal-Wallis ANOVA, omitting displays:
```

anova1(strength,alloy,'off')
ans =
1.5264e-004
kruskalwallis(strength,alloy,'off')
ans =
0.0018

```

Both tests find that the three alloys are significantly different, though the result is less significant according to the Kruskal-Wallis test. It is typical that when a data set has a reasonable fit to the normal distribution, the classical ANOVA test is more sensitive to differences between groups.

To understand when a nonparametric test may be more appropriate, let's see how the tests behave when the distribution is not normal. You can simulate this by replacing one of the values by an extreme value (an outlier).
```

strength(20)=120;
anova1(strength,alloy,'off')
ans =
0.2501

```
kruskalwallis(strength, alloy, 'off')
ans =
    0.0060

Now the classical ANOVA test does not find a significant difference, but the nonparametric procedure does. This illustrates one of the properties of nonparametric procedures - they are often not severely affected by changes in a small portion of the data.

Purpose Kernel smoothing function estimate
```

Syntax $\quad[f, x i]=$ ksdensity $(x)$
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(x,pts,Name,Value)
[f,xi,bw] = ksdensity( __ )
ksdensity (__ )
ksdensity (ax, __ )

```

\section*{Description}
[f,xi] = ksdensity(x) returns a probability density estimate, \(f\), for the sample in the vector \(x\). The estimate is based on a normal kernel function, and is evaluated at 100 equally spaced points, \(x i\), that cover the range of the data in \(x\).
ksdensity works best with continuously distributed samples.
[ \(f, x i]=k s d e n s i t y(x, p t s)\) returns a probability density estimate, f , for the sample in the vector x , evaluated at the specified values in vector pts. Here, the xi and pts vectors contain identical values.
[f,xi] = ksdensity(x,pts,Name, Value) returns a probability density estimate, \(f\), for the sample in the vector \(x\), with additional options specified by one or more Name, Value pair arguments.
For example, you can define the function type ksdensity evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.
[f,xi,bw] = ksdensity( __ ) also returns the bandwidth of the kernel smoothing window, bw. The default bandwidth is the optimal for normal densities.
ksdensity (__ ) plots the kernel smoothing function estimate.
ksdensity (ax, __ ) plots the results using axes with the handle, ax, instead of the current axes returned by gca.

\section*{Input \\ Arguments}

\section*{x-Sample data}
column vector
Sample data, for which ksdensity returns \(f\) values, specified as a column vector.

Example: [f,xi] = ksdensity (x)

\section*{Data Types}
single | double

\section*{pts - Points to evaluate \(f\)}
vector
Points to evaluate f at, specified as a vector. pts can be a row or column vector. f has the same dimensions as pts .
Example: pts = (0:1:25); ksdensity(x,pts);

\section*{Data Types}
single | double

\section*{ax - Axes handle}

\section*{handle}

Axes handle for the figure ksdensity plots to, specified as a handle.
For example, if h is a handle for a figure, then ksdensity can plot to that figure as follows.

\section*{Example: ksdensity (h,x)}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.
```

Example:
'censoring',cens,'kernel','triangle','npoints', 20,'function','cdf'
specifies that ksdensity estimates the cdf by evaluating at
20 equally spaced points that covers the range of data, using
the triangle kernel smoothing function and accounting for the
censored data information in vector cens.

```

\section*{'censoring' - Logical vector}
vector of 0 s (default) | vector of 0 s and 1 s
Logical vector indicating which entries are censored, specified as a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring.
Example: 'censoring', censdata

\section*{Data Types}
logical
```

'kernel' - Type of kernel smoother
'normal' (default) | 'box' | 'triangle' | 'epanechnikov' |
function handle | string

```

Type of kernel smoother, specified as the comma-separated pair consisting of 'kernel' and one of the following.
- 'normal' (default)
- 'box'
- 'triangle'
- 'epanechnikov'
- You can also specify a custom kernel function, as a function handle or as a string, e.g., @normpdf or 'normpdf'. This calls the function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When 'function' is 'pdf', this kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'function' is 'icdf' returns an error.

If 'support' is 'positive', then ksdensity transforms x using a log function, estimates the density of the transformed values, and transforms back to the original scale. If 'support' is a vector [L U], then ksdensity uses the transformation \(\log ((X-L) /(U-X))\). The width parameter and bw outputs are on the scale of the transformed values.

Example: 'kernel', 'box'

\section*{Data Types}
char | function_handle

\section*{'npoints' - Number of equally spaced points}

100 (default) | scalar value
Number of equally spaced points in xi, specified as the comma-separated pair consisting of 'npoints' and a scalar value.
For instance, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:
Example: 'npoints', 80

\section*{Data Types}
single | double

\section*{'support' - Support for the density}
'unbounded' (default) | 'positive' | two-element vector, [L U]
Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

\section*{ksdensity}
\begin{tabular}{l|l}
\hline 'unbounded' & \begin{tabular}{l} 
Default. Allow the density to extend over the \\
whole real line.
\end{tabular} \\
\hline 'positive' & Restrict the density to positive values. \\
\hline \begin{tabular}{l} 
Two-element \\
vector, [L U]
\end{tabular} & \begin{tabular}{l} 
Give the finite lower and upper bounds for the \\
support of the density.
\end{tabular} \\
\hline
\end{tabular}

Example: 'support','positive'
Example: 'support', [0 10]

\section*{Data Types \\ single | double | char}

\section*{'weights' - Weights for each x value}
vector
Weights for each \(x\) value, specified as the comma-separated pair consisting of 'weights' and a vector of the same length as \(x\).

For instance, if the weights for the data values are in vector xw , then you can specify the weights as follows.

Example: 'weights',xw
```

Data Types
single | double

```

\section*{'bandwidth' - Bandwidth of the kernel smoothing window}
optimal value for normal densities (default) | scalar value
The bandwidth of the kernel-smoothing window, which is a function of the number of points in \(x\), specified as the comma-separated pair consisting of 'width' and a scalar. The default is optimal for estimating normal densities, but you might want to choose a larger or smaller value to smooth more or less.

Example: 'bandwidth', 0.8

\section*{Data Types}
single | double

\section*{'function' - Function to estimate}
'pdf' (default) | 'cdf' | 'icdf' | 'survivor' | 'cumhazard'
Function to estimate, specified as the comma-separated pair consisting of 'function' and one of the following.
\begin{tabular}{|c|c|}
\hline 'pdf' & Default. Probability density function. \\
\hline 'cdf' & Cumulative distribution function. \\
\hline 'icdf' & Inverse cumulative distribution function. For 'icdf', \\
\hline 'survivor' & Survivor function. \\
\hline 'cumhazard' & Cumulative hazard function. \\
\hline
\end{tabular}

Example: 'function','icdf'
Data Types
char

\section*{Output \\ Arguments}

\section*{Examples}

\section*{f-Estimated function values}
vector
Estimated function values, returned as a vector of the same dimension as xi or pts.
xi-Evaluation points
100 equally spaced points (default) | vector
Evaluation points at which ksdensity calculates f, returned as a vector. Default is 100 equally spaced points that cover the range of data in \(x\).

\section*{bw - Bandwidth of smoothing window}
scalar value
Bandwidth of smoothing window, returned as a scalar value.

\section*{Estimate Density}

Generate a sample data set from a mixture of two normal distributions.

\section*{ksdensity}
```

rng('default') % for reproducibility
x = [randn (30,1); 5+randn(30,1)];

```

Plot the estimated density.
[f,xi] = ksdensity(x);
figure()
plot(xi,f);

The density estimate shows the bimodality of the sample.

\section*{Estimate Cumulative Distribution Function at Specified Values}

Load the sample data.
load hospital
Compute and plot the estimated cdf evaluated at a specified set of values.
```

pts = (min(hospital.Weight):2:max(hospital.Weight));
figure()
ecdf(hospital.Weight)
hold on
ksdensity(hospital.Weight,pts,'support','positive','function','cdf');
xlabel('Patient weights')
ylabel('Estimated cdf')

```

ksdensity seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.
[f,xi,bw] = ksdensity(hospital.Weight,xi,'support','positive','function', bw
bw =
\[
0.1070
\]

Plot the cumulative distribution function estimate using a smaller bandwidth.
[f,xi] = ksdensity(hospital.Weight,pts,'support','positive','function plot(xi,f,'--r','LineWidth',2) hold off

\section*{ksdensity}

The ksdensity estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

\section*{Plot Estimated Cumulative Density Function for Given Number of Points}

Load the sample data.
load hospital
Plot the estimated cdf evaluated at 50 equally spaced points.
```

figure()
ksdensity(hospital.Weight,'support','positive','function','cdf',...
'npoints',50)
xlabel('Patient weights')
ylabel('Estimated cdf')

```

\section*{Estimate Survivor and Cumulative Hazard for Censored Failure Data}

Generate sample data from an exponential distribution with mean 3.
rng('default') \% for reproducibility
\(x=\) random('exp',3,100,1);
Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

\section*{ksdensity}
```

T = 10;
cens = (x>10);

```

Compute and plot the estimated density function.
figure()
ksdensity(x,'support','positive','censoring', cens);

Compute and plot the survivor and cumulative hazard functions.
```

figure()
ksdensity(x,'support','positive','censoring',cens,...
'function','survivor');

```

figure()
ksdensity(x,'support','positive','censoring',cens,...
'function','cumhazard');

\section*{Estimate Inverse Cumulative Distribution Function for Specified Probability Values}

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.
```

rng('default') % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);

```
figure()
ksdensity(x,pi,'function','icdf');

\section*{Return Bandwidth of Smoothing Window}

Generate a mixture of two normal distributions.
```

rng('default') \% for reproducibility

```
\(x=[r a n d n(30,1) ; 5+r a n d n(30,1)] ;\)

\section*{ksdensity}

Return the bandwidth of the smoothing window for the probability density estimate.
[f,xi,bw] = ksdensity(x);
bw
bw =
1.5141

The default bandwidth is optimal for normal densities.
Plot the estimated density.
figure()
plot(xi,f);

Plot the density using an increased bandwidth value.
figure()
ksdensity(x,'width',1.8);

\section*{ksdensity}

A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.
```

figure()
ksdensity(x,'width',0.8);

```

A smaller bandwidth smooths the density estimate less, which exaggerate some characteristics of the sample.

\section*{Purpose \\ One-sample Kolmogorov-Smirnov test}

Syntax
h = kstest \((x)\)
h = kstest(x,Name, Value)
[h, p] = kstest(__ )
[h, p,ksstat, cv] = kstest( ___ )

Description

\section*{Input Arguments}
\(h=\) kstest \((x)\) returns a test decision for the null hypothesis that the data in vector \(x\) comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test. The result h is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, or 0 otherwise.
\(\mathrm{h}=\) kstest (x,Name, Value) returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.
[h, p] = kstest (__ ) also returns the \(p\)-value p of the hypothesis test, using any of the input arguments from the previous syntaxes.
[h, p, ksstat, cv] = kstest (__ ) also returns the value of the test statistic ksstat and the approximate critical value cv of the test.

\section*{x-Sample data}
vector
Sample data, specified as a vector.

\section*{Data Types}
single | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding
value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Tail', 'right', 'Alpha', 0.01 specifies a right-tailed hypothesis test at the \(1 \%\) significance level.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

Example: 'Alpha', 0.01

\author{
Data Types \\ single | double
}

\section*{'CDF' - cdf of hypothesized continuous distribution}
matrix | probability distribution object
cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of 'CDF' and either a two-column matrix or a continuous probability distribution object. When CDF is a matrix, column 1 contains a set of possible \(x\) values, and column 2 contains the corresponding hypothesized cumulative distribution function values \(G(x)\). The calculation is most efficient if CDF is specified such that column 1 contains the values in the data vector \(x\). If there are values in x not found in column 1 of CDF, kstest approximates \(G(x)\) by interpolation. All values in x must lie in the interval between the smallest and largest values in the first column of CDF. By default, kstest tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test x against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use lillietest instead.

\section*{Data Types \\ single | double \\ 'Tail' - Type of alternative hypothesis \\ 'both' (default) | 'right' | 'left'}

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.
\begin{tabular}{ll} 
'both' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean is not m.
\end{tabular} \\
'right' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean is greater than m.
\end{tabular} \\
'left' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean is less than \(m\).
\end{tabular}
\end{tabular}

If the values in the data vector \(x\) tend to be larger than expected from the hypothesized distribution, the empirical distribution function of \(x\) tends to be smaller, and vice versa.
```

Example: 'Tail','right'

```

\section*{Output Arguments}
```

h - Hypothesis test result
1 | 0

```

Hypothesis test result, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(h=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{p - p -value}
scalar value in the range \((0,1)\)
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme
than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.

\section*{ksstat - Test statistic}
nonnegative scalar value
Test statistic of the hypothesis test, returned as a nonnegative scalar value.

\section*{cv-Critical value}
nonnegative scalar value
Critical value, returned as a nonnegative scalar value.

\section*{Examples Test for a Standard Normal Distribution}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
```

load examgrades;
test1 = grades(:,1);

```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10 . Use these parameters to center and scale each element of the data vector since, by default, kstest tests for a standard normal distribution.
```

x = (test1-75)/10;
h = kstest(x)
h =
0

```

The returned value of \(\mathrm{h}=0\) indicates that kstest fails to reject the null hypothesis at the default \(5 \%\) significance level.

Plot the empirical cumulative distribution function (cdf) and the standard normal cdf for a visual comparison.
```

[f,x_values] = ecdf(x);
F = plot(x_values,f);
set(F,'LineWidth',2);
hold on;
G = plot(x_values,normcdf(x_values,0,1),'r-');
set(G,'LineWidth',2);
legend([F G],...
'Empirical CDF','Standard Normal CDF',...
'Location','SE');

```

The plot shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

\section*{Specify the Hypothesized Distribution Using a Two-Column Matrix}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
```

load examgrades;
x = grades(:,1);

```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector \(x\). Column 2 contains cdf values evaluated at each value in x for a hypothesized Student's \(t\) distribution with a location parameter of 75 , a scale parameter of 10 , and one degree of freedom.
```

test_cdf = [x,cdf('tlocationscale',x,75,10,1)];

```

Test if the data are from the hypothesized distribution.
```

h = kstest(x,'CDF',test_cdf)
h =
1

```

The returned value of \(h=1\) indicates that kstest rejects the null hypothesis at the default \(5 \%\) significance level.

\section*{Specify the Hypothesized Distribution Using a Probability Distribution Object}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
```

load examgrades;
x = grades(:,1);

```

Create a probability distribution object to test if the data comes from a Student's \(t\) distribution with a location parameter of 75 , a scale parameter of 10 , and one degree of freedom.
```

test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);

```

Test the null hypothesis that the data comes from the hypothesized distribution.
```

h = kstest(x,'CDF',test_cdf)
h =
1

```

The returned value of \(h=1\) indicates that kstest rejects the null hypothesis at the default \(5 \%\) significance level.

\section*{Test the Hypothesis at Different Significance Levels}

Load the sample data. Create a vector containing the first column of the students' exam grades.
```

load examgrades;
test1 = grades(:,1);

```

Create a probability distribution object to test if the data comes from a Student's \(t\) distribution with a location parameter of 75 , a scale parameter of 10 , and one degree of freedom.
```

test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);

```

Test the null hypothesis that data comes from the hypothesized distribution at the \(1 \%\) significance level.
```

[h,p] = kstest(x,'CDF',test_cdf,'Alpha',0.01)
h =
1

```

\section*{kstest}
```

p =
0.0021

```

The returned value of \(\mathrm{h}=1\) indicates that kstest rejects the null hypothesis at the \(1 \%\) significance level.

\section*{Conduct a One-Sided Hypothesis Test}

Load the sample data. Create a vector containing the third column of the stock return data matrix.
load stockreturns;
x = stocks(: 3);
Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the empirical cdf of the data is larger than the standard normal cdf.
```

[h,p,k,c] = kstest(x,'Tail','larger')
h =
1
p =
5.0854e-05
k =
0.2197
C =
0.1207

```

The returned value of \(h=1\) indicates that kstest rejects the null hypothesis in favor of the alternative hypothesis at the default \(5 \%\) significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.
```

[f,x_values] = ecdf(x);
J = plot(x_values,f);
hold on;

```
```

K = plot(x_values,normcdf(x_values),'r--');
set(J,'LineWidth',2);
set(K,'LineWidth',2);
legend([J K],'Empirical CDF','Standard Normal CDF','Location','SE');

```

The plot shows the difference between the empirical cdf of the data vector x and the cdf of the standard normal distribution.

\section*{Definitions}

\section*{One-Sample Kolmogorov-Smirnov Test}

The one-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the empirical cdf of the data and the cdf of the hypothesized distribution over the range of \(x\) in the data set.

The two-sided test uses the maximum absolute difference between the empirical cdf and the hypothesized cdf. The test statistic is
\[
D^{*}=\max _{x}(|F(x)-G(x)|),
\]
where \(\hat{F}(x)\) is the empirical cdf and \(G(x)\) is the cdf of the hypothesized distribution.

The one-sided test uses the actual value of the difference between the empirical cdf and the hypothesized cdf rather than the absolute value. The test statistic is
\[
D^{*}=\max _{x}(F(x)-G(x)) .
\]
kstest computes the critical value cv using an approximate formula or by interpolation in a table. The formula and table cover the range 0.01 \(\leq\) alpha \(\leq 0.2\) for two-sided tests and \(0.005 \leq\) alpha \(\leq 0.1\) for one-sided tests. CV is returned as NaN if alpha is outside this range.

\section*{Algorithms}
kstest decides to reject the null hypothesis by comparing the \(p\)-value p with the significance level Alpha, not by comparing the test statistic ksstat with the critical value cv. Since cv is approximate, comparing ksstat with CV occasionally leads to a different conclusion than comparing p with Alpha.

}

Purpose Two-sample Kolmogorov-Smirnov test

Syntax
Description

Input Arguments
```

h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2(___)
[h,p,ks2stat] = kstest2(___)

```
\(h=\) kstest2 \((x 1, x 2)\) returns a test decision for the null hypothesis that the data in vectors \(x 1\) and \(x 2\) are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test. The alternative hypothesis is that \(\times 1\) and \(\times 2\) are from different continuous distributions. The result \(h\) is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, and 0 otherwise.
h = kstest2 ( \(\mathrm{x} 1, \mathrm{x} 2\), Name, Value) returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.
[h,p] = kstest2( __ ) also returns the asymptotic \(p\)-value p , using any of the input arguments from the previous syntaxes.
[h, p,ks2stat] = kstest2( __ ) also returns the test statistic ks2stat.

\section*{x 1 - Sample data}
vector
Sample data from the first sample, specified as a vector. Data vectors x 1 and x 2 do not need to be the same size.

Data Types
single | double

\section*{x2-Sample data}
vector

Sample data from the second sample, specified as a vector. Data vectors \(x 1\) and \(x 2\) do not need to be the same size.

Data Types
single | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.
Example:

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

Example: 'Alpha', 0.01

\section*{Data Types}
single | double

\section*{'Tail' - Type of alternative hypothesis \\ 'both' (default) | 'right' | 'left'}

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

\footnotetext{
'unequal' Test the alternative hypothesis that the empirical cdf of \(x 1\) is unequal to the empirical cdf of \(\times 2\).
'larger' Test the alternative hypothesis that the empirical cdf of x 1 is larger than the empirical cdf of x 2 .
'smaller' Test the alternative hypothesis that the empirical cdf of x 1 is smaller than the empirical cdf of x 2 .
}

If the data values in \(x 1\) tend to be larger than those in \(x 2\), the empirical distribution function of \(x 1\) tends to be smaller than that of \(x 2\), and vice versa.

Example: 'Tail', 'right'

\section*{Output Arguments}

\section*{h - Hypothesis test result}

1 | 0
Hypothesis test result, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(\mathrm{h}=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{p-Asymptotic \(\boldsymbol{p}\)-value}
scalar value in the range \((0,1)\)
Asymptotic \(p\)-value of the test, returned as a scalar value in the range \((0,1)\). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic \(p\)-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes n 1 and n 2 , such that \((\mathrm{n} 1 * \mathrm{n} 2) /(\mathrm{n} 1+\mathrm{n} 2) \geq 4\).

\section*{ks2stat - Test statistic}
nonnegative scalar value
Test statistic, returned as a nonnegative scalar value.

\section*{Examples Test Two Samples for the Same Distribution}

Generate sample data from two different Weibull distributions.
```

rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);

```

Test the null hypothesis that data in vectors x 1 and x 2 comes from populations with the same distribution.
```

h = kstest2(x1,x2)
h =
1

```

The returned value of \(h=1\) indicates that kstest rejects the null hypothesis at the default \(5 \%\) significance level.

\section*{Test the Hypothesis at Different Significance Levels}

Generate sample data from two different Weibull distributions.
```

rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);

```

Test the null hypothesis that data vectors x 1 and x 2 are from populations with the same distribution at the \(1 \%\) significance level.
```

[h,p] = kstest2(x1,x2,'Alpha',0.01)

```
\(\mathrm{h}=\)
    0
\(p=\)
    0.0317

The returned value of \(h=0\) indicates that kstest does not reject the null hypothesis at the \(1 \%\) significance level.

\section*{One-Sided Hypothesis Test}

Generate sample data from two different Weibull distributions.
```

rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);

```

Test the null hypothesis that data in vectors x 1 and x 2 comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of \(x 1\) is larger than the \(c d f\) of the distribution of \(\times 2\).
```

[h,p,k] = kstest2(x1,x2,'Tail','larger')
h =
1
p =
0.0158
k =
0.2800

```

The returned value of \(h=1\) indicates that kstest rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of \(\times 1\) is larger than the cdf of the distribution of \(\times 2\), at the default \(5 \%\) significance level. The returned value of \(k\) is the test statistic for the two-sample Kolmogorov-Smirnov test.

\section*{Definitions}

\section*{Two-Sample Kolmogorov-Smirnov Test}

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of \(x\) in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is
\[
D^{*}=\max _{x}\left(\left|F_{1}(x)-F_{2}(x)\right|\right)
\]
where \(\hat{F}_{1}(x)\) is the proportion of x 1 values less than or equal to \(x\) and \(\hat{F}_{2}(x)\) is the proportion of x 2 values less than or equal to \(x\).

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is
\[
D^{*}=\max _{x}\left(F_{1}(x)-F_{2}(x)\right) .
\]

\section*{Algorithms}

In kstest2, the decision to reject the null hypothesis is based on comparing the \(p\)-value p with the significance level Alpha, not by comparing the test statistic ks2stat with a critical value.

\section*{References}

\section*{See Also}
kstest | lillietest | adtest

Purpose Kurtosis
Syntax \(\quad k=\) kurtosis \((X)\)
k = kurtosis(X,flag)
k = kurtosis(X,flag,dim)

Description

Algorithms
\(k=\) kurtosis \((X)\) returns the sample kurtosis of \(X\). For vectors, kurtosis ( \(x\) ) is the kurtosis of the elements in the vector \(x\). For matrices kurtosis ( X ) returns the sample kurtosis for each column of \(X\). For N -dimensional arrays, kurtosis operates along the first nonsingleton dimension of \(X\).
\(\mathrm{k}=\) kurtosis \((\mathrm{X}, \mathrm{flag})\) specifies whether to correct for bias (flag is 0 ) or not ( flag is 1 , the default). When \(X\) represents a sample from a population, the kurtosis of X is biased, that is, it will tend to differ from the population kurtosis by a systematic amount that depends on the size of the sample. You can set flag to 0 to correct for this systematic bias.
\(\mathrm{k}=\) kurtosis( \(\mathrm{X}, \mathrm{flag}, \mathrm{dim})\) takes the kurtosis along dimension dim of \(X\).
kurtosis treats NaNs as missing values and removes them.
Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution is 3 . Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3 ; distributions that are less outlier-prone have kurtosis less than 3.

The kurtosis of a distribution is defined as
\[
k=\frac{E(x-\mu)^{4}}{\sigma^{4}}
\]
where \(\mu\) is the mean of \(x, \sigma\) is the standard deviation of \(x\), and \(E(t)\) represents the expected value of the quantity \(t\). kurtosis computes a sample version of this population value.

Note Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0 . The kurtosis function does not use this convention.

When you set flag to 1 , the following equation applies:
\[
k_{1}=\frac{\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{4}}{\left(\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}\right)^{2}}
\]

When you set flag to 0 , the following equation applies:
\[
k_{0}=\frac{n-1}{(n-2)(n-3)}\left((n+1) k_{1}-3(n-1)\right)+3
\]

This bias-corrected formula requires that X contain at least four elements.
```

Examples }\quadX=\operatorname{randn}([$$
\begin{array}{ll}{5}&{4}\end{array}
$$]

```

\section*{See Also}
mean | moment | skewness | std | var

\section*{categorical.labels property}
Purpose Text labels for levels

Description Text labels for levels. Access labels with getlabels.

\section*{Purpose Regularized least-squares regression using lasso or elastic net algorithms}
```

Syntax
B = lasso(X,Y)
[B,FitInfo] = lasso(X,Y)
[B,FitInfo] = lasso(X,Y,Name,Value)

```

Description

\section*{Input \\ Arguments}

B = lasso( \(\mathrm{X}, \mathrm{Y}\) ) returns fitted least-squares regression coefficients for a set of regularization coefficients Lambda.
[B,FitInfo] = lasso(X,Y) returns a structure containing information about the fits.
[B,FitInfo] = lasso(X,Y,Name, Value) fits regularized regressions with additional options specified by one or more Name, Value pair arguments.

\section*{x}

Numeric matrix with n rows and p columns. Each row represents one observation, and each column represents one predictor (variable).

\section*{Y}

Numeric vector of length \(n\), where \(n\) is the number of rows of \(X . Y(i)\) is the response to row \(i\) of \(X\).

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

\section*{'Alpha'}

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso \(\left(L^{1}\right)\) versus ridge \(\left(L^{2}\right)\) optimization. Alpha \(=1\) represents lasso regression, Alpha close to 0 approaches ridge regression, and other
values represent elastic net optimization. See "Definitions" on page 20-1289.

\section*{Default: 1}

\section*{'CV'}

Method lasso uses to estimate mean squared error:
- K, a positive integer - lasso uses K-fold cross validation.
- cvp, a cvpartition object - lasso uses the cross-validation method expressed in cvp. You cannot use a 'leaveout' partition with lasso.
- 'resubstitution' - lasso uses \(X\) and \(Y\) to fit the model and to estimate the mean squared error, without cross validation.

Default: 'resubstitution'

\section*{'DFmax'}

Maximum number of nonzero coefficients in the model. lasso returns results only for Lambda values that satisfy this criterion.

Default: Inf

\section*{'Lambda'}

Vector of nonnegative Lambda values. See "Definitions" on page 20-1289.
- If you do not supply Lambda, lasso calculates the largest value of Lambda that gives a nonnull model. In this case, LambdaRatio gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply Lambda, lasso ignores LambdaRatio and NumLambda.

Default: Geometric sequence of NumLambda values, the largest just sufficient to produce \(B=0\)

\section*{'LambdaRatio'}

Positive scalar, the ratio of the smallest to the largest Lambda value when you do not set Lambda.

If you set LambdaRatio \(=0\), lasso generates a default sequence of Lambda values, and replaces the smallest one with 0 .

Default: 1e-4

\section*{'MCReps'}

Positive integer, the number of Monte Carlo repetitions for cross validation.
- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', MCReps must be 1.
- If CV is a cvpartition of type 'holdout', MCReps must be greater than 1.

\section*{Default: 1}

\section*{'NumLambda'}

Positive integer, the number of Lambda values lasso uses when you do not set Lambda. lasso can return fewer than NumLambda fits if the if the residual error of the fits drops below a threshold fraction of the variance of \(Y\).

Default: 100

\section*{'Options'}

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the Options structure with statset. Option fields:
- UseParallel - Set to true to compute in parallel. Default is false.
- UseSubstreams - Set to true to compute in parallel in a reproducible fashion. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. Default is false.
- Streams - A RandStream object or cell array consisting of one such object. If you do not specify Streams, lasso uses the default stream.

\section*{'PredictorNames'}

Cell array of strings representing names of the predictor variables, in the order in which they appear in X .

Default: \{\}

\section*{'RelTol'}

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the \(L^{2}\) norm by a relative amount less than RelTol.

Default: 1e-4

\section*{'Standardize'}

Boolean value specifying whether lasso scales \(X\) before fitting the models.

Default: true

\section*{'Weights'}

Observation weights, a nonnegative vector of length n , where n is the number of rows of X . lasso scales Weights to sum to 1.

Default: \(1 / n\) * ones ( \(\mathrm{n}, 1\) )

\section*{Output \\ B}

Arguments
Fitted coefficients, a \(p\)-by-L matrix, where \(p\) is the number of predictors (columns) in \(X\), and \(L\) is the number of Lambda values.

\section*{FitInfo}

Structure containing information about the model fits.
\begin{tabular}{l|l}
\hline Field in Fitlnfo & Description \\
\hline Intercept & \begin{tabular}{l} 
Intercept term \(\beta_{0}\) for each linear model, a 1-by-L \\
vector
\end{tabular} \\
\hline Lambda & \begin{tabular}{l} 
Lambda parameters in ascending order, a 1-by-L \\
vector
\end{tabular} \\
\hline Alpha & Value of Alpha parameter, a scalar \\
\hline DF & \begin{tabular}{l} 
Number of nonzero coefficients in B for each \\
value of Lambda, a 1-by-L vector
\end{tabular} \\
\hline MSE & Mean squared error (MSE), a 1-by-L vector \\
\hline
\end{tabular}

If you set the CV name-value pair to cross validate, the FitInfo structure contains additional fields.
\begin{tabular}{l|l}
\hline Field in FitInfo & Description \\
\hline SE & \begin{tabular}{l} 
The standard error of MSE for each Lambda, \\
as calculated during cross validation, a 1-by-L \\
vector
\end{tabular} \\
\hline LambdaMinMSE & The Lambda value with minimum MSE, a scalar \\
\hline Lambda1SE & \begin{tabular}{l} 
The largest Lambda such that MSE is within one \\
standard error of the minimum, a scalar
\end{tabular} \\
\hline IndexMinMSE & \begin{tabular}{l} 
The index of Lambda with value LambdaMinMSE, \\
a scalar
\end{tabular} \\
\hline Index1SE & \begin{tabular}{l} 
The index of Lambda with value Lambda1SE, a \\
scalar
\end{tabular} \\
\hline
\end{tabular}

\section*{Definitions}

\section*{Lasso}

For a given value of \(\lambda\), a nonnegative parameter, lasso solves the problem
\[
\min _{\beta_{0}, \beta}\left(\frac{1}{2 N} \sum_{i=1}^{N}\left(y_{i}-\beta_{0}-x_{i}^{T} \beta\right)^{2}+\lambda \sum_{j=1}^{p}\left|\beta_{j}\right|\right)
\]
where
- \(N\) is the number of observations.
- \(y_{i}\) is the response at observation \(i\).
- \(x_{i}\) is data, a vector of \(p\) values at observation \(i\).
- \(\lambda\) is a nonnegative regularization parameter corresponding to one value of Lambda.
- The parameters \(\beta_{0}\) and \(\beta\) are scalar and \(p\)-vector respectively.

As \(\lambda\) increases, the number of nonzero components of \(\beta\) decreases.
The lasso problem involves the \(L^{1}\) norm of \(\beta\), as contrasted with the elastic net algorithm.

\section*{Elastic Net}

For an \(a\) strictly between 0 and 1 , and a nonnegative \(\lambda\), elastic net solves the problem
\[
\min _{\beta_{0}, \beta}\left(\frac{1}{2 N} \sum_{i=1}^{N}\left(y_{i}-\beta_{0}-x_{i}^{T} \beta\right)^{2}+\lambda P_{\alpha}(\beta)\right),
\]
where
\[
P_{\alpha}(\beta)=\frac{(1-\alpha)}{2}\|\beta\|_{2}^{2}+\alpha\|\beta\|_{1}=\sum_{j=1}^{p}\left(\frac{(1-\alpha)}{2} \beta_{j}^{2}+\alpha\left|\beta_{j}\right|\right) .
\]

Elastic net is the same as lasso when \(a=1\). As \(a\) shrinks toward 0 , elastic net approaches ridge regression. For other values of \(a\), the penalty term \(P_{a}(\beta)\) interpolates between the \(L^{1}\) norm of \(\beta\) and the squared \(L^{2}\) norm of \(\beta\).

\section*{Examples Remove Redundant Predictors}

Construct a data set with redundant predictors, and identify those predictors using cross-validated lasso.

Create a matrix \(X\) of 100 five-dimensional normal variables and a response vector \(Y\) from just two components of \(X\), with small added noise.
\(X=r a n d n(100,5)\);
\(r=[0 ; 2 ; 0 ;-3 ; 0] ;\) o only two nonzero coefficients
\(Y=X * r+r a n d n(100,1)^{*} .1\); \% small added noise
Construct the default lasso fit.
B = lasso(X,Y);
Find the coefficient vector for the 25 th value in B.
B(: ,25)
ans \(=\)

0
1.6093

0
\(-2.5865\)
0
lasso identifies and removes the redundant predictors.

\section*{Plot a Regularized Fit with Cross Validation}

Visually examine the cross-validated error of various levels of regularization.

Load the acetylene data and prepare the data with interactions for fitting.
```

load acetylene
Xs = [x1 x2 x3];

```
```

X = x2fx(Xs,'interaction');
X(:,1) = []; % No constant term

```

Construct the lasso fit using ten-fold cross validation. Include the FitInfo output so you can plot the result.
[B FitInfo] = lasso(X,y,'CV',10);
Plot the cross-validated fits.
lassoPlot(B,FitInfo,'PlotType','CV');

Cross-validated MSE of Lasso fit

Purpose

Syntax
\(B=\operatorname{lassoglm}(X, Y)\)
[B,FitInfo] = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y,distr)
[B,FitInfo] = lassoglm(X,Y,distr, Name, Value)

\section*{Description}

\section*{Input \\ Arguments}

Lasso or elastic net regularization for generalized linear model regression
\(B=\operatorname{lassoglm}(X, Y)\) returns penalized maximum-likelihood fitted coefficients for a generalized linear model of the response \(Y\) to the data matrix \(X\). \(Y\) are assumed to have a Gaussian probability distribution.
[B,FitInfo] = lassoglm( \(\mathrm{X}, \mathrm{Y}\) ) returns a structure containing information about the fits.
[ B, FitInfo] = lassoglm( \(\mathrm{X}, \mathrm{Y}, \mathrm{distr}\) ) fits the model using the probability distribution type for \(Y\) as specified in distr.
[B,FitInfo] = lassoglm(X,Y,distr,Name, Value) fits regularized generalized linear regressions with additional options specified by one or more Name, Value pair arguments.

\section*{X}

Numeric matrix with \(n\) rows and \(p\) columns. Each row represents one observation, and each column represents one predictor (variable).

\section*{Y}

When distr is not 'binomial', Y is a numeric vector of length n , where \(n\) is the number of rows of \(X\). \(Y(i)\) is the response to row \(i\) of \(X\).

When distr is 'binomial', \(Y\) is either a:
- Numeric vector of length n , where each entry represents success (1) or failure (0)
- Logical vector of length n , where each entry represents success or failure
- Two column numeric matrix, where the first column contains the number of successes for each observation, and the second column contains the total number of trials

\section*{distr}

Distributional family for the nonsystematic variation in the responses, a string. Choices:
- 'normal'
- 'binomial'
- 'poisson'
- 'gamma'
- 'inverse gaussian'

By default, lassoglm uses the canonical link function corresponding to distr. Specify another link function using the 'link' name-value pair.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

\section*{'Alpha'}

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso \(\left(L^{1}\right)\) versus ridge ( \(L^{2}\) ) optimization. Alpha \(=1\) represents lasso regression, and other values represent elastic net optimization. Alpha close to 0 approaches ridge regression. See "Definitions" on page 20-1289.

Default: 1

\section*{'CV'}

Method lassoglm uses to estimate deviance:
- K, a positive integer - lassoglm uses K-fold cross validation.
- cvp, a cvpartition object - lassoglm uses the cross-validation method expressed in cvp. You cannot use a 'leaveout' partition with lassoglm.
- 'resubstitution' - lassoglm uses X and Y to fit the model and to estimate the deviance, without cross validation.

Default: 'resubstitution'

\section*{'DFmax'}

Maximum number of nonzero coefficients in the model. lassoglm returns results for Lambda values that satisfy this criterion.

Default: Inf

\section*{'Lambda'}

Vector of nonnegative Lambda values. See "Lasso" on page 20-1302.
- If you do not supply Lambda, lassoglm estimates the largest value of Lambda that gives a nonnull model. In this case, LambdaRatio gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply Lambda, lassoglm ignores LambdaRatio and NumLambda.

Default: Geometric sequence of NumLambda values, the largest just sufficient to produce \(B=0\)

\section*{'LambdaRatio'}

Positive scalar, the ratio of the smallest to the largest Lambda value when you do not explicitly set Lambda.

If you set LambdaRatio \(=0\), lassoglm generates a default sequence of Lambda values, and replaces the smallest one with 0 .

Default: 1e-4

\section*{'Link'}

Specify the mapping between the mean \(\mu\) of the response and the linear predictor \(X b\).
\begin{tabular}{l|l}
\hline Value & Description \\
\hline 'comploglog ' & \(\log (-\log ((1-\mu)))=X b\) \\
\hline \begin{tabular}{l} 
'identity ', default for the \\
distribution 'normal'
\end{tabular} & \(\mu=X b\) \\
\hline \begin{tabular}{l} 
'log', default for the \\
distribution 'poisson'
\end{tabular} & \(\log (\mu)=X b\) \\
\hline \begin{tabular}{l} 
'logit', default for the \\
distribution 'binomial'
\end{tabular} & \(\log (\mu /(1-\mu))=X b\) \\
\hline 'loglog' & \(\log (-\log (\mu))=X b\) \\
\hline 'probit' & \begin{tabular}{l}
\(\Phi^{-1}(\mu)=X b\), where \(\Phi\) is the normal \\
\((G a u s s i a n) \mathrm{CDF}\) function
\end{tabular} \\
\hline \begin{tabular}{l} 
'reciprocal ', default for \\
the distribution 'gamma'
\end{tabular} & \(\mu^{-1}=X b\) \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Value & Description \\
\hline \begin{tabular}{l} 
p (a number), default for \\
the distribution 'inverse \\
gaussian' (with \(p=-2\) )
\end{tabular} & \(\mu^{p}=X b\) \\
\hline \begin{tabular}{l} 
Cell array of the form \\
\{FL FD FI \}, containing \\
three function handles, \\
created using @, that \\
define the link (FL), the \\
derivative of the link \\
(FD), and the inverse
\end{tabular} & \begin{tabular}{l} 
"Custom Link Function" on page 9-147) \\
link (FI). Equivalently, \\
can be a structure of \\
function handles with field \\
Link containing FL, field \\
Derivative containing FD, \\
and field Inverse containing
\end{tabular} \\
\hline FI. & \\
\hline
\end{tabular}

\section*{'MCReps'}

Positive integer, the number of Monte Carlo repetitions for cross validation.
- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', MCReps must be 1.
- If CV is a cvpartition of type 'holdout', MCReps must be greater than 1.

Default: 1

\section*{'NumLambda'}

Positive integer, the number of Lambda values lassoglm uses when you do not set Lambda. lassoglm can return fewer than NumLambda fits if the
deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors \(X\) ).

Default: 100

\section*{'Offset'}

Numeric vector with the same number of rows as X. lassoglm uses Offset as an additional predictor variable, but keeps its coefficient value fixed at 1.0.

\section*{'Options'}

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the Options structure with statset. Option fields:
- UseParallel - Set to true to compute in parallel. Default is false.
- UseSubstreams - Set to true to compute in parallel in a reproducible fashion. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. Default is false.
- Streams - RandStream object or cell array consisting of one such object. If you do not specify Streams, lassoglm uses the default stream.

\section*{'PredictorNames'}

Cell array of strings representing names of the predictor variables, in the order in which they appear in X .

Default: \{\}

\section*{'RelTol'}

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the \(L^{2}\) norm by a relative amount less than RelTol.

\section*{Default: 1e-4}

\section*{'Standardize'}

Boolean value specifying whether lassoglm scales \(X\) before fitting the models.

\section*{Default: true}

\section*{'Weights'}

Observation weights, a nonnegative vector of length \(n\), where \(n\) is the number of rows of \(X\). At least two values must be positive.

Default: \(1 / \mathrm{n}\) * ones ( \(\mathrm{n}, 1\) )

\section*{Output \\ Arguments}

\section*{B}

Fitted coefficients, a \(p\)-by-L matrix, where \(p\) is the number of predictors (columns) in \(X\), and \(L\) is the number of Lambda values.

\section*{FitInfo}

Structure containing information about the model fits.
\begin{tabular}{l|l}
\hline Field in Fitlnfo & Description \\
\hline Alpha & Value of Alpha parameter, a scalar. \\
\hline Deviance & \begin{tabular}{l} 
Deviance of the fitted model for each value of \\
Lambda, a 1-by-L vector. \\
If cross validation was performed, the values \\
for Deviance represent the estimated expected \\
deviance of the model applied to new data, \\
as calculated by cross validation. Otherwise, \\
Deviance is the deviance of the fitted model \\
applied to the data used to perform the fit.
\end{tabular} \\
\hline DF & \begin{tabular}{l} 
Number of nonzero coefficients in B for each \\
Lambda value, a 1-by-L vector.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Field in Fitlnfo & Description \\
\hline Intercept & \begin{tabular}{l} 
Intercept term \(\beta_{0}\) for each linear model, a \\
1 -by-L vector.
\end{tabular} \\
\hline Lambda & \begin{tabular}{l} 
Lambda parameters in ascending order, a 1-by-L \\
vector.
\end{tabular} \\
\hline
\end{tabular}

If you set the CV name-value pair to cross validate, the FitInfo structure contains additional fields.
\begin{tabular}{l|l}
\hline Field in FitInfo & Description \\
\hline IndexMinDeviance & \begin{tabular}{l} 
Index of Lambda with value \\
LambdaMinDeviance, a scalar.
\end{tabular} \\
\hline Index1SE & Index of Lambda with value Lambda1SE, a scalar. \\
\hline LambdaMinDeviance & \begin{tabular}{l} 
Lambda value with minimum expected deviance, \\
as calculated by cross validation, a scalar.
\end{tabular} \\
\hline Lambda1SE & \begin{tabular}{l} 
Largest Lambda such that Deviance is within \\
one standard error of the minimum, a scalar.
\end{tabular} \\
\hline SE & \begin{tabular}{l} 
Standard error of Deviance for each Lambda, \\
as calculated during cross validation, a 1-by-L \\
vector.
\end{tabular} \\
\hline
\end{tabular}

\section*{Definitions}

\section*{Link Function}

A link function \(f(\mu)\) maps a distribution with mean \(\mu\) to a linear model with data \(X\) and coefficient vector \(b\) using the formula
\[
f(\mu)=X b .
\]

Find the formulas for the link functions in the Link name-value pair description. Here, "typical" means a link function that is typically used for the listed distribution.
\begin{tabular}{l|l}
\hline Distributional Family & Link Function (typical, \{default\}) \\
\hline 'normal' & \(\{\) 'identity' \(\}\) \\
\hline 'binomial' & \begin{tabular}{l} 
'comploglog', 'loglog', 'probit', \\
\{'logit'\}
\end{tabular} \\
\hline 'poisson' & \(\{\) 'log'\} \\
\hline 'gamma' & \(\{\) 'reciprocal' \(\}\) \\
\hline 'inverse gaussian' & \(\{-2\}\) \\
\hline
\end{tabular}

\section*{Lasso}

For a nonnegative value of \(\lambda\), lasso solves the problem
\[
\min _{\beta_{0}, \beta}\left(\frac{1}{N} \operatorname{Deviance}\left(\beta_{0}, \beta\right)+\lambda \sum_{j=1}^{p}\left|\beta_{j}\right|\right),
\]
where
- Deviance is the deviance of the model fit to the responses using intercept \(\beta_{0}\) and predictor coefficients \(\beta\). The formula for Deviance depends on the distr parameter you supply to lassoglm. Minimizing the \(\lambda\)-penalized deviance is equivalent to maximizing the \(\lambda\)-penalized log likelihood.
- \(N\) is the number of observations.
- \(\lambda\) is a nonnegative regularization parameter corresponding to one value of Lambda.
- Parameters \(\beta_{0}\) and \(\beta\) are scalar and \(p\)-vector respectively.

As \(\lambda\) increases, the number of nonzero components of \(\beta\) decreases.
The lasso problem involves the \(L^{1}\) norm of \(\beta\), as contrasted with the elastic net algorithm.

\section*{Elastic Net}

For an \(\alpha\) strictly between 0 and 1 , and a nonnegative \(\lambda\), elastic net solves the problem
\[
\min _{\beta_{0}, \beta}\left(\frac{1}{N} \operatorname{Deviance}\left(\beta_{0}, \beta\right)+\lambda P_{\alpha}(\beta)\right),
\]
where
\[
P_{\alpha}(\beta)=\frac{(1-\alpha)}{2}\|\beta\|_{2}^{2}+\alpha\|\beta\|_{1}=\sum_{j=1}^{p}\left(\frac{(1-\alpha)}{2} \beta_{j}^{2}+\alpha\left|\beta_{j}\right|\right) .
\]

Elastic net is the same as lasso when \(\alpha=1\). For other values of \(\alpha\), the penalty term \(P_{a}(\beta)\) interpolates between the \(L^{1}\) norm of \(\beta\) and the squared \(L^{2}\) norm of \(\beta\). As \(\alpha\) shrinks toward 0 , elastic net approaches ridge regression.

\section*{Examples}

\section*{Lasso Regularization of a Generalized Linear Model}

Construct data from a Poisson model, and identify the important predictors using lassoglm.

Create data with 20 predictors, and Poisson responses using just three of the predictors, plus a constant.
```

rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);

```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.
```

[B FitInfo] = lassoglm(X,y,'poisson','CV',10);

```

Examine the cross-validation plot to see the effect of the Lambda regularization parameter.

\section*{lassoglm}
```

lassoPlot(B,FitInfo,'plottype','CV');

```

The green circle and dashed line locate the Lambda with minimal cross-validation error. The blue circle and dashed line locate the point with minimal cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.
minpts = find(B(:,FitInfo.IndexMinDeviance))
```

minpts =
3
5
6
10
11
1 5
1 6
min1pts = find(B(:,FitInfo.Index1SE))
min1pts =
5
10
1 5

```

The coefficients from the minimal plus one standard error point are exactly those coefficients used to create the data.

\section*{Purpose Trace plot of lasso fit}

Syntax \(\quad a x=\) lassoPlot \((B)\)
ax = lassoPlot(B,FitInfo)
ax = lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot(B,...)

Description

\section*{Input Arguments}
ax = lassoPlot (B) creates a trace plot of the values in B against the \(L^{1}\) norm of B . ax is a handle to the plot axis.
ax = lassoPlot (B,FitInfo) creates a plot with type depending on the data type of FitInfo and the value, if any, of the plotType name-value pair.
ax = lassoPlot(B,FitInfo, Name, Value) creates a plot with additional options specified by one or more Name, Value pair arguments.
[ax,figh] = lassoPlot ( \(B, \ldots\) ) returns a handle to the figure window.

\section*{B}

Coefficients of a sequence of regression fits, as returned from the lasso or lassoglm functions. B is a p-by-NLambda matrix, where \(p\) is the number of predictors, and each column of \(B\) is a set of coefficients lasso calculates using one Lambda penalty value.

\section*{FitInfo}

Information controlling the plot:
- FitInfo is a structure, especially as returned from lasso or lassoglm - lassoPlot creates a plot based on the PlotType name-value pair.
- FitInfo is a vector - lassoPlot forms the \(x\)-axis of the plot from the values in FitInfo. The length of FitInfo must equal the number of columns of B.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'Parent'}

Axis in which to draw the plot.
Default: New plot

\section*{'PlotType'}

Choose the plot type when you give a FitInfo vector or structure:
\begin{tabular}{l|l|l}
\hline FitInfo Type & PlotType & Plot \\
\hline \begin{tabular}{l} 
Vector or \\
Structure
\end{tabular} & 'L1' & \begin{tabular}{l} 
plotLasso creates the \(x\)-axis from the \(L^{1}\) norm of the \\
coefficients in B. The \(x\)-axis at the top of the plot contains \\
the degrees of freedom (df), meaning the number of nonzero \\
coefficients of B.
\end{tabular} \\
\hline Structure & 'Lambda' & \begin{tabular}{l} 
plotLasso creates the x-axis from the Lambda field of \\
FitInfo. The x-axis at the top of the plot contains the \\
degrees of freedom (df), meaning the number of nonzero \\
coefficients of B.
\end{tabular} \\
\hline \begin{tabular}{l} 
Cross-Validated \\
Structure
\end{tabular} & 'CV' & \begin{tabular}{l} 
- For each Lambda, plots an estimate of the mean squared \\
prediction error on new data for the model fitted by lasso \\
with that value of Lambda.
\end{tabular} \\
- Plots error bars for the estimates. \\
- Plots the value of Lambda with minimum cross-validated \\
MSE.
\end{tabular}
\begin{tabular}{l} 
FitInfo Type \\
\hline \multicolumn{1}{|l|}{ PlotType } \\
\multicolumn{1}{|l|}{\begin{tabular}{l} 
Plot \\
\\
\end{tabular} \begin{tabular}{l} 
- \begin{tabular}{l} 
Plots the greatest Lambda that is within one standard \\
error of minimum MSE (so makes the sparsest model \\
within that region).
\end{tabular} \\
\hline
\end{tabular}}
\end{tabular}

\section*{Default: 'L1'}

\section*{'PredictorNames'}

Cell array of strings to label each coefficient of \(B\). If the length of PredictorNames is less than the number of rows of B, the remaining labels are padded with default values.
lassoPlot uses the predictor names in FitInfo only if:
- You created FitInfo with a call to lasso that included a PredictorNames name-value pair.
- You call lassoPlot without a PredictorNames name-value pair.
- You include FitInfo in your lassoPlot call.

Default: \{'B1','B2',...\}

\section*{'XScale'}
- 'linear' for linear x-axis
- ' \(\log\) ' for logarithmic scaled x -axis

Default: 'linear', except 'log' for the 'CV' plot type

\section*{Output}

Arguments

\section*{ax}

Handle to the axis of the plot (see "Setting Axis Parameters").

\section*{figh}

Handle to the figure window (see "Graphics Windows — the Figure").

\section*{lassoPlot}

Examples
Fit a regularized model of the acetylene data with lasso, and plot the fits with the default plot type:
```

load acetylene
x = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
B = lasso(D,y);
lassoPlot(B);

```

Trace Plot of coefficients fit by Lasso.

Fit a regularized model of the acetylene data with lasso, and plot the fits with the Lambda plot type and logarithmic scaling:
```

load acetylene
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
[B FitInfo] = lasso(D,y);
lassoPlot(B,FitInfo,'PlotType','Lambda','XScale','log');

```

Trace Plot of coefficients fit by Lasso
df

Fit a regularized model of the acetylene data with lasso and cross validation, and plot the cross-validated fits:
load acetylene

\section*{lassoPlot}
```

X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
[B FitInfo] = lasso(D,y,'CV',10);
lassoPlot(B,FitInfo,'PlotType','CV');

```

Cross-validated MSE of Lasso fit

- "Lasso and Elastic Net" on page 9-123
\begin{tabular}{ll} 
Purpose & Less than or equal relation for handles \\
Syntax & h1 <= h2 \\
Description & \begin{tabular}{l} 
Handles are equal if they are handles for the same object. All \\
comparisons use a number associated with each handle object. Nothing \\
can be assumed about the result of a handle comparison except that the \\
repeated comparison of two handles in the same MATLAB session will \\
yield the same result. The order of handle values is purely arbitrary \\
and has no connection to the state of the handle objects being compared.
\end{tabular} \\
h1 <= h2 performs element-wise comparisons between handle arrays \\
h1 and h2. h1 and h2 must be of the same dimensions unless one is a \\
scalar. The result is a logical array of the same dimensions, where each \\
element is an element-wise <= result.
\end{tabular}

\section*{qrandset.Leap property}

\section*{Purpose Interval between points}

Description

Examples
Experiment with different leap values:
\% No leaping produces the standard Halton sequence. P = haltonset(5); P(1:5,:)
\% Set a leap of 1. The point set now includes every other \% point from the sequence.
P.Leap = 1;

P(1:5,:)
See Also net | qrandset | Skip | subsref | haltonset
Purpose Length of dataset array
Syntax \(\mathrm{n}=\) length \((\mathrm{A})\)
Description \(\mathrm{n}=\) length \((\mathrm{A})\) returns the number of observations in the dataset A . length is equivalent to size ( \(\mathrm{A}, 1\) ).
See Also ..... size

\section*{qrandset.length}
Purpose Length of point set
Syntax length(p)
Description length \((p)\) returns the number of points in the point set \(p\). It is equivalent to size ( \(p, 1\) ).
See Also qrandset | size

\section*{Purpose Length of categorical array}

\section*{Syntax \(\quad n=\) length \((A)\)}

Description \(\quad n=\) length \((A)\) returns the size of the longest dimension of the categorical array \(A\) when \(A\) is not empty. If \(A\) is a vector, this is the same as its length. length is equivalent to \(\max (\operatorname{size}(x))\) for nonempty arrays, and 0 for empty arrays.

See Also isempty | isscalar | size

Purpose Element counts by level
```

Syntax C = levelcounts(A)
C = levelcounts(A,dim)

```
\(C=\) levelcounts(A) for a categorical vector \(A\) counts the number of elements in \(A\) equal to each of the possible levels in \(A\). The output is a vector \(C\) containing those counts, and has as many elements as A has levels. For matrix A, C is a matrix of column counts. For N -dimensional arrays, levelcounts operates along the first nonsingleton dimension. \(C=\) levelcounts(A,dim) operates along the dimension dim.

\section*{Examples}

Count the number of patients in each age group in the data in hospital.mat:
```

load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
disp(labels')
'Os' '10s' '20s' '30s' '40s' '50s' '60s' '70s' '80s' '90s'
AgeGroup = ordinal(hospital.Age,labels,[],edges);
I = islevel(labels,AgeGroup);
disp(I')
0
c = levelcounts(AgeGroup);
disp(c')
0
AgeGroup = droplevels(AgeGroup);
I = islevel(labels,AgeGroup);
disp(I')
0
c = levelcounts(AgeGroup);
disp(c')
154142 2

```

\author{
See Also islevel | ismember | summary
}

\section*{Purpose Leverage}
\begin{tabular}{ll} 
Syntax & \(h=\) leverage (data) \\
& \(h=\) leverage (data, model \()\)
\end{tabular}

Description

\section*{Algorithms}

\section*{Examples}

\section*{References}
\(h=\) leverage(data) finds the leverage of each row (point) in the matrix data for a linear additive regression model.
\(\mathrm{h}=\) leverage(data, model) finds the leverage on a regression, using a specified model type, where model can be one of these strings:
- 'linear' - includes constant and linear terms
- 'interaction ' - includes constant, linear, and cross product terms
- 'quadratic' - includes interactions and squared terms
- 'purequadratic' - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.
```

[Q,R] = qr(x2fx(data,'model'));
leverage = (sum(Q'.*Q'))'

```

One rule of thumb is to compare the leverage to \(2 p / n\) where \(n\) is the number of observations and \(p\) is the number of parameters in the model. For the Hald data set this value is 0.7692 .
```

load hald
h = max(leverage(ingredients,'linear'))
h =
0.7004

```

Since \(0.7004<0.7692\), there are no high leverage points using this rule.

Handbook in Statistics. Vol. 9, Amsterdam: Elsevier/North-Holland, 1993.

How To • regstats

Purpose Latin hypercube sample
```

Syntax }\quadx=lhsdesign(n,p
X = lhsdesign(...,'smooth','off')
X = lhsdesign(...,'criterion',criterion)
X = lhsdesign(...,'iterations',k)

```

\section*{Description}

See Also
\(\mathrm{X}=\operatorname{lhsdesign}(\mathrm{n}, \mathrm{p})\) returns an \(n\)-by- \(p\) matrix, X , containing a latin hypercube sample of \(n\) values on each of \(p\) variables. For each column of \(X\), the n values are randomly distributed with one from each interval \((0,1 / n),(1 / n, 2 / n), \ldots,(1-1 / n, 1)\), and they are randomly permuted. \(\mathrm{X}=\operatorname{lnsdesign}\left(\ldots,{ }^{\prime}\right.\) smooth', 'off') produces points at the midpoints of the above intervals: \(0.5 / \mathrm{n}, 1.5 / \mathrm{n}, \ldots, 1-0.5 / \mathrm{n}\). The default is 'on'.

X = lhsdesign(...,'criterion',criterion) iteratively generates latin hypercube samples to find the best one according to the criterion criterion, which can be one of the following strings.
\begin{tabular}{l|l}
\hline Criterion & Description \\
\hline 'none' & No iteration. \\
\hline 'maximin' & \begin{tabular}{l} 
Maximize minimum distance between points. \\
This is the default.
\end{tabular} \\
\hline 'correlation' & Reduce correlation. \\
\hline
\end{tabular}
\(X=\) lhsdesign(...,'iterations', \(k\) ) iterates up to \(k\) times in an attempt to improve the design according to the specified criterion. The default is \(\mathrm{k}=5\).
haltonset | sobolset | lhsnorm | unifrnd

\section*{Purpose Lilliefors test}

Syntax
Description

Input
Arguments
```

h = lillietest(x)
h = lillietest(x,Name,Value)
[h, p] = lillietest(__ )
[h, p,kstat, critval] = lillietest( __ )

```
\(\mathrm{h}=\) lillietest( x ) returns a test decision for the null hypothesis that the data in vector \(x\) comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result h is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, and 0 otherwise.
\(\mathrm{h}=\) lillietest( x, Name, Value) returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the \(p\)-value using a Monte Carlo approximation.
[h, p] = lillietest (__ ) also returns the \(p\)-value p , using any of the input arguments from the previous syntaxes.
[h, p,kstat,critval] = lillietest(__ ) also returns the test statistic kstat and the critical value critval for the test.
x-Sample data
vector
Sample data, specified as a vector.
Data Types
single | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding
value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Distr','exp','Alpha', 0.01 tests the null hypothesis that the population distribution belongs to the exponential distribution family at the \(1 \%\) significance level.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).
- If MCTol is not used, Alpha must be in the range [0.001,0.50].
- If MCTol is used, Alpha must be in the range \((0,1)\).

Example: 'Alpha', 0.01
Data Types
single | double

\section*{'Distr' - Distribution family}
'norm' (default) | 'exp' | 'ev'
Distribution family for the hypothesis test, specified as the comma-separated pair consisting of 'Distr' and one of the following.
\begin{tabular}{ll} 
'norm' & Normal distribution \\
'exp' & Exponential distribution \\
'ev' & Extreme value distribution
\end{tabular}

Example: 'Distr','exp'

\section*{'MCTol' - Maximum Monte Carlo standard error}
scalar value in the range \((0,1)\)

\section*{lillietest}

\section*{Output Arguments}

Maximum Monte Carlo standard error for p , the \(p\)-value of the test, specified as the comma-separated pair consisting of 'MCTOL' and a scalar value in the range \((0,1)\).

Example: 'MCTol', 0.001
```

Data Types
single | double

```

\section*{h-Hypothesis test result}

1 | 0
Hypothesis test result, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(h=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{\(p-p\)-value}

\section*{scalar value in the range \((0,1)\)}
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.
- If MCTol is not used, p is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. lillietest warns when \(p\) is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If MCTol is used, lillietest conducts a Monte Carlo simulation to compute a more accurate \(p\)-value, and p is returned as a scalar value in the range \((0,1)\).

\section*{kstat - Test statistic}
nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

\section*{critval - Critical value}
nonnegative scalar value
Critical value for the hypothesis test, returned as a nonnegative scalar value.

\section*{Examples Test for a Normal Distribution}

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.
```

load carbig.mat;
[h,p,k,c] = lillietest(MPG)
Warning: P is less than the smallest tabulated value, returning 0.001
h =
1
p =
1.0000e-003
k =
0.0789
c =
0.0451

```

The test statistic \(k\) is greater than the critical value c, so lillietest returns a result of \(h=1\) to indicate rejection of the null hypothesis at the default \(5 \%\) significance level. The warning indicates that the returned \(p\)-value is the smallest value in the table of precomputed values. To find a more accurate \(p\)-value, use MCTol to run a Monte Carlo approximation.

\section*{Test the Hypothesis at Different Significance Levels}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
```

load examgrades;
x = grades(:,1);

```

Test the null hypothesis that the sample data comes from a normal distribution at the \(1 \%\) significance level.
```

[h,p] = lillietest(x,'Alpha',0.01)
h =
0
p =
0.0348

```

The returned value of \(\mathrm{h}=0\) indicates that lillietest does not reject the null hypothesis at the \(1 \%\) significance level.

\section*{Test for an Exponential Distribution}

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.
```

load carbig.mat;
h = lillietest(MPG,'Distr','exp')
h =
1

```

The returned value of \(h=1\) indicates that lillietest rejects the null hypothesis at the default \(5 \%\) significance level.

\section*{Determine the p-value Using Monte Carlo Approximation}

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the \(p\)-value using a Monte Carlo approximation with a maximum Monte Carlo standard error of 1e-4.
```

load carbig.mat;
[h,p] = lillietest(MPG,'MCTol',1e-4)

```
```

h =
1
p =
0

```

The returned value of \(h=1\) indicates that lillietest rejects the null hypothesis that the data comes from a normal distribution at the \(5 \%\) significance level.

\section*{Definitions Lilliefors Test}

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:
\[
D^{*}=\max _{x}|F(x)-G(x)|,
\]
where \(\hat{F}(x)\) is the empirical cdf of the sample data and \(G(x)\) is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.
lillietest can be used to test whether the data vector x has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:
- To test x for a lognormal distribution, test if \(\exp (x)\) has a normal distribution.
- To test x for a Weibull distribution, test if \(\log (\mathrm{x})\) has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

\section*{Monte Carlo Standard Error}

The Monte Carlo standard error is calculated as:
\[
S E=\sqrt{\frac{(\hat{\mathrm{p}})(1-\hat{\mathrm{p}})}{\text { mcreps }}}
\]
where \(\hat{\mathrm{p}}\) is the estimated \(p\)-value of the hypothesis test, and moreps is the number of Monte Carlo replications performed.
The number of Monte Carlo replications, moreps, is determined such that the Monte Carlo standard error for \(\hat{p}\) less than the value specified for MCTOL.

\section*{Algorithms}

To compute the critical value for the hypothesis test, lillietest interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50 . The table used by lillietest is larger and more accurate than the table originally introduced by Lilliefors. If a more accurate \(p\)-value is desired, or if the desired significance level is less than 0.001 or greater than 0.50 , the MCTol input argument can be used to run a Monte Carlo simulation to calculate the \(p\)-value more exactly.

When the computed value of the test statistic is greater than the critical value, lillietest rejects the null hypothesis at significance level Alpha.
lillietest treats \(N a N\) values in x as missing values and ignores them.

\section*{LinearModel}
Purpose Linear regression model class
DescriptionAn object comprising training data, model description, diagnosticinformation, and fitted coefficients for a linear regression. Predictmodel responses with the predict or feval methods.
Constructionmdl = LinearModel.fit(ds) or mdl = LinearModel.fit(X,y) createa linear model of a dataset array ds, or of the responses \(y\) to a datamatrix X. For details, see LinearModel.fit.
mdl = LinearModel.stepwise(ds) or mdl =
LinearModel.stepwise ( \(X, y\) ) create a linear model of a dataset array
ds, or of the responses \(y\) to a data matrix \(X\), with unimportant predictors
excluded. For details, see LinearModel.stepwise.

\section*{Input Arguments}

\section*{ds}
Dataset array, where by default the last column is the response variable, and all other columns are the predictors. Predictors can be numeric, or can be any grouping variable type, such as logical or categorical (see "Grouping Variables" on page 2-51). The response must be numeric or logical.
To set a different column as the response variable, use the ResponseVar name-value pair. To use a subset of the columns as predictors, use the PredictorVars name-value pair.

\section*{X}
Matrix of predictor values. Each column of X represents one variable, and each row represents one observation.
\(y\)
Vector of response values with the same number of rows as X . Each entry in \(y\) is the response to the data in the corresponding row of \(X\).

\section*{Properties}

\section*{CoefficientCovariance}

Covariance matrix of coefficient estimates.

\section*{CoefficientNames}

Cell array of strings containing a label for each coefficient.

\section*{Coefficients}

Table of coefficient values in a dataset array. Coefficients has one row for each coefficient and these columns:
- Estimate - Estimated coefficient value
- SE - Standard error of the estimate
- tStat - \(t\) statistic for a test that the coefficient is zero
- pValue - \(p\)-value for the \(t\) statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in mdl the estimated coefficient vector is
beta = mdl.Coefficients.Estimate

Use coeftest to perform other tests on the coefficients.

\section*{DFE}

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

\section*{Diagnostics}

Dataset array with the same number of rows as the input data (ds or X). Diagnostics contains diagnostics helpful in finding outliers and influential observations. Many diagnostics describe the effect on the fit of deleting single observations. Diagnostics contains the following fields.

\section*{LinearModel}
\begin{tabular}{l|l|l}
\hline Field & Meaning & Utility \\
\hline Leverage & \begin{tabular}{l} 
Diagonal elements of \\
HatMatrix
\end{tabular} & \begin{tabular}{l} 
Leverage indicates to what extent the predicted \\
value for an observation is determined by \\
the observed value for that observation. A \\
value close to 1 indicates that the prediction is \\
largely determined by that observation, with \\
little contribution from the other observations. \\
A value close to 0 indicates the fit is largely \\
determined by the other observations. For a \\
model with P coefficients and N observations, \\
the average value of Leverage is P/N. An \\
observation with Leverage larger than 2*P/N \\
can be regarded as having high leverage.
\end{tabular} \\
\hline CooksDistance & \begin{tabular}{l} 
Cook's measure of \\
scaled change in \\
fitted values
\end{tabular} & \begin{tabular}{l} 
CooksDistance is a measure of scaled \\
change in fitted values. An observation with \\
CooksDistance larger than three times the \\
mean Cook's distance can be an outlier.
\end{tabular} \\
\hline Dffits & \begin{tabular}{l} 
Delete-1 scaled \\
differences in \\
fitted values vs. \\
observation number
\end{tabular} & \begin{tabular}{l} 
Dffits is the scaled change in the fitted values \\
for each observation that would result from \\
excluding that observation from the fit. Values \\
with an absolute value larger than 2*sqrt (P/N) \\
may be considered influential.
\end{tabular} \\
\hline S2_i & \begin{tabular}{l} 
Delete-1 variance vs. \\
observation number
\end{tabular} & \begin{tabular}{l} 
S2_i is a set of residual variance estimates \\
obtained by deleting each observation in turn. \\
These can be compared with the value of the \\
mSE property.
\end{tabular} \\
\hline CovRatio & \begin{tabular}{l} 
Delete-1 ratio of \\
determinant of \\
covariance vs. \\
observation number
\end{tabular} & \begin{tabular}{l} 
CovRatio is the ratio of the determinant of \\
the coefficient covariance matrix with each \\
observation deleted in turn to the determinant of \\
the covariance matrix for the full model. Values \\
larger than 1+3*P/N or smaller than 1-3*P/N \\
indicate influential points.
\end{tabular} \\
\hline
\end{tabular}

\section*{LinearModel}
\begin{tabular}{l|l|l}
\hline Field & Meaning & Utility \\
\hline Dfbetas & \begin{tabular}{l} 
Delete-1 scaled \\
differences in \\
covariance estimates \\
vs. observation \\
number
\end{tabular} & \begin{tabular}{l} 
Dfbetas is an N-by-P matrix of the scaled change \\
in the coefficient estimates that would result \\
from excluding each observation in turn. Values \\
larger than 3/sqrt (N) in absolute value indicate \\
that the observation has a large influence on the \\
corresponding coefficient.
\end{tabular} \\
\hline HatMatrix & \begin{tabular}{l} 
Projection matrix to \\
compute fitted from \\
observed responses
\end{tabular} & \begin{tabular}{l} 
HatMatrix is an N-by-N matrix such that \\
Fitted = HatMatrix*Y, where Y is the response \\
vector and Fitted is the vector of fitted response \\
values.
\end{tabular} \\
\hline
\end{tabular}

Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain NaN values.

Rows not used in the fit because of excluded values (in ObservationInfo.Excluded) contain NaN values, with the following exception: Delete-1 diagnostics refer to the statistic with and without that observation (row) included in the fit. These diagnostics help identify important observations.

\section*{Fitted}

Predicted response to the input data by using the model. Use predict to compute predictions for other predictor values, or to compute confidence bounds on Fitted.

\section*{Formula}

Object containing information about the model.

\section*{LogLikelihood}

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

\section*{ModelCriterion}

\section*{LinearModel}

AIC and other information criteria for comparing models. A structure with fields:
- AIC - Akaike information criterion
- AICc - Akaike information criterion corrected for sample size
- BIC - Bayesian information criterion
- CAIC - Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model mdl, the AIC value aic is:
aic = mdl.ModelCriterion.AIC

\section*{MSE}

Mean squared error (residuals), SSE/DFE.

\section*{NumCoefficients}

Number of coefficients in the model, a positive integer. NumCoefficients includes coefficients that are set to zero when the model terms are rank deficient.

\section*{NumEstimatedCoefficients}

Number of estimated coefficients in the model, a positive integer. NumEstimatedCoefficients does not include coefficients that are set to zero when the model terms are rank deficient. NumEstimatedCoefficients is the degrees of freedom for regression.

\section*{NumObservations}

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original dataset or matrix, minus any excluded rows (set with the Excluded name-value pair) or rows with missing values.

\section*{NumPredictors}

\section*{LinearModel}

Number of variables LinearModel.fit used as predictors for fitting.

\section*{NumVariables}

Number of variables in the data. NumVariables is the number of variables in the original dataset when the fit is based on a dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

\section*{ObservationInfo}

Dataset with the same number of rows as the input data (ds or X).
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Weights & Observation weights. Default is all 1. \\
\hline Excluded & \begin{tabular}{l} 
Logical value, 1 indicates an observation that \\
you excluded from the fit with the Exclude \\
name-value pair.
\end{tabular} \\
\hline Missing & \begin{tabular}{l} 
Logical value, 1 indicates a missing value in \\
the input. Missing values are not used in the \\
fit.
\end{tabular} \\
\hline Subset & \begin{tabular}{l} 
Logical value, 1 indicates the observation is \\
not excluded or missing, so is used in the fit.
\end{tabular} \\
\hline
\end{tabular}

\section*{ObservationNames}

Cell array of strings containing the names of the observations used in the fit.
- If the fit is based on a dataset containing observation names, ObservationNames uses those names.
- Otherwise, ObservationNames is an empty cell array

\section*{PredictorNames}

\section*{LinearModel}

Cell array of strings, the names of the predictors used in fitting the model.

\section*{Residuals}

Dataset array containing a table of residuals, with one row for each observation and these variables.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Raw & Observed minus fitted values. \\
\hline Pearson & Raw residuals divided by RMSE. \\
\hline Standardized & \begin{tabular}{l} 
Raw residuals divided by their estimated \\
standard deviation.
\end{tabular} \\
\hline Studentized & \begin{tabular}{l} 
Residual divided by an independent estimate \\
of the residual standard deviation. The \\
residual for observation \(i\) is divided by an \\
estimate of the error standard deviation based \\
on all observations except for observation \(i\).
\end{tabular} \\
\hline
\end{tabular}

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model mdl, the ordinary raw residual vector \(r\) is:
\(r\) = mdl.Residuals.Raw
Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain NaN values.

Rows not used in the fit because of excluded values (in ObservationInfo.Excluded) contain NaN values, with the following exceptions:
- raw contains the difference between the observed and predicted values.
- standardized is the residual, standardized in the usual way.
- studentized matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

\section*{ResponseName}

String giving naming the response variable.

\section*{RMSE}

Root mean squared error (residuals), sqrt(MSE).

\section*{Robust}

Structure that is empty unless LinearModel.fit constructed the model using robust regression.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline WgtFun & \begin{tabular}{l} 
Robust weighting function, such as \\
'bisquare ' (see robustfit)
\end{tabular} \\
\hline Tune & \begin{tabular}{l} 
Value specified for tuning parameter (can be \\
{\([\) ] \()\)}
\end{tabular} \\
\hline Weights & \begin{tabular}{l} 
Vector of weights used in final iteration of \\
robust fit
\end{tabular} \\
\hline
\end{tabular}

\section*{Rsquared}

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:
```

Rsquared = SSR/SST = 1 - SSE/SST.

```

Rsquared is a structure with two fields:
- Ordinary - Ordinary (unadjusted) R-squared
- Adjusted - R-squared adjusted for the number of coefficients

\section*{LinearModel}

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in mdl is
r2 = mdl.Rsquared.Adjusted

\section*{SSE}

Sum of squared errors (residuals).
The Pythagorean theorem implies
```

SST = SSE + SSR.

```

\section*{SSR}

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
SST = SSE + SSR.

\section*{SST}

Total sum of squares, the sum of squared deviations of \(y\) from mean(y).

The Pythagorean theorem implies
SST = SSE + SSR.

\section*{Steps}

Structure that is empty unless LinearModel.stepwise constructed the model.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Start & Formula representing the starting model \\
\hline Lower & \begin{tabular}{l} 
Formula representing the lower bound model, \\
these terms that must remain in the model
\end{tabular} \\
\hline Upper & \begin{tabular}{l} 
Formula representing the upper bound model, \\
model cannot contain more terms than Upper
\end{tabular} \\
\hline Criterion & \begin{tabular}{l} 
Criterion used for the stepwise algorithm, \\
such as 'sse '
\end{tabular} \\
\hline PEnter & Value of the parameter, such as 0.05 \\
\hline PRemove & Value of the parameter, such as 0.10 \\
\hline History & Dataset representing the steps taken in the fit \\
\hline
\end{tabular}

The History dataset has one row for each step including the initial fit, and the following variables (columns).
\begin{tabular}{|c|c|}
\hline Field & Description \\
\hline Action & \begin{tabular}{l}
Action taken during this step, one of: \\
- 'Start' - First step \\
- 'Add ' - A term is added \\
- 'Remove' - A term is removed
\end{tabular} \\
\hline TermName & \begin{tabular}{l}
- 'Start' step: The starting model specification \\
- 'Add' or 'Remove' steps: The term moved in that step
\end{tabular} \\
\hline Terms & \begin{tabular}{l}
Terms matrix (see modelspec in \\
"Input Arguments" on page 20-799 of LinearModel.fit)
\end{tabular} \\
\hline DF & Regression degrees of freedom after this step \\
\hline
\end{tabular}

\section*{LinearModel}
\begin{tabular}{l|l}
\hline Field & Description \\
\hline delDF & \begin{tabular}{l} 
Change in regression degrees of freedom from \\
previous step (negative for steps that remove \\
a term)
\end{tabular} \\
\hline Deviance & \begin{tabular}{l} 
Deviance (residual sum of squares) at that \\
step
\end{tabular} \\
\hline FStat & \(F\) statistic that led to this step \\
\hline PValue & \(p\)-value of the \(F\) statistic \\
\hline
\end{tabular}

\section*{Variablelnfo}

Dataset array containing metadata about Variables. There is one row for each term in the model, and the following columns.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Class & String giving variable class, such as 'double ' \\
\hline Range & \begin{tabular}{l} 
Cell array giving variable range: \\
• Continuous variable - Two-element vector \\
[min, max ], the minimum and maximum \\
values \\
- Categorical variable - Cell array of \\
distinct variable values
\end{tabular} \\
\hline InModel & \begin{tabular}{l} 
Logical vector, where true indicates the \\
variable is in the model
\end{tabular} \\
\hline IsCategorical & \begin{tabular}{l} 
Logical vector, where true indicates a \\
categorical variable
\end{tabular} \\
\hline
\end{tabular}

\section*{VariableNames}

Cell array of strings containing names of the variables in the fit.
- If the fit is based on a dataset, this property provides the names of the variables in that dataset.
- If the fit is based on a predictor matrix and response vector, VariableNames is the values in the VarNames name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

\section*{Variables}

Dataset array containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a dataset array, Variables is a copy of that dataset. Otherwise, Variables is a dataset created from the input data matrix \(X\) and response vector \(y\).

\section*{Methods}
\begin{tabular}{ll} 
addTerms & \begin{tabular}{l} 
Add terms to linear regression \\
model
\end{tabular} \\
anova & \begin{tabular}{l} 
Analysis of variance for linear \\
model
\end{tabular} \\
coefCI & \begin{tabular}{l} 
Confidence intervals of coefficient \\
estimates of linear model
\end{tabular} \\
coefTest & \begin{tabular}{l} 
Linear hypothesis test on linear \\
regression model coefficients
\end{tabular} \\
disp & \begin{tabular}{l} 
Display linear regression model
\end{tabular} \\
dwtest & \begin{tabular}{l} 
Durbin-Watson test of linear \\
model
\end{tabular} \\
feval & \begin{tabular}{l} 
Evaluate linear regression model \\
prediction
\end{tabular} \\
fit & \begin{tabular}{l} 
Create linear regression model
\end{tabular} \\
plot & \begin{tabular}{l} 
Scatter plot or added variable \\
plot of linear model
\end{tabular} \\
plotAdded & \begin{tabular}{l} 
Added variable plot or leverage \\
plot for linear model
\end{tabular}
\end{tabular}

\section*{LinearModel}
\begin{tabular}{ll} 
plotAdjustedResponse & \begin{tabular}{l} 
Adjusted response plot for linear \\
regression model
\end{tabular} \\
plotDiagnostics & \begin{tabular}{l} 
Plot diagnostics of linear \\
regression model
\end{tabular} \\
plotEffects & \begin{tabular}{l} 
Plot main effects of each predictor \\
in linear regression model
\end{tabular} \\
plotInteraction & \begin{tabular}{l} 
Plot interaction effects of two \\
predictors in linear regression \\
model
\end{tabular} \\
plotResiduals & \begin{tabular}{l} 
Plot residuals of linear regression \\
model
\end{tabular} \\

Plot of slices through fitted linear \\
regression surface
\end{tabular} \\
predict & \begin{tabular}{l} 
Predict response of linear \\
regression model
\end{tabular} \\
random & \begin{tabular}{l} 
Simulate responses for linear \\
regression model
\end{tabular} \\
removeTerms & \begin{tabular}{l} 
Remove terms from linear model
\end{tabular} \\
step & \begin{tabular}{l} 
Improve linear regression model \\
by adding or removing terms
\end{tabular} \\
stepwise & \begin{tabular}{l} 
Create linear regression model by \\
stepwise regression
\end{tabular} \\
\hline
\end{tabular}

Copy
Semantics

\section*{Definitions}

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

\section*{Hat Matrix}

The hat matrix \(H\) is defined in terms of the data matrix \(X\) :
\[
H=X\left(X^{T} X\right)^{-1} X^{T} .
\]

The diagonal elements \(H_{i i}\) satisfy
\[
\begin{aligned}
& 0 \leq h_{i i} \leq 1 \\
& \sum_{i=1}^{n} h_{i i}=p,
\end{aligned}
\]
where \(n\) is the number of observations (rows of \(X\) ), and \(p\) is the number of coefficients in the regression model.

\section*{Leverage}

The leverage of observation \(i\) is the value of the \(i\) th diagonal term of the hat matrix \(H_{i i}\). Because the sum of the leverage values is \(p\) (the number of coefficients in the regression model), an observation \(i\) can be considered to be an outlier if its leverage substantially exceeds \(p / n\), where \(n\) is the number of observations.

\section*{Cook's Distance}

Cook's distance is the scaled change in fitted values. Each element in CooksDistance is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance, \(D_{i}\), of observation \(i\) is
\[
D_{i}=\frac{\sum_{j=1}^{n}\left(\hat{y}_{j}-\hat{y}_{j(i)}\right)^{2}}{p M S E},
\]
where
- \(\hat{y}_{j}\) is the \(j\) th fitted response value.
- \(\hat{y}_{j(i)}\) is the \(j\) th fitted response value, where the fit does not include observation \(i\).
- \(M S E\) is the mean squared error.
- \(p\) is the number of coefficients in the regression model.

\section*{LinearModel}

Cook's distance is algebraically equivalent to the following expression:
\[
D_{i}=\frac{r_{i}^{2}}{p M S E}\left(\frac{h_{i i}}{\left(1-h_{i i}\right)^{2}}\right)
\]
where \(r_{i}\) is the \(i\) th residual, and \(h_{i i}\) is the \(i\) th leverage value.
CooksDistance is an \(n\)-by- 1 column vector in the Diagnostics dataset array of the LinearModel object.

\section*{Examples Linear Regression Model of Matrix Data}

Fit a linear model of the Hald data.
Load the data.
load hald
X = ingredients; \% predictor variables
y = heat; \% response
Fit a default linear model to the data.
```

mdl = LinearModel.fit(X,y)
mdl =
Linear regression model:
y ~ 1 + x1 + x2 + x3 + x4

```

Estimated Coefficients:
\begin{tabular}{lrcrr} 
& Estimate & SE & tStat & \multicolumn{1}{l}{ pValue } \\
(Intercept) & 62.405 & 70.071 & 0.8906 & 0.39913 \\
x1 & 1.5511 & 0.74477 & 2.0827 & 0.070822 \\
x2 & 0.51017 & 0.72379 & 0.70486 & 0.5009 \\
x3 & 0.10191 & 0.75471 & 0.13503 & 0.89592 \\
x4 & -0.14406 & 0.70905 & -0.20317 & 0.84407
\end{tabular}

Number of observations: 13, Error degrees of freedom: 8
```

Root Mean Squared Error: 2.45
R-squared: 0.982, Adjusted R-Squared 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07

```

\section*{Linear Regression with Categorical Predictor and Nonlinear Model}

Fit a model of a dataset array that contains a categorical predictor. Use a nonlinear response formula.

Load the carsmall data.
```

load carsmall

```

Construct a dataset containing continuous predictor variable Weight, nominal predictor variable Year, and response variable MPG.
```

ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);

```

Create a fitted model of MPG as a function of Year, Weight, and Weight \({ }^{2}\). (You don't have to include Weight explicitly in your formula because it is a lower-order term of Weight \({ }^{2}\). For details, see "Definitions" on page 20-805.)
```

mdl = LinearModel.fit(ds,'MPG ~ Year + Weight^2')
mdl =
Linear regression model:
MPG ~ 1 + Weight + Year + Weight^2

```
Estimated Coefficients:
\begin{tabular}{lrrrr} 
& Estimate & \multicolumn{1}{l}{ SE } & \multicolumn{1}{l}{ tStat } & \multicolumn{1}{l}{ pValue } \\
(Intercept) & 54.206 & 4.7117 & 11.505 & \(2.6648 \mathrm{e}-19\) \\
Weight & -0.016404 & 0.0031249 & -5.2493 & \(1.0283 \mathrm{e}-06\) \\
Year_76 & 2.0887 & 0.71491 & 2.9215 & 0.0044137 \\
Year_82 & 8.1864 & 0.81531 & 10.041 & \(2.6364 \mathrm{e}-16\) \\
Weight^2 & \(1.5573 \mathrm{e}-06\) & \(4.9454 \mathrm{e}-07\) & 3.149 & 0.0022303
\end{tabular}
```

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885, Adjusted R-Squared 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41

```

\section*{Robust Linear Regression Model}

Fit a linear regression model of the Hald data using robust fitting.
Load the data.
load hald
\(\mathrm{X}=\) ingredients; \% predictor variables
y = heat; \% response
Fit a robust linear model to the data.
```

mdl = LinearModel.fit(X,y,'linear','RobustOpts','on')
mdl =
Linear regression model (robust fit):
y ~ 1 + x1 + x2 + x3 + x4

```
Estimated Coefficients:
\begin{tabular}{lrrrr} 
& Estimate & \multicolumn{1}{l}{ SE } & tStat & pValue \\
( Intercept) & 60.09 & 75.818 & 0.79256 & 0.4509 \\
x1 & 1.5753 & 0.80585 & 1.9548 & 0.086346 \\
x2 & 0.5322 & 0.78315 & 0.67957 & 0.51596 \\
x3 & 0.13346 & 0.8166 & 0.16343 & 0.87424 \\
x4 & -0.12052 & 0.7672 & -0.15709 & 0.87906
\end{tabular}

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
Algorithms The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is robustfit.
Alternatives To remove redundant predictors in linear regression using lasso or elastic net, use the lasso function.
To regularize a regression with correlated terms using ridge regression, use the ridge or lasso functions.
To regularize a regression with correlated terms using partial least squares, use the plsregress function.

\section*{linhyptest}

Purpose Linear hypothesis test
```

Syntax p = linhyptest(beta,covb, c,H,dfe)
[p,t,r] = linhyptest(...)

```

Description \(\quad \mathrm{p}=\) linhyptest (beta, COVB, \(\mathrm{c}, \mathrm{H}, \mathrm{dfe}\) ) returns the \(p\) value p of a hypothesis test on a vector of parameters. beta is a vector of \(k\) parameter estimates. COVB is the \(k\)-by- \(k\) estimated covariance matrix of the parameter estimates. c and H specify the null hypothesis in the form \(H^{*} \mathrm{~b}=\mathrm{c}\), where b is the vector of unknown parameters estimated by beta. dfe is the degrees of freedom for the COVB estimate, or Inf if COVB is known rather than estimated.
beta is required. The remaining arguments have default values:
- COVB \(=\) eye(k)
- \(c=z e r o s(k, 1)\)
- H = eye(K)
- \(d f e=\) Inf

If H is omitted, c must have \(k\) elements and it specifies the null hypothesis values for the entire parameter vector.

Note The following functions return outputs suitable for use as the COVB input argument to linhyptest: nlinfit, coxphfit, glmfit, mnrfit, regstats, robustfit. nlinfit returns COVB directly; the other functions return COVB in stats.covb.
[ \(p, t, r\) ] = linhyptest(...) also returns the test statistic \(t\) and the rank \(r\) of the hypothesis matrix \(H\). If dfe is Inf or is not given, \(t * r\) is a chi-square statistic with \(r\) degrees of freedom. If dfe is specified as a finite value, t is an \(F\) statistic with r and dfe degrees of freedom.
linhyptest performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation

\section*{linhyptest}
procedure for which the parameter covariances are available, such as regstats or glmfit. For linear regression, the \(p\)-values are exact. For other procedures, the \(p\)-values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

\section*{Examples}

Fit a multiple linear model to the data in hald.mat:
```

load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
62.4054
1.5511
0.5102
0.1019
-0.1441

```

Perform an \(F\)-test that the last two coefficients are both 0 :
```

SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhyptest(beta,SIGMA,c,H,dfe)
p =
0.4668
F =
0.8391

```

\section*{See Also}
regstats | glmfit | robustfit | mnrfit | nlinfit | coxphfit

Purpose Agglomerative hierarchical cluster tree
Syntax
Z = linkage( X )
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X, method,pdist_inputs)
Z = linkage(X,method,metric,'savememory', value)
Z = linkage( Y )
Z = linkage( Y , method)

\section*{Description}

Tips
\(Z=\) linkage \((X)\) returns a matrix \(Z\) that encodes a tree of hierarchical clusters of the rows of the real matrix \(X\).
\(Z=\) linkage (X, method) creates the tree using the specified method, where method describes how to measure the distance between clusters.

Z = linkage(X,method,metric) performs clustering using the distance measure metric to compute distances between the rows of \(X\).
Z = linkage( X , method, pdist_inputs) passes parameters to the pdist function, which is the function that computes the distance between rows of \(X\).

Z = linkage(X,method,metric,'savememory', value) uses a memory-saving algorithm when value is 'true', and uses the standard algorithm when value is 'false'.
\(Z=\) linkage \((Y)\) uses a vector representation \(Y\) of a distance matrix. \(Y\) can be a distance matrix as computed by pdist, or a more general dissimilarity matrix conforming to the output format of pdist.
\(Z=\) linkage \((Y\), method) creates the tree using the specified method, where method describes how to measure the distance between clusters.
- Computing linkage ( Y ) can be slow when Y is a vector representation of the distance matrix. For the 'centroid', 'median', and 'ward' methods, linkage checks whether Y is a Euclidean distance. Avoid this time-consuming check by passing in X instead of Y .
- The centroid and median methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters, \(r\) and \(s\), to a third cluster is less than the distance between \(r\) and \(s\). In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3 . This leads to a nonmonotonic tree.
- You can provide the output \(Z\) to other functions including dendrogram to display the tree, cluster to assign points to clusters, inconsistent to compute inconsistent measures, and cophenet to compute the cophenetic correlation coefficient.

\section*{Input Arguments}

\section*{X}

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

\section*{method}

\section*{linkage}

Algorithm for computing distance between clusters.
\begin{tabular}{l|l}
\hline Method & Description \\
\hline 'average' & Unweighted average distance (UPGMA) \\
\hline 'centroid' & \begin{tabular}{l} 
Centroid distance (UPGMC), appropriate for \\
Euclidean distances only
\end{tabular} \\
\hline 'complete' & Furthest distance \\
\hline 'median' & \begin{tabular}{l} 
Weighted center of mass distance (WPGMC), \\
appropriate for Euclidean distances only
\end{tabular} \\
\hline 'single' & Shortest distance \\
\hline 'ward' & \begin{tabular}{l} 
Inner squared distance (minimum variance \\
algorithm), appropriate for Euclidean distances only
\end{tabular} \\
\hline 'weighted ' & Weighted average distance (WPGMA) \\
\hline
\end{tabular}

Default: 'single'

\section*{metric}

Any distance metric that the pdist function accepts.
\begin{tabular}{l|l}
\hline Metric & Description \\
\hline 'euclidean' & Euclidean distance (default). \\
\hline 'seuclidean' & \begin{tabular}{l} 
Standardized Euclidean distance. Each \\
coordinate difference between rows in X is \\
scaled by dividing by the corresponding \\
element of the standard deviation \\
S=nanstd (X). To specify another value for \\
S, use D=pdist (X, 'seuclidean ' , S).
\end{tabular} \\
\hline 'cityblock' & City block metric. \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Metric & Description \\
\hline 'minkowski' & \begin{tabular}{l} 
Minkowski distance. The default exponent is \\
2. To specify a different exponent, use D \(=\) \\
pdist (X, 'minkowski' , P), where P is a scalar
\end{tabular} \\
\hline 'chebychev' & \begin{tabular}{l} 
Chebychev distance (maximum coordinate \\
difference).
\end{tabular} \\
\hline 'mahalanobis' & \begin{tabular}{l} 
Mahalanobis distance, using the sample \\
covariance of X as computed by nancov. To \\
compute the distance with a different covariance, \\
use D = pdist (X, 'mahalanobis ' , C), where \\
the matrix C is symmetric and positive definite.
\end{tabular} \\
\hline 'cosine' & \begin{tabular}{l} 
One minus the cosine of the included angle \\
between points (treated as vectors).
\end{tabular} \\
\hline 'correlation' & \begin{tabular}{l} 
One minus the sample correlation between \\
points (treated as sequences of values).
\end{tabular} \\
\hline 'spearman' & \begin{tabular}{l} 
One minus the sample Spearman's rank \\
correlation between observations (treated as \\
sequences of values).
\end{tabular} \\
\hline 'hamming' & \begin{tabular}{l} 
Hamming distance, which is the percentage of \\
coordinates that differ.
\end{tabular} \\
\hline 'jaccard' & \begin{tabular}{l} 
One minus the Jaccard coefficient, which is the \\
percentage of nonzero coordinates that differ.
\end{tabular} \\
\hline \begin{tabular}{l} 
custom distance \\
function
\end{tabular} & \begin{tabular}{l} 
A distance function specified using @: \\
D = pdist (X, adistfun) \\
A distance function must be of form
\end{tabular} \\
d2 = distfun (XI , XJ)
\end{tabular}

\section*{linkage}
\begin{tabular}{l|l}
\hline Metric & Description \\
\hline & \begin{tabular}{l} 
with an arbitrary number of rows. distfun \\
must return an \(m 2\)-by-1 vector of distances d2, \\
whose \(k\) th element is the distance between XI \\
and XJ \((\mathrm{k},:)\).
\end{tabular} \\
\hline
\end{tabular}

Default: 'euclidean'

\section*{pdist_inputs}

A cell array of parameters accepted by the pdist function. For example, to set the metric to minkowski and use an exponent of 5 , set pdist_inputs to \{'minkowski', 5 \}.

\section*{savememory}

A string, either 'on' or 'off'. When applicable, the 'on' setting causes linkage to construct clusters without computing the distance matrix. savememory is applicable when:
- linkage is 'centroid', 'median', or 'ward'
- distance is 'euclidean' (default)

When savememory is 'on', linkage run time is proportional to the number of dimensions (number of columns of \(X\) ). When savememory is 'off', linkage memory requirement is proportional to \(\mathrm{N}^{2}\), where \(N\) is the number of observations. So choosing the best (least-time) setting for savememory depends on the problem dimensions, number of observations, and available memory. The default savememory setting is a rough approximation of an optimal setting.

Default: 'on' when X has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise 'off'

\section*{Y}

A vector of distances with the same format as the output of the pdist function:
- A row vector of length \(m(m-1) / 2\), corresponding to pairs of observations in a matrix \(X\) with \(m\) rows
- Distances arranged in the order \((2,1),(3,1), \ldots,(m, 1),(3,2), \ldots,(m, 2)\), ..., ( \(m, m-1\) ))
\(Y\) can be a more general dissimilarity matrix conforming to the output format of pdist.

\section*{Output \\ Arguments}

\section*{Definitions}

\section*{Linkages}

The following notation is used to describe the linkages used by the various methods:
- Cluster r is formed from clusters p and q .
- \(\mathrm{n}_{r}\) is the number of objects in cluster \(r\).
- \(\mathrm{x}_{r i}\) is the ith object in cluster r .

\section*{linkage}
- Single linkage, also called nearest neighbor, uses the smallest distance between objects in the two clusters:
\[
d(r, s)=\min \left(\operatorname{dist}\left(x_{r i}, x_{s j}\right)\right), i \in\left(i, \ldots, n_{r}\right), j \in\left(1, \ldots, n_{s}\right)
\]
- Complete linkage, also called furthest neighbor, uses the largest distance between objects in the two clusters:
\[
d(r, s)=\max \left(\operatorname{dist}\left(x_{r i}, x_{s j}\right)\right), i \in\left(1, \ldots, n_{r}\right), j \in\left(1, \ldots, n_{s}\right)
\]
- Average linkage uses the average distance between all pairs of objects in any two clusters:
\[
d(r, s)=\frac{1}{n_{r} n_{s}} \sum_{i=1}^{n_{r}} \sum_{j=1}^{n_{s}} \operatorname{dist}\left(x_{r i}, x_{s j}\right)
\]
- Centroid linkage uses the Euclidean distance between the centroids of the two clusters:
\[
d(r, s)=\left\|\bar{x}_{r}-\bar{x}_{s}\right\|_{2}
\]
where
\[
\bar{x}_{r}=\frac{1}{n_{r}} \sum_{i=1}^{n_{r}} x_{r i}
\]
- Median linkage uses the Euclidean distance between weighted centroids of the two clusters,
\[
d(r, s)=\left\|\tilde{x}_{r}-\tilde{x}_{s}\right\|_{2}
\]
where \(\tilde{x}_{r}\) and \(\tilde{x}_{s}\) are weighted centroids for the clusters \(r\) and \(s\). If cluster \(r\) was created by combining clusters \(p\) and \(q, \tilde{x}_{r}\) is defined recursively as
\[
\tilde{x}_{r}=\frac{1}{2}\left(\tilde{x}_{p}+\tilde{x}_{q}\right)
\]
- Ward's linkage uses the incremental sum of squares; that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares measure is equivalent to the following distance measure \(d(r, s)\), which is the formula linkage uses:
\[
d(r, s)=\sqrt{\frac{2 n_{r} n_{s}}{\left(n_{r}+n_{s}\right)}}\left\|\bar{x}_{r}-\bar{x}_{s}\right\|_{2},
\]
where
- \| \(\|_{2}\) is Euclidean distance
- \(\bar{x}_{r}\) and \(\bar{x}_{s}\) are the centroids of clusters \(r\) and \(s\)
- \(n_{r}\) and \(n_{s}\) are the number of elements in clusters \(r\) and \(s\)

In some references the Ward linkage does not use the factor of 2 multiplying \(n_{r} n_{s}\). The linkage function uses this factor so the distance between two singleton clusters is the same as the Euclidean distance.
- Weighted average linkage uses a recursive definition for the distance between two clusters. If cluster \(r\) was created by combining clusters \(p\) and \(q\), the distance between \(r\) and another cluster \(s\) is defined as the average of the distance between \(p\) and \(s\) and the distance between \(q\) and \(s\) :
\[
d(r, s)=\frac{(d(p, s)+d(q, s))}{2}
\]

\section*{linkage}

Examples Compute four clusters of the Fisher iris data using Ward linkage and ignoring species information, and see how the cluster assignments correspond to the three species.
```

load fisheriris
Z = linkage(meas,'ward','euclidean');
c = cluster(Z,'maxclust',4);
crosstab(c,species)
firstfive = Z(1:5,:) % first 5 rows of Z
dendrogram(Z)
ans =
0 25 1
0 24 14
0 1 35
50 0 0
firstfive =
102.0000 143.0000 0
8.0000 40.0000 0.1000
1.0000 18.0000 0.1000
10.0000 35.0000 0.1000
129.0000 133.0000 0.1000

```

Create a hierarchical cluster tree for a data with 20000 observations using Ward's linkage. If you set savememory to 'off', you can get an out-of-memory error if your machine doesn't have enough memory to hold the distance matrix. Cluster the data into four groups and plot the result.
\(X=\) rand \((20000,3)\);
Z = linkage(X,'ward','euclidean','savememory','on');
c = cluster(Z,'maxclust',4);
scatter3(X(:,1),X(:,2),X(:,3),10, c)

\section*{Definitions Loglogistic Distribution}

The loglogistic distribution is closely related to the logistic distribution. If \(x\) is distributed \(\operatorname{loglogistically}\) with parameters \(\mu\) and \(\sigma\), then \(\log (x)\) is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline mu & Log mean & \(\mu>0\) \\
\hline sigma & Log scale parameter & \(\sigma>0\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid \mu, \sigma)=\frac{1}{\sigma} \frac{1}{x} \frac{e^{z}}{\left(1+e^{z}\right)^{2}} \quad ; \quad x \geq 0
\]
where \(z=\frac{\log (x)-\mu}{\sigma}\).

\section*{Examples Create a Loglogistic Distribution Object Using Default Parameters}

Create a loglogistic distribution object using the default parameter values.
```

pd = makedist('Loglogistic')
pd =

```

LoglogisticDistribution
```

    Log-Logistic distribution
        mu = 0
    sigma = 1
    ```

\section*{Create a Loglogistic Distribution Object Using Specified Parameters}

Create a loglogistic distribution object by specifying the parameter values.

\section*{prob.LoglogisticDistribution}
```

pd = makedist('Loglogistic','mu',5,'sigma',2)
pd =
LoglogisticDistribution
Log-Logistic distribution
mu = 5
sigma = 2

```

Generate random numbers from the loglogistic distribution and compute their log values.
rng(19) \% for reproducibility
x = random(pd,10000,1);
\(\log x=\log (x)\);

Compute the mean of the log values.
\(m=\operatorname{mean}(\log x)\)
m =
4.9828

The mean of the \(\log\) of \(x\) is equal to the mu parameter of \(x\), since \(x\) has a loglogistic distribution.

Plot logx.
hist(logx,50)

The plot shows that the log values of \(x\) have a logistic distribution.

\section*{Purpose Lognormal cumulative distribution function}
```

Syntax $\quad P=\operatorname{logncdf}(X$, mu, sigma $)$
[P,PLO,PUP] = logncdf(X,mu,sigma,pcov,alpha)

```

\section*{Description}
\(P=\operatorname{logncdf}(X, m u\), sigma \()\) returns values at \(X\) of the lognormal cdf with distribution parameters mu and sigma. mu and sigma are the mean and standard deviation, respectively, of the associated normal distribution. X, mu, and sigma can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for X , mu, or sigma is expanded to a constant array with the same dimensions as the other inputs.
[P, PLO, PUP] = logncdf(X,mu,sigma, pcov,alpha) returns confidence bounds for \(P\) when the input parameters mu and sigma are estimates. pcov is the covariance matrix of the estimated parameters. alpha specifies \(100(1-\) alpha \() \%\) confidence bounds. The default value of alpha is 0.05 . PLO and PUP are arrays of the same size as P containing the lower and upper confidence bounds.
logncdf computes confidence bounds for P using a normal approximation to the distribution of the estimate
\[
\frac{X-\hat{\mu}}{\hat{\sigma}}
\]
and then transforming those bounds to the scale of the output P. The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and pcov from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal cdf is
\[
p=F(x \mid \mu, \sigma)=\frac{1}{\sigma \sqrt{2 \pi}} \int_{0}^{x} \frac{e^{\frac{-(\ln (t)-\mu)^{2}}{2 \sigma^{2}}}}{t} d t
\]

\section*{Examples}
```

x = (0:0.2:10);
y = logncdf(x,0,1);
plot(x,y); grid;
xlabel('x'); ylabel('p');

```

How To

\section*{Purpose Lognormal parameter estimates}
```

Syntax parmhat = lognfit(data)
[parmhat,parmci] = lognfit(data)
[parmhat,parmci] = lognfit(data,alpha)
[...] = lognfit(data,alpha,censoring)
[...] = lognfit(data,alpha,censoring,freq)
[...] = lognfit(data,alpha,censoring,freq,options)

```

\section*{Description}
parmhat = lognfit(data) returns a vector of maximum likelihood estimates parmhat(1) = mu and parmhat(2) = sigma of parameters for a lognormal distribution fitting data. mu and sigma are the mean and standard deviation, respectively, of the associated normal distribution.
[parmhat, parmci] = lognfit(data) returns \(95 \%\) confidence intervals for the parameter estimates mu and sigma in the 2 -by- 2 matrix parmci. The first column of the matrix contains the lower and upper confidence bounds for parameter mu, and the second column contains the confidence bounds for parameter sigma.
[parmhat,parmci] = lognfit(data,alpha) returns 100(1-alpha) \% confidence intervals for the parameter estimates, where alpha is a value in the range ( 01 ) specifying the width of the confidence intervals. By default, alpha is 0.05 , which corresponds to \(95 \%\) confidence intervals.
[...] = lognfit(data, alpha, censoring) accepts a Boolean vector censoring, of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.
[...] = lognfit(data, alpha,censoring,freq) accepts a frequency vector, freq, of the same size as data. Typically, freq contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for alpha, censoring, or freq to use their default values.
[...] = lognfit(data,alpha, censoring,freq,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The lognormal fit function accepts an options
structure which can be created using the function statset. Enter statset('lognfit') to see the names and default values of the parameters that lognfit accepts in the options structure. See the reference page for statset for more information about these options.

Note With no censoring, lognfit computes sigma using the square root of the unbiased estimator of the variance. With censoring, sigma is the maximum likelihood estimate.
```

Examples This example generates 100 independent samples of lognormally
distributed data with }\mu=0\mathrm{ and }\sigma=3\mathrm{ . parmhat estimates }\mu\mathrm{ and }\sigma\mathrm{ and
parmci gives 99% confidence intervals around parmhat. Notice that
parmci contains the true values of }\mu\mathrm{ and }\sigma\mathrm{ .
data = lognrnd(0,3,100,1);
[parmhat,parmci] = lognfit(data,0.01)
parmhat =
-0.2480 2.8902
parmci =
-1.0071 2.4393
0.5111 3.5262

How To . "Lognormal Distribution" on page B-64

\section*{Purpose Lognormal inverse cumulative distribution function}
```

Syntax $\quad X=\operatorname{logninv}(P$, mu, sigma $)$
[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)

```
\(X=\) logninv( \(P\), mu, sigma) returns values at \(P\) of the inverse lognormal cdf with distribution parameters mu and sigma. mu and sigma are the mean and standard deviation, respectively, of the associated normal distribution. mu and sigma can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of X . A scalar input for P , mu, or sigma is expanded to a constant array with the same dimensions as the other inputs.
[X,XLO, XUP] = logninv(P,mu,sigma, pcov,alpha) returns confidence bounds for \(X\) when the input parameters mu and sigma are estimates. pcov is the covariance matrix of the estimated parameters. alpha specifies \(100(1-a l p h a) \%\) confidence bounds. The default value of alpha is 0.05 . XLO and XUP are arrays of the same size as \(X\) containing the lower and upper confidence bounds.
logninv computes confidence bounds for P using a normal approximation to the distribution of the estimate
\[
\hat{\mu}+\hat{\sigma} q
\]
where \(q\) is the Pth quantile from a normal distribution with mean 0 and standard deviation 1 . The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and pcov from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal inverse function is defined in terms of the lognormal cdf as
\[
x=F^{-1}(p \mid \mu, \sigma)=\{x: F(x \mid \mu, \sigma)=p\}
\]
where
\[
p=F(x \mid \mu, \sigma)=\frac{1}{\sigma \sqrt{2 \pi}} \int_{0}^{x} \frac{e^{\frac{-(\ln (t)-\mu)^{2}}{2 \sigma^{2}}}}{t} d t
\]

\section*{Examples}
```

p = (0.005:0.01:0.995);
crit = logninv(p,1,0.5);
plot(p,crit)
xlabel('Probability'); ylabel('Critical Value'); grid

```

\section*{Description}

See Also
How To
nlogL = lognlike(params, data) returns the negative log-likelihood of data for the lognormal distribution with parameters params. params (1) is the mean of the associated normal distribution, mu, and params (2) is the standard deviation of the associated normal distribution, sigma. The values of mu and sigma are scalars, and the output nlogL is a scalar.
[nlogL, avar] = lognlike(params, data) returns the inverse of Fisher's information matrix. If the input parameter value in params is the maximum likelihood estimate, avar is its asymptotic variance. avar is based on the observed Fisher's information, not the expected information.
[...] = lognlike(params, data, censoring) accepts a Boolean vector, censoring, of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.
[...] = lognlike(params, data, censoring,freq) accepts a frequency vector, freq, of the same size as data. The vector freq typically contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for censoring to use its default value.

\section*{Definitions Lognormal Distribution}

The lognormal distribution is closely related to the normal distribution. If \(x\) is distributed lognormally with parameters \(\mu\) and \(\sigma\), then \(\log (x)\) is distributed normally with mean \(\mu\) and standard deviation \(\sigma\). The lognormal distribution is applicable when the quantity of interest must be positive, since \(\log (x)\) exists only when \(x\) is positive.

The lognormal distribution uses the following parameters.

\section*{prob.LognormalDistribution}
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline mu & Log mean & \(-\infty<\mu<\infty\) \\
\hline sigma & \begin{tabular}{l} 
Log standard \\
deviation
\end{tabular} & \(\sigma \geq 0\) \\
\hline
\end{tabular}

The probability density function (pdf) of the lognormal distribution is
\[
f(x \mid \mu, \sigma)=\frac{1}{x \sigma \sqrt{2 \pi}} \exp \left\{\frac{-(\ln x-\mu)^{2}}{2 \sigma^{2}}\right\} \quad ; \quad x>0 .
\]

\section*{Examples Create a Lognormal Distribution Object Using Default Parameters}

Create a lognormal distribution object using the default parameter values.
```

pd = makedist('Lognormal')
pd =

```

LognormalDistribution
```

Lognormal distribution
mu = 0
sigma = 1

```

\section*{Create a Lognormal Distribution Object Using Specified Parameters}

Create a lognormal distribution object by specifying the parameter values.
```

pd = makedist('Lognormal','mu',5,'sigma',2)
pd =

```

\section*{LognormalDistribution}
```

Lognormal distribution
mu = 5
sigma = 2

```

Compute the mean of the lognormal distribution.
```

mean(pd)

```
ans =
\(1.0966 \mathrm{e}+03\)

The mean of the lognormal distribution is not equal to the mu parameter.
Generate random numbers from the lognormal distribution and compute their log values.
```

rng(47); % for reproducibility
x = random(pd,10000,1);
logx = log(x);

```

Compute the mean of the log values.
\(\mathrm{m}=\mathrm{mean}(\log \mathrm{x})\)
m =
4.9999

The mean of the \(\log\) of \(x\) is equal to the mu parameter of \(x\), since \(x\) has a lognormal distribution.

Plot logx.
hist(logx,50)

The plot shows that the log values of \(x\) are normally distributed with a mean equal to 5 and a standard deviation equal to 2 .

\section*{Purpose}

Lognormal probability density function

\section*{Syntax}

Description
\(Y=\) lognpdf( \(X, m u\), sigma \()\)
\(Y=\) lognpdf( \(X, \mathrm{mu}\), sigma \()\) returns values at \(X\) of the lognormal pdf with distribution parameters mu and sigma. mu and sigma are the mean and standard deviation, respectively, of the associated normal distribution. X , mu, and sigma can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for X , mu, or sigma is expanded to a constant array with the same dimensions as the other inputs.

The lognormal pdf is
\[
y=f(x \mid \mu, \sigma)=\frac{1}{x \sigma \sqrt{2 \pi}} e^{\frac{-(\ln x-\mu)^{2}}{2 \sigma^{2}}}
\]

The normal and lognormal distributions are closely related. If \(X\) is distributed lognormally with parameters \(\mu\) and \(\sigma\), then \(\log (X)\) is distributed normally with mean \(\mu\) and standard deviation \(\sigma\).

The mean \(m\) and variance \(v\) of a lognormal random variable are functions of \(\mu\) and \(\sigma\) that can be calculated with the lognstat function. They are:
\[
\begin{aligned}
& m=\exp \left(\mu+\sigma^{2} / 2\right) \\
& v=\exp \left(2 \mu+\sigma^{2}\right)\left(\exp \left(\sigma^{2}\right)-1\right)
\end{aligned}
\]

A lognormal distribution with mean \(m\) and variance \(v\) has parameters
\[
\begin{aligned}
& \mu=\log \left(m^{2} / \sqrt{v+m^{2}}\right) \\
& \sigma=\sqrt{\log \left(v / m^{2}+1\right)}
\end{aligned}
\]

\section*{lognpdf} must be positive, since \(\log (X)\) exists only when \(X\) is positive.

\section*{Examples}
```

x = (0:0.02:10);
y = lognpdf(x,0,1);
plot(x,y); grid;
xlabel('x'); ylabel('p')

```

- "Lognormal Distribution" on page B-64
}

\section*{Purpose}

Lognormal random numbers
Syntax
R = lognrnd(mu,sigma)
R = lognrnd(mu,sigma,m,n,...)
\(R\) = lognrnd(mu,sigma, \([m, n, \ldots])\)

\section*{Description}
\(R=\) lognrnd(mu, sigma) returns an array of random numbers generated from the lognormal distribution with parameters mu and sigma. mu and sigma are the mean and standard deviation, respectively, of the associated normal distribution. mu and sigma can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of R. A scalar input for mu or sigma is expanded to a constant array with the same dimensions as the other input.
\(R=\operatorname{lognrnd}(m u\), sigma, \(m, n, \ldots) \quad\) or \(R=\)
lognrnd(mu, sigma, \([m, n, \ldots]\) ) generates an \(m\)-by-n-by-... array. The mu, sigma parameters can each be scalars or arrays of the same size as R.

The normal and lognormal distributions are closely related. If \(X\) is distributed lognormally with parameters \(\mu\) and \(\sigma\), then \(\log (X)\) is distributed normally with mean \(\mu\) and standard deviation \(\sigma\).

The mean \(m\) and variance \(v\) of a lognormal random variable are functions of \(\mu\) and \(\sigma\) that can be calculated with the lognstat function. They are:
\[
\begin{aligned}
& m=\exp \left(\mu+\sigma^{2} / 2\right) \\
& v=\exp \left(2 \mu+\sigma^{2}\right)\left(\exp \left(\sigma^{2}\right)-1\right)
\end{aligned}
\]

A lognormal distribution with mean \(m\) and variance \(v\) has parameters
\[
\begin{aligned}
& \mu=\log \left(m^{2} / \sqrt{v+m^{2}}\right) \\
& \sigma=\sqrt{\log \left(v / m^{2}+1\right)}
\end{aligned}
\]

Examples Generate one million lognormally distributed random numbers with mean 1 and variance 2 :
```

m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));
[M,V]= lognstat(mu,sigma)
M =
1
V =
2.0000
X = lognrnd(mu,sigma,1,1e6);
MX = mean(X)
MX =
0.9974
VX = var(X)
VX =
1.9776

```

How To . "Lognormal Distribution" on page B-64

\section*{CompactClassificationDiscriminant.logP}

Purpose
Syntax
lp = logP(obj,Xnew)

Input
Arguments

\section*{Output}

Arguments

Log of the unconditional probability density
\(l p=\log P(o b j, X n e w)\) returns the log of the unconditional probability density of each row of Xnew, computed using the discriminant analysis model obj.
obi
Discriminant analysis classifier, produced using ClassificationDiscriminant.fit.

\section*{Xnew}

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in Xnew must equal the number of predictors in obj.

\section*{Ip}

Column vector with the same number of rows as Xnew. Each entry is the logarithm of the unconditional probability density of the corresponding row of Xnew.

\section*{Definitions}

\section*{Unconditional Probability Density}

The unconditional probability density of a point \(x\) of a discriminant analysis model is
\[
P(x)=\sum_{k=1}^{K} P(x, k),
\]
where \(P(x, k)\) is the conditional density of the model at \(x\) for class \(k\), when the total number of classes is \(K\).

The conditional density \(P(x, k)\) is

\section*{CompactClassificationDiscriminant.logP}
\[
P(x, k)=P(k) P(x \mid k),
\]
where \(P(k)\) is the prior probability of class \(k\), and \(P(x \mid k)\) is the conditional density of \(x\) given class \(k\). The conditional density function of the multivariate normal with mean \(\mu_{k}\) and covariance \(\Sigma_{k}\) at a point \(x\) is
\[
P(x \mid k)=\frac{1}{\left(2 \pi\left|\Sigma_{k}\right|\right)^{1 / 2}} \exp \left(-\frac{1}{2}\left(x-\mu_{k}\right)^{T} \Sigma_{k}^{-1}\left(x-\mu_{k}\right)\right),
\]
where \(\left|\Sigma_{k}\right|\) is the determinant of \(\Sigma_{k}\), and \(\Sigma_{k}^{-1}\) is the inverse matrix.

\section*{Examples}

\section*{\(\log \mathbf{P}\) Calculation}

Construct a discriminant analysis classifier for the Fisher iris data, and examine its prediction for an average measurement.

Load the Fisher iris data and construct a default discriminant analysis classifier.
```

load fisheriris
mdl = ClassificationDiscriminant.fit(meas,species);

```

Find the \(\log\) probability of the discriminant model applied to an average iris.
```

logpaverage = logP(mdl,mean(meas))
logpaverage =

```
    \(-1.7254\)

See Also CompactClassificationDiscriminant \| mahal \|
Concepts - "Discriminant Analysis" on page 14-3

\section*{Purpose}

Loss of \(k\)-nearest neighbor classifier
Syntax
L = loss(mdl, X,Y)
L = loss(mdl, X,Y,Name,Value)

\section*{Input Arguments}
\(\mathrm{L}=\) loss \((\mathrm{mdl}, \mathrm{X}, \mathrm{Y})\) returns a scalar representing how well mdl classifies the data in \(X\), when \(Y\) contains the true classifications.

When computing the loss, loss normalizes the class probabilities in \(Y\) to the class probabilities used for training, stored in the Prior property of mdl.

L = loss(mdl, X, Y, Name, Value) returns the loss with additional options specified by one or more Name, Value pair arguments.

\section*{mdl}
\(k\)-nearest neighbor classifier, created by ClassificationKNN.fit.

\section*{X}

Matrix of predictor values. Each column of \(X\) represents one variable, and each row represents one observation.

\section*{Y}

Grouping variables of response values with the same number of elements (rows) as \(X\). Each entry in \(Y\) is the response to the data in the corresponding row of \(X\).

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'lossfun '}

\section*{ClassificationKNN.loss}

Function handle or string representing a loss function. The built-in loss functions are:
- 'binodeviance ' - See "Loss Functions" on page 20-1403.
- 'exponential' - See "Loss Functions" on page 20-1403.
- 'classiferror' - Fraction of misclassified observations. See "Loss Functions" on page 20-1403.
- 'mincost' - Smallest misclassification cost as given by the mdl. Cost matrix. See "Loss Functions" on page 20-1403.

You can write your own loss function using the syntax described in "Loss Functions" on page 20-1403.

Default: 'mincost'

\section*{'weights'}

Numeric vector of length \(N\), where \(N\) is the number of rows of \(X\). weights are nonnegative. loss normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply weights, loss computes weighted classification loss.

Default: ones (N, 1)

\section*{Output Arguments}

\section*{Definitions}

L
Classification error, a scalar. The meaning of the error depends on the values in weights and lossfun. See "Classification Error" on page 20-1408.

\section*{Classification Error}

The default classification error is the fraction of data \(X\) that mdl misclassifies, where \(Y\) represents the true classifications.

The weighted classification error is the sum of weight \(i\) times the Boolean value that is 1 when mdl misclassifies the \(i\) th row of X , divided by the sum of the weights.

\section*{Loss Functions}

The built-in loss functions are:
- 'binodeviance' - For binary classification, assume the classes \(y_{n}\) are -1 and 1 . With weight vector \(w\) normalized to have sum 1, and predictions of row \(n\) of data \(X\) as \(f\left(X_{n}\right)\), the binomial deviance is
\[
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
\]
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is
\[
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
\]
- 'classiferror' - Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' - Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the Cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:
```

function loss = lossfun(C,S,W,COST)

```
- \(N\) is the number of rows of \(X\).
- \(K\) is the number of classes in the classifier, represented in the ClassNames property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.

\section*{ClassificationKNN.loss}
- \(S\) is an \(N\)-by-K numeric matrix. \(S\) is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.
- \(W\) is a numeric vector with \(N\) elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use COST = ones (K) - eye (K), which means a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

\section*{True Misclassification Cost}

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.
You can set the true misclassification cost per class in the Cost name-value pair when you run ClassificationKNN.fit. Cost( \(i, j\) ) is the cost of classifying an observation into class \(j\) if its true class is i. By default, \(\operatorname{Cost}(i, j)=1\) if \(i \sim=j\), and \(\operatorname{Cost}(i, j)=0\) if \(i=j\). In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

\section*{Expected Cost}

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of predict is the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier mdl. Suppose you have K classes. You place the observations into a matrix Xnew with one observation per row. The command
[label,score,cost] = predict(mdl,Xnew)

\section*{ClassificationKNN.loss}
returns, among other outputs, a cost matrix of size Nobs-by-K. Each row of the cost matrix contains the expected (average) cost of classifying the observation into each of the \(K\) classes. cost \((n, k)\) is
\[
\sum_{i=1}^{K} \hat{P}(i \mid X n e w(n)) C(k \mid i)
\]
where
- \(K\) is the number of classes.
- \(\hat{P}(i \mid \operatorname{Xnew}(n))\) is the posterior probability of class \(i\) for observation Xnew(n).
- \(C(k \mid i)\) is the true misclassification cost of classifying an observation as \(k\) when its true class is \(i\).

\section*{Examples}

\section*{Loss Calculation}

Construct a \(k\)-nearest neighbor classifier for the Fisher iris data, where \(k=5\).

Load the data.
load fisheriris
Construct a classifier for 5-nearest neighbors.
```

mdl = ClassificationKNN.fit(meas,species,'NumNeighbors',5);

```

Examine the loss of the classifier for a mean observation classified 'versicolor'.
\(X=\) mean(meas);
Y = \{'versicolor'\};
L = loss(mdl, X,Y)
L =

\section*{ClassificationKNN.loss}
0The classifier has no doubt that 'versicolor' is the correctclassification (all five nearest neighbors classify as 'versicolor').

\section*{CompactClassificationDiscriminant.loss}

\section*{'lossfun '}

Function handle or string representing a loss function. Built-in loss functions:
- 'binodeviance' - See "Loss Functions" on page 20-1409.
- 'classiferror' - Fraction of misclassified observations. See "Loss Functions" on page 20-1409.
- 'exponential' - See "Loss Functions" on page 20-1409.
- 'mincost' - Smallest misclassification cost as given by the obj . Cost matrix. See "Loss Functions" on page 20-1409.

You can write your own loss function using the syntax described in "Loss Functions" on page 20-1409.

Default: 'mincost'

\section*{'weights'}

Numeric vector of length \(N\), where \(N\) is the number of rows of \(X\). weights are nonnegative. loss normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply weights, loss computes weighted classification loss.

Default: ones ( \(\mathrm{N}, 1\) )

\section*{Output} Arguments

\section*{Definitions}

L
Classification error, a scalar. The meaning of the error depends on the values in weights and lossfun. See "Classification Error" on page 20-1408.

\section*{Classification Error}

The default classification error is the fraction of data \(X\) that obj misclassifies, where Y represents the true classifications.

\section*{CompactClassificationDiscriminant.loss}

Weighted classification error is the sum of weight \(i\) times the Boolean value that is 1 when obj misclassifies the \(i\) th row of X , divided by the sum of the weights.

\section*{Loss Functions}

The built-in loss functions are:
- 'binodeviance' - For binary classification, assume the classes \(y_{n}\) are -1 and 1 . With weight vector \(w\) normalized to have sum 1, and predictions of row \(n\) of data \(X\) as \(f\left(X_{n}\right)\), the binomial deviance is
\[
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
\]
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is
\[
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right) .
\]
- 'classiferror' - Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' - Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:
```

function loss = lossfun(C,S,W,COST)

```
- \(N\) is the number of rows of \(X\).
- \(K\) is the number of classes in the classifier, represented in the ClassNames property.
- \(C\) is an \(N\)-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.

\section*{CompactClassificationDiscriminant.loss}
- \(S\) is an \(N\)-by-K numeric matrix. \(S\) is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.
- \(W\) is a numeric vector with \(N\) elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use COST = ones (K) - eye (K), which means a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

\section*{Posterior Probability}

The posterior probability that a point \(z\) belongs to class \(j\) is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean \(\mu_{j}\) and covariance \(\Sigma_{j}\) at a point \(z\) is
\[
P(x \mid k)=\frac{1}{\left(2 \pi\left|\Sigma_{k}\right|\right)^{1 / 2}} \exp \left(-\frac{1}{2}\left(x-\mu_{k}\right)^{T} \Sigma_{k}^{-1}\left(x-\mu_{k}\right)\right),
\]
where \(\left|\Sigma_{k}\right|\) is the determinant of \(\Sigma_{k}\), and \(\Sigma_{k}^{-1}\) is the inverse matrix.
Let \(P(k)\) represent the prior probability of class \(k\). Then the posterior probability that an observation \(x\) is of class \(k\) is
\[
\hat{P}(k \mid x)=\frac{P(x \mid k) P(k)}{P(x)},
\]
where \(P(x)\) is a normalization constant, the sum over \(k\) of \(P(x \mid k) P(k)\).

\section*{Prior Probability}

The prior probability is one of three choices:

\section*{CompactClassificationDiscriminant.loss}
- 'uniform' - The prior probability of class k is one over the total number of classes.
- 'empirical' - The prior probability of class \(k\) is the number of training samples of class k divided by the total number of training samples.
- Custom - The prior probability of class k is the kth element of the prior vector. See ClassificationDiscriminant.fit.

After creating a classifier obj, you can set the prior by dot addressing:
```

obj.Prior = v;

```
where \(v\) is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

\section*{Cost}

The matrix of expected costs per observation is defined in "Cost" on page 14-8.

\section*{Examples Compute the resubstituted classification error for the Fisher iris data:}
```

load fisheriris
obj = ClassificationDiscriminant.fit(meas,species);
L = loss(obj,meas,species)
L =
0.0200

```

\section*{CompactClassificationEnsemble.loss}
specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. loss uses only these learners for calculating loss.

Default: 1:NTrained

\section*{'lossfun'}

Function handle or string representing a loss function. Built-in loss functions:
- 'binodeviance ' - See "Loss Functions" on page 20-1414
- 'classiferror' - Fraction of misclassified data
- 'exponential' - See "Loss Functions" on page 20-1414

You can write your own loss function in the syntax described in "Loss Functions" on page 20-1414.

Default: 'classiferror'

\section*{'mode'}

String representing the meaning of the output L:
- 'ensemble' - L is a scalar value, the loss for the entire ensemble.
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - \(L\) is a vector in which element \(J\) is obtained by using learners \(1: J\) from the input list of learners.

Default: 'ensemble'

\section*{CompactClassificationEnsemble.loss}

\section*{'UseObsForLearner'}

A logical matrix of size N -by-T, where:
- \(N\) is the number of rows of \(X\).
- T is the number of weak learners in ens.

When UseObsForLearner( \(\mathrm{i}, \mathrm{j})\) is true, learner j is used in predicting the class of row i of \(X\).

Default: \(\operatorname{true}(\mathrm{N}, \mathrm{T})\)

\section*{'weights'}

Vector of observation weights, with nonnegative entries. The length of weights must equal the number of rows in \(X\). When you specify weights, loss normalizes the weights so that observation weights in each class sum to the prior probability of that class.

Default: ones(size(X,1),1)

\section*{Output L}

Arguments

\section*{Definitions}

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

\section*{Classification Error}

The default classification error is the fraction of the data \(X\) that ens misclassifies, where Y are the true classifications.

Weighted classification error is the sum of weight \(i\) times the Boolean value that is 1 when tree misclassifies the \(i\) th row of X , divided by the sum of the weights.

\section*{Loss Functions}

The built-in loss functions are:

\section*{CompactClassificationEnsemble.loss}
- 'binodeviance' - For binary classification, assume the classes \(y_{n}\) are - 1 and 1 . With weight vector \(w\) normalized to have sum 1, and predictions of row \(n\) of data \(X\) as \(f\left(X_{n}\right)\), the binomial deviance is
\[
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
\]
- 'classiferror' - Fraction of misclassified data, weighted by \(w\).
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is
\[
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
\]

To write your own loss function, create a function file of the form
```

function loss = lossfun(C,S,W,COST)

```
- \(N\) is the number of rows of ens. \(X\).
- K is the number of classes in ens, represented in ens.ClassNames.
- C is an N -by-K logical matrix, with one true per row for the true class. The index for each class is its position in tree.ClassNames.
- \(S\) is an \(N\)-by-K numeric matrix. \(S\) is a matrix of posterior probabilities for classes with one row per observation, similar to the score output from predict.
- \(W\) is a numeric vector with \(N\) elements, the observation weights.
- COST is a K-by-K numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

\section*{CompactClassificationEnsemble.loss}

\section*{See Also \\ loss | edge | margin | predict}

\section*{CompactClassificationTree.loss}
Purpose
Syntax

Description

Classification error
L = loss(tree, \(\mathrm{X}, \mathrm{Y}\) )
L = loss(tree, \(\mathrm{X}, \mathrm{Y}\), Name, Value)
L = loss(tree, X, Y, 'subtrees', subtreevector)
[L,se] = loss(tree, X,Y,'subtrees',subtreevector)
[L,se,NLeaf] = loss(tree, \(\mathrm{X}, \mathrm{Y}\), 'subtrees', subtreevector)
[L,se,NLeaf,bestlevel] = loss(tree, X,Y,'subtrees', subtreevector)
[L,...] =
loss(tree, \(\mathrm{X}, \mathrm{Y}\), 'subtrees', subtreevector, Name, Value)

\section*{Description}
\(\mathrm{L}=\) loss(tree, \(\mathrm{X}, \mathrm{Y})\) returns a scalar representing how well tree classifies the data in \(X\), when \(Y\) contains the true classifications.

When computing the loss, loss normalizes the class probabilities in \(Y\) to the class probabilities used for training, stored in the Prior property of tree.
\(\mathrm{L}=\) loss (tree, \(\mathrm{X}, \mathrm{Y}\), Name, Value) returns the loss with additional options specified by one or more Name, Value pair arguments.

L = loss(tree, X, Y, 'subtrees', subtreevector) returns a vector of classification errors for the trees in the pruning sequence subtreevector.
[L,se] = loss(tree, \(\mathrm{X}, \mathrm{Y}\), 'subtrees', subtreevector) returns the vector of standard errors of the classification errors.

Note loss returns se and further outputs only when the lossfun name-value pair is the default 'classiferror'.
[L, se, NLeaf] = loss(tree, X, Y,'subtrees', subtreevector) returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

\section*{CompactClassificationTree.loss}

\end{aligned}
\]

\section*{CompactClassificationTree.loss}

Function handle or string representing a loss function. Built-in loss functions:
- 'binodeviance ' - See "Loss Functions" on page 20-1421
- 'classiferror' - Fraction of misclassified observations. See "Loss Functions" on page 20-1421.
- 'exponential' - See "Loss Functions" on page 20-1421
- 'mincost' - Smallest misclassification cost as given by the tree. Cost matrix. See "Loss Functions" on page 20-1421.

You can write your own loss function in the syntax described in "Loss Functions" on page 20-1421.

Default: 'mincost'

\section*{'weights'}

A numeric vector of length \(N\), where \(N\) is the number of rows of \(X\). weights are nonnegative. loss normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply weights, loss computes weighted classification loss.

Default: ones( \(\mathrm{N}, 1\) )
Name, Value arguments associated with pruning subtrees:

\section*{'subtrees'}

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level max(tree. PruneList). You can set subtrees to 'all', meaning the entire pruning sequence.

Default: 0

\section*{'treesize'}

\section*{CompactClassificationTree.loss}

One of the following strings:
- 'se' - loss returns the highest pruning level with loss within one standard deviation of the minimum ( \(L+s e\), where \(L\) and se relate to the smallest value in subtrees).
- 'min' - loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

\section*{Output Arguments}

\section*{Definitions}

L
Classification error, a vector the length of subtrees. The meaning of the error depends on the values in weights and lossfun; see "Classification Error" on page 20-1420.
se
Standard error of loss, a vector the length of subtrees.

\section*{NLeaf}

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

\section*{bestlevel}

A scalar whose value depends on treesize:
- treesize \(=\) 'se' - loss returns the highest pruning level with loss within one standard deviation of the minimum ( \(\mathrm{L}+\mathrm{se}\), where \(L\) and se relate to the smallest value in subtrees).
- treesize \(=\) 'min' - loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

\section*{Classification Error}

The default classification error is the fraction of data \(X\) that tree misclassifies, where \(Y\) represents the true classifications.

\section*{CompactClassificationTree.loss}

Weighted classification error is the sum of weight \(i\) times the Boolean value that is 1 when tree misclassifies the \(i\) th row of X , divided by the sum of the weights.

\section*{Loss Functions}

The built-in loss functions are:
- 'binodeviance' - For binary classification, assume the classes \(y_{n}\) are -1 and 1 . With weight vector \(w\) normalized to have sum 1, and predictions of row \(n\) of data \(X\) as \(f\left(X_{n}\right)\), the binomial deviance is
\[
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
\]
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is
\[
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right) .
\]
- 'classiferror' - Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' - Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the Cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:
```

function loss = lossfun(C,S,W,COST)

```
- \(N\) is the number of rows of \(X\).
- \(K\) is the number of classes in the classifier, represented in the ClassNames property.
- \(C\) is an \(N\)-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.

\section*{CompactClassificationTree.loss}
- \(S\) is an \(N\)-by-K numeric matrix. \(S\) is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.
- \(W\) is a numeric vector with \(N\) elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use COST = ones (K) - eye (K), which means a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

\section*{True Misclassification Cost}

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the Cost name-value pair when you create the classifier using the ClassificationTree.fit method. Cost( \(i, j\) ) is the cost of classifying an observation into class \(j\) if its true class is \(i\). By default, \(\operatorname{Cost}(i, j)=1\) if \(i \sim=j\), and \(\operatorname{Cost}(i, j)=0\) if \(i=j\). In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

\section*{Expected Misclassification Cost}

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier. Suppose you have K classes. You place the observations into a matrix Xnew with one observation per row.

\section*{CompactClassificationTree.loss}

The expected cost matrix CE has size Nobs-by-K. Each row of CE contains the expected (average) cost of classifying the observation into each of the \(K\) classes. \(\operatorname{CE}(\mathrm{n}, \mathrm{k})\) is
\[
\sum_{i=1}^{K} \hat{P}(i \mid X n e w(n)) C(k \mid i)
\]
where
- \(K\) is the number of classes.
- \(\hat{P}(i \mid \operatorname{Xnew}(n))\) is the posterior probability of class \(i\) for observation Xnew(n).
- \(C(k \mid i)\) is the true misclassification cost of classifying an observation as \(k\) when its true class is \(i\).

\section*{Score (tree)}

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when \(\mathrm{X}<0.15\) or \(X>0.95\), and \(X\) is false otherwise.

1
Generate 100 random points and classify them:
```

rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - . 55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')

```

\section*{CompactClassificationTree.loss}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Click to display: & Identity & \(\checkmark\) & Magnification: & 100\% & \(\checkmark\) & Pruning level: & 0 of 2 & - \\
\hline
\end{tabular}

2
Prune the tree:
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')

\section*{CompactClassificationTree.loss}

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than . 15 should be about \(.05 / .85=.06\) for true, and about \(.8 / .85=.94\) for false.

\section*{3}

Compute the prediction scores for the first 10 rows of X :
```

[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
ans =

| 0.9059 | 0.0941 | 0.8147 |
| ---: | ---: | ---: |
| 0.9059 | 0.0941 | 0.9058 |
| 0 | 1.0000 | 0.1270 |
| 0.9059 | 0.0941 | 0.9134 |
| 0.9059 | 0.0941 | 0.6324 |
| 0 | 1.0000 | 0.0975 |

    0.9059 0.0941 0.2785
    ```

\section*{CompactClassificationTree.loss}
\begin{tabular}{lll}
0.9059 & 0.0941 & 0.5469 \\
0.9059 & 0.0941 & 0.9575 \\
0.9059 & 0.0941 & 0.9649
\end{tabular}

Indeed, every value of \(X\) (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1 , while the other values of \(X\) have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in \(X\) in the range \((.95,1)\) instead of the expected 5 observations.

\section*{Examples Compute the resubstituted classification error for the ionosphere data:}
```

load ionosphere
tree = ClassificationTree.fit(X,Y);
L = loss(tree,X,Y)
L =
0.0114

```

See Also margin | edge | predict

\section*{CompactRegressionEnsemble.loss}

\section*{Purpose Regression error}

Syntax \(\quad L=\) loss (ens \(, X, Y\) )
L = loss(ens, \(\mathrm{X}, \mathrm{Y}\), Name, Value)

Description

\section*{Input Arguments}
\(\mathrm{L}=\) loss (ens, \(\mathrm{X}, \mathrm{Y}\) ) returns the mean squared error between the predictions of ens to the data in X , compared to the true responses Y .
\(\mathrm{L}=\) loss(ens, \(\mathrm{X}, \mathrm{Y}\), Name, Value) computes the error in prediction with additional options specified by one or more Name, Value pair arguments.

\section*{ens}

A regression ensemble created with fitensemble, or the compact method.

\section*{X}

A matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

NaN values in \(X\) are taken to be missing values. Observations with all missing values for \(X\) are not used in the calculation of loss.

\section*{Y}

A numeric column vector with the same number of rows as \(X\). Each entry in \(Y\) is the response to the data in the corresponding row of \(X\).

NaN values in Y are taken to be missing values. Observations with missing values for Y are not used in the calculation of loss.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{CompactRegressionEnsemble.loss}

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NTrained

\section*{'lossfun'}

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle fun, loss calls it as
fun(Y,Yfit,W)
where \(\mathrm{Y}, \mathrm{Yfit}\), and W are numeric vectors of the same length.
- Y is the observed response.
- Yfit is the predicted response.
- \(W\) is the observation weights.

The returned value fun(Y,Yfit, W) should be a scalar.
Default: 'mse'

\section*{'mode'}

String representing the meaning of the output L:
- 'ensemble' - L is a scalar value, the loss for the entire ensemble.
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - \(L\) is a vector in which element \(J\) is obtained by using learners \(1: J\) from the input list of learners.

\title{
CompactRegressionEnsemble.loss
}

Default: 'ensemble'

\section*{'UseObsForLearner'}

A logical matrix of size N -by-NTrained, where N is the number of observations in ens.X, and NTrained is the number of weak learners. When UseObsForLearner (I, J) is true, predict uses learner \(J\) in predicting observation I.

Default: true(N,NTrained)

\section*{'weights'}

Numeric vector of observation weights with the same number of elements as Y. The formula for loss with weights is in "Weighted Mean Squared Error" on page 20-1429.

Default: ones(size(Y))

\section*{Output} Arguments

\section*{Definitions}

\section*{Weighted Mean Squared Error}

Let \(n\) be the number of rows of data, \(x_{j}\) be the \(j\) th row of data, \(y_{j}\) be the true response to \(x_{j}\), and let \(f\left(x_{j}\right)\) be the response prediction of ens to \(x_{j}\). Let \(w\) be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: \(w \rightarrow w / \Sigma w\). The mean squared error \(L\) is
\[
L=\sum_{j=1}^{n} w_{j}\left(f\left(x_{j}\right)-y_{j}\right)^{2} .
\]

Examples Find the loss of an ensemble predictor of the carsmall data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

\section*{CompactRegressionEnsemble.loss}
```

load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
L = loss(ens,X,MPG)
L =
4.3904

```
See Also predict | fitensemble

\section*{CompactRegressionTree.loss}

\section*{Purpose \\ Syntax \\ Description}

\section*{Input Arguments}

L = loss(tree, X,Y)
[L,se] = loss(tree, X, Y)
[L,se,NLeaf] = loss(tree, X,Y)
[L,se,NLeaf,bestlevel] = loss(tree, X,Y)
L = loss(tree, X, Y, Name, Value)
Regression error
\(\mathrm{L}=\) loss (tree, \(\mathrm{X}, \mathrm{Y})\) returns the mean squared error between the predictions of tree to the data in X , compared to the true responses Y .
[L,se] = loss(tree, X,Y) returns the standard error of the loss.
[L,se,NLeaf] = loss(tree, \(X, Y\) ) returns the number of leaves (terminal nodes) in the tree.
[L,se,NLeaf,bestlevel] = loss(tree, X, Y) returns the optimal pruning level for tree.

L = loss(tree, \(\mathrm{X}, \mathrm{Y}\), Name, Value) computes the error in prediction with additional options specified by one or more Name, Value pair arguments.

\section*{tree}

Regression tree created with RegressionTree.fit, or the compact method.

\section*{X}

A matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

\section*{Y}

A numeric column vector with the same number of rows as \(X\). Each entry in \(Y\) is the response to the data in the corresponding row of \(X\).

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding

\section*{CompactRegressionTree.loss}
value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'lossfun'}

Function handle for loss, or the string 'mse' representing mean-squared error. If you pass a function handle fun, loss calls fun as:
fun(Y,Yfit,W)
- \(Y\) is the vector of true responses.
- Yfit is the vector of predicted responses.
- W is the observation weights. If you pass W , the elements are normalized to sum to 1 .

All the vectors have the same number of rows as Y .
Default: 'mse'

\section*{'subtrees'}

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level max(tree. PruneList). You can set subtrees to 'all', meaning the entire pruning sequence.

Default: 0

\section*{'treesize'}

A string, either:
- 'se' - loss returns bestlevel that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.

\section*{CompactRegressionTree.loss}
- 'min' - loss returns bestlevel that corresponds to the minimal MSE tree.

\section*{'weights'}

Numeric vector of observation weights with the same number of elements as Y.

Default: ones(size(Y))

\section*{Output \\ Arguments}

L
Classification error, a vector the length of subtrees. The error for each tree is the mean squared error, weighted with weights. If you include lossfun, L reflects the loss calculated with lossfun.
se
Standard error of loss, a vector the length of subtrees.

\section*{NLeaf}

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

\section*{bestlevel}

A scalar whose value depends on treesize:
- treesize \(=\) 'se' - loss returns the highest pruning level with loss within one standard deviation of the minimum ( \(L+s e\), where \(L\) and se relate to the smallest value in subtrees).
- treesize \(=\) 'min' - loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

\section*{Mean Squared Error}

The mean squared error \(m\) of the predictions \(f\left(X_{n}\right)\) with weight vector \(w\) is

\section*{CompactRegressionTree.loss}
\[
m=\frac{\sum w_{n}\left(f\left(X_{n}\right)-Y_{n}\right)^{2}}{\sum w_{n}} .
\]

\section*{Examples}

Find the loss of a regression tree predictor of the carsmall data to find MPG as a function of engine displacement, horsepower, and vehicle weight:
```

load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
L = loss(tree,X,MPG)
L =
4.8952

```

Find the pruning level that gives the optimal level of loss for the carsmall data:
```

load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
[L,se,NLeaf,bestlevel] = loss(tree,X,MPG,'Subtrees','all');
bestlevel
bestlevel =
4

```
```

Purpose Lower Pareto tails parameters
Syntax params = lowerparams(obj)
Description params = lowerparams(obj) returns the 2-element vector params of shape and scale parameters, respectively, of the lower tail of the Pareto tails object obj. lowerparams does not return a location parameter.
Examples $\quad$ Fit Pareto tails to a $t$ distribution at cumulative probabilities 0.1 and 0.9 :
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
lowerparams(obj)
ans =

\section*{qrandstream.lt}

Purpose Less than relation for handles

\section*{Syntax \\ h1 < h2}

Description \(\quad \mathrm{h} 1<\mathrm{h} 2\) performs element-wise comparisons between handle arrays h 1 and h2. h 1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise < result.

If one of h 1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.
\(\mathrm{tf}=\mathrm{lt}(\mathrm{h} 1, \mathrm{~h} 2)\) stores the result in a logical array of the same dimensions.

See Also qrandstream | eq | ge | gt | le | ne

\section*{Purpose}

Add least-squares line to scatter plot

\section*{Syntax}
lsline
h = lsline
lsline superimposes a least-squares line on each scatter plot in the current axes. Scatter plots are produced by the MATLAB scatter and plot functions. Data points connected with solid, dashed, or dash-dot lines ('-', '--', or '.-') are not considered to be scatter plots by lsline, and are ignored.
\(\mathrm{h}=\) lsline returns a column vector of handles h to the least-squares lines.

\section*{Examples}

Use lsline together with scatter plots produced by scatter and various line styles of plot:
```

x = 1:10;
y1 = x + randn(1,10);
scatter(x,y1,25,'b','*')
hold on
y2 = 2*x + randn(1,10);
plot(x,y2,'mo')
y3 = 3*x + randn(1,10);
plot(x,y3,'rx:')
y4 = 4*x + randn(1,10);
plot(x,y4,'g+--')
lsline

```

\section*{Isline}

Purpose Mean or median absolute deviation
Syntax \(\quad\)\begin{tabular}{l}
\(y=\operatorname{mad}(X)\) \\
\(Y=\operatorname{mad}(X, 1)\) \\
\(Y=\operatorname{mad}(X, 0)\)
\end{tabular}
\(y=\operatorname{mad}(X)\) returns the mean absolute deviation of the values in \(X\). For vector input, \(y\) is mean \((\operatorname{abs}(X-m e a n(X)))\). For a matrix input, \(y\) is a row vector containing the mean absolute deviation of each column of X. For \(N\)-dimensional arrays, mad operates along the first nonsingleton dimension of \(X\).
\(Y=\operatorname{mad}(X, 1)\) returns the median absolute deviation of the values in \(X\). For vector input, y is median(abs(X-median(X))). For a matrix input, \(y\) is a row vector containing the median absolute deviation of each column of X . For \(N\)-dimensional arrays, mad operates along the first nonsingleton dimension of \(X\).
\(Y=\operatorname{mad}(X, 0)\) is the same as mad \((X)\), and returns the mean absolute deviation of the values in \(X\).
\(\operatorname{mad}(X, f l a g, d i m)\) computes absolute deviations along the dimension dim of X . flag is 0 or 1 to indicate mean or median absolute deviation, respectively.
mad treats NaNs as missing values and removes them.
For normally distributed data, multiply mad by one of the following factors to obtain an estimate of the normal scale parameter \(\sigma\) :
- sigma \(=1.253^{*}\) mad \((X, 0)\) - For mean absolute deviation
- sigma \(=1.4826 * \operatorname{mad}(X, 1)-\) For median absolute deviation

\section*{Examples}

The following compares the robustness of different scale estimates for normally distributed data in the presence of outliers:
```

x = normrnd(0,1,1,50);
xo = [x 10]; % Add outlier

```
```

r1 = std(xo)/std(x)
r1 =
1.7385
r2 = mad(x0,0)/mad(x,0)
r2 =
1.2306
r3 = mad(xo,1)/mad(x,1)
r3 =
1.0602

```

```

Purpose Mahalanobis distance
Syntax d = mahal (Y,X)
Description d = mahal( }\textrm{Y},\textrm{X})\mathrm{ computes the Mahalanobis distance (in squared units)
of each observation in Y from the reference sample in matrix X. If Y is
n-by-m, where n}\mathrm{ is the number of observations and m}\mathrm{ is the dimension
of the data, d is n-by-1. X and Y must have the same number of columns,
but can have different numbers of rows. X must have more rows than
columns.
For observation I, the Mahalanobis distance is defined by $d(I)=$ (Y(I,:)-mu)*inv(SIGMA)*(Y(I,:)-mu)', where mu and SIGMA are the sample mean and covariance of the data in $X$. mahal performs an equivalent, but more efficient, computation.

```

\section*{Examples Generate some correlated bivariate data in \(X\) and compare the}
``` Mahalanobis and squared Euclidean distances of observations in \(Y\) :
```

```
X = mvnrnd([0;0],[1 .9;.9 1],100);
```

X = mvnrnd([0;0],[1 .9;.9 1],100);
Y = [1 1;1 -1;-1 1;-1 -1];
Y = [1 1;1 -1;-1 1;-1 -1];
d1 = mahal(Y,X) % Mahalanobis
d1 = mahal(Y,X) % Mahalanobis
d1 =
d1 =
1.3592
1.3592
21.1013
21.1013
23.8086
23.8086
1.4727
1.4727
d2 = sum((Y-repmat(mean(X),4,1)).^2, 2) % Squared Euclidean
d2 = sum((Y-repmat(mean(X),4,1)).^2, 2) % Squared Euclidean
d2 =
d2 =
1.9310
1.9310
1.8821
1.8821
2.1228
2.1228
2.0739
2.0739
scatter(X(:,1),X(:,2))

```
scatter(X(:,1),X(:,2))
```

```
hold on
scatter(Y(:, 1),Y(:, 2),100,d1,'*','LineWidth', 2)
hb = colorbar;
ylabel(hb,'Mahalanobis Distance')
legend('X','Y','Location','NW')
```

The observations in $Y$ with equal coordinate values are much closer to $X$ in Mahalanobis distance than observations with opposite coordinate values, even though all observations are approximately equidistant from the mean of X in Euclidean distance. The Mahalanobis distance, by considering the covariance of the data and the scales of the different variables, is useful for detecting outliers in such cases.

## CompactClassificationDiscriminant.mahal

## Purpose Mahalanobis distance to class means

M = mahal(obj, X)
M = mahal(obj, X,Name, Value)

Description $\quad M=\operatorname{mahal}(\mathrm{obj}, \mathrm{X})$ returns the squared Mahalanobis distances from

## Syntax

Input Arguments observations in $X$ to the class means in obj.
$M=$ mahal(obj, X, Name, Value) computes the squared Mahalanobis distance with additional options specified by one or more Name, Value pair arguments.
obi
Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with ClassificationDiscriminant.fit.

## X

Numeric matrix of size $n$-by- $p$, where $p$ is the number of predictors in obj, and $n$ is any positive integer. mahal computes the Mahalanobis distances from the rows of $X$ to each of the $K$ means of the classes in obj.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'ClassLabels'

Class labels consisting of $n$ elements of obj.Y, where $n$ is the number of rows of $X$.

## CompactClassificationDiscriminant.mahal

## Output <br> Arguments

## Definitions

Examples Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas,species,...
    'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))
mahadist =
    220.0667 5.0254 30.5804
```

See Also CompactClassificationDiscriminant \| mahal \| gmdistribution
How To . "Discriminant Analysis" on page 14-3

Purpose
Mahalanobis distance to component means

## Syntax <br> D = mahal (obj, X)

$\mathrm{D}=$ mahal $(\mathrm{obj}, \mathrm{X})$ computes the Mahalanobis distance (in squared units) of each observation in X to the mean of each of the $k$ components of the Gaussian mixture distribution defined by obj. obj is an object created by gmdistribution or fit. X is an $n$-by- $d$ matrix, where $n$ is the number of observations and $d$ is the dimension of the data. D is $n$-by- $k$, with $\mathrm{D}(\mathrm{I}, \mathrm{J})$ the distance of observation I from the mean of component J.

## Examples

Generate data from a mixture of two bivariate Gaussian distributions using the mvnrnd function:

```
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];
scatter(X(:,1),X(:,2),10,'.')
hold on
```

## gmdistribution.mahal

Fit a two-component Gaussian mixture model:

```
obj = gmdistribution.fit(X,2);
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Compute the Mahalanobis distance of each point in $X$ to the mean of each component of obj:

```
D = mahal(obj,X);
delete(h)
scatter(X(:,1),X(:,2),10,D(:,1),'.')
hb = colorbar;
ylabel(hb,'Mahalanobis Distance to Component 1')
```

## gmdistribution.mahal

See Also gmdistribution | cluster | posterior | mahal

## Purpose

Syntax

## Description

Main effects plot for grouped data

```
maineffectsplot(Y,GROUP)
maineffectsplot(Y,GROUP,param1,val1,param2,val2,...)
[figh,AXESH] = maineffectsplot(...)
```

maineffectsplot (Y,GROUP) displays main effects plots for the group means of matrix $Y$ with groups defined by entries in the cell array GROUP. $Y$ is a numeric matrix or vector. If $Y$ is a matrix, the rows represent different observations and the columns represent replications of each observation. Each cell of GROUP must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. GROUP can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as Y . The number of grouping variables must be greater than 1 .
The display has one subplot per grouping variable, with each subplot showing the group means of $Y$ as a function of one grouping variable.
maineffectsplot(Y,GROUP,param1,val1,param2,val2,...) specifies one or more of the following name/value pairs:

- 'varnames ' - Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2', ... .
- 'statistic' - String values that indicate whether the group mean or the group standard deviation should be plotted. Use 'mean' or 'std'. The default is 'mean'. If the value is 'std', $Y$ is required to have multiple columns.
- 'parent' - A handle to the figure window for the plots. The default is the current figure window.
[figh,AXESH] = maineffectsplot(...) returns the handle figh to the figure window and an array of handles AXESH to the subplot axes.

## maineffectsplot

Examples
Display main effects plots for car weight with two grouping variables, model year and number of cylinders:
load carsmall;
maineffectsplot(Weight, \{Model_Year, Cylinders\}, ...
'varnames',\{'Model Year','\# of Cylinders'\})

See Also interactionplot | multivarichart
How To

- "Grouping Variables" on page 2-51

## ClassificationDiscriminant.make

## Purpose

Construct discriminant analysis classifier from parameters
Syntax

Description

Tips

Input
Arguments

```
cobj = ClassificationDiscriminant.make(Mu,Sigma)
cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value)
```

cobj = ClassificationDiscriminant.make(Mu,Sigma) constructs a compact discriminant analysis classifier from the class means Mu and covariance matrix Sigma.
cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value) constructs a compact classifier with additional options specified by one or more Name, Value pair arguments.

- You can change the discriminant type using dot addressing after constructing cobj:
cobj.DiscrimType = 'discrimType'
where discrimType is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.
- cobj is a linear classifier when Sigma is a matrix. cobj is a quadratic classifier when Sigma is a three-dimensional array.

## Mu

Matrix of class means of size K-by-p, where $K$ is the number of classes, and $p$ is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

## Sigma

Within-class covariance matrix or matrices.

## ClassificationDiscriminant.make

- For a linear discriminant, Sigma is a symmetric, positive semidefinite matrix of size $p$-by- $p$, where $p$ is the number of predictors.
- For a quadratic discriminant, Sigma is an array of size p-by-p-by-K, where K is the number of classes. For each i, Sigma(:,:,i) is a symmetric, positive semidefinite matrix.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'ClassNames'

Array of class names. Use any data type for a grouping variable: a numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings.

ClassNames names the classes, as ordered in Mu.
Default: 1:K, where K is the number of classes (the number of rows of Mu)

## 'Cost'

Square matrix, where $\operatorname{Cost}(i, j)$ is the cost of classifying a point into class $j$ if its true class is i. Alternatively, Cost can be a structure S having two fields: S . ClassNames containing the group names as a variable of the same type as Y , and S.ClassificationCosts containing the cost matrix.

Default: $\operatorname{Cost}(i, j)=1$ if $i \sim=j$, and $\operatorname{Cost}(i, j)=0$ if $i=j$

## 'PredictorNames'

## ClassificationDiscriminant.make

Cell array of names for the predictor variables, in the order in which they appear in $X$.

Default: \{'x1','x2',...\}

## 'prior'

Prior probabilities for each class. Specify as one of:

- 'uniform', a string meaning all class prior probabilities are equal
- A vector (one scalar value for each class)
- A structure S with two fields:
- S.ClassNames containing the class names as a variable of the same type as ClassNames
- S.ClassProbs containing a vector of corresponding probabilities

Default: 'uniform'

## 'ResponseName'

Name of the response variable Y , a string.
Default: ' $Y$ '

## Output Arguments

## Examples

cobi
Discriminant analysis classifier, of class CompactClassificationDiscriminant.

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data:

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
```

## ClassificationDiscriminant.make

```
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));
mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
CC = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})
cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
        ResponseName: 'Y'
            ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
        DiscrimType: 'linear'
            Mu: [3\times4 double]
            Coeffs: [3x3 struct]
```

See Also ClassificationDiscriminant.fit | compact | CompactClassificationDiscriminant
How To - "Discriminant Analysis" on page 14-3

Purpose
Syntax

Description

Input Arguments

Create probability distribution object

```
pd = makedist(distname)
pd = makedist(distname,Name,Value)
```

pd = makedist(distname) creates a probability distribution object for the distribution distname, using the default parameter values.
pd = makedist(distname, Name, Value) creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

## distname - Distribution name

string
Distribution name, specified as one of the following strings. The distribution specified by distname determines the class type of the returned probability distribution object.

| Distribution Name | Description | Distribution Class |
| :--- | :--- | :--- |
| 'Beta' | Beta distribution | prob.BetaDistribution |
| 'Binomial' | Binomial distribution | prob.BinomialDistribution |
| 'BirnbaumSaunders' | Birnbaum-Saunders <br> distribution | prob.BirnbaumSaundersDistribl |
| 'Burr' | Burr distribution | prob.BurrDistribution |

## makedist

| Distribution Name | Description | Distribution Class |
| :--- | :--- | :--- |
| 'GeneralizedPareto' | Generalized Pareto <br> distribution | prob.GeneralizedParetoDistributi |
| 'InverseGaussian' | Inverse Gaussian <br> distribution | prob.InverseGaussianDistribution |
| 'Logistic' | Logistic distribution | prob.LogisticDistribution |
| 'Loglogistic' | Loglogistic <br> distribution | prob.LoglogisticDistribution |
| 'Lognormal' | Lognormal <br> distribution | prob.LognormalDistribution |
| 'Multinomial' | Multinomial <br> distribution | prob.MultinomialDistribution |
| 'Nakagami' | Nakagami <br> distribution | prob.NakagamiDistribution |
| 'NegativeBinomial' | Negative Binomial <br> distribution | prob.NegativeBinomialDistributio |
| 'Normal' | Normal distribution | prob.NormalDistribution |
| 'PiecewiseLinear' | Piecewise Linear <br> distribution | prob.PiecewiseLinearDistribution |
| 'Poisson' | Poisson distribution | prob.PoissonDistribution |
| 'Rayleigh' | Rayleigh distribution | prob.RayleighDistribution |
| 'Rician' | Rician distribution | prob.RicianDistribution |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

Example: makedist('Normal','mu',10) specifies a normal distribution with parameter mu equal to 10 , and parameter sigma equal to the default value of 1 .

## Beta Distribution

## Output pd - Probability distribution

```
Arguments
probability distribution object
Probability distribution, returned as a probability distribution object of the type specified by distname.
```

## Examples Create a Normal Distribution Object

```
Create a normal distribution object using the default parameter values.
```

```
pd = makedist('Normal')
```

pd = makedist('Normal')
pd =
NormalDistribution

```
```

    Normal distribution
    ```
    Normal distribution
        mu = 0
        mu = 0
        sigma = 1
        sigma = 1
Compute the interquartile range of the distribution.
```

```
r = iqr(pd)
```

```
r = iqr(pd)
```

1.3490

## Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
pd =
    GammaDistribution
    Gamma distribution
        a = 1
        b = 1
```

Compute the mean of the gamma distribution.

```
mean = mean(pd)
```

mean =
1
Specify Parameters for a Normal Distribution Object
Create a normal distribution object with parameter values mu $=75$
and sigma $=10$.
pd = makedist('Normal','mu',75,'sigma',10)
pd =

NormalDistribution

```

## makedist

## Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value $\mathrm{a}=3$ and the default value $b=1$.
pd = makedist('Gamma','a',3)
pd =
GammaDistribution

Gamma distribution
a $=3$
b $=1$

## Alternative Functionality

## App

dfittool opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object.

See Also fitdist | dfittool

## Purpose <br> Syntax <br> Description

One-way multivariate analysis of variance
d = manova1 (X,group)
d = manova1(X,group,alpha)
[d,p] = manova1(...)
[d,p,stats] = manova1(...)
d = manova1 (X, group) performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of X , grouped by group. X is an $m$-by- $n$ matrix of data values, and each row is a vector of measurements on $n$ variables for a single observation. group is a grouping variable defined as a categorical variable, vector, string array, or cell array of strings. Two observations are in the same group if they have the same value in the group array. The observations in each group represent a sample from a population.

The function returns d, an estimate of the dimension of the space containing the group means. manova1 tests the null hypothesis that the means of each group are the same $n$-dimensional multivariate vector, and that any difference observed in the sample X is due to random chance. If $d=0$, there is no evidence to reject that hypothesis. If $d=1$, then you can reject the null hypothesis at the $5 \%$ level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if $d=2$ the multivariate means may lie on the same plane in $n$-dimensional space, but not on the same line.
d = manova1 ( X, group, alpha) gives control of the significance level, alpha. The return value $d$ will be the smallest dimension having $\mathrm{p}>$ alpha, where p is a $p$-value for testing whether the means lie in a space of that dimension.
$[\mathrm{d}, \mathrm{p}]=$ manova1(...) also returns a p , a vector of $p$-values for testing whether the means lie in a space of dimension 0,1 , and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of $p$ for each dimension up to, but not including, the largest.

If the $i$ th $p$-value is near zero, this casts doubt on the hypothesis that the group means lie on a space of $i-1$ dimensions. The choice of a
critical $p$-value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument alpha. It is common to declare a result significant if the $p$-value is less than 0.05 or 0.01 .
[d,p,stats] = manova1(...) also returns stats, a structure containing additional MANOVA results. The structure contains the following fields.

| Field | Contents |
| :--- | :--- |
| W | Within-groups sum of squares and cross-products <br> matrix |
| B | Between-groups sum of squares and cross-products <br> matrix |
| T | Total sum of squares and cross-products matrix |
| dfW | Degrees of freedom for $W$ |
| dfB | Degrees of freedom for B |
| dfT | Degrees of freedom for T |
| lambda | Vector of values of Wilk's lambda test statistic for <br> testing whether the means have dimension 0,1, etc. |
| chisq | Transformation of lambda to an approximate <br> chi-square distribution |
| chisqdf | Degrees of freedom for chisq |
| eigenval | Eigenvalues of $W^{-1} B$ |
| eigenvec | Eigenvectors of $W^{-1} B ;$ these are the coefficients for <br> the canonical variables $C$, and they are scaled so the <br> within-group variance of the canonical variables is 1 |
| canon | Canonical variables $C$, equal to XC*eigenvec, where XC <br> is X with columns centered by subtracting their means |

| Field | Contents |
| :--- | :--- |
| mdist | A vector of Mahalanobis distances from each point <br> to the mean of its group |
| gmdist | A matrix of Mahalanobis distances between each pair <br> of group means |

The canonical variables C are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically, C(:,1) is the linear combination of the $X$ columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant $F$ statistic in a one-way analysis of variance. C(:,2) has the maximum separation subject to it being orthogonal to $C(:, 1)$, and so on.
You may find it useful to use the outputs from manova1 along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using gplotmatrix. You can use gscatter to visualize the group separation using the first two canonical variables. You can use manovacluster to graph a dendrogram showing the clusters among the group means.

## Assumptions

The MANOVA test makes the following assumptions about the data in $X$ :

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

## Examples

you can use manova1 to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
```

                                    Origin)
    d =
3
p =
0
0.0000
0.0075
0.1934
There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. manova1 shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

## Purpose

Dendrogram of group mean clusters following MANOVA

## Description

## Examples

```
manovacluster(stats)
manovacluster(stats,method)
H = manovacluster(stats,method)
```

manovacluster(stats) generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). stats is the output stats structure from manova1. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See dendrogram for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.
manovacluster(stats, method) uses the specified method in place of single linkage. method can be any of the following character strings that identify ways to create the cluster hierarchy. (See linkage for additional information.)

| Method | Description |
| :--- | :--- |
| 'single' | Shortest distance (default) |
| 'complete' | Largest distance |
| 'average ' | Average distance |
| 'centroid' | Centroid distance |
| 'ward' | Incremental sum of squares |

H = manovacluster(stats, method) returns a vector of handles to the lines in the figure.

Let's analyze the larger car data set to determine which countries produce cars with the most similar characteristics.

```
load carbig
```

```
X = [MPG Acceleration Weight Displacement];
[d,p,stats] = manova1(X,Origin);
manovacluster(stats)
```

## ClassificationKNN.margin

## Purpose Margin of $k$-nearest neighbor classifier

$$
\text { Syntax } \quad m=\operatorname{margin}(m d l, x, Y)
$$

Description $\quad m=\operatorname{margin}(\mathrm{mdl}, \mathrm{X}, \mathrm{Y})$ returns the classification margins for the matrix of predictors X and class labels Y . For the definition, see "Margin" on page 20-1477.

## Input Arguments

Output
Arguments

## Definitions

## mdl

$k$-nearest neighbor classifier, created by ClassificationKNN.fit.

## X

Matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

## Y

Grouping variables of response values with the same number of elements (rows) as X. Each entry in $Y$ is the response to the data in the corresponding row of $X$.
m
Numeric column vector of length size ( $X, 1$ ). Each entry in $m$ represents the margin for the corresponding rows of $X$ and (true class) Y, computed using mdl.

## Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

## Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more

## ClassificationKNN.margin

detailed definition that includes weights and prior probabilities, see "Posterior Probability" on page 20-2181.

## Examples

## Margin Calculation

Construct a $k$-nearest neighbor classifier for the Fisher iris data, where $k=5$.

Load the data.
load fisheriris

Construct a classifier for 5-nearest neighbors.
mdl = ClassificationKNN.fit(meas,species,'NumNeighbors',5);
Examine the margin of the classifier for a mean observation classified 'versicolor'.
$\mathrm{X}=$ mean(meas);
$Y=$ \{'versicolor'\};
$m=\operatorname{margin}(m d l, X, Y)$
m =

1

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

See Also<br>ClassificationKNN | edge | loss |<br>Concepts • "Classification Using Nearest Neighbors" on page 15-9

## CompactClassificationDiscriminant.margin

Purpose Classification margins

Syntax $\quad m=\operatorname{margin}(o b j, x, y)$
Description $m=\operatorname{margin}\left(\mathrm{obj}_{\mathrm{j}}, \mathrm{X}, \mathrm{Y}\right)$ returns the classification margins for the matrix of predictors X and class labels Y . For the definition, see "Definitions" on page 20-1479.

## Input Arguments

## Output <br> Arguments

## Definitions

obj
Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with ClassificationDiscriminant.fit.

## X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in obj.

## Y

Class labels, with the same data type as exists in obj. The number of elements of $Y$ must equal the number of rows of $X$.

## m

Numeric column vector of length size( $X, 1$ ). Each entry in $m$ represents the margin for the corresponding rows of $X$ and (true class) Y , computed using obj.

## Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix $X$. A high value of margin indicates a more reliable prediction than a low value.

## CompactClassificationDiscriminant.margin

## Score (discriminant analysis)

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 14-7.

Examples Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = ClassificationDiscriminant.fit(X,species);
M = margin(obj,X,species);
M(end-10:end)
ans =
    0.6551
    0.4838
    0.6551
    -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
    -0.1439
    -0.4444
```

The classifier trained on all the data is better:
obj = ClassificationDiscriminant.fit(meas,species);
M = margin(obj,meas,species);
M(end-10: end)
ans =
0.9983
1.0000

# CompactClassificationDiscriminant.margin 

$$
\begin{aligned}
& 0.9991 \\
& 0.9978 \\
& 1.0000 \\
& 1.0000 \\
& 0.9999 \\
& 0.9882 \\
& 0.9937 \\
& 1.0000 \\
& 0.9649
\end{aligned}
$$

How To . "Discriminant Analysis" on page 14-3

## CompactClassificationEnsemble.margin

Purpose Classification margins
Syntax M = margin(ens, $X, Y$ ) $M$ = margin(ens, $X, Y$, Name, Value)
Description $M=\operatorname{margin}(e n s, X, Y)$ returns the classification margin for thepredictions of ens on data $X$, when the true classifications are $Y$.$M=$ margin(ens, $X, Y$, Name, Value) calculates margin with additionaloptions specified by one or more Name, Value pair arguments.
Input ensArgumentsClassification ensemble created with fitensemble, or a compactclassification ensemble created with compact.
X
Matrix of data to classify. Each row of X represents oneobservation, and each column represents one predictor. X musthave the same number of columns as the data used to train ens. $X$should have the same number of rows as the number of elementsin $Y$.
Y
Classification of $X$. $Y$ should be of the same type as the classification used to train ens, and its number of elements should equal the number of rows of X .

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'learners'

## CompactClassificationEnsemble.margin

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NTrained

## 'UseObsForLearner'

A logical matrix of size N -by-T, where:

- $N$ is the number of rows of $X$.
- $T$ is the number of weak learners in ens.

When UseObsForLearner( $i, j)$ is true, learner $j$ is used in predicting the class of row i of $X$.

Default: true ( $\mathrm{N}, \mathrm{T}$ )

## Output

 Arguments
## M

A numeric column vector with the same number of rows as $X$. Each row of $M$ gives the classification margin for that row of $X$.

## Definitions <br> Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X .

## Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

## CompactClassificationEnsemble.margin

- AdaBoostM1 scores range from $-\infty$ to $\infty$.
- Bag scores range from 0 to 1 .

```
Examples Find the margin for classifying an average flower from the Fisheriris data as 'versicolor':
load fisheriris \% X = meas, \(Y\) = species
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
flower = mean(meas);
predict(ens,flower)
ans =
    'versicolor'
margin(ens,mean(meas),'versicolor')
ans =
    3.2140
```

See Also predict | edge | loss

## CompactClassificationTree.margin

## Purpose Classification margins

$$
\text { Syntax } \quad m=\operatorname{margin}(\text { tree }, X, Y)
$$

Description $\quad m=\operatorname{margin}($ tree $, \mathrm{X}, \mathrm{Y})$ returns the classification margins for the matrix of predictors X and class labels Y . For the definition, see "Margin" on page 20-1485.

## Input Arguments

## Output

Arguments

Definitions

## tree

A classification tree created by ClassificationTree.fit, or a compact classification tree created by compact.

## X

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in tree.

## Y

Class labels, with the same data type as exists in tree.

## m

A numeric column vector of length size ( $\mathrm{X}, 1$ ). Each entry in m represents the margin for the corresponding rows of $X$ and (true class) Y , computed using tree.

## Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix $X$.

## Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that

## CompactClassificationTree.margin

lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X<0.15$ or $X>0.95$, and $X$ is false otherwise.

1
Generate 100 random points and classify them:
rng(0,'twister') \% for reproducibility
$X=r a n d(100,1) ;$
$Y=(a b s(X-.55)>.4) ;$
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')

2
Prune the tree:

```
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')
```

## CompactClassificationTree.margin

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than . 15 should be about $.05 / .85=.06$ for true, and about $.8 / .85=.94$ for false.

## 3

Compute the prediction scores for the first 10 rows of X :

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
ans =
\begin{tabular}{rrr}
0.9059 & 0.0941 & 0.8147 \\
0.9059 & 0.0941 & 0.9058 \\
0 & 1.0000 & 0.1270 \\
0.9059 & 0.0941 & 0.9134 \\
0.9059 & 0.0941 & 0.6324 \\
0 & 1.0000 & 0.0975
\end{tabular}
    0.9059 0.0941 0.2785
```

## CompactClassificationTree.margin

| 0.9059 | 0.0941 | 0.5469 |
| :--- | :--- | :--- |
| 0.9059 | 0.0941 | 0.9575 |
| 0.9059 | 0.0941 | 0.9649 |

Indeed, every value of $X$ (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1 , while the other values of $X$ have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95,1) instead of the expected 5 observations.

## Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
tree = ClassificationTree.fit(X,species);
M = margin(tree,X,species);
M(end-10:end)
ans =
    0.1111
    0.1111
    0.1111
    -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
    0.2000
```

The classification tree trained on all the data is better:

```
tree = ClassificationTree.fit(meas,species);
M = margin(tree,meas,species);
M(end-10:end)
```

## CompactClassificationTree.margin

```
ans =
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
```

## CompactTreeBagger.margin

| Purpose | Classification margin |
| :---: | :---: |
| Syntax | ```mar = margin(B,X,Y) mar = margin(B,X,Y,'param1',val1,'param2',val2,\ldots.)``` |
| Description | mar $=$ margin $(B, X, Y)$ computes the classification margins for predictors $X$ given true response $Y$. The $Y$ can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. mar is a numeric array of size Nobs-by-NTrees, where Nobs is the number of rows of $X$ and $Y$, and NTrees is the number of trees in the ensemble B. For observation I and tree $J$, $\operatorname{mar}(I, J)$ is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only. <br> mar $=$ margin( $B, X, Y, ' p a r a m 1 ', v a l 1, ' p a r a m 2 ', v a l 2, \ldots)$ specifies optional parameter name/value pairs: |
|  | 'mode' String indicating how the method computes errors. If set to 'cumulative' (default), margin computes cumulative errors and mar is an Nobs-by-NTrees matrix, where the first column gives error from trees(1), second column gives error fromtrees (1:2) etc, up to trees(1:NTrees). If set to 'individual', mar is a Nobs-by-NTrees matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', mar a single column of length Nobs showing the cumulative margins for the entire ensemble. |
|  | 'trees ' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative ' mode, the first element |

## CompactTreeBagger.margin

gives error from trees(1), the second element gives error from trees ( $1: 2$ ) etc.
'treeweights ' Vector of tree weights. This vector must have the same length as the 'trees ' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual ' mode.
'useifort' Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

## mat2dataset

## Purpose Convert matrix to dataset array

Syntax $\quad$| ds | $=\operatorname{mat2dataset}(X)$ |
| ---: | :--- |
| ds | $=\operatorname{mat2dataset}(X$, Name, Value $)$ |

Description $d s=$ mat2dataset $(X)$ converts a matrix to a dataset array.
ds = mat2dataset(X,Name, Value) performs the conversion using additional options specified by one or more Name, Value pair arguments.

## Input <br> Arguments

X - Input matrix
matrix
Input matrix to convert to a dataset array, specified as an $M$-by- $N$ numeric matrix. Each column of X becomes a variable in the output $M$-by- $N$ dataset array.

Data Types<br>single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'NumCols', [1, 1, 2, 1] specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

## 'VarNames' - Variable names for output dataset array cell array of strings

Variable names for the output dataset array, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings. You must provide a variable name for each variable in ds. The names must be valid MATLAB identifiers, and must be unique.

## Example: 'VarNames', \{'myVar1','myVar2','myVar3'\}

## 'ObsNames' - Observation names for output dataset array cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings. The names do not need to be valid MATLAB identifiers, but they must be unique.

## 'NumCols' - Number of columns for each variable vector of nonnegative integers

Number of columns for each variable in ds, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, mat2dataset combines multiple columns in X into a single variable in ds. The vector you assign to NumCols must sum to size (X,2).

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1, 1, 3, 1, 2].

## Output <br> Arguments

## ds - Output dataset array

dataset array
Output dataset array, returned by default with a variable for each column of $X$, and an observation for each row of $X$. If you specify NumCols, then the number of variables in ds is equal to the length of the specified vector of column numbers.

## Examples Convert Matrix to Dataset Array

Convert a matrix to a dataset array using the default options.
Load sample data.
load('fisheriris')
X = meas;

```
size(X)
ans =
    150 4
Convert the matrix to a dataset array.
ds = mat2dataset(X);
size(ds)
ans =
    150 4
ds(1:5,:)
ans =
\begin{tabular}{llll} 
X1 & X2 & X3 & X4
\end{tabular}
    5.1 3.5 1.4 0.2
    4.9 3 1.4 0.2
    4.7 3.2 1.3 0.2
    4.6 3.1 1.5 0.2
    5 3.6 1.4 0.2
```

When you do not specify variable names, mat2dataset uses the matrix name and column numbers to create default variable names.

## Convert Matrix to Dataset Array with Variable Names

Load sample data.
load('fisheriris')
X = meas;
size(X)
ans =

Convert the matrix to a dataset array, providing a variable name for each of the four column of $X$.

```
ds = mat2dataset(X,'VarNames',{'SLength',...
'SWidth','PLength','PWidth'});
size(ds)
ans =
    150 4
ds(1:5,:)
ans =
SWidth SLength PWidth PLength
    5.1 3.5 1.4 0.2
    4.9 3 1.4 0.2
    4.7 3.2 1.3 0.2
    4.6 3.1 1.5 0.2
    5 llll
```

## Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.
Load sample data.
load('fisheriris')
X = meas;
size(X)
ans $=$
$150 \quad 4$

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named SepalMeas, and the petal measurements (third and fourth columns) into one variable names PetalMeas.

```
ds = mat2dataset(X,'NumCols',[2,2],...
```

'VarNames', \{'SepalMeas','PetalMeas'\});
ds(1:5,:)
ans $=$

SepalMeas
PetalMeas
$\begin{array}{llll}5.1 & 3.5 & 1.4 & 0.2\end{array}$
$\begin{array}{llll}4.9 & 3 & 1.4 & 0.2\end{array}$
$\begin{array}{llll}4.7 & 3.2 & 1.3 & 0.2\end{array}$
$\begin{array}{llll}4.6 & 3.1 & 1.5 & 0.2\end{array}$
$\begin{array}{llll}5 & 3.6 & 1.4 & 0.2\end{array}$

The output dataset array has 150 observations and 2 variables.
size(ds)
ans =
$150 \quad 2$

## Purpose Nonclassical multidimensional scaling

Syntax $\quad Y=\operatorname{mdscale}(D, p)$
[Y,stress] = mdscale(D, p)
[Y,stress,disparities] = mdscale(D, p)
[...] = mdscale(D, p,'Name', value)
Description
$Y=$ mdscale ( $D, p$ ) performs nonmetric multidimensional scaling on the $n$-by- $n$ dissimilarity matrix D , and returns Y , a configuration of $n$ points (rows) in $p$ dimensions (columns). The Euclidean distances between points in $Y$ approximate a monotonic transformation of the corresponding dissimilarities in D. By default, mdscale uses Kruskal's normalized stress1 criterion.

You can specify D as either a full $n$-by- $n$ matrix, or in upper triangle form such as is output by pdist. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. mdscale treats NaNs in D as missing values, and ignores those elements. Inf is not accepted.

You can also specify D as a full similarity matrix, with ones along the diagonal and all other elements less than one. mdscale transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in Y approximate sqrt(1-D). To use a different transformation, transform the similarities prior to calling mdscale.
[ $\mathrm{Y}, \mathrm{stress}$ ] = mdscale ( $\mathrm{D}, \mathrm{p}$ ) returns the minimized stress, i.e., the stress evaluated at $Y$.
[Y,stress,disparities] = mdscale(D,p) returns the disparities, that is, the monotonic transformation of the dissimilarities $D$.
[...] = mdscale(D, p, 'Name', value) specifies one or more optional parameter name/value pairs that control further details of mdscale. Specify Name in single quotes. Available parameters are

## mdscale

- Criterion- The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that mdscale performs. Choices for non-metric scaling are:
- 'stress' - Stress normalized by the sum of squares of the inter-point distances, also known as stress1. This is the default.
- 'sstress' - Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

- 'metricstress' - Stress, normalized with the sum of squares of the dissimilarities.
- 'metricsstress' - Squared stress, normalized with the sum of 4th powers of the dissimilarities.
- 'sammon' - Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
- 'strain' - A criterion equivalent to that used in classical multidimensional scaling.
- Weights - A matrix or vector the same size as D, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of $D$ in computing and minimizing stress. Elements of D corresponding to zero weights are effectively ignored.

Note When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of $D$ do not enter into the stress calculation.

- Start - Method used to choose the initial configuration of points for Y. The choices are
- 'cmdscale' - Use the classical multidimensional scaling solution. This is the default. 'cmdscale' is not valid when there are zero weights.
- 'random' - Choose locations randomly from an appropriately scaled p-dimensional normal distribution with uncorrelated coordinates.
- An $n$-by-p matrix of initial locations, where n is the size of the matrix $D$ and $p$ is the number of columns of the output matrix $Y$. In this case, you can pass in [] for $p$ and mdscale infers $p$ from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.
- Replicates - Number of times to repeat the scaling, each with a new initial configuration. The default is 1 .
- Options - Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by statset. For example,

```
opts = statset(param1,val1,param2,val2, ...);
[...] = mdscale(...,'Options',opts)
```

The choices of statset parameters are

- 'Display' - Level of display output. The choices are 'off' (the default), 'iter', and 'final'.
- 'MaxIter' - Maximum number of iterations allowed. The default is 200 .
- 'TolFun' - Termination tolerance for the stress criterion and its gradient. The default is 1e-4.
- 'TolX' - Termination tolerance for the configuration location step size. The default is $1 \mathrm{e}-4$.

## CompactTreeBagger.mdsProx

| Purpose | Multidimensional scaling of proximity matrix |
| :---: | :---: |
| Syntax | $\begin{aligned} {[S C, E I G E N] } & =\operatorname{mdsProx}(B, X) \\ {[S C, E I G E N] } & =\operatorname{mdsProx}(B, X, ' p a r a m 1 ', \text { val1,'param2',val2, } . .) \end{aligned}$ |
| Description | [SC,EIGEN] = mdsProx (B, X) applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix $X$, and returns scaled coordinates SC and eigenvalues EIGEN of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as 1-prox, where prox is the proximity matrix returned by the proximity method. |
|  | You can supply the proximity matrix directly by using the 'data' parameter. <br> [SC,EIGEN] = mdsProx (B, X,'param1', val1,'param2', val2, ...) specifies optional parameter name/value pairs: |
|  | 'data' Flag indicating how the method treats the X input argument. If set to 'predictors' (default), mdsProx assumes $X$ to be a matrix of predictors and used for computation of the proximity matrix. If set to 'proximity ', the method treats X as a proximity matrix returned by the proximity method. |
|  | 'colors' If you supply this argument, mdsProx makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, mdsProx only plots the first C classes, where C is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in $X$. |

## CompactTreeBagger.mdsProx

'labels' Vector of true class labels for a classification ensemble. True class labels can be either a numeric vector, character matrix, or cell array of strings. If supplied, this vector must have as many elements as there are observations (rows) in X. This argument has no effect unless you also supply the 'colors' argument.
'mdscoords' Indices of the two scaled coordinates to plot. By default, mdsProx makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument.

## TreeBagger.mdsProx

| Purpose | Multidimensional scaling of proximity matrix |
| :---: | :---: |
| Syntax | ```[S,E] = mdsProx(B) [S,E] = mdsProx(B,'param1',val1,'param2',val2,...)``` |
| Description | [S,E] = mdsProx(B) returns scaled coordinates, S, and eigenvalues, E , for the proximity matrix in the ensemble B . An earlier call to fillProximities(B) must create the proximity matrix. |
|  |  optional parameter name/value pairs: |
|  | keep ' Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues. |
|  | 'colors ' If you supply this argument, mdsProx makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, mdsProx only plots the first C classes, where $C$ is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in $X$. |
|  | 'mdscoords' Indices of the two scaled coordinates to plot. By default, mdsProx makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument. |

## prob.KernelDistribution.mean

Purpose Mean of probability distribution object
Syntax $\quad m=\operatorname{mean}(p d)$
Description $m=$ mean $(p d)$ returns the mean $m$ of the probability distribution $p d$.
Input
Arguments
pd - Probability distribution
probability distribution object
Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using fitdist or dfittool.

## Output <br> Arguments

## Examples

m-Mean
scalar value
Mean of the probability distribution, returned as a scalar value.

## Mean of a Kernel Distribution

Load the sample data. Create a probability distribution object by fitting a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG,'Kernel')
pd =
```

KernelDistribution
Kernel = normal
Bandwidth $=4.11428$
Support = unbounded

Compute the mean of the distribution.

```
mean(pd)
```

```
ans =
    23.7181
```

## ProbDistUnivParam.mean

## Purpose Return mean of ProbDistUnivParam object

## Syntax $\quad M=\operatorname{mean}(P D)$

Description
$M=$ mean $(P D)$ returns $M$, the mean of the ProbDistUnivParam object $P D$.

Input
$P D$
An object of the class ProbDistUnivParam.
Arguments

Output $\quad M$
Arguments
The mean of the ProbDistUnivParam object $P D$.

See Also mean

## prob.ParametricTruncatableDistribution.mean

## Purpose Mean of probability distribution object

## Syntax $\quad m=\operatorname{mean}(p d)$

Description $m=$ mean $(p d)$ returns the mean $m$ of the probability distribution $p d$.

## Input <br> Arguments

## Output <br> Arguments

## m-Mean

scalar value
Mean of the probability distribution, returned as a scalar value.

## Examples Mean of a Uniform Distribution

Create a uniform distribution object

```
pd = makedist('Uniform','lower',-3,'upper',5)
pd =
```

UniformDistribution

Uniform distribution
Lower = -3
Upper = 5
Compute the mean of the distribution.
$\mathrm{m}=\mathrm{mean}(\mathrm{pd})$
m =

## Purpose Mean of probability distribution object

$$
\text { Syntax } \quad m=\operatorname{mean}(p d)
$$

Description $\mathrm{m}=$ mean $(\mathrm{pd})$ returns the mean m of the probability distribution pd .
Input
Arguments
pd - Probability distribution
probability distribution object
Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, create a probability distribution object by fitting it to data using fitdist or dfittool.

## Output <br> Arguments

## m-Mean

scalar value
Mean of the probability distribution, returned as a scalar value.

## Examples Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
pd =
```

NormalDistribution
Normal distribution $\mathrm{mu}=75.0083 \quad[73.4321,76.5846]$

## prob.ToolboxFittableParametricDistribution.mean

```
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
```

m =
75.0083

The mean of the normal distribution is equal to the parameter mu.

## Mean of a Skewed Distribution

Create a Weibull probability distribution object.
pd = makedist('Weibull','a',5,'b',2)
pd $=$
WeibullDistribution

Weibull distribution
$\mathrm{A}=5$
$B=2$

## CompactTreeBagger.meanMargin

| Purpose | Mean classification margin |
| :---: | :---: |
| Syntax | ```mar = meanMargin(B,X,Y) mar = meanMargin(B,X,Y,'param1',val1,'param2',val2,\ldots)``` |
| Description | mar $=$ meanMargin $(B, X, Y)$ computes average classification margins for predictors $X$ given true response $Y$. The $Y$ can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. meanMargin averages the margins over all observations (rows) in $X$ for each tree. mar is a matrix of size 1-by-NTrees, where NTrees is the number of trees in the ensemble $B$. This method is available for classification ensembles only. <br> mar $=$ meanMargin( $B, X, Y$, 'param1', val1,'param2', val2, $\ldots$ ) specifies optional parameter name/value pairs: <br> 'mode' <br> String indicating how meanMargin computes errors. If set to 'cumulative' (default), is a vector of length NTrees where the first element gives mean margin from trees(1), second column gives mean margins from trees(1:2) etc, up to trees(1:NTrees). If set to 'individual', mar is a vector of length NTrees, where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', mar is a scalar showing the cumulative mean margin for the entire ensemble. |
|  | 'trees ' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element |

## CompactTreeBagger.meanMargin

> gives mean margin from trees(1), the second element gives mean margin from trees(1:2) etc.
> 'treeweights ' Vector of tree weights. This vector must have the same length as the 'trees' vector. meanMargin uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

## Predictive Measure of Association

The predictive measure of association between the optimal split on variable $i$ and a surrogate split on variable $j$ is:

## CompactClassificationTree.meanSurrVarAssoc

$$
\lambda_{i, j}=\frac{\min \left(P_{L}, P_{R}\right)-\left(1-P_{L_{i} L_{j}}-P_{R_{i} R_{j}}\right)}{\min \left(P_{L}, P_{R}\right)}
$$

Here

- $P_{L}$ and $P_{R}$ are the node probabilities for the optimal split of node $i$ into Left and Right nodes respectively.
- $P_{L_{i} L_{j}}$ is the probability that both (optimal) node $i$ and (surrogate) node $j$ send an observation to the Left.
- $P_{R_{j} R_{j}}$ is the probability that both (optimal) node $i$ and (surrogate) node $j$ send an observation to the Right.

Clearly, $\lambda_{i, j}$ lies from $-\infty$ to 1 . Variable $j$ is a worthwhile surrogate split for variable $i$ if $\lambda_{i, j}>0$.
Element ma( $\mathrm{i}, \mathrm{j})$ is the predictive measure of association averaged over surrogate splits on predictor $j$ for which predictor $i$ is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor $j$ and dividing by the total number of optimal splits on predictor $i$, including splits for which the predictive measure of association between predictors $i$ and $j$ is negative.

## Examples

Find the mean predictive measure of association between the variables in the Fisher iris data:

```
load fisheriris
obj = ClassificationTree.fit(meas,species,'surrogate','on');
msva = meanSurrVarAssoc(obj)
msva =
\begin{tabular}{rrrr}
1.0000 & 0 & 0 & 0 \\
0 & 1.0000 & 0 & 0 \\
0.4633 & 0.2500 & 1.0000 & 0.5000
\end{tabular}
```

## CompactClassificationTree.meanSurrVarAssoc

$$
\begin{array}{llll}
0.2065 & 0.1413 & 0.4022 & 1.0000
\end{array}
$$

Find the mean predictive measure of association averaged over the odd-numbered nodes in obj:

N = 1:2:obj.NumNodes;
msva = meanSurrVarAssoc(obj,N)

| msva $=$ |  |  |  |
| ---: | ---: | ---: | ---: |
| 1.0000 | 0 | 0 | 0 |
| 0 | 1.0000 | 0 | 0 |
| 0.7600 | 0.5000 | 1.0000 | 1.0000 |
| 0.4130 | 0.2826 | 0.8043 | 1.0000 |

## CompactRegressionTree.meanSurrVarAssoc

## Purpose

Syntax

Description

Input
Arguments

## Output <br> Arguments

Mean predictive measure of association for surrogate splits in decision tree
ma = meanSurrVarAssoc(tree)
ma = meanSurrVarAssoc(tree,N)
$\mathrm{ma}=$ meanSurrVarAssoc(tree) returns a matrix of predictive measures of association for the predictors in tree.
$\mathrm{ma}=$ meanSurrVarAssoc (tree, N ) returns a matrix of predictive measures of association averaged over the nodes in vector $N$.

## tree

A regression tree constructed with RegressionTree.fit, or a compact regression tree constructed with compact.

## N

Vector of node numbers in tree.

## ma

- ma = meanSurrVarAssoc(tree) returns a P-by-P matrix, where $P$ is the number of predictors in tree. ma( $i, j)$ is the predictive measure of association between the optimal split on variable i and a surrogate split on variable j. See "Predictive Measure of Association" on page 20-1523.
- ma $=$ meanSurrVarAssoc (tree, $N$ ) returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector $N$. $N$ contains node numbers from 1 to max (tree. NumNodes).

## Definitions

## Predictive Measure of Association

The predictive measure of association between the optimal split on variable $i$ and a surrogate split on variable $j$ is:

## CompactRegressionTree.meanSurrVarAssoc

$$
\lambda_{i, j}=\frac{\min \left(P_{L}, P_{R}\right)-\left(1-P_{L_{i} L_{j}}-P_{R_{i} R_{j}}\right)}{\min \left(P_{L}, P_{R}\right)} .
$$

Here

- $P_{L}$ and $P_{R}$ are the node probabilities for the optimal split of node $i$ into Left and Right nodes respectively.
- $P_{L_{i} L_{j}}$ is the probability that both (optimal) node $i$ and (surrogate) node $j$ send an observation to the Left.
- $P_{R_{i} R_{j}}$ is the probability that both (optimal) node $i$ and (surrogate) node $j$ send an observation to the Right.

Clearly, $\lambda_{i, j}$ lies from $-\infty$ to 1 . Variable $j$ is a worthwhile surrogate split for variable $i$ if $\lambda_{i, j}>0$.
Element ma( $\mathrm{i}, \mathrm{j})$ is the predictive measure of association averaged over surrogate splits on predictor $j$ for which predictor $i$ is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor $j$ and dividing by the total number of optimal splits on predictor $i$, including splits for which the predictive measure of association between predictors $i$ and $j$ is negative.

## Examples

Find the mean predictive measure of association between the Displacement, Horsepower, and Weight variables in the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
ma = meanSurrVarAssoc(tree)
ma =
\begin{tabular}{lll}
1.0000 & 0.2708 & 0.3854 \\
0.4764 & 1.0000 & 0.4568
\end{tabular}
```

tree = RegressionTree.fit(X,MPG,'surrogate','on');

## CompactRegressionTree.meanSurrVarAssoc

$$
0.3472 \quad 0.2326 \quad 1.0000
$$

Find the mean predictive measure of association averaged over the odd-numbered nodes in tree:

```
N = 1:2:tree.NumNodes;
ma = meanSurrVarAssoc(tree,N)
ma =
    1.0000 0.2500 0.3750
    0.5910 1.0000 0.5861
    0.5000 0.2361 1.0000
```

## ProbDistUnivKernel.median

Purpose Return median of ProbDistUnivKernel object
Syntax ..... $M=\operatorname{median}(P D)$
Description $M=$ median (PD) returns $M$, the median of the ProbDistUnivKernel object $P D$.
Input ..... PD
An object of the class ProbDistUnivKernel.
Arguments
Output ..... M
Arguments
See Also ..... median

## ProbDistUnivParam.median

## Purpose Return median of ProbDistUnivParam object

Syntax
$M=$ median (PD)

Description $\quad \begin{aligned} & M=\text { median }(P D) \text { returns } M \text {, the median of the ProbDistUnivParam } \\ & \text { object } P D .\end{aligned}$

## Input <br> $P D$ <br> An object of the class ProbDistUnivParam.

## Output <br> Arguments <br> M

See Also median

The median of the ProbDistUnivParam object $P D$.

## prob.TruncatableDistribution.median

Purpose Median of probability distribution object
Syntax $\quad m=\operatorname{median}(p d)$
Description $\quad \mathrm{m}=$ median $(\mathrm{pd})$ returns the median m for the probability distribution pd.

Input pd - Probability distribution
Arguments
probability distribution object
Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using fitdist or dfittool.

## Output <br> Arguments <br> m-Median <br> scalar value

Median of the probability distribution, returned as a scalar value. The value of $m$ is the 50 th percentile of the probability distribution.

## Examples Median of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
pd =
```

NormalDistribution

```
Normal distribution
        mu = 75.0083 [73.4321, 76.5846]
    sigma = 8.7202 [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
```

m =
75.0083

For a symmetrical distribution such as the normal distribution, the median will be equal to the mean, mu.

## Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

pd $=$

WeibullDistribution

Weibull distribution
$A=5$
$B=2$
Compute the median of the distribution.
$\mathrm{m}=$ median(pd)
$\mathrm{m}=$
4.1628

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

## prob.TruncatableDistribution.median

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =
```

    4.4311
    The mean of the distribution is greater than the median.
Plot the pdf to visualize the distribution.
$x=[0: .1: 15] ;$
pdf = pdf(pd,x);
plot(x,pdf)

## TreeBagger.MergeLeaves property

Purpose Flag to merge leaves that do not improve risk

# Description <br> The MergeLeaves property is true if decision trees have their leaves with the same parent merged for splits that do not decrease the total risk, and false otherwise. The default value is false. 

See Also<br>classregtree

## Purpose Merge levels

```
Syntax
B = mergelevels(A,oldlevels,newlevel)
B = mergelevels(A,oldlevels)
```

Description

## Examples Example 1

For nominal data:

```
load fisheriris
species = nominal(species);
species = mergelevels(species,...
    {'setosa','virginica'},'parent');
species = setlabels(species,'hybrid','versicolor');
getlabels(species)
ans =
    'hybrid' 'parent'
```

## ordinal.mergelevels

## Example 2

For ordinal data:

```
A = ordinal([1 2 3 2 1],{'lo','med','hi'})
A =
    lo med hi med lo
A = mergelevels(A,{'lo','med'},'bad') 
```

See Also
addlevels | droplevels | islevel | reorderlevels | getlabels

## TreeBagger.Method property

Purpose Method used by trees (classification or regression)
Description The Method property is 'classification' for classification ensembles and 'regression' for regression ensembles.

Purpose
Metropolis-Hastings sample
Syntax

```
smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,
    'proprnd',proprnd)
smpl = mhsample(...,'symmetric',sym)
smpl = mhsample(...,'burnin',K)
smpl = mhsample(...,'thin',m)
smpl = mhsample(...,'nchain',n)
[smpl,accept] = mhsample(...)
```

## Description

smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf, 'proprnd', proprnd) draws nsamples random samples from a target stationary distribution pdf using the Metropolis-Hastings algorithm.
start is a row vector containing the start value of the Markov Chain, nsamples is an integer specifying the number of samples to be generated, and pdf, proppdf, and proprnd are function handles created using @. proppdf defines the proposal distribution density, and proprnd defines the random number generator for the proposal distribution. pdf and proprnd take one argument as an input with the same type and size as start. proppdf takes two arguments as inputs with the same type and size as start.
smpl is a column vector or matrix containing the samples. If the log density function is preferred, 'pdf' and 'proppdf' can be replaced with 'logpdf' and 'logproppdf'. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.
The proposal distribution $q(x, y)$ gives the probability density for choosing $x$ as the next point when $y$ is the current point. It is sometimes written as $q(x \mid y)$.

If the proppdf or logproppdf satisfies $q(x, y)=q(y, x)$, that is, the proposal distribution is symmetric, mhsample implements Random Walk Metropolis-Hastings sampling. If the proppdf or logproppdf satisfies $q(x, y)=q(x)$, that is, the proposal distribution is independent of current values, mhsample implements Independent Metropolis-Hastings sampling.
smpl = mhsample(...,'symmetric',sym) draws nsamples random samples from a target stationary distribution pdf using the Metropolis-Hastings algorithm. sym is a logical value that indicates whether the proposal distribution is symmetric. The default value is false, which corresponds to the asymmetric proposal distribution. If sym is true, for example, the proposal distribution is symmetric, proppdf and logproppdf are optional.
smpl = mhsample(...,'burnin',K) generates a Markov chain with values between the starting point and the $\mathrm{k}^{\text {th }}$ point omitted in the generated sequence. Values beyond the $k^{\text {th }}$ point are kept. $k$ is a nonnegative integer with default value of 0 .
smpl = mhsample(...,'thin',m) generates a Markov chain with $m-1$ out of $m$ values omitted in the generated sequence. $m$ is a positive integer with default value of 1 .
smpl = mhsample(...,'nchain', n) generates $n$ Markov chains using the Metropolis-Hastings algorithm. $n$ is a positive integer with a default value of 1 . smpl is a matrix containing the samples. The last dimension contains the indices for individual chains.
[smpl, accept] = mhsample(...) also returns accept, the acceptance rate of the proposed distribution. accept is a scalar if a single chain is generated and is a vector if multiple chains are generated.

## Examples

Estimate the second order moment of a Gamma distribution using the Independent Metropolis-Hastings sampling.

```
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); %target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
    exprnd(floor(alpha)/alpha,floor(alpha),1));
nsamples = 5000;
smpl = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...
    'proppdf',proppdf);
xxhat = cumsum(smpl.^2)./(1:nsamples)';
```

Generate random samples from $N(0,1)$ using the Random Walk Metropolis-Hastings sampling.

```
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
histfit(x,50)
h = get(gca,'Children');
set(h(2),'FaceColor',[.8 . 8 1])
```

## TreeBagger.MinLeaf property

Purpose Minimum number of observations per tree leaf
$\begin{array}{ll}\text { Description } & \text { The MinLeaf property specifies the minimum number of observations } \\ \text { per tree leaf. The default values are } 1 \text { for classification and } 5 \text { for } \\ \text { regression. For classregtree training, the 'minparent' value is set to } \\ & 2 * \text { MinLeaf. }\end{array}$
See Also
classregtree

## Purpose Maximum likelihood estimates

```
Syntax phat = mle(data)
phat = mle(data,'distribution',dist)
phat = mle(data,'pdf',pdf,'start',start)
phat = mle(data,'pdf',pdf,'start',start,'cdf',cdf)
phat = mle(data,'logpdf',logpdf,'start',start)
phat =
mle(data,'logpdf',logpdf,'start',start,'logsf',logsf)
phat = mle(data,'nloglf',nloglf,'start',start)
phat = mle(___,Name,Value)
[phat,pci] = mle(___)
```

## Description

phat $=$ mle(data) returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector data.
phat $=$ mle(data, 'distribution',dist) returns parameter estimates for a distribution specified by dist.
phat $=$ mle(data,'pdf',pdf,'start',start) returns parameter estimates for a custom distribution specified by the probability density function pdf. You must also specify the initial parameter values, start.
phat = mle(data, 'pdf', pdf,'start',start,'cdf',cdf) returns parameter estimates for a custom distribution specified by the probability density function pdf and custom cumulative distribution function cdf.
phat $=$ mle(data, 'logpdf', logpdf,'start',start) returns parameter estimates for a custom distribution specified by the log
probability density function logpdf. You must also specify the initial parameter values, start.
phat =
mle(data,'logpdf',logpdf,'start',start,'logsf',logsf) returns parameter estimates for a custom distribution specified by the log probability density function logpdf and custom log survival function logsf.
phat $=$ mle(data, 'nloglf', nloglf,'start',start) returns parameter estimates for the custom distribution specified by the negative loglikelihood function nloglf. You must also specify the initial parameter values, start.
phat = mle( __ , Name, Value) also returns the parameter estimates with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.
[phat, pci] = mle( __ ) also returns the $95 \%$ confidence intervals for the parameters.

## Input Arguments

## data-Sample data

vector
Sample data mle uses to estimate the distribution parameters, specified as a vector.

## Data Types

single | double
dist-Distribution type
'normal' (default) | string
Distribution type to estimate parameters for, specified as one of the following.

| dist | Description | Parameter 1 | Parameter 2 | Parameter <br> $\mathbf{3}$ |
| :--- | :--- | :--- | :--- | :--- |
| 'bernoulli' | "Bernoulli Distribution" <br> on page B-3 | p: probability <br> of success for <br> each trial | - | - |
| 'beta' or 'Beta' | "Beta Distribution" on <br> page B-4 | a | b | - |
| 'bino' or <br> 'Binomial' | "Binomial Distribution" <br> on page B-7 | $\mathrm{n}:$ number of <br> trials | p: probability <br> of success for <br> each trial | - |
| 'birnbaumsaunder | "Birnbaum-Saunders <br> Distribution" on page <br> B-10 | $\beta$ : scale | $\gamma$ : shape | - |
| 'burr' or 'Burr' | "Burr Type XII <br> Distribution" on page <br> B-12 | a: scale | c: first shape | k: <br> second <br> shape |
| 'Discrete <br> Uniform' or <br> 'unid' | "Uniform Distribution <br> (Discrete)" on page B-114 | N: maximum <br> observable <br> value | - | - |
| 'exp' or <br> 'Exponential' | "Exponential <br> Distribution" on page <br> B-29 | $\mu:$ mean | - | - |
| 'ev' or 'Extreme <br> Value' | "Extreme Value <br> Distribution" on page <br> B-32 | $\mu$ : location | $\sigma:$ scale | - |
| 'gam' or 'Gamma' | "Gamma Distribution" <br> on page B-40 | a: shape | b: scale | - |
| 'gev' or <br> 'Generalized <br> Extreme Value' | "Generalized Extreme <br> Value Distribution" on <br> page B-45 | k: shape | $\sigma:$ scale | $\mu:$ <br> location |

| dist | Description | Parameter 1 | Parameter 2 | Parameter $3$ |
| :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { 'gp' or } \\ & \text { 'Generalized } \\ & \text { Pareto' } \end{aligned}$ | "Generalized Pareto Distribution" on page B-50 | k: tail index (shape) | $\sigma$ : scale | $\theta$ : threshold |
| $\begin{aligned} & \text { 'geo' or } \\ & \text { 'Geometric' } \end{aligned}$ | "Geometric Distribution" on page B-54 | p: probability | - | - |
| 'inversegaussian | '"Inverse Gaussian Distribution" on page B-58 | $\mu$ : scale | $\lambda$ : shape | - |
| 'logistic' | "Logistic Distribution" on page B-62 | $\mu$ : location | $\sigma$ : scale | - |
| 'loglogistic' | "Loglogistic Distribution" on page B-63 | $\mu$ : log location | $\sigma$ : $\log$ scale | - |
| 'logn' or <br> 'Lognormal' | "Lognormal Distribution" on page B-64 | $\mu$ : log location | $\sigma$ : $\log$ scale | - |
| 'nakagami' | "Nakagami Distribution" on page B-83 | $\mu$ : shape | $\omega$ : scale | - |
| 'nbin' or 'Negative Binomial' | "Negative Binomial Distribution" on page B-85 | $r$ : number of successes | p: probability of success in a single trial | - |
| 'norm' or 'Normal' | "Normal Distribution" on page B-96 | $\mu$ : location (mean) | $\sigma$ : scale (standard deviation) | - |
| 'poiss' or 'Poisson' | "Poisson Distribution" on page B-102 | $\lambda:$ mean | - | - |
| 'rayl' or 'Rayleigh' | "Rayleigh Distribution" on page B-104 | b: scale | - | - |

| dist | Description | Parameter 1 | Parameter 2 | Parameter <br> $\mathbf{3}$ |
| :--- | :--- | :--- | :--- | :--- |
| 'rician' | "Rician Distribution" on <br> page B-106 | $\mathrm{s}:$ <br> noncentrality | $\sigma:$ scale | - |
| 'tlocationscale' | "t Location-Scale <br> Distribution" on page <br> B-110 | $\mu$ : location | $\sigma$ : scale | : <br> degrees <br> of <br> freedom <br> 'unif' or <br> 'Uniform' <br> "Uniform Distribution <br> (Continuous)" on page <br> B-112 <br> a: lower <br> endpoint <br> (minimum) <br> 'wbl' or <br> 'Weibull'"Weibull Distribution" <br> on page B-116 |
| a: scale | b: upper <br> (maximum) | - |  |  |

Example: 'rician'

## pdf - Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.
This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.
For example, if the name of the custom probability density function is newpdf, then you can specify the function handle in mle as follows.

## Example: @newpdf

Data Types
function_handle
cdf - Custom cumulative distribution function
function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define cdf with pdf if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify cdf while using pdf.

For example, if the name of the custom cumulative distribution function is newcdf, then you can specify the function handle in mle as follows.

## Example: @newcdf

## Data Types <br> function_handle

## logpdf - Custom log probability density function

function handle
Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is customlogpdf, then you can specify the function handle in mle as follows.

## Example: @customlogpdf

Data Types<br>function_handle

## logsf - Custom log survival function

function handle

Custom log survival function, specified as a function handle created using @.
This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.
You must define logsf with logpdf if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify logsf while using logpdf.

For example, if the name of the custom log survival function is logsurvival, then you can specify the function handle in mle as follows.
Example: @logsurvival

## Data Types

function_handle

## nloglf - Custom negative loglikelihood function

function handle
Custom negative loglikelihood function, specified as a function handle created using @.
This custom function accepts the following input arguments.

| params | Vector of distribution parameter values. mle detects <br> tho numbor of noramotore from tho numbor of |
| :--- | :--- |
| data | Vector of data. |
| cens | Boolean vector of censored values. |
| freq | Vector of integer data frequencies. |

nloglf must accept all four arguments even if you do not use the 'censoring' or 'frequency' name-value pair arguments. You can write 'nloglf' to ignore cens and freq arguments in that case.
nloglf returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'options').

If the name of the custom negative log likelihood function is negloglik, then you can specify the function handle in mle as follows.

Example: @negloglik

Data Types<br>function_handle

## start - Initial parameter values

scalar | vector
Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use start when you fit custom distributions, that is, when you use pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 0.05
Example: [100,2]

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'censoring', Cens, 'alpha', 0.01, 'options', Opt specifies that mle estimates the parameters for the distribution of censored data specified by array Cens, computes the $99 \%$ confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure Opt.

## 'censoring' - Indicator for censoring

array of 0 s (default) | array of 0 s and 1 s

Indicator for censoring, specified as the comma-separated pair consisting of 'censoring' and a Boolean array of the same size as data. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

Censoring is not supported for all distributions.
For example, if the censored data information is in the binary array called Censored, then you can specify the censored data as follows.

```
Example: 'censoring', Censored
```

## Data Types

logical

## 'frequency' - Frequency of observations

array of 1 s (default) | vector of nonnegative integer counts
Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and an array containing nonnegative integer counts, which is the same size as data. The default is one observation per element of data.

For example, if the observation frequencies are stored in an array named Freq, you can specify the frequencies as follows.
Example: 'frequency ', Freq
Data Types
single | double

## 'alpha' - Confidence level

0.05 (default) | scalar value in the range ( 0,1 )

Confidence level for the confidence interval of parameter estimates, pci, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range $(0,1)$. The confidence level of pci is $100(1-\mathrm{alpha}) \%$. The default is 0.05 for $95 \%$ confidence.

For example, for $99 \%$ confidence limits, you can specify the confidence level as follows.

# Example: 'alpha',0.01 

```
Data Types
single | double
'ntrials' - Number of trials
```

scalar value | vector

Number of trials for the corresponding element of data, specified as the comma-separated pair consisting of 'ntrials' and a scalar or a vector of the same size as data.

Applies only to binomial distribution.
Example: 'ntrials', total

## Data Types <br> single | double

## 'options' - Fitting algorithm control parameters

structure
Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'options' and a structure returned by statset.

Not applicable to all distributions.
Use the 'options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type statset('mlecustom'). You can set the options under a new name and use that in the name-value pair argument. mle interprets the following statset parameters for custom distribution fitting.

| Parameter | Value |
| :--- | :--- |
| 'GradObj' | Default is 'off' <br> 'on' or 'off ', indicating whether or not fmincon <br> can expect the custom function provided with the <br> nloglf input argument to return the gradient vector <br> of the negative log-likelihood as a second output. |
| 'DerivStep' | Default is eps^(1/3). <br> The relative difference, specified as a scalar or <br> a vector the same size as start, used in finite <br> difference derivative approximations when using <br> fmincon, and 'GradObj ' is 'off'. <br> mle ignores 'DerivStep' when using fminsearch. |
| 'FunValCheck' | Default is ' on '. <br> 'on' or ' off', indicating whether or not mle should <br> check the values returned by the custom distribution <br> functions for validity. |
| A poor choice of starting point can sometimes cause <br> these functions to return NaNs, infinite values, or <br> out-of-range values if they are written without <br> suitable error checking. |  |
| 'TolBnd' | Default is 1e -6.An offset for upper and lower bounds <br> when using fmincon. |
| mle treats upper and lower bounds as strict |  |
| inequalities, that is, open bounds. With fmincon, |  |
| this is approximated by creating closed bounds |  |
| inset from the specified upper and lower bounds by |  |
| TolBnd. |  |

Example: 'options',statset('mlecustom')
Data Types
struct

## 'lowerbound' - Lower bounds for distribution parameters <br> $-\infty$ (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of 'lowerbound ' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logcdf, or nloglf input arguments.

Example: 'lowerbound',0
Data Types
single | double

## 'upperbound' - Upper bounds for distribution parameters

$\infty$ (default) | vector
Upper bounds for distribution parameters, specified as the comma-separated pair consisting of 'upperbound ' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'upperbound',1

## Data Types <br> single | double

## 'optimfun' - Optimization function

'fminsearch' (default) | 'fmincon'
Optimization function mle uses in maximizing the likelihood, specified as the comma-separated pair consisting of 'optimfun' and either 'fminsearch' or 'fmincon'.

Default is 'fminsearch'.
You can only specify 'fmincon' if Optimization Toolbox is available.

The 'optimfun' name-value pair argument is valid only when you fit custom distributions, that is, when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'optimfun','fmincon'

## Output Arguments

## Examples Estimate Parameters of Burr Distribution

Load the sample data.

## load carbig

The variable MPG has the miles per gallon for different models of cars.
Draw a histogram of MPG data.
hist(MPG)

The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```
phat = mle(MPG,'distribution','burr')
phat =
```

## $34.6447 \quad 3.7898 \quad 3.5722$

The maximum likelihood estimates for the scale parameter a is 34.6447. The estimates for the two shape parameters $c$ and $k$ of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

## Fit Custom Distribution to Censored Data

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

## load readmissiontimes

The data includes ReadmissionTime, which has readmission times for 100 patients. The column vector Censored has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter, lambda, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'pdf',custpdf,...
'cdf',custcdf,'start',0.05,'Censoring',Censored)
phat
```

phat $=$
0.1096

## Fit Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.
load readmissiontimes
The data includes ReadmissionTime, which has readmission times for 100 patients. The column vector Censored has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
    +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, lambda and $k$, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
phat =
    9.2090 1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223 , respectively.

## Fit Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.
load readmissiontimes
The data includes ReadmissionTime, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf=@(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

phat $=$
0.1462

## Estimate Probability of Success

Generate 100 random observations from a binomial distribution with the number of trials, $n=20$, and the probability of success, $p=0.75$.

```
data = binornd(20,0.75,100,1);
```

Estimate the probability of success and $95 \%$ confidence limits using the simulated sample data.

```
[phat,pci] = mle(data,'distribution','binomial',...
    'alpha',.05,'ntrials',20)
```

phat $=$
0.7370
pci $=$
0.7171

The estimate of probability of success is 0.737 and the lower and upper limits of the $95 \%$ confidence interval are 0.7171 and 0.7562 . This interval covers the true value used to simulate the data.

## Definitions

Tips
When you supply distribution functions, mle computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause mle to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

## Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t)=1-F(t)$.

[^7]| Purpose | Asymptotic covariance of maximum likelihood estimators |
| :---: | :---: |
| Syntax | acov = mlecov(params, data, 'pdf', pdf) |
|  | acov = mlecov(params, data,'pdf', pdf, 'cdf', cdf) |
|  | acov = mlecov(params,data,'logpdf',logpdf) |
|  | acov = mlecov(params, data,'logpdf',logpdf,'logsf',logsf |
|  | acov = mlecov(params, data, 'nloglf', nloglf) |
|  | acov $=$ mlecov( __ , Name, Value $)$ |
| Description | acov = mlecov(params,data, 'pdf',pdf) returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function pdf. |
|  | mlecov computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates params, given the observed data, and returns the negative inverse of that Hessian. |
|  | acov = mlecov(params,data,'pdf',pdf,'cdf',cdf) returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function pdf and cumulative distribution function cdf. |
|  | acov = mlecov(params,data,'logpdf',logpdf) returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function logpdf. |
|  | acov $=$ mlecov(params, data, 'logpdf',logpdf,'logsf',logsf) returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution |

specified by the custom log probability density function logpdf and custom log survival function logsf.
acov $=$ mlecov(params,data,'nloglf',nloglf) returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom negative loglikelihood function nloglf.
acov $=m l e c o v(\ldots$, , Name, Value) also returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

## Input Arguments

params - Parameter estimates<br>scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by mle.

Data Types
single | double

## data-Sample data

vector
Sample data mle uses to estimate the distribution parameters, specified as a vector.

Data Types
single | double
pdf - Custom probability density function
function handle

Custom probability distribution function, specified as a function handle created using @.
This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.
For example, if the name of the custom probability density function is newpdf, then you can specify the function handle in mlecov as follows.

## Example: @newpdf

## Data Types

function_handle

## cdf - Custom cumulative distribution function

## function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define cdf with pdf if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify cdf while using pdf.

For example, if the name of the custom cumulative distribution function is newcdf, then you can specify the function handle in mlecov as follows.

## Example: @newcdf

## Data Types

function_handle

## logpdf - Custom log probability density function

function handle
Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is customlogpdf, then you can specify the function handle in mlecov as follows.

## Example: @customlogpdf

## Data Types <br> function_handle

## logsf - Custom log survival function

function handle
Custom log survival function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define logsf with logpdf if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify logsf while using logpdf.

For example, if the name of the custom log survival function is logsurvival, then you can specify the function handle in mlecov as follows.

## Example: @logsurvival

## Data Types <br> function_handle

## nloglf - Custom negative loglikelihood function

function handle
Custom negative loglikelihood function, specified as a function handle created using @.

This custom function accepts the following input arguments.

| params | Vector of distribution parameter values |
| :--- | :--- |
| data | Vector of data |
| cens | Boolean vector of censored values |
| freq | Vector of integer data frequencies |

nloglf must accept all four arguments even if you do not use the 'censoring' or 'frequency' name-value pair arguments. You can write 'nloglf' to ignore cens and freq arguments in that case.
nloglf returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'options').

If the name of the custom negative log likelihood function is negloglik, then you can specify the function handle in mlecov as follows.
Example: @negloglik

## Data Types

function_handle

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'censoring', cens, 'options', opt specifies that mlecov reads the censored data information from the vector cens and performs according to the new options structure opt.

'censoring' - Indicator for censoring

array of 0 s (default) | array of 0 s and 1 s

Indicator for censoring, specified as the comma-separated pair consisting of 'censoring' and a Boolean array of the same size as data. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use cdf with pdf, or logsf with logpdf, or nloglf must be defined to account for censoring.

For example, if the censored data information is in the binary array called Censored, then you can specify the censored data as follows.

Example: 'censoring', Censored

## Data Types

logical

## 'frequency' - Frequency of observations

array of 1s (default) | vector of nonnegative integer counts
Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and an array containing nonnegative integer counts, which is the same size as data. The default is one observation per element of data.

For example, if the observation frequencies are stored in an array named Freq, you can specify the frequencies as follows.

Example: 'frequency',Freq
Data Types
single | double

## 'options' - Numerical options

structure
Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of 'options' and a structure returned by statset.

You can set the options under a new name and use it in the name-value pair argument. The applicable statset parameters are as follows.

| Parameter | Value |
| :--- | :--- |
| 'GradObj ' | Default is 'off '. <br> 'on' or 'off ', indicating whether or not the function <br> provided with the nloglf input argument can return <br> the gradient vector of the negative log-likelihood as <br> a second output. |
| 'DerivStep' | Default is eps^ $(1 / 4)$. <br> Relative step size used in finite difference for <br> Hessian calculations. It can be a scalar, or the same <br> size as params. A smaller value than the default <br> might be appropriate if 'GradObj ' is 'on '. |

Example: 'options',statset('mlecov')

## Data Types

struct

## Output Arguments

## Examples

acov - Approximation to asymptotic covariance matrix $p$-by-p matrix

Approximation to asymptotic covariance matrix, returned as a $p$-by- $p$ matrix, where $p$ is the number of parameters in params.

## Custom Probability Density Function

Load the sample data.

## load carbig

The vector Weight shows the weights of 406 cars.
In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as lognormpdf.m.
function newpdf $=$ lognormpdf(data,mu,sigma)

```
newpdf = exp((-(log(data)-mu).^2)/(2*sigma^2))./(data*sigma*sqrt(2*pi));
```

Estimate the parameters, mu and sigma, of the custom-defined distribution.
phat $=$ mle(Weight,'pdf', @lognormpdf,'start',[4.5 0.3])
phat $=$
$7.9600 \quad 0.2804$

Compute the approximate covariance matrix of the parameter estimates.
acov $=$ mlecov(phat,Weight, 'pdf', @lognormpdf)
acov =
1.0e-03 *
$0.1937-0.0000$
-0.0000 0.0968

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))
se =
    0.0139
    0.0098
```

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098 , respectively.

## Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as betalogpdf.m.

```
function logpdf = betalogpdf(x,a,b)
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaln(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')
x = betarnd(1.23,3.45,25,1);
phat = mle(x,'dist','beta')
phat =
```

$$
1.1213 \quad 2.7182
$$

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)
```

acov $=$

$$
\begin{array}{ll}
0.0810 & 0.1646 \\
0.1646 & 0.6074
\end{array}
$$

## Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

The sample data includes ReadmissionTime, which has readmission times for 100 patients. The column vector Censored has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
    +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, lambda and $k$, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
```

'logsf', custlogsf,'start',[1,0.75],'Censoring',Censored)
phat $=$

$$
9.2090 \quad 1.4223
$$

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223 , respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,ReadmissionTime,...
'logpdf',custlogpdf,'logsf',custlogsf,'Censoring',Censored)
acov =
    0.5653 0.0102
    0.0102 0.0163
```

## Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes ReadmissionTime, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
phat =
    0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
acov =
    2.1374e-04
```

Compute the standard error.

```
sqrt(acov)
```

ans $=$

## Definitions

## Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t)=1-F(t)$.

## See Also mle

Concepts • "What Is Survival Analysis?" on page 11-2

## Purpose Multinomial probability density function

## Syntax $\quad Y=\operatorname{mnpdf}(X, P R O B)$

Description
$Y=\operatorname{mnpdf}(X, P R O B)$ returns the pdf for the multinomial distribution with probabilities PROB, evaluated at each row of $X . X$ and PROB are $m$-by- $k$ matrices or 1 -by- $k$ vectors, where $k$ is the number of multinomial bins or categories. Each row of PROB must sum to one, and the sample sizes for each observation (rows of $X$ ) are given by the row sums sum ( $X, 2$ ). $Y$ is an $m$-by- $k$ matrix, and mnpdf computes each row of $Y$ using the corresponding rows of the inputs, or replicates them if needed.

## Examples

```
% Compute the distribution
p = [1/2 1/3 1/6]; % Outcome probabilities
n = 10; % Sample size
x1 = 0:n;
x2 = 0:n;
[X1,X2] = meshgrid(x1,x2);
X3 = n-(X1+X2);
Y = mnpdf([X1(:),X2(:),X3(:)],repmat(p,(n+1)^2,1));
% Plot the distribution
Y = reshape(Y, n+1,n+1);
bar3(Y)
set(gca,'XTickLabel',0:n)
set(gca,'YTickLabel',0:n)
xlabel('x_1')
ylabel('x_2')
zlabel('Probability Mass')
title('Trinomial Distribution')
```

Note that the visualization does not show $x_{3}$, which is determined by the constraint $x_{1}+x_{2}+x_{3}=n$.

| Purpose | Multinomial logistic regression |
| :--- | :--- |
| Syntax | $B=m n r f i t(X, Y)$ |
|  | $B=m n r f i t(X, Y$, Name, Value $)$ |
|  | $[B, \operatorname{dev}, \operatorname{stats}]=\operatorname{mnrfit}\left(\_\right)$ |

## Description

## Input Arguments

$B=\operatorname{mnrfit}(X, Y)$ returns a matrix, $B$, of coefficient estimates for a multinomial logistic regression of the nominal responses in $Y$ on the predictors in X .
$B=m n r f i t(X, Y, N a m e$, Value $)$ returns a matrix, $B$, of coefficient estimates for a multinomial model fit with additional options specified by one or more Name, Value pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.
[B, dev, stats] = mnrfit( __ ) also returns the deviance of the fit, dev, and the structure stats for any of the previous input arguments. stats contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

## X-Observations on predictor variables

$n$-by-p matrix
Observations on predictor variables, specified as an $n$-by- $p$ matrix. X contains $n$ observations for $p$ predictors.

Note mnrfit automatically includes a constant term (intercept) in all
models. Do not include a column of 1 s in X .

Data Types<br>single | double

## Y-Response values

## $n$-by- $k$ matrix | $n$-by- 1 column vector

Response values, specified as a column vector or a matrix. Y can be one of the following:

- An $n$-by- $k$ matrix, where $Y(i, j)$ is the number of outcomes of the multinomial category $j$ for the predictor combinations given by $X(i,:)$. In this case, the number of observations are made at each predictor combination.
- An $n$-by- 1 column vector of scalar integers from 1 to $k$ indicating the value of the response for each observation. In this case, all sample sizes are 1.

## Data Types <br> single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'model', 'ordinal', 'link', 'probit' specifies an ordinal model with a probit link function.

```
'model' - Type of model to fit
'nominal' (default) | 'ordinal' | 'hierarchical'
```

Type of model to fit, specified as the comma-separated pair consisting of 'model' and one of the following.

| 'nominal' | Default. There is no ordering among the response <br> categories. |
| :--- | :--- |
| 'ordinal' | There is a natural ordering among the response <br> categories. |
| 'hierarchical' | The choice of response category is <br> sequential/nested. |

Example: 'model','ordinal'

## 'interactions' - Indicator for interaction between multinomial categories and coefficients

'on' | 'off'
Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of 'interactions' and one of the following.

| 'on ' | Default for nominal and hierarchical models. Fit a model <br> with different coefficients across categories. |
| :--- | :--- |
| 'off' | Default for ordinal models. Fit a model with a common <br> set of coefficients for the predictor variables, across all <br> multinomial categories. This is often described as parallel <br> regression or the proportional odds model. |

In all cases, the model has different intercepts across categories. The choice of 'interactions' determines the dimensions of the output array B.

Example: 'interactions', 'off'
Data Types
logical
'link' - Link function
'logit' (default) | 'probit' | 'comploglog' | 'loglog

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

| 'logit' | Default. $f(\gamma)=\ln (\gamma /(1-\gamma))$ |
| :--- | :--- |
| 'probit' | $f(\gamma)=\Phi^{-1}(\gamma)-$ error term is normally distributed <br> with variance 1 |
| 'comploglog' | Complementary log-log $f(\gamma)=\ln (-\ln (1-\gamma))$ |
| 'loglog' | $f(\gamma)=\ln (-\ln (\gamma))$ |

The link function defines the relationship between response probabilities and the linear combination of predictors, $X \beta$. The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model, $\gamma$ represents the cumulative probability of being in categories 1 to $j$ and the model with a logit link function as follows:

$$
\ln \left(\frac{\gamma}{1-\gamma}\right)=\ln \left(\frac{\pi_{1}+\pi_{2}+\cdots+\pi_{j}}{\pi_{j+1}+\cdots+\pi_{k}}\right)=\beta_{0 j}+\beta_{1} X_{1}+\beta_{2} X_{2}+\cdots+\beta_{p} X_{p}
$$

where $k$ represents the last category.
You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

$$
\ln \left(\frac{\pi_{j}}{\pi_{r}}\right)=\beta_{j 0}+\beta_{j 1} X_{j 1}+\beta_{j 2} X_{j 2}+\cdots+\beta_{j p} X_{j p}, \quad j=1, \ldots, k-1
$$

where $\Pi$ stands for a categorical probability, and $r$ corresponds to the reference category. mnrfit uses the last category as the reference category for nominal models.
Example: 'link', 'loglog'

## 'estdisp' - Indicator for estimating dispersion parameter

[^8]Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'estdisp' and one of the following.

| 'off' | Default. Use the theoretical dispersion value of 1. |
| :--- | :--- |
| 'on ' | Estimate a dispersion parameter for the multinomial <br> distribution in computing standard errors. |

Example: 'estdisp','on'

## Output Arguments

## B - Coefficient estimates

## vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in Y , returned as a vector or a matrix.

- If 'interaction' is 'off', then B is a $k-1+p$ vector. The first $k-1$ rows of B correspond to the intercept terms, one for each $k-$ 1 multinomial categories, and the remaining $p$ rows correspond to the predictor coefficients, which are common for all of the first $k-1$ categories.
- If 'interaction' is 'on ', then $\mathbf{B}$ is a $(p+1)$-by- $(k-1)$ matrix. Each column of $B$ corresponds to the estimated intercept term and predictor coefficients, one for each of the first $k-1$ multinomial categories.

The estimates for the $k$ th category are taken to be zero as mnrfit takes the last category as the reference category.

## dev - Deviance of the fit

scalar value
Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$
d e v=2 * \sum_{i}^{n} \sum_{j}^{k} y_{i j} * \log \left(\frac{y_{i j}}{\pi_{i j} * m_{i}}\right)=\sum_{i}^{n} r d_{i},
$$

where $r d_{i}$ are the deviance residuals. For deviance residuals see stats.

## stats - Model statistics

## structure

Model statistics, returned as a structure that contains the following fields.

| beta | The coefficient estimates. These are the same as B. |
| :---: | :---: |
| dfe | Degrees of freedom for error <br> - If 'interactions' is 'off', then degrees of freedom is $n^{*}(k-1)-(k-1+p)$. <br> - If 'interactions' is 'on', then degrees of freedom is $(n-p+1)^{*}(k-1)$. |
| sfit | Estimated dispersion parameter. |
| S | Theoretical or estimated dispersion parameter. <br> - If estdisp is 'off', then s is the theoretical dispersion parameter, 1 . <br> - If estdisp is 'on', then $s$ is equal to the estimated dispersion parameter, sfit. |
| estdisp | Indicator for a theoretical or estimated dispersion parameter. |
| se | Standard errors of coefficient estimates, B. |
| coeffcorr | Estimated correlation matrix for B. |
| covb | Estimated covariance matrix for B. |
| t | $t$ statistics for B. |
| $p$ | $p$-values for B. |

| resid | Raw residuals. Observed minus fitted values, $r_{i j}=y_{i j}-\hat{\pi}_{i j} * m_{i}, \quad\left\{\begin{array}{l} i=1, \cdots, n \\ j=1, \cdots, k \end{array}\right.$ <br> where $\Pi_{i j}$ is the categorical, cumulative or conditional probability, and $m_{i}$ is the corresponding sample size. |
| :---: | :---: |
| residp | Pearson residuals, which are the raw residuals scaled by the estimated standard deviation: $r p_{i j}=\frac{r_{i j}}{\hat{\sigma}_{i j}}=\frac{y_{i j}-\hat{\pi}_{i j} * m_{i}}{\sqrt{\hat{\pi}_{i j} *\left(1-\hat{\pi}_{i j}\right) * m_{i}}}, \quad\left\{\begin{array}{l} i=1, \cdots, n \\ j=1, \cdots, k \end{array}\right.$ <br> where $\Pi_{i j}$ is the categorical, cumulative, or conditional probability, and $m_{i}$ is the corresponding sample size. |
| residd | Deviance residuals: $r d_{i}=2 * \sum_{j}^{k} y_{i j} * \log \left(\frac{y_{i j}}{\pi_{i j} * m_{i}}\right), \quad i=1, \cdots, n .$ <br> where $\Pi_{i j}$ is the categorical, cumulative, or conditional probability, and $m_{i}$ is the corresponding sample size. |

## Examples

## Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.
load('fisheriris.mat')

## mnrfit

The column vector, species, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix meas consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in sp, 1, 2, and 3 indicate the species setosa, versicolor, and virginica, respectively.

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
B
B =
\begin{tabular}{rr}
13.3860 & 15.4492 \\
2.4623 & 1.8196 \\
5.2948 & 2.5700 \\
-7.4916 & -4.3714 \\
-8.9322 & -7.6467
\end{tabular}
```

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of meas. The first row of B contains the intercept terms for the relative risk of the first two response categories, setosa and versicolor versus the reference category, virginica. The last four rows contain the slopes for the models for the first two categories. mnrfit accepts the third category as the reference category.

The models for the relative risk of an iris flower being a setosa versus a virginica, and the relative risk of an iris flower being a versicolor species versus a virginica species are respectively

$$
\ln \left(\frac{\pi_{\text {setosa }}}{\pi_{\text {virginica }}}\right)=13.38+2.46 X_{1}+5.29 X_{2}-7.49 X_{3}-8.93 X_{4}
$$

and

$$
\ln \left(\frac{\pi_{\text {versicolor }}}{\pi_{\text {virginica }}}\right)=15.45+1.82 X_{1}+2.57 X_{2}-4.37 X_{3}-7.65 X_{4}
$$

The coefficients express the effects of the predictor variables on the relative risk or the log odds of being in one category versus the reference category.
For example, the estimated coefficient 2.46 indicates that the probability of being species 1 (setosa) compared to the probability of being species 3 (virginica) (the relative risk of being a setosa versus a virginica) increases $\exp (2.46)$ times for each unit increase in $X_{1}$, the first measurement, given all else equal.

In terms of log odds, you can say that the relative log odds of being a setosa versus a virginica increases 2.46 times with a one-unit increase in $X_{1}$ given all else is equal.

Check the statistical significance of the model coefficients.
stats.p
ans =

| 0.2457 | 0.0031 |
| :--- | :--- |
| 0.4543 | 0.1048 |
| 0.0773 | 0.0815 |
| 0.0258 | 0.0007 |
| 0.1856 | 0.0002 |

The $p$-value of 0.0258 indicates that the third measure is significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3 ). The $p$-values of 0.0007 and 0.0002 indicate that the third and fourth measures are significant on the relative risk of being a versicolor versus a virginica (species 2 compared to species 3 ).

Request the standard errors of coefficient estimates.

```
stats.se
ans =
\begin{tabular}{rr}
11.5316 & 5.2201 \\
3.2905 & 1.1218 \\
2.9976 & 1.4753 \\
3.3609 & 1.2869 \\
6.7474 & 2.0846
\end{tabular}
```

Calculate the $95 \%$ confidence limits for the coefficients.

```
LL = stats.beta - 1.96.*stats.se;
UL = stats.beta + 1.96.*stats.se;
```

Display the confidence intervals for the coefficients of the model for the relative risk of being a setosa versus a virginica (the first column of coefficients in B).
[LL(:,1) UL(:,1)]
ans =
$-9.2160 \quad 35.9880$
-3.9869 8.9116
-0.5805 11.1701
-14.0790 -0.9043
-22.1570 4.2926

Find the confidence intervals for the coefficients of the model for the relative risk of being a versicolor versus a virginica (the second column of coefficients in B).
[LL(: , 2) UL(: 2)]
ans =

| 5.2177 | 25.6807 |
| ---: | ---: |
| -0.3791 | 4.0184 |
| -0.3216 | 5.4615 |
| -6.8938 | -1.8490 |
| -11.7324 | -3.5610 |

## Multinomial Regression for Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range $9-19$ as 1 , $20-29$ as $2,30-39$ as 3 , and $40-48$ as 4 .

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
miles = double(miles);
```

Fit an ordinal response model for the response variable miles.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
```

B

## mnrfit

$B=$
-16.6895
-11.7208
-8. 0606
0.1048
0.0103
0.0645
0.0017

The first three elements of $B$ are the intercept terms for the models, and the last four elements of $B$ are the coefficients of the covariates, assumed common across all categories. This model corresponds to parallel regression, which is also called the proportional odds model, where there is a different intercept but common slopes among categories. You can specify this using the 'interactions', 'off' name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
ans =
    -16.6895 -11.7208 -8.0606
    0.1048 0.1048 0.1048
    0.0103 0.0103 0.0103
    0.0645 0.0645 0.0645
    0.0017 0.0017 0.0017
```

The link function in the model is logit ('link', 'logit'), which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$
\begin{aligned}
& \ln \left(\frac{P(m p g \leq 19)}{P(m p g>19)}\right)=-16.6895+0.1048 X_{A}+0.0103 X_{D}+0.0645 X_{H}+0.0017 X_{W} \\
& \ln \left(\frac{P(m p g \leq 29)}{P(m p g>29)}\right)=-11.7208+0.1048 X_{A}+0.0103 X_{D}+0.0645 X_{H}+0.0017 X_{W} \\
& \ln \left(\frac{P(m p g \leq 39)}{P(m p g>39)}\right)=-8.0606+0.1048 X_{A}+0.0103 X_{D}+0.0645 X_{H}+0.0017 X_{W}
\end{aligned}
$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19 , or being less than or equal to 29 versus greater than 29 , or being less than or equal to 39 versus greater than 39 , by a factor of $\exp (0.01048)$ given all else is equal.

Assess the significance of the coefficients.

```
stats.p
ans =
    0.0000
    0.0000
    0.0000
    0.1899
    0.0350
    0.0000
    0.0118
```

The $p$-values of $0.035,0.0000$, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

## Hierarchical Multinomial Regression Model

Fit a hierarchical multinomial regression model.
Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.
load smoking
The data set smoking contains five variables: sex, age, weight, and systolic and diastolic blood pressure. Sex is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = nominal(smoking.Smoker);
Y = double(Y);
```

The data in Smoker has four categories:

- 0 : Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1-5 cigarettes a day
- 2: Smoker, 6-10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...
    smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');
B
```

$B=$

| 43.8148 | 5.9571 | 44.0712 |
| ---: | ---: | ---: |
| 1.8709 | -0.0230 | 0.0662 |
| 0.0188 | 0.0625 | 0.1335 |
| 0.0046 | -0.0072 | -0.0130 |
| -0.2170 | 0.0416 | -0.0324 |
| -0.2273 | -0.1449 | -0.4824 |

The first column of B includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking $1-5$ cigarettes a day versus more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6-10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions', 'on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$
\begin{aligned}
& \ln \left(\frac{P(y=0)}{P(y>0)}\right)=43.8148+1.8709 X_{S}+0.0188 X_{A}+0.0046 X_{W}-0.2170 X_{S B P}-0.2 \\
& \ln \left(\frac{P(1 \leq y \leq 5)}{P(y>5)}\right)=5.9571-0.0230 X_{S}+0.0625 X_{A}+0.0072 X_{W}+0.0416 X_{S B P}-0 \\
& \ln \left(\frac{P(6 \leq y \leq 10)}{P(y>10)}\right)=44.0712+0.0662 X_{S}+0.1335 X_{A}-0.0130 X_{W}-0.0324 X_{S B P}
\end{aligned}
$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by $\exp (1.8709)=6.49$ times as the gender changes from female to male given everything else held constant.

## mnrfit

Assess the statistical significance of the terms.
stats.p
ans =

| 0.0000 | 0.5363 | 0.2149 |
| :--- | :--- | :--- |
| 0.3549 | 0.9912 | 0.9835 |
| 0.6850 | 0.2676 | 0.2313 |
| 0.9032 | 0.8523 | 0.8514 |
| 0.0009 | 0.5187 | 0.8165 |
| 0.0004 | 0.0483 | 0.0545 |

Sex, age, or weight don't appear significant on any level. The $p$-values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The $p$-value of 0.0483 shows that only diastolic blood pressure is significant on the odds of a person smoking $0-5$ cigarettes a day versus more than 5 cigarettes a day. Similarly, the $p$-value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking $6-10$ cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()
gscatter(smoking.Age,smoking.Weight,smoking.Sex)
legend('Male','Female')
xlabel('Age')
ylabel('Weight')
```

The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

X = double([smoking.Sex smoking.SystolicBP...

```
smoking.DiastolicBP]);
[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');
B
B =
\begin{tabular}{ccc}
44.8456 & 5.3230 & 25.0248 \\
1.6045 & 0.2330 & 0.4982 \\
-0.2161 & 0.0497 & 0.0179 \\
-0.2222 & -0.1358 & -0.3092
\end{tabular}
```

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by $\exp (1.6045)=4.97$ times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an $\exp (-.2161)=0.8056$ decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an $\exp (-.2222)$ $=0.8007$ decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
```

ans =

| 0.0000 | 0.4715 | 0.2325 |
| :--- | :--- | :--- |
| 0.0210 | 0.7488 | 0.6362 |
| 0.0010 | 0.4107 | 0.8899 |
| 0.0003 | 0.0483 | 0.0718 |

The $p$-values of $0.0210,0.0010$, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the $p$-value of 0.0483 , diastolic blood pressure appears significant on the relative risk of a person smoking $1-5$ cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the $p$-values on the third column are less than 0.05 ,
you can say that none of the variables are statistically significant on the relative risk of a person smoking from 6-10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

Algorithms mnrfit treats NaNs in either X or Y as missing values, and ignores them.

- "Multinomial Distribution" on page B-67

## Purpose Multinomial logistic regression values

```
Syntax pihat = mnrval(B,X)
[pihat,dlow,dhi] = mnrval(B,X,stats)
[pihat,dlow,dhi] = mnrval(B,X,stats,Name,Value)
yhat = mnrval(B,X,ssize)
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats,Name,Value)
```

## Description

pihat $=m n r v a l(B, X)$ returns the predicted probabilities for the multinomial logistic regression model with predictors, $X$, and the coefficient estimates, B.
pihat is an $n$-by- $k$ matrix of predicted probabilities for each multinomial category. $B$ is the vector or matrix that contains the coefficient estimates returned by mnrfit. And X is an $n$-by- $p$ matrix which contains $n$ observations for $p$ predictors.

Note mnrval automatically includes a constant term in all models. Do not enter a column of 1 s in X .
[pihat, dlow, dhi] = mnrval(B, X, stats) also returns $95 \%$ error bounds on the predicted probabilities, pihat, using the statistics in the structure, stats, returned by mnrfit.

The lower and upper confidence bounds for pihat are pihat minus dlow and pihat plus dhi, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.
[pihat, dlow,dhi] = mnrval(B,X,stats,Name, Value) returns the predicted probabilities and $95 \%$ error bounds on the predicted probabilities pihat, with additional options specified by one or more Name, Value pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.
yhat $=$ mnrval $(B, X, s s i z e)$ returns the predicted category counts for sample sizes, ssize.
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats) also computes 95\% error bounds on the predicted counts yhat, using the statistics in the structure, stats, returned by mnrfit.

The lower and upper confidence bounds for yhat are yhat minus dlo and yhat plus dhi, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats,Name,Value) returns the predicted category counts and $95 \%$ error bounds on the predicted counts yhat, with additional options specified by one or more Name, Value pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

## Input Arguments

## B - Coefficient estimates <br> vector or matrix returned by mnrfit

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by mnrfit. It is a vector or matrix depending on the model and interactions.

Example: $B=\operatorname{mnrfit}(X, y) ;$ pihat $=m n r v a l(B, X)$

## Data Types

single | double

## X - Sample data

matrix

Sample data on predictors, specified as an $n$-by- $p$. X contains $n$ observations for $p$ predictors.

Note mnrval automatically includes a constant term in all models. Do not enter a column of 1 s in X .

```
Example: pihat = mnrval(B,X)
```

```
Data Types
single | double
```

stats - Model statistics
structure returned by mnrfit
Model statistics, specified as a structure returned by mnrfit. You must use the stats input argument in mnrval to compute the lower and upper error bounds on the category probabilities and counts.

Example: [B,dev,stats] = mnrfit(X,y);[pihat,dlo,dhi] = mnrval( $B, X$, stats)

## ssize - Sample sizes

column vector of positive integers
Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an $n$-by- 1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is $y_{1}, y_{2}$, and $y_{3}$, respectively, then the sample size, $m$, for that observation is $m=$ $y_{1}+y_{2}+y_{3}$.
If the sample sizes for $n$ observations are in vector sample, then you can enter the sample sizes as follows.

Example: yhat = mnrval(B,X,sample)

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example:
'model','ordinal','link','probit','type','cumulative' specifies that mnrval returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

## 'model' - Type of multinomial model

'nominal' (default) | 'ordinal' | 'hierarchical
Type of multinomial model fit by mnrfit, specified as the comma-separated pair consisting of 'model' and one of the following.

| 'nominal' | Default. Specify when there is no ordering among the <br> response categories. |
| :--- | :--- |
| 'ordinal' | Specify when there is a natural ordering among the <br> response categories. |
| 'hierarchic\&pecify when the choice of response category is |  |
| sequential. |  |

Example: 'model','ordinal'

## 'interactions' - Indicator for interaction between multinomial categories and coefficients

```
'on' | 'off'
```

Indicator for an interaction between the multinomial categories and coefficients in the model fit by mnrfit, specified as the comma-separated pair consisting of 'interactions ' and one of the following.

| 'on ' | Default for nominal and hierarchical models. Specify to fit <br> a model with different intercepts and coefficients across <br> categories. |
| :--- | :--- |
| 'off' | Default for ordinal models. Specify to fit a model with <br> different intercepts, but a common set of coefficients for the <br> predictor variables, across all multinomial categories. This <br> is often described as parallel regression or proportional <br> odds model. |

Example: 'interactions','off'

## Data Types

logical

## 'link' - Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'
Link function mnrfit uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

| 'logit' | Default. $f(\gamma)=\ln (\gamma /(1-\gamma))$ |
| :--- | :--- |
| 'probit' | $f(\gamma)=\Phi^{-1}(\gamma)-$ error term is normally distributed <br> with variance 1 |
| 'comploglog' | Complementary $\log -\log f(\gamma)=\ln (-\ln (1-\gamma))$ |
| 'loglog' | $f(\gamma)=\ln (-\ln (\gamma))$ |

The link function defines the relationship between response probabilities and the linear combination of predictors, $X \beta$.
$\gamma$ might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

$$
\ln \left(\frac{\pi_{j}}{\pi_{r}}\right)=\beta_{j 0}+\beta_{j 1} X_{j 1}+\beta_{j 2} X_{j 2}+\cdots+\beta_{j p} X_{j p}, \quad j=1, \ldots, k-1,
$$

where $\Pi$ stands for a categorical probability, and $r$ corresponds to the reference category, $k$ is the total number of response categories, $p$ is the number of predictor variables. mnrfit uses the last category as the reference category for nominal models.

## Example: 'link','loglog'

## 'type' - Type of probabilities or counts to estimate <br> 'category' (default) | 'cumulative' | 'conditional'

Type of probabilities or counts to estimate, specified as the comma-separated pair including 'type' and one of the following.

| 'category' | Default. Specify to return predictions and error <br> bounds for the probabilities (or counts) of the $k$ <br> multinomial categories. |
| :--- | :--- |
| 'cumulative' | Specify to return predictions and confidence <br> bounds for the cumulative probabilities (or <br> counts) of the first $k-1$ multinomial categories, <br> as an $n$-by- $(k-1)$ matrix. The predicted <br> cumulative probability for the $k$ th category is <br> always 1. |
| 'conditional' | Specify to return predictions and error bounds <br> in terms of the first $k-1$ conditional category <br> probabilities (counts), i.e., the probability (count) <br> for category $j$, given an outcome in category $j$ or <br> higher. When ' type' is 'conditional ', and <br> you supply the sample size argument ssize, the <br> predicted counts at each row of $X$ are conditioned <br> on the corresponding element of ssize, across <br> all categories. |

Example: 'type','cumulative'

# 'confidence' - Confidence level <br> 0.95 (default) | Scalar value in the range $(0,1)$ 

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range $(0,1)$.

For example, for $99 \%$ error bounds, you can specify the confidence as follows:

```
Example: 'confidence',0.99
```

```
Data Types
single | double
```

## Output

Arguments
pihat - Probability estimates
$n$-by- $(k-1)$ matrix
Probability estimates for each multinomial category, returned as an $n$-by-( $k-1$ ) matrix, where $n$ is the number of observations, and $k$ is the number of response categories.

## yhat - Count estimates

$n$-by- $k-1$ matrix
Count estimates for the number in each response category, returned as an $n$-by- $k-1$ matrix, where $n$ is the number of observations, and $k$ is the number of response categories.

## dlow - Lower error bound

column vector
Lower error bound to compute the lower confidence bound for pihat or yhat, returned as a column vector.

The lower confidence bound for pihat is pihat minus dlow. Similarly, the lower confidence bound for yhat is yhat minus dlow. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

## dhi - Upper error bound

[^9]Upper error bound to compute the upper confidence bound for pihat or yhat, returned as a column vector.
The upper confidence bound for pihat is pihat plus dhi. Similarly, the upper confidence bound for yhat is yhat plus dhi. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

## Examples

## Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, species, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix meas consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in sp, 1, 2, and 3 indicate the species setosa, versicolor, and virginica, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.
[B,dev,stats] = mnrfit(meas,sp);
Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.2, 3.7, 5.8, 0.2).
$\mathrm{x}=[6.2,3.7,5.8,0.2]$;

```
pihat = mnrval(B,meas);
pihat
pihat =
    0.0017 0.9982 0.0001
```

The probability of an iris flower having the measurements (6.2, 3.7, 5.8, 0.2 ) being a setosa is 0.0017 , a versicolor is 0.9982 , and a virginica is 0.0001.

## Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg .

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48 , respectively.

Fit a multinomial regression model for the response variable miles. For an ordinal model, the default 'link' is logit and the default 'interactions' is 'off'.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
```

Compute the probability estimates and $95 \%$ error bounds for probability confidence intervals for miles per gallon of a car with $x=(12,113$, 110, 2670).

```
x = [12,113,110,2670];
[pihat,dlow,hi] = mnrval(B,x,stats,'model','ordinal');
pihat
pihat =
    0.0615 0.8426 0.0932 0.0027
```

Calculate the confidence bounds for the category probability estimates.
LL = pihat - dlow;
UL = pihat + hi;
[LL;UL]
ans =

| 0.0073 | 0.7829 | 0.0283 | -0.0003 |
| ---: | ---: | ---: | ---: |
| 0.1157 | 0.9022 | 0.1580 | 0.0057 |

## Estimate Category Counts and Error Bounds for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.
load('fisheriris.mat')

The column vector, species, consists of iris flowers of three different species, setosa, versicolor, and virginica. The double matrix meas consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.
sp = nominal(species);
sp = double(sp);
Now in sp, 1, 2, and 3 indicate the species setosa, versicolor, and virginica, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2,3.7,5.8,0.2];
yhat = mnrval(B,x,18)
yhat =
    0.0314 17.9671 0.0016
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrval(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;
UL = yhat + hi;
[LL;UL]
ans =
```

| -0.7084 | 17.2272 | -0.0115 |
| ---: | ---: | ---: |
| 0.7711 | 18.7069 | 0.0146 |

## Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10;...
    5 14 6; 7 13 5; 8 11 6];
[Y x]
ans =
```

| 1 | 11 | 13 | -3 |
| ---: | ---: | ---: | ---: |
| 2 | 9 | 14 | -2 |
| 6 | 14 | 5 | -1 |
| 5 | 10 | 10 | 0 |
| 5 | 14 | 6 | 1 |
| 7 | 13 | 5 | 2 |
| 8 | 11 | 6 | 3 |

There are observations on seven different values of the predictor variable $x$. The response variable $Y$ has three categories and the data shows how many of the 25 individuals are in each category of $Y$ for each observation of $x$. For example, when $x$ is $-3,1$ of 25 individuals is observed in category 1,11 observed in category 2 , and 13 observed in category 3 . Similarly, when $x$ is 1,5 of the individuals are observed in category 1,14 are observed in category 2 , and 6 are observed in category 3.

Plot the number in each category versus the x values, on a stacked bar graph.

```
bar(x,Y,'stacked');
ylim([0 25]);
```

Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable, x , for each category.

```
betaHatNom = mnrfit(x,Y,'model','nominal',...
    'interactions','on')
betaHatNom =
\[
\begin{array}{rr}
-0.6028 & 0.3832 \\
0.4068 & 0.1948
\end{array}
\]
```

The first row of betaHatNom contains the intercept terms for the first two response categories. The second row contains the slopes. mnrfit accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.
xx = linspace(-4,4)';
piHatNom = mnrval(betaHatNom,xx,'model','nominal',...
'interactions', 'on');
The probability of being in the third category is simply $1-\mathrm{P}(y=1)$ $-\mathrm{P}(y=2)$.

Plot the estimated cumulative number in each category on the bar graph.
line(xx, cumsum(25*piHatNom,2),'LineWidth',2);

The cumulative probability for the third category is always 1 .
Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable, $x$, across all categories:

```
betaHatOrd = mnrfit(x,Y,'model','ordinal',...
```

    'interactions','off')
    betaHatOrd =

$$
\begin{array}{r}
-1.5001 \\
0.7266 \\
0.2642
\end{array}
$$

The first two elements of betaHatOrd are the intercept terms for the first two response categories. The last element of betaHatOrd is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1 .

```
piHatOrd = mnrval(betaHatOrd,xx,'type','cumulative',...
    'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()
bar(x,cumsum(Y,2),'grouped');
ylim([0 25]);
line(xx,25*pHatOrd,'LineWidth',2);
```

## Concepts

- "Multinomial Models for Nominal Responses" on page 10-2
- "Multinomial Models for Ordinal Responses" on page 10-5
- "Hierarchical Multinomial Models" on page 10-9

## Purpose Central moments

## Syntax <br> m = moment(X,order) <br> moment (X,order,dim)

## Description

Note that the central first moment is zero, and the second central moment is the variance computed using a divisor of $n$ rather than $n-$ 1 , where $n$ is the length of the vector x or the number of rows in the matrix $X$.

The central moment of order $k$ of a distribution is defined as

$$
m_{k}=E(x-\mu)^{k}
$$

where $E(x)$ is the expected value of $x$.

## Examples

```
X = randn([6 5])
X =
    1.1650 0.0591 1.2460 -1.2704 -0.0562
    0.6268 1.7971 -0.6390 0.9846 0.5135
    0.0751 0.2641 0.5774 -0.0449 0.3967

## gmdistribution.Mu property

Purpose Input matrix of means MU
Description Input matrix of means mu.
Purpose Multiple comparison test
Syntax $\quad c=$ multcompare (stats)
c = multcompare(stats,param1,val1,param2,val2,...)
[c,m] = multcompare(...)
[c,m,h] = multcompare(...)
[c,m,h,gnames] = multcompare(...)
c = multcompare(stats) performs a multiple comparison test using the information in the stats structure, and returns a matrix c of pairwise comparison results. It also displays an interactive graph of the estimates with comparison intervals around them. See "Examples" on page 20-1620.
In a one-way analysis of variance, you compare the means of several groups to test the hypothesis that they are all the same, against the general alternative that they are not all the same. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A test that can provide such information is called a multiple comparison procedure.
When you perform a simple t-test of one group mean against another, you specify a significance level that determines the cutoff value of the t statistic. For example, you can specify the value alpha $=0.05$ to insure that when there is no real difference, you will incorrectly find a significant difference no more than $5 \%$ of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary t-test in this situation, the alpha value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that any comparison will be incorrectly found significant.
The output c contains the results of the test in the form of a five-column matrix. Each row of the matrix represents one test, and there is one row for each pair of groups. The entries in the row indicate the means being compared, the estimated difference in means, and a confidence interval for the difference.

For example, suppose one row contains the following entries.

$$
\begin{array}{lllll}
2.0000 & 5.0000 & 1.9442 & 8.2206 & 14.4971
\end{array}
$$

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206 , and a $95 \%$ confidence interval for the true difference of the means is [1.9442, 14.4971].

In this example the confidence interval does not contain 0.0 , so the difference is significant at the 0.05 level. If the confidence interval did contain 0.0 , the difference would not be significant at the 0.05 level.

The multcompare function also displays a graph with each group mean represented by a symbol and an interval around the symbol. Two means are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. You can use the mouse to select any group, and the graph will highlight any other groups that are significantly different from it.
c = multcompare(stats,param1,val1,param2,val2,...) specifies one or more of the parameter name/value pairs described in the following table.

| Parameter | Values |
| :--- | :--- |
| ' alpha' | Scalar between 0 and 1 that determines the <br> confidence levels of the intervals in the matrix <br> c and in the figure (default is 0.05). The <br> confidence level is 100(1-alpha)\%. |
| 'display' | Either 'on ' (the default) to display a graph <br> of the estimates with comparison intervals <br> around them, or ' off ' to omit the graph. See <br> "Examples" on page 20-1620. |
| 'ctype' | Specifies the type of critical value to use for the <br> multiple comparison. "Values of ctype" on page <br> 20-1618 describes the allowed values for ctype. |

| Parameter | Values |
| :--- | :--- |
| 'dimension' | A vector specifying the dimension or dimensions <br> over which the population marginal means <br> are to be calculated. Use only if you create <br> stats with the function anovan. The default <br> is 1 to compute over the first dimension. See <br> "Dimension Parameter" on page 20-1620 for <br> more information. |
| 'estimate' | Specifies the estimate to be compared. The <br> allowable values of estimate depend on the <br> function that was the source of the stats <br> structure, as described in "Values of estimate" <br> on page 20-1619 |

[c,m] = multcompare(...) returns an additional matrix $m$. The first column of $m$ contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.
[ $\mathrm{c}, \mathrm{m}, \mathrm{h}]=$ multcompare (...) returns a handle h to the comparison graph. Note that the title of this graph contains instructions for interacting with the graph, and the $x$-axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the $x$-axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')
xlabel('')
```

[ $\mathrm{c}, \mathrm{m}, \mathrm{h}$, gnames] = multcompare(...) returns gnames, a cell array with one row for each group, containing the names of the groups.

The intervals shown in the graph are computed so that to a very close approximation, two estimates being compared are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. (This is exact for multiple comparison of means from
anova1, if all means are based on the same sample size.) You can click on any estimate to see which means are significantly different from it.

## Values of ctype

The following table describes the allowed values for the parameter ctype.

| Value | Description |
| :--- | :--- |
| 'hsd ' or <br> 'tukey-kramer' | Use Tukey's honestly significant difference <br> criterion. This is the default, and it is based on the <br> Studentized range distribution. It is optimal for <br> balanced one-way ANOVA and similar procedures <br> with equal sample sizes. It has been proven <br> to be conservative for one-way ANOVA with <br> different sample sizes. According to the unproven <br> Tukey-Kramer conjecture, it is also accurate for <br> problems where the quantities being compared <br> are correlated, as in analysis of covariance with <br> unbalanced covariate values. |
| 'lsd' | Use Tukey's least significant difference procedure. <br> This procedure is a simple t-test. It is reasonable <br> if the preliminary test (say, the one-way ANOVA <br> $F$ statistic) shows a significant difference. If it is <br> used unconditionally, it provides no protection <br> against multiple comparisons. |
| 'bonferroni' | Use critical values from the t distribution, after a <br> Bonferroni adjustment to compensate for multiple <br> comparisons. This procedure is conservative, but <br> usually less so than the Scheffé procedure. |

| Value | Description |
| :--- | :--- |
| 'dunn-sidak' | Use critical values from the t distribution, after <br> an adjustment for multiple comparisons that was <br> proposed by Dunn and proved accurate by Sidák. <br> This procedure is similar to, but less conservative <br> than, the Bonferroni procedure. |
| 'scheffe' | Use critical values from Scheffés S procedure, <br> derived from the F distribution. This procedure <br> provides a simultaneous confidence level for <br> comparisons of all linear combinations of the <br> means, and it is conservative for comparisons of <br> simple differences of pairs. |

## Values of estimate

The allowable values of the parameter 'estimate' depend on the function that was the source of the stats structure, according to the following table.

| Source | Values |
| :--- | :--- |
| 'anova1' | Ignored. Always compare the group means. |
| 'anova2' | Either 'column' (the default) or 'row ' to <br> compare column or row means. |
| 'anovan' | Ignored. Always compare the population <br> marginal means as specified by the dim <br> argument. |
| 'aoctool' | Either 'slope ', 'intercept', or 'pmm' to <br> compare slopes, intercepts, or population <br> marginal means. If the analysis of covariance <br> model did not include separate slopes, then <br> 'slope' is not allowed. If it did not include <br> separate intercepts, then no comparisons are <br> possible. |

| Source | Values |
| :--- | :--- |
| 'friedman ' | Ignored. Always compare average column ranks. |
| 'kruskalwallis' | Ignored. Always compare average group ranks. |

## Dimension Parameter

The dimension parameter is a vector specifying the dimension or dimensions over which the population marginal means are to be calculated. For example, if $\operatorname{dim}=1$, the estimates that are compared are the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If dim = [ $\left.\begin{array}{ll}1 & 3\end{array}\right]$, population marginal means are computed for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN .
Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by dim, and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means ignoring other factors. For surveys and other studies where the number of observations at each combination does have meaning, population marginal means may be harder to interpret.

## Examples

## Example 1

The following example performs a 1 -way analysis of variance (ANOVA) and displays group means with their names.

```
load carsmall
```

```
[p,t,st] = anova1(MPG,Origin,'off');
[c,m,h,nms] = multcompare(st,'display','off');
[nms num2cell(m)]
ans =
\begin{tabular}{lll} 
'USA' & {\([21.1328]\)} & {\([0.8814]\)} \\
'Japan' & {\([31.8000]\)} & {\([1.8206]\)} \\
'Germany' & {\([28.4444]\)} & {\([2.3504]\)} \\
'France' & {\([23.6667]\)} & {\([4.0711]\)} \\
'Sweden' & {\([22.5000]\)} & {\([4.9860]\)} \\
'Italy' & {\([28.0000]\)} & {\([7.0513]\)}
\end{tabular}
```

multcompare also displays the following graph of the estimates with comparison intervals around them.

You can click the graphs of each country to compare its mean to those of other countries.

## Example 2

The following continues the example described in the anova1 reference page, which is related to testing the material strength in structural beams. From the anova1 output you found significant evidence that the three types of beams are not equivalent in strength. Now you can determine where those differences lie. First you create the data arrays and you perform one-way ANOVA.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
    78 75 76 77 79 79 77 78 82 79];
alloy = {'st','st','st','st','st','st','st','st',...
    'al1','al1','al1','al1','al1','al1',...
    'al2','al2','al2','al2','al2','al2'};
[p,a,s] = anova1(strength,alloy);
```

Among the outputs is a structure that you can use as input to multcompare.

```
[c,m,h,nms] = multcompare(s);
[nms num2cell(c)]
ans =
\begin{tabular}{lllllll} 
'st' & {\([1]\)} & {\([2]\)} & {\([3.6064]\)} & {\([8]\)} & {\([10.3936]\)} \\
'al1' & {\([1]\)} & {\([3]\)} & {\([1.6064]\)} & {\([5]\)} & {\([8.3936]\)} \\
'al2' & {\([2]\)} & {\([3]\)} & {\([-5.6280]\)} & {\([-2]\)} & {\([8.6280]\)}
\end{tabular}
```

The third row of the output matrix shows that the differences in strength between the two alloys is not significant. A $95 \%$ confidence interval for the difference is $[-5.6,1.6]$, so you cannot reject the hypothesis that the true difference is zero.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. In other words, those differences are significant. The graph shows the same information.

## Superclasses ParametricTruncatableDistribution

Purpose Multinomial probability distribution object
Description prob.MultinomialDistribution is an object consisting of parameters and a model description for a multinomial probability distribution. Create a probability distribution object with specified parameters using makedist.

## Construction pd = makedist('Multinomial') creates a multinomial probability

 distribution object using the default parameter values.pd = makedist('Multinomial','Probabilities', probabilities) creates a multinomial distribution object using the specified parameter value.

## Input Arguments

## probabilities - outcome probabilities

## [0.500 0.500] (default) | vector of scalar values in the range [0,1]

Outcome probabilities, specified as a vector of scalar values in the range $[0,1]$. Each vector element is the probability that a multinomial trial has a particular corresponding outcome. The values in probabilities must sum to 1 .

Data Types<br>single | double

## Properties

## probabilities

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range $[0,1]$. The values in probabilities must sum to 1 .

## Data Types

single | double
DistributionName

## prob.MultinomialDistribution

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## IsTruncated

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

```
Data Types
single | double
```

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

Variance of probability distribution object

## Definitions

## Multinomial Distribution

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of "successes" in $n$ independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in $n$ independent trials of a $k$-outcome process. The probability of each outcome in any one trial is given by the fixed probabilities $p_{1}, \ldots, p_{\mathrm{k}}$.
The multinomial distribution uses the following parameters.

| Parameter | Description | Support |
| :--- | :--- | :--- |
| probabilities | Outcome <br> probabilities | $0 \leq \operatorname{probabilities~}(i) \leq 1 ; \sum_{\text {all }(i)} \operatorname{probabilities}(i)=1$ |

The probability density function (pdf) is
where $x=\left(x_{1}, \ldots, x_{k}\right)$ gives the number of each $k$ outcome in $n$ trials of a process with fixed probabilities $p=\left(p_{1}, \ldots, p_{k}\right)$ of individual outcomes in any one trial.

## Examples Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')
pd =
```

MultinomialDistribution

Probabilities:
$0.5000 \quad 0.5000$

## Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of $1 / 2$, outcome 2 has a probability of $1 / 3$, and outcome 3 has a probability of $1 / 6$.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])
pd =
```

MultinomialDistribution
Probabilities:
$0.5000 \quad 0.3333 \quad 0.1667$
Generate a random outcome from the distribution.

```
rng('default'); % for reproducibility
```

$r=r a n d o m(p d)$
$r=$

## prob.MultinomialDistribution

The result of this trial is outcome 2. By default, the number of trials in each experiment, $n$, equals 1 .

Generate random outcomes from the distribution when the number of trials in each experiment, $n$, equals 1 , and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
```

$r=\operatorname{random}(p d, 10,1)$
$r=$

$$
\begin{aligned}
& 2 \\
& 3 \\
& 1 \\
& 3 \\
& 2 \\
& 2 \\
& 1 \\
& 1 \\
& 2 \\
& 3 \\
& 3
\end{aligned}
$$

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment, $n$, equals 5 , and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
```

$r=\operatorname{random}(p d, 10,5)$
$r=$

| 2 | 1 | 2 | 2 | 1 |
| :--- | :--- | :--- | :--- | :--- |
| 3 | 3 | 1 | 1 | 1 |

| 1 | 3 | 3 | 1 | 2 |
| :--- | :--- | :--- | :--- | :--- |
| 3 | 1 | 3 | 1 | 2 |
| 2 | 2 | 2 | 1 | 1 |
| 1 | 1 | 2 | 2 | 1 |
| 1 | 1 | 2 | 2 | 1 |
| 2 | 3 | 1 | 1 | 2 |
| 3 | 2 | 2 | 3 | 2 |
| 3 | 3 | 1 | 1 | 2 |

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2 .

- Property Attributes

## multivarichart

Purpose Multivari chart for grouped data
Syntax $\left.\quad \begin{array}{l}\text { multivarichart(y, GROUP) } \\ \text { multivarichart(Y) } \\ \\ \text { multivarichart }(\ldots, \text { param1, val1, param2, val2, ...) } \\ \end{array}\right]$
Description
multivarichart ( $y$, GROUP) displays the multivari chart for the vector y grouped by entries in the cell array GROUP. Each cell of GROUP must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. GROUP can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of elements as $y$. The number of grouping variables must be 2,3 , or 4 .
Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The $x$-axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position $(i, j)$ is the multivari chart for the subset of $y$ at the $i$ th level of the third grouping variable and the $j$ th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.
multivarichart $(\mathrm{Y})$ displays the multivari chart for a matrix Y . The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.
multivarichart(...,param1,val1,param2,val2,...) specifies one or more of the following name/value pairs:

- 'varnames ' - Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2', ... .
- 'plotorder' - A string with the value 'sorted' or a vector containing a permutation of the integers from 1 to the number of grouping variables.

If 'plotorder' is a string with value 'sorted', the grouping variables are rearranged in descending order according to the number of levels in each variable.

If 'plotorder' is a vector, it indicates the order in which each grouping variable should be plotted. For example, [2,3,1,4] indicates that the second grouping variable should be used as the $x$-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.
[charthandle,AXESH] = multivarichart(...) returns a handle charthandle to the figure window and a matrix AXESH of handles to the subplot axes.

Examples Display a multivari chart for data with two grouping variables:

```
y = randn(100,1); % response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```

Display a multivari chart for data with four grouping variables:

```
y = randn(1000,1); % response
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...
    ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};
multivarichart(y,group)
```

$$
\circ \quad \times 2=1 \quad \square \quad \times 2=2 \quad \Leftrightarrow \quad \times 2=3
$$

## Purpose Multivariate normal cumulative distribution function

Syntax
$y=\operatorname{mvncdf}(X)$
$y=\operatorname{mvncdf}(X, m u$, SIGMA $)$
$y=\operatorname{mvncdf}(x l, x u, m u, S I G M A)$
[y,err] = mvncdf(...)
[...] = mvncdf(...,options)

## Description

$y=m v n c d f(X)$ returns the cumulative probability of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of $X$. Rows of the $n$-by- $d$ matrix X correspond to observations or points, and columns correspond to variables or coordinates. y is an $n$-by- 1 vector.
$y=m v n c d f(X$, mu, SIGMA $)$ returns the cumulative probability of the multivariate normal distribution with mean mu and covariance SIGMA, evaluated at each row of X. mu is a 1 -by- $d$ vector, and SIGMA is a $d$-by- $d$ symmetric, positive definite matrix. mu can also be a scalar value, which mvncdf replicates to match the size of $X$. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, SIGMA may also be specified as a 1-by-d vector containing just the diagonal. Pass in the empty matrix [] for mu to use as its default value when you want to only specify SIGMA.

The multivariate normal cumulative probability at X is defined as the probability that a random vector V , distributed as multivariate normal, will fall within the semi-infinite rectangle with upper limits defined by X , for example, $\operatorname{Pr}\{\mathrm{V}(1) \leq \mathrm{X}(1), \mathrm{V}(2) \leq \mathrm{X}(2), \ldots, \mathrm{V}(d) \leq \mathrm{X}(d)\}$. $y=m v n c d f(x l, x u, m u, S I G M A)$ returns the multivariate normal cumulative probability evaluated over the rectangle with lower and upper limits defined by $x l$ and $x u$, respectively.
[y,err] $=\operatorname{mvncdf}(\ldots)$ returns an estimate of the error in $y$. For bivariate and trivariate distributions, mvncdf uses adaptive quadrature on a transformation of the $t$ density, based on methods developed by Drezner and Wesolowsky and by Genz, as described in the references. The default absolute error tolerance for these cases is 1e-8. For four or more dimensions, mvncdf uses a quasi-Monte Carlo integration
algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is $1 \mathrm{e}-4$.
[...] = mvncdf(..., options) specifies control parameters for the numerical integration used to compute $y$. This argument can be created by a call to statset. Choices of statset parameters:

- 'TolFun' - Maximum absolute error tolerance. Default is 1e-8 when $d<4$, or $1 \mathrm{e}-4$ when $d \geq 4$.
- 'MaxFunEvals' - Maximum number of integrand evaluations allowed when $d \geq 4$. Default is 1 e 7 . 'MaxFunEvals' is ignored when $d<4$.
- 'Display' - Level of display output. Choices are 'off' (the default), 'iter', and 'final'. 'Display' is ignored when $d<4$.

```
Examples mu = [1 -1]; SIGMA = [.9 .4; .4 .3];
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
p = mvncdf(X,mu,SIGMA);
surf(X1,X2,reshape(p,25,25));
```

How To . "Multivariate Normal Distribution" on page B-71

Purpose Multivariate normal probability density function
Syntax $\quad \begin{aligned} y & =\operatorname{mvnpdf}(X) \\ y & =\operatorname{mvnpdf}(X, M U) \\ y & =\operatorname{mvnpdf}(X, M U, \text { SIGMA })\end{aligned}$
Description
$\mathrm{y}=\operatorname{mvnpdf}(\mathrm{X})$ returns the $n$-by- 1 vector y , containing the probability density of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the $n$-by- $d$ matrix X. Rows of X correspond to observations and columns correspond to variables or coordinates.
$\mathrm{y}=\mathrm{mvnpdf}(\mathrm{X}, \mathrm{MU})$ returns the density of the multivariate normal distribution with mean mu and identity covariance matrix, evaluated at each row of X . MU is a 1 -by- $d$ vector, or an $n$-by- $d$ matrix. If MU is a matrix, the density is evaluated for each row of $X$ with the corresponding row of MU. MU can also be a scalar value, which mvnpdf replicates to match the size of $X$.
$y=m v n p d f(X, M U, S I G M A)$ returns the density of the multivariate normal distribution with mean MU and covariance SIGMA, evaluated at each row of X. SIGMA is a $d$-by- $d$ matrix, or a $d$-by- $d$-by- $n$ array, in which case the density is evaluated for each row of $X$ with the corresponding page of SIGMA, i.e., mvnpdf computes y(i) using X(i,:) and SIGMA (:,:,i). If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, SIGMA may also be specified as a 1-by- $d$ vector or a 1-by- $d$-by- $n$ array, containing just the diagonal. Specify [] for MU to use its default value when you want to specify only SIGMA.

If X is a 1 -by- $d$ vector, mvnpdf replicates it to match the leading dimension of mu or the trailing dimension of SIGMA.

## Examples

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
X = mvnrnd(mu,SIGMA,10);
p = mvnpdf(X,mu,SIGMA);
```

## Purpose Multivariate linear regression

```
Syntax beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress(___)
[beta,Sigma,E,CovB,logL] = mvregress(___)
```

## Description

## Input <br> Arguments

beta $=$ mvregress $(\mathrm{X}, \mathrm{Y})$ returns a $K$-by- 1 vector of estimated coefficients for a multivariate normal regression of the $d$-dimensional responses in Y on the design matrices in X .
mvregress treats NaN values in X or Y as missing values. Rows with missing values in X are ignored. Missing values in Y are handled according to the estimation algorithm.
beta $=$ mvregress $(X, Y$, Name, Value $)$ uses additional estimation options specified by one or more name-value pair arguments.
[beta,Sigma] = mvregress ( _ _ ) additionally returns the estimated $d$-by- $d$ variance-covariance matrix of Y. You can use any of the input arguments in the previous syntaxes.
[beta,Sigma, E, CovB,logL] = mvregress( $\qquad$ ) returns a matrix of residuals $E$, estimated variance-covariance matrix of the regression coefficients CovB, and the value of the log likelihood objective function after the last iteration logL.

## X - Design matrices

matrix | cell array of matrices
Design matrices for the multivariate regression, specified as an $N$-by- $K$ matrix, or a cell array of $d$-by- $K$ matrices, where $K$ is the number of regression coefficients to estimate.

To include a constant term in the regression model, each design matrix should have a column of 1 s .

- If $d=1$, then specify X as a single $N$-by- $K$ matrix.
- If $d>1$, then specify X as a cell array of matrices. If you are using the same $d$-by- $K$ design matrix for all $N$ observations, then X can be a single cell. Otherwise, specify X as a length- $N$ cell array of $d$-by- $K$ matrices.

## Data Types

single | double | cell

## Y - Response variables

matrix
Response variables, specified as an $N$-by- $d$ matrix. When $d=1$, mvregress treats the values in Y like $N$ independent response values.

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

Example: 'algorithm','cwls','covar0', C specifies covariance-weighted least squares estimation using the covariance matrix $C$.

'algorithm' - Estimation algorithm<br>'mvn' | 'ecm' | 'cwls'

Estimation algorithm, specified as the comma-separated pair consisting of 'algorithm' and one of the following strings:

| 'mvn' | Ordinary multivariate normal maximum <br> likelihood estimation. |
| :--- | :--- |
| 'ecm' | Maximum likelihood estimation via the ECM <br> algorithm. |
| 'cwls' | Covariance-weighted least squares estimation. |

The default algorithm depends on the presence of missing data.

- For complete data, the default is 'mvn'.
- If there are any missing responses (indicated by NaN), the default is 'ecm', provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is 'cwls'.

Note If algorithm has value 'mvn', then mvregress removes observations with missing response values before estimation.

Example: 'algorithm', ecm'

## 'beta0' - Initial estimates for regression coefficients

vector
Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of 'beta0' and a vector with $K$ elements. The default value is a vector of 0s.

The beta0 argument is not used if the estimation algorithm is 'mvn'.
For example, suppose b0 is a $K$-element vector of initial estimates.
Example: 'beta0', b0

## 'covar0' - Initial estimate for variance-covariance matrix <br> matrix

Initial estimate for the variance-covariance matrix, Sigma, specified as the comma-separated pair consisting of 'covaro' and a symmetric, positive definite, $d$-by- $d$ matrix. The default value is the identity matrix.

If the estimation algorithm is 'cwls', then mvregress uses covar0 as the weighting matrix at each iteration, without changing it.

For example, suppose C is a valid $d$-by- $d$ covariance matrix.
Example: 'covaro', C

## 'covtype' - Type of variance-covariance matrix

'full' (default) | 'diagonal'
Type of variance-covariance matrix to estimate for Y , specified as the comma-separated pair consisting of 'covtype' and one of 'full' or 'diagonal'.

- If the value is 'full', then mvregress estimates all $d(d+1) / 2$ variance-covariance elements.
- If the value is 'diagonal', then mvregress estimates only the $d$ diagonal elements of the variance-covariance matrix.

Example: 'covtype', 'diagonal'

## 'maxiter' - Maximum number of iterations

100 (default) | positive integer
Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of 'maxiter' and a positive integer.

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are zero, then mvregress performs maxiter iterations with no convergence tests.

Example: 'maxiter',50

'outputfen' - Function to evaluate each iteration<br>function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of 'outputfon' and a function handle. The function must return a logical true or false. At each iteration, mvregress evaluates the function. If the result is true, iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns true if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates.
- Structure with three fields:

| Covar | Current value of the variance-covariance <br> matrix |
| :--- | :--- |
| iteration | Current iteration number |
| fval | Current value of the loglikelihood objective <br> function |

- Text string that takes these three values:

| 'init' | For when the function is called during <br> initialization |
| :--- | :--- |
| 'iter' | For when the function is called after an <br> iteration |
| 'done' | For when called after completion |

'tolbeta' - Convergence tolerance for regression coefficients
sqrt(eps) (default) | positive scalar value
Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of 'tolbeta' and a positive scalar value. The default tolerance is sqrt(eps).

Let $\mathbf{b}^{t}$ denote the estimate of the coefficient vector at iteration $t$, and
$\tau_{\beta}$ be the tolerance specified by tolbeta. The convergence criterion for regression coefficient estimation is

$$
\left\|\mathbf{b}^{t}-\mathbf{b}^{t-1}\right\|<\tau_{\beta} \sqrt{K}\left(1+\left\|\mathbf{b}^{t}\right\|\right),
$$

where $K$ is the length of $\mathbf{b}^{t}$ and $\|\mathbf{v}\|$ is the norm of a vector $\mathbf{v}$.
Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are zero, then mvregress performs maxiter iterations with no convergence tests.

Example: 'tolbeta', 1e-5

## 'tolobj' - Convergence tolerance for loglikelihood objective function

eps^(3/4) (default) | positive scalar value
Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of 'tolobj' and a positive scalar value. The default tolerance is $\mathrm{eps}^{\wedge}(3 / 4)$.

Let $L^{t}$ denote the value of the loglikelihood objective function at iteration $t$, and $\tau_{\ell}$ be the tolerance specified by tolobj. The convergence criterion for the objective function is

$$
\left|L^{t}-L^{t-1}\right|<\tau_{\ell}\left(1+\left|L^{t}\right|\right) .
$$

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are zero, then mvregress performs maxiter iterations with no convergence tests.

Example: 'tolobj',1e-5

## 'varformat' - Format for parameter estimate variance-covariance matrix <br> ```'beta' (default) | 'full'```

Format for the parameter estimate variance-covariance matrix, CovB, specified as the comma-separated pair consisting of 'varformat' and one of these strings:

| 'beta' | Return the variance-covariance matrix for only <br> the regression coefficient estimates, beta. |
| :--- | :--- |
| 'full' | Return the variance-covariance matrix for both <br> the regression coefficient estimates, beta, <br> and the variance-covariance matrix estimate, |
| Sigma. |  |

Example: 'varformat','full'

## 'vartype' - Type of variance-covariance matrix for parameter estimates

```
'hessian' (default) | 'fisher'
```

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of 'vartype' and either 'hessian' or 'fisher'.

- If the value is 'hessian', then mvregress uses the Hessian, or observed information, matrix to compute CovB.
- If the value is 'fisher', then mvregress uses the complete-data Fisher, or expected information, matrix to compute CovB.

The 'hessian' method takes into account the increase uncertainties due to missing data, while the 'fisher' method does not.

Example: 'vartype', 'fisher'

## Output Arguments

## beta - Estimated regression coefficients

column vector
Estimated regression coefficients, returned as a $K$-by- 1 vector.

## Sigma-Estimate variance-covariance matrix <br> square matrix <br> Estimated variance-covariance matrix for the responses in Y, returned as a $d$-by- $d$ square matrix.

Note The estimated variance-covariance matrix, Sigma, is not the sample covariance matrix of the residual matrix, E .

## E - Residuals

matrix
Residuals for the fitted regression model, returned as an $N$-by- $d$ matrix.
If algorithm has value 'ecm' or 'cwls', then mvregress computes the residual values corresponding to missing values in Y as the difference between conditionally-imputed values and the fitted values.

Note If algorithm has value 'mvn', then mvregress removes observations with missing response values before estimation.

## CovB - Parameter estimate variance-covariance matrix square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If varformat has value 'beta' (the default), then CovB is the estimated variance-covariance matrix of the coefficient estimates in beta.
- If varformat has value 'full', then CovB is the estimated variance-covariance matrix of the combined estimates in beta and Sigma.

## logL - Loglikelihood objective function value

## scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

## Examples

## Multivariate Regression Model for Panel Data with Different Intercepts

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load sample data.
load('flu')

The dataset array, flu, contains national CDC flu estimates, and nine separate regional estimates based on Google ${ }^{\circledR}$ queries.

Extract response and predictor data.
Y = double(flu(:,2:end-1));
[N,d] = size(Y);
The responses are the Google query estimates. There are observations for every week, so $N=52$. The dimension of the responses corresponds to the regions, so $d=9$.
x = flu.WtdILI;

The predictors are national CDC flu estimates.

```
regions = flu.Properties.VarNames(2:end-1);
figure()
plot(x,Y,'x')
legend(regions,'Location','NorthWest')
```

Fit the multivariate regression model

$$
y_{i j}=\alpha_{j}+\beta x_{i j}+\varepsilon_{i j}, i=1, \ldots, N ; j=1, \ldots, d,
$$

with between-region concurrent correlation,

$$
\operatorname{COV}\left(\varepsilon_{i j}, \varepsilon_{i j^{\prime}}\right)=\sigma_{j j^{\prime}}, j=1, \ldots, d
$$

There are $K=10$ regression coefficients to estimate: 9 intercept terms and a common slope. The input argument X should be an $N$-element cell array of $d$-by- $K$ design matrices.

```
X = cell(N,1);
for i=1:N
    X{i} = [eye(d) repmat(x(i),d,1)];
```

end
[beta,Sigma] $=$ mvregress $(X, Y)$;
beta contains estimates of the $K$-dimensional coefficient vector,

$$
\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{9}, \beta\right)^{\prime}
$$

Sigma contains estimates of the $d$-by- $d$ variance-covariance matrix for the between-region concurrent correlations,

$$
\left(\begin{array}{ccc}
\sigma_{11} & \ldots & \sigma_{1,9} \\
\vdots & \ddots & \vdots \\
\sigma_{9,1} & \cdots & \sigma_{9,9}
\end{array}\right)
$$

Plot the fitted regression model.

```
B = [beta(1:d)';repmat(beta(end),1,d)];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;
figure()
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end
legend(regions,'Location','NorthWest')
```

## Multivariate Regression for Panel Data with Different Slopes

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load sample data.
load('flu')
The dataset array, flu, contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract response and predictor data.

```
Y = double(flu(:,2:end-1));
[N,d] = size(Y);
```

The responses are the Google query estimates. There are observations for every week, so $N=52$. The dimension of the responses corresponds to the regions, so $d=9$.

```
x = flu.WtdILI;
```

The predictors are national CDC flu estimates.
Fit the multivariate regression model

$$
y_{i j}=\alpha_{j}+\beta_{j} x_{i j}+\varepsilon_{i j}, i=1, \ldots, N ; j=1, \ldots, d,
$$

with between-region concurrent correlation,

$$
\operatorname{COV}\left(\varepsilon_{i j}, \varepsilon_{i j^{\prime}}\right)=\sigma_{j j^{\prime}}, \quad j=1, \ldots, d
$$

There are $K=18$ regression coefficients to estimate: 9 intercept terms and 9 slope terms. The input argument X should be an $N$-element cell array of $d$-by- $K$ design matrices.

```
X = cell(N,1);
for i=1:N
    X{i} = [eye(d) x(i)*eye(d)];
end
[beta,Sigma] = mvregress(X,Y,'algorithm','cwls');
```

beta contains estimates of the $K$-dimensional coefficient vector,

$$
\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{9}, \beta_{1}, \beta_{2}, \ldots, \beta_{9}\right)^{\prime}
$$

Plot the fitted regression model.

```
B = [beta(1:d)';beta(d+1:end)'];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;
figure()
```

```
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end
regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest')
```

## Definitions

## Multivariate Normal Regression

Multivariate normal regression is the regression of a $d$-dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated. The model is

$$
\mathbf{y}_{i}=\mathbf{X}_{i} \beta+\mathbf{e}_{i}, \quad i=1, \ldots, N
$$

where

- $\mathbf{y}_{i}$ is a $d$-dimensional vector of responses.
- $\mathbf{X}_{i}$ is a $d$-by- $K$ design matrix of predictor variables.
- $\beta$ is a $K$-dimensional vector of regression coefficients.
- $\mathbf{e}_{i}$ is a d-dimensional vector of error terms, with multivariate normal distribution

$$
\mathbf{e}_{i} \sim M V N_{d}(\mathbf{0}, \Sigma)
$$

## Conditionally-Imputed Values

The expectation/conditional maximization ('ecm') and covariance-weighted least squares ('cwls') estimation algorithms include imputation of missing response values.

Let $\tilde{\mathbf{y}}$ denote missing observations. The conditionally-imputed values are the expected value of the missing observation given the observed data, $\mathrm{E}(\tilde{\mathbf{y}} \mid \mathbf{y})$.
The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$
\binom{\tilde{\mathbf{y}}}{\mathbf{y}} \sim M V N\left\{\binom{\tilde{\mathbf{x}} \beta}{\mathbf{X} \beta},\left(\begin{array}{cc}
\Sigma_{\tilde{y}} & \Sigma_{\tilde{y} y} \\
\Sigma_{y \tilde{y}} & \Sigma_{y}
\end{array}\right)\right\} .
$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$
\mathrm{E}(\tilde{\mathbf{y}} \mid \mathbf{y})=\tilde{\mathbf{x}} \beta+\Sigma_{\tilde{y} y} \Sigma_{y}^{-1}(\mathbf{y}-\mathbf{X} \beta)
$$

> Note mvregress only imputes missing response values. Observations with missing values in the design matrix are removed.

Purpose Negative log-likelihood for multivariate regression
Syntax $\quad \begin{array}{ll}\text { nlogL }=\text { mvregresslike }(X, Y, b, S I G M A, ~ a l g) ~ \\ {[n l o g L, C O V B]=\text { mvregresslike }(\ldots)} \\ & {[\text { nlogL }, \text { COVB }]=\text { mvregresslike }(\ldots, \text { type, format })}\end{array}$

## Description

nlogL $=$ mvregresslike $(X, Y, b$, SIGMA,$a l g)$ computes the negative log-likelihood nlogL for a multivariate regression of the $d$-dimensional multivariate observations in the $n$-by- $d$ matrix Y on the predictor variables in the matrix or cell array $X$, evaluated for the $p$-by- 1 column vector b of coefficient estimates and the $d$-by- $d$ matrix SIGMA specifying the covariance of a row of Y . If $d=1, \mathrm{X}$ can be an $n$-by- $p$ design matrix of predictor variables. For any value of $d, \mathrm{X}$ can also be a cell array of length $n$, with each cell containing a $d$-by- $p$ design matrix for one multivariate observation. If all observations have the same $d$-by- $p$ design matrix, $X$ can be a single cell.
NaN values in $X$ or $Y$ are taken as missing. Observations with missing values in $X$ are ignored. Treatment of missing values in $Y$ depends on the algorithm specified by alg.
alg should match the algorithm used by mvregress to obtain the coefficient estimates $b$, and must be one of the following:

- 'ecm' - ECM algorithm
- 'cwls' - Least squares conditionally weighted by SIGMA
- 'mvn' - Multivariate normal estimates computed after omitting rows with any missing values in $Y$
[nlogL,COVB] = mvregresslike(...) also returns an estimated covariance matrix COVB of the parameter estimates $b$.
[nlogL,COVB] = mvregresslike(...,type,format) specifies the type and format of COVB.
type is either:
- 'hessian' - To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- 'fisher' - To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.
format is either:
- 'beta' - To compute COVB for $b$ only. This is the default.
- 'full' - To compute COVB for both b and SIGMA.

mvregress | manova1

- "Multivariate Normal Distribution" on page B-71

## Purpose Multivariate normal random numbers

```
Syntax \(\quad R=\operatorname{mvnrnd}(M U, S I G M A)\)
\(r=\) mvnrnd(MU,SIGMA, cases)
```

$R=$ mvnrnd(MU,SIGMA) returns an $n$-by- $d$ matrix $R$ of random vectors chosen from the multivariate normal distribution with mean MU, and covariance SIGMA. MU is an $n$-by- $d$ matrix, and mvnrnd generates each row of R using the corresponding row of mu. SIGMA is a $d$-by- $d$ symmetric positive semi-definite matrix, or a $d$-by- $d$-by-n array. If SIGMA is an array, mvnrnd generates each row of R using the corresponding page of SIGMA, i.e., mvnrnd computes R(i,:) using MU(i,:) and SIGMA(:,:,i). If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, SIGMA may also be specified as a 1 -by- $d$ vector or a 1-by- $d$-by- $n$ array, containing just the diagonal. If $M U$ is a 1 -by- $d$ vector, mvnrnd replicates it to match the trailing dimension of SIGMA.
$r=$ mvnrnd(MU,SIGMA, cases) returns a cases-by-d matrix R of random vectors chosen from the multivariate normal distribution with a common 1-by-d mean vector MU, and a common d-by-d covariance matrix SIGMA.

## Examples <br> mu = [2 3]; <br> SIGMA = [1 1.5; 1.5 3]; <br> $r=m v n r n d(m u, S I G M A, 100) ;$ <br> plot(r(:,1),r(:,2),'+')

How To . "Multivariate Normal Distribution" on page B-71

```
Purpose Multivariate \(t\) cumulative distribution function
Syntax \(\quad y=\operatorname{mvtcdf}(X, C, D F)\)
\(y=\operatorname{mvtcdf}(x l, x u, C, D F)\)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

## Description

$y=m v t c d f(X, C, D F)$ returns the cumulative probability of the multivariate $t$ distribution with correlation parameters C and degrees of freedom DF, evaluated at each row of X. Rows of the $n$-by- $d$ matrix $X$ correspond to observations or points, and columns correspond to variables or coordinates. y is an n -by- 1 vector.

C is a symmetric, positive definite, $d$-by- $d$ matrix, typically a correlation matrix. If its diagonal elements are not 1, mvtcdf scales $C$ to correlation form. mvtcdf does not rescale X. DF is a scalar, or a vector with $n$ elements.

The multivariate $t$ cumulative probability at X is defined as the probability that a random vector T , distributed as multivariate $t$, will fall within the semi-infinite rectangle with upper limits defined by $x$, i.e., $\operatorname{Pr}\{T(1) \leq X(1), T(2) \leq X(2), \ldots T(d) \leq X(d)\}$.
$\mathrm{y}=\operatorname{mvtcdf}(\mathrm{xl}, \mathrm{xu}, \mathrm{C}, \mathrm{DF})$ returns the multivariate $t$ cumulative probability evaluated over the rectangle with lower and upper limits defined by $x l$ and $x u$, respectively.
[y,err] $=\operatorname{mvtcdf}(\ldots)$ returns an estimate of the error in $y$. For bivariate and trivariate distributions, mvtcdf uses adaptive quadrature on a transformation of the $t$ density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is $1 e-8$. For four or more dimensions, mvtcdf uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is 1e-4.
[...] = mvntdf(..., options) specifies control parameters for the numerical integration used to compute $y$. This argument can be created by a call to statset. Choices of statset parameters are:

- 'TolFun' - Maximum absolute error tolerance. Default is 1e-8 when $d<4$, or $1 \mathrm{e}-4$ when $d \geq 4$.
- 'MaxFunEvals' - Maximum number of integrand evaluations allowed when $d \geq 4$. Default is 1e7. 'MaxFunEvals' is ignored when $d<4$.
- 'Display' - Level of display output. Choices are 'off' (the default), 'iter', and 'final'. 'Display' is ignored when $d<4$.

```
Examples
C = [1 .4; .4 1]; df = 2;
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
p = mvtcdf(X,C,df);
surf(X1,X2,reshape(p,25,25));
```

Purpose Multivariate $t$ probability density function

## Syntax $\quad y=\operatorname{mvtpdf}(x, C, d f)$

Description
$y=m v t p d f(X, C, d f)$ returns the probability density of the multivariate $t$ distribution with correlation parameters C and degrees of freedom df , evaluated at each row of X . Rows of the $n$-by- $d$ matrix X correspond to observations or points, and columns correspond to variables or coordinates. C is a symmetric, positive definite, $d$-by- $d$ matrix, typically a correlation matrix. If its diagonal elements are not 1, mvtpdf scales C to correlation form. mvtcdf does not rescale $X$. $d f$ is a scalar, or a vector with $n$ elements. y is an $n$-by- 1 vector.

## Examples Visualize a multivariate $t$ distribution:

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
C = [1 .4; .4 1];
df = 2;
p = mvtpdf(X,C,df);
surf(X1,X2,reshape(p,25,25))
```

## Purpose Multivariate $t$ random numbers

```
Syntax \(\quad R=\operatorname{mvtrnd}(C, d f\), cases \()\)
R = mvtrnd(C,df)
```

Description

Examples
$R=m v t r n d(C, d f$, cases $)$ returns a matrix of random numbers chosen from the multivariate $t$ distribution, where C is a correlation matrix. $d f$ is the degrees of freedom and is either a scalar or is a vector with cases elements. If $p$ is the number of columns in C , then the output $R$ has cases rows and $p$ columns.

Let $t$ represent a row of $R$. Then the distribution of $t$ is that of a vector having a multivariate normal distribution with mean 0 , variance 1 , and covariance matrix C , divided by an independent chi-square random value having df degrees of freedom. The rows of $R$ are independent.
$C$ must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if C is a covariance matrix rather than a correlation matrix), mvtrnd rescales C to transform it to a correlation matrix before generating the random numbers.
$R=m v t r n d(C, d f)$ returns a single random number from the multivariate $t$ distribution.

SIGMA = [1 0.8;0.8 1];
R = mvtrnd(SIGMA, 3,100);
plot(R(:,1),R(:,2),'+')

Semantics

Examples Predict the class label using the Naive Bayes classifier:
load fisheriris
Use the default Gaussian distribution and a confusion matrix:

```
01 = NaiveBayes.fit(meas,species);
C1 = 01.predict(meas);
cMat1 = confusionmat(species,C1)
```

This returns:
cMat1 $=$

| 50 | 0 | 0 |
| ---: | ---: | ---: |
| 0 | 47 | 3 |
| 0 | 3 | 47 |

Use the Gaussian distribution for features 1 and 3 and use the kernel density estimation for features 2 and 4 :

```
02 = NaiveBayes.fit(meas,species,'dist',...
{'normal','kernel','normal','kernel'});
C2 = 02.predict(meas);
cMat2 = confusionmat(species,C2)
```

This returns:
cMat2 $=$

| 50 | 0 | 0 |
| ---: | ---: | ---: |
| 0 | 47 | 3 |
| 0 | 3 | 47 |

Superclasses ToolboxFittableParametricDistribution
Purpose Nakagami probability distribution object
Description prob.NakagamiDistribution is an object consisting of parameters, a model description, and sample data for a Nakagami probability distribution.

Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

## Construction

pd = makedist('Nakagami') creates a Nakagami probability distribution object using the default parameter values.
pd = makedist('Nakagami','mu', mu,'omega',omega) creates a Nakagami probability distribution object using the specified parameter values.

## Input Arguments

mu - Shape parameter
1 (default) | positive scalar value
Shape parameter for the Nakagami distribution, specified as a positive scalar value.

## Data Types <br> single | double <br> omega - Scale parameter

1 (default) | positive scalar value
Scale parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types<br>single | double

## prob.NakagamiDistribution

## Properties

mu
Shape parameter for the Nakagami distribution, stored as a positive scalar value.

## Data Types <br> single | double <br> omega

Scale parameter for the Nakagami distribution, stored as a positive scalar value.

## Data Types <br> single | double

## DistributionName

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types <br> char

## InputData

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

single | double

## IsTruncated

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated.

If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a $p$-by- $p$ matrix, where $p$ is the number of parameters in the distribution. The ( $i, j$ ) element is the covariance between the estimates of the $i$ th parameter and the $j$ th parameter. The ( $i, i$ ) element is the estimated variance of the ith parameter. If parameter $i$ is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## Parameterlsfixed

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## prob.NakagamiDistribution

## Data Types <br> logical <br> ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types <br> single | double <br> Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

```

## Definitions Nakagami Distribution

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

| Parameter | Description | Support |
| :--- | :--- | :--- |
| mu | Shape parameter | $\mu>0$ |
| omega | Scale parameter | $\omega>0$ |

## prob.NakagamiDistribution

The probability density function (pdf) is

$$
f(x \mid \mu, \omega)=2\left(\frac{\mu^{\mu}}{\omega}\right) \frac{1}{\Gamma(\mu)} x^{(2 \mu-1)} \exp \left\{\frac{-\mu}{\omega} x^{2}\right\} \quad ; \quad x>0
$$

where $\Gamma(\cdot)$ is the Gamma function.

## Examples

## Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')
pd =
```

NakagamiDistribution
Nakagami distribution
mu $=1$
omega = 1

## Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami','mu',5,'omega',2)
pd =
```

NakagamiDistribution
Nakagami distribution
mu $=5$
omega = 2

## prob.NakagamiDistribution

Compute the mean of the distribution.
$\mathrm{m}=\mathrm{mean}(\mathrm{pd})$
$\mathrm{m}=$

## Purpose Covariance ignoring NaN values

## Syntax <br> Description

$Y=n a n c o v(X)$
$Y=\operatorname{nancov}(X 1, X 2)$
$Y=\operatorname{nancov}(. . ., 1)$
Y = nancov(...,'pairwise')

Examples observations with NaN values. (rows) containing any NaN values are removed. X2(:)]. normalization by $n$, use $Y=\operatorname{nancov}(\ldots, 1)$. matrix.
$Y=\operatorname{nancov}(X)$ is the covariance cov of $X$, computed after removing

For vectors $x$, $\operatorname{nancov}(x)$ is the sample variance of the remaining elements, once NaN values are removed. For matrices X, nancov (X) is the sample covariance of the remaining observations, once observations
$Y=\operatorname{nancov}(X 1, X 2)$, where $X 1$ and $X 2$ are matrices with the same number of elements, is equivalent to nancov $(X)$, where $X=[X 1(:)$
nancov removes the mean from each variable (column for matrix $X$ ) before calculating Y. If $n$ is the number of remaining observations after removing observations with NaN values, nancov normalizes Y by either $n-1$ or $n$, depending on whether $n>1$ or $n=1$, respectively. To specify
$Y=$ nancov(...,'pairwise') computes $Y(i, j)$ using rows with no NaN values in columns i or $j$. The result $Y$ may not be a positive definite

Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147 0.1576
        NaN NaN
    0.1270 0.9572
```

| 0.9134 | NaN |
| :--- | ---: |
| 0.6324 | NaN |
| 0.0975 | 0.1419 |
| 0.2785 | 0.4218 |
| 0.5469 | 0.9157 |
| 0.9575 | 0.7922 |
| 0.9649 | NaN |

Establish a correlation between a third variable and the other two variables:

| $\mathrm{X}(:, 3)=\operatorname{sum}(X, 2)$ |  |  |
| :--- | ---: | ---: |
| $X=$ |  |  |
| 0.8147 | 0.1576 | 0.9723 |
| NaN | NaN | NaN |
| 0.1270 | 0.9572 | 1.0842 |
| 0.9134 | NaN | NaN |
| 0.6324 | NaN | NaN |
| 0.0975 | 0.1419 | 0.2394 |
| 0.2785 | 0.4218 | 0.7003 |
| 0.5469 | 0.9157 | 1.4626 |
| 0.9575 | 0.7922 | 1.7497 |
| 0.9649 | NaN | NaN |

Compute the covariance matrix for the three variables after removing observations (rows) with NaN values:

```
Y = nancov(X)
Y =
\begin{tabular}{lll}
0.1311 & 0.0096 & 0.1407 \\
0.0096 & 0.1388 & 0.1483 \\
0.1407 & 0.1483 & 0.2890
\end{tabular}
```

See Also

## Purpose Maximum ignoring NaN values

```
Syntax
y = nanmax(X)
Y = nanmax(X1,X2)
y = nanmax(X,[],dim)
[y,indices] = nanmax(...)
```

Description

Examples
Find column maxima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN 1 NaN
        3 NaN
        4 ~ N a N ~ N a N
[y,indices] = nanmax(X)
y =
    4 NaN
indices =
    3 2 1
```

## See Also

## Purpose Mean ignoring NaN values

Syntax $\quad y=$ nanmean $(X)$
y = nanmean(X,dim)
Description $\quad y=$ nanmean $(X)$ is the mean of $X$, computed after removing NaN values.
For vectors $x$, nanmean $(x)$ is the mean of the remaining elements, once NaN values are removed. For matrices $X$, nanmean (X) is a row vector of column means, once NaN values are removed. For multidimensional arrays $X$, nanmean operates along the first nonsingleton dimension.
$\mathrm{y}=$ nanmean( $\mathrm{X}, \mathrm{dim}$ ) takes the mean along dimension dim of X .

Note If X contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0 . Since the mean involves division by 0 , its value is NaN . The output NaN is not a mean of NaN values.

Examples Find column means for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN 1 NaN
        3 5 NaN
        4 ~ N a N ~ N a N
y = nanmean(X)
y =
    3.5000 3.0000 NaN
```

## See Also

NaN | mean | nanmedian

## Purpose Median ignoring NaN values

```
Syntax
y = nanmedian(X)
y = nanmedian(X,dim)
```

$y=$ nanmedian $(X)$ is the median of $X$, computed after removing NaN values.

For vectors $x$, nanmedian $(x)$ is the median of the remaining elements, once NaN values are removed. For matrices X , nanmedian (X) is a row vector of column medians, once NaN values are removed. For multidimensional arrays X , nanmedian operates along the first nonsingleton dimension.
$\mathrm{y}=$ nanmedian( $\mathrm{X}, \mathrm{dim}$ ) takes the mean along dimension dim of X .

## Examples <br> Find column medians for data with missing values: <br> ```X = magic(3); \\ X([1 6:9]) = repmat(NaN,1,5) \\ X = \\ NaN 1 NaN \\ 3 5 NaN \\ NaN NaN \\ y = nanmedian(X) \\ y = \\ 3.5000 3.0000 NaN```

See Also NaN | median | nanmean

## Purpose Minimum ignoring NaN values

```
Syntax y = nanmin(X)
Y = nanmin(X1,X2)
y = nanmin(X,[],dim)
[y,indices] = nanmin(...)
```

Description $\quad y=n a n m i n(X)$ is the minimum min of $X$, computed after removing NaN values.

For vectors x , nanmin $(\mathrm{x})$ is the minimum of the remaining elements, once NaN values are removed. For matrices $X$, nanmin $(X)$ is a row vector of column minima, once NaN values are removed. For multidimensional arrays $X$, nanmin operates along the first nonsingleton dimension.
$\mathrm{Y}=$ nanmin( $\mathrm{X} 1, \mathrm{X} 2)$ returns an array Y the same size as X 1 and X 2 with $Y(i, j)=\operatorname{nanmin}(X 1(i, j), X 2(i, j))$. Scalar inputs are expanded to an array of the same size as the other input.
$\mathrm{y}=\operatorname{nanmin}(\mathrm{X},[\mathrm{l}, \mathrm{dim})$ operates along the dimension $\operatorname{dim}$ of X .
[ $y$, indices] $=$ nanmin(...) also returns the row indices of the minimum values for each column in the vector indices.

## Examples <br> Find column minima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN 1 NaN
        3 5 NaN
        4 ~ N a N ~ N a N
[y,indices] = nanmin(X)
y =
    3 1 NaN
indices =
    2 1 1
```

## See Also <br> NaN | min | nanmax

## Purpose Standard deviation ignoring NaN values

```
Syntax y = nanstd(X)
y = nanstd(X,1)
y = nanstd(X,flag,dim)
```

## Description

## Examples Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN 1 NaN
        3 5 NaN
        4 ~ N a N ~ N a N
y = nanstd(X)
y =
    0.7071 2.8284 NaN
```

See Also NaN \| std \| nanvar | nanmean

## Purpose <br> Sum ignoring NaN values

Syntax

```
y = nansum(X)
y = nansum(X,dim)
```

Description
$y=$ nansum $(X)$ is the sum of $X$, computed after removing NaN values.
For vectors $x$, nansum ( $x$ ) is the sum of the remaining elements, once NaN values are removed. For matrices $X$, nansum (X) is a row vector of column sums, once NaN values are removed. For multidimensional arrays $X$, nansum operates along the first nonsingleton dimension.
$\mathrm{y}=$ nansum(X, dim) takes the sum along dimension dim of X .

Note If X contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0 . The output 0 is not a sum of NaN values.

## Examples Find column sums for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN 1 NaN
        3 NaN
        4 ~ N a N ~ N a N
y = nansum(X)
y =
    7 6 0
```

## See Also <br> NaN | sum

## Purpose Variance, ignoring NaN values

```
Syntax
y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,w)
y = nanvar(X,w,dim)
```

Description

Examples Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN 1 NaN
        3 NaN
        N NaN NaN
y = nanvar(X)
```

$$
y=0.5000 \mathrm{NaN}
$$

See Also NaN | var | nanstd | nanmean

Purpose Negative binomial cumulative distribution function

## Syntax $\quad Y=\operatorname{nbincdf}(X, R, P)$

Description
$Y=n b i n c d f(X, R, P)$ computes the negative binomial cdf at each of the values in $X$ using the corresponding number of successes, $R$ and probability of success in a single trial, P. X, R, and P can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for $\mathrm{X}, \mathrm{R}$, or P is expanded to a constant array with the same dimensions as the other inputs.

The negative binomial cdf is

$$
y=F(x \mid r, p)=\sum_{i=0}^{x}\binom{r+i-1}{i} p^{r} q^{i} I_{(0,1, \ldots)}(i)
$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability $P$ of success. The number of extra trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, nbincdf allows $R$ to be any positive value, including nonintegers. When $R$ is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$
\frac{\Gamma(r+i)}{\Gamma(r) \Gamma(i+1)}
$$

## Examples

```
x = (0:15);
p = nbincdf(x, 3,0.5);
stairs(x,p)
```

See Also cdf | nbinpdf | nbininv | nbinstat | nbinfit | nbinrnd
How To . "Negative Binomial Distribution" on page B- 85

Purpose Negative binomial parameter estimates

```
Syntax parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)
```

## Description

parmhat $=$ nbinfit(data) returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector data.
[parmhat, parmci] = nbinfit(data,alpha) returns MLEs and 100 (1-alpha) percent confidence intervals. By default, alpha $=0.05$, which corresponds to $95 \%$ confidence intervals.
[...] = nbinfit(data,alpha,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an options structure which you can create using the function statset. Enter statset('nbinfit') to see the names and default values of the parameters that nbinfit accepts in the options structure. See the reference page for statset for more information about these options.

Note The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in data is less than its sample mean, nbinfit cannot compute MLEs. You should use the poissfit function instead.

See Also nbincdf | nbininv | nbinpdf | nbinrnd | nbinstat | mle | statset
How To . "Negative Binomial Distribution" on page B-85
Purpose Negative binomial inverse cumulative distribution function
Syntax $\quad X=\operatorname{nbininv}(Y, R, P)$
Description
$X=$ nbininv $(Y, R, P)$ returns the inverse of the negative binomial cdf with corresponding number of successes, $R$ and probability of success in a single trial, P. Since the binomial distribution is discrete, nbininv returns the least integer $X$ such that the negative binomial cdf evaluated at $X$ equals or exceeds $Y$. $Y, R$, and $P$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of $X$. A scalar input for $Y, R$, or $P$ is expanded to a constant array with the same dimensions as the other inputs.
The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability $P$ of success. The number of extra trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, nbininv allows $R$ to be any positive value, including nonintegers.

## Examples

How many times would you need to flip a fair coin to have a $99 \%$ probability of having observed 10 heads?
flips = nbininv(0.99,10,0.5) + 10
flips = nbininv(0.99,10,0.5) + 10
flips =
flips =
33
33

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10 .

How To . "Negative Binomial Distribution" on page B-85

Purpose Negative binomial probability density function

## Syntax $\quad Y=\operatorname{nbinpdf}(X, R, P)$

Description
$Y=n b i n p d f(X, R, P)$ returns the negative binomial pdf at each of the values in $X$ using the corresponding number of successes, $R$ and probability of success in a single trial, P. X, R, and P can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for $\mathrm{X}, \mathrm{R}$, or P is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in X are integers.

The negative binomial pdf is

$$
y=f(x \mid r, p)=\binom{r+x-1}{x} p^{r} q^{x} I_{(0,1, \ldots)}(x)
$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability $P$ of success. The number of extra trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, nbinpdf allows $R$ to be any positive value, including nonintegers. When $R$ is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$
\frac{\Gamma(r+x)}{\Gamma(r) \Gamma(x+1)}
$$

## Examples

```
x = (0:10);
y = nbinpdf(x,3,0.5);
plot(x,y,'+')
set(gca,'Xlim',[-0.5,10.5])
```

- "Negative Binomial Distribution" on page B-85

RND = nbinrnd ( $R, P$ ) is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, R and probability of success in a single trial, P. R and P can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of RND. A scalar input for R or P is expanded to a constant array with the same dimensions as the other input.

RND $=n b i n r n d(R, P, m, n, \ldots)$ or RND $=n b i n r n d(R, P,[m, n, \ldots])$ generates an m-by-n-by-... array. The R, P parameters can each be scalars or arrays of the same size as R.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability P of success. The number of extra trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, nbinrnd allows $R$ to be any positive value, including nonintegers.

## Purpose Negative binomial mean and variance

## Syntax <br> [M,V] = nbinstat(R,P)

## Description

$[M, V]=$ nbinstat $(R, P)$ returns the mean of and variance for the negative binomial distribution with corresponding number of successes, $R$ and probability of success in a single trial, P. R and P can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V . A scalar input for R or P is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters $r$ and $p$ is $r q / p$, where $q=1-p$. The variance is $r q / p^{2}$.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability P of success. The number of extra trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, nbinstat allows R to be any positive value, including nonintegers.

## Examples

```
p = 0.1:0.2:0.9;

## Purpose Noncentral $F$ cumulative distribution function

$$
\text { Syntax } \quad P=\operatorname{ncfcdf}(X, N U 1, N U 2, D E L T A)
$$

Description
$\mathrm{P}=\mathrm{ncfcdf}(\mathrm{X}, \mathrm{NU} 1, \mathrm{NU} 2, \mathrm{DELTA})$ computes the noncentral $F \mathrm{cdf}$ at each of the values in $X$ using the corresponding numerator degrees of freedom in NU1, denominator degrees of freedom in NU2, and positive noncentrality parameters in DELTA. NU1, NU2, and DELTA can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of P. A scalar input for X, NU1, NU2, or DELTA is expanded to a constant array with the same dimensions as the other inputs.

The noncentral $F$ cdf is

$$
F\left(x \mid v_{1}, v_{2}, \delta\right)=\sum_{j=0}^{\infty}\left(\frac{\left(\frac{1}{2} \delta\right)^{j}}{j!} e^{\frac{-\delta}{2}}\right) Z\left(\left.\frac{v_{1} \cdot x}{v_{2}+v_{1} \cdot x} \right\rvert\, \frac{v_{1}}{2}+j, \frac{v_{2}}{2}\right)
$$

where $I(x \mid a, b)$ is the incomplete beta function with parameters $a$ and $b$.

## Examples

Compare the noncentral $F$ cdf with $\delta=10$ to the $F$ cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';
p1 = ncfcdf(x,5,20,10);
p = fcdf(x,5,20);
plot(x,p,'-',x,p1,'-')
```

How To

- "Noncentral F Distribution" on page B-91

## Purpose Noncentral $F$ inverse cumulative distribution function

$$
\text { Syntax } \quad X=\operatorname{ncfinv}(P, N U 1, N U 2, D E L T A)
$$

Description $\quad X=$ ncfinv $(P, N U 1, N U 2, D E L T A)$ returns the inverse of the noncentral $F$ cdf with numerator degrees of freedom NU1, denominator degrees of freedom NU2, and positive noncentrality parameter DELTA for the corresponding probabilities in P. P, NU1, NU2, and DELTA can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of X. A scalar input for P, NU1, NU2, or DELTA is expanded to a constant array with the same dimensions as the other inputs.

## Examples

One hypothesis test for comparing two sample variances is to take their ratio and compare it to an $F$ distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```
critical = finv(0.95,5,20)
critical =
    2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```
prob = 1 - ncfcdf(critical,5,20,2)
prob =
    0.1297
```

If the true ratio of variances is 2 , what is the typical (median) value you would expect for the $F$ statistic?

```
ncfinv(0.5,5,20,2)
ans =
    1.2786
```

Purpose Number of dimensions of categorical array

## Syntax $\quad n=\operatorname{ndims}(A)$

Description $\quad n=\operatorname{ndims}(A)$ returns the number of dimensions in the categorical array A. The number of dimensions in an array is always greater than or equal to 2. Trailing singleton dimensions are ignored. Put simply, ndims(A) is length (size(A)).

See Also size

## gmdistribution.NDimensions property

$\begin{array}{ll}\text { Purpose } & \text { Dimension } d \text { of multivariate Gaussian distributions } \\ \text { Description } & \text { The dimension } d \text { of the multivariate Gaussian distributions. }\end{array}$

## dataset.ndims

Purpose Number of dimensions of dataset array

## Syntax $\quad n=\operatorname{ndims}(A)$

Description $n=$ ndims $(A)$ returns the number of dimensions in the dataset $A$. The number of dimensions in an array is always 2 .

See Also size
Purpose Number of dimensions in matrix
Syntax

$\mathrm{n}=\operatorname{ndims}(\mathrm{p})$

Description $\quad n=$ ndims $(p)$ returns the number of dimensions in the matrix that is created by the $\operatorname{syntax} p(:,:)$. Since this is always a 2 -D matrix, $n$ is always equal to 2 .

See Also qrandset | size

## NaiveBayes.NDims property

## Purpose Number of dimensions

Description The NDims property specifies the number of dimensions, which is equal to the number of features in the training data used to create the Naive Bayes classifier.

## Purpose Not equal relation for handles

## Syntax <br> h1 ~= h2

Description Handles are equal if they are handles for the same object and are unequal otherwise.
h1 ~= h2 performs element-wise comparisons between handle arrays h 1 and h2. h 1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise $\sim=$ result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.
$\mathrm{tf}=\mathrm{ne}(\mathrm{h} 1, \mathrm{~h} 2)$ stores the result in a logical array of the same dimensions.

## prob.NegativeBinomialDistribution

Superclasses ToolboxFittableParametricDistribution
Purpose Negative binomial distribution object
Description prob.NegativeBinomialDistribution is an object consisting of parameters, a model description, and sample data for a negative binomial probability distribution.
Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

## Construction

pd = makedist('NegativeBinomial') creates a negative binomial probability distribution object using the default parameter values.
pd = makedist('NegativeBinomial','R', r,' ${ }^{\prime}$ ', p) creates a negative binomial probability distribution object using the specified parameter values.

## Input Arguments

## $\mathbf{r}$ - Number of successes

1 (default) | positive scalar value
Number of successes for the negative binomial distribution, specified as a positive scalar value.

## Data Types <br> single | double

## p - Probability of success

0.5 (default) | positive scalar value in the range $(0,1]$

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range $(0,1]$.

Data Types<br>single | double

## Properties

Number of successes for the negative binomial distribution, stored as a positive scalar value.

## Data Types

single | double

## p

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range $(0,1]$.

## Data Types

single | double

## DistributionName

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## InputData

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.
Data Types
single | double

## IsTruncated

## prob.NegativeBinomialDistribution

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a $p$-by- $p$ matrix, where $p$ is the number of parameters in the distribution. The ( $\mathrm{i}, \mathrm{j}$ ) element is the covariance between the estimates of the $i$ ith parameter and the $j$ th parameter. The ( $i, i$ ) element is the estimated variance of the ith parameter. If parameter $i$ is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types <br> char

## ParameterlsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames
array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types <br> char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

```
Data Types
single | double
```

## Methods Inherited Methods

| cdf | Cumulative distribution function <br> of probability distribution object |
| :--- | :--- |
| icdf | Inverse cumulative distribution <br> function of probability <br> distribution object |

## Definitions Negative Binomial Distribution

The negative binomial distribution models the number of failures $x$ before a specified number of successes is reached in a series of independent, identical trials. This distribution can also model count data, in which case $r$ does not need to be an integer value.

The negative binomial distribution uses the following parameters.

| Parameter | Description | Support |
| :--- | :--- | :--- |
| R | Number of successes | $r>0$ |
| p | Probability of success | $0<p \leq 1$ |

The probability density function (pdf) when $r$ is an integer is

$$
f(x \mid r, p)=\binom{r+x+1}{x} p^{r} q^{x} \quad ; \quad x=1,2, \ldots, \infty
$$

where $q=1-p$ and $\binom{r+x+1}{x}$ is the binomial coefficient.
When $r$ is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$
\frac{\Gamma(r+x)}{\Gamma(r) \Gamma(x+1)},
$$

where $\Gamma(\cdot)$ is the Gamma function.

## Examples <br> Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')
pd =
```

NegativeBinomialDistribution
Negative Binomial distribution
$R=1$
$P=0.5$

## prob.NegativeBinomialDistribution

## Create a Negative Binomial Distribution Object Using Specified Parameters

Create a negative binomial distribution object by specifying the parameter values.

```
pd = makedist('NegativeBinomial','r',5,'p',.1)
pd =
```

    NegativeBinomialDistribution

| Purpose | Nearest neighbor search object |
| :--- | :--- |
| Description | NeighborSearcher is an abstract class used for nearest neighbor <br> search. You cannot create instances of this class directly. Instead, <br> create an instance of a derived class such as ExhaustiveSearcher or <br> KDTreeSearcher either by calling the derived class constructor or by <br> calling the function createns. |
| Construction | NeighborSearcher is an abstract class. You cannot create instances of <br> this class directly. You can construct an object in a subclass, such as <br> KDTreeSearcher or ExhaustiveSearcher, either by calling the subclass <br> constructors or by using the createns function. |
| Properties | X $\quad$A matrix used to create the object. |
|  | Distance |
| A string specifying a built-in distance metric (applies to both |  |
| ExhaustiveSearcher and kDTreeSearcher) or a function handle |  |
| (only appliest to ExhaustiveSearcher) that you provide when you |  |
| create the object. This property is the default distance metric used |  |
| when you call the knnsearch method to find nearest neighbors |  |
| for future query points. |  |

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance. (Applies for both ExhaustiveSearcher and KDTreeSearcher.)
- If 'Distance' is 'mahalanobis': A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance. (Only applies for ExhaustiveSearcher.)

## NeighborSearcher

- If 'Distance' is 'seuclidean': A vector representing the scale value of the data when computing the 'seuclidean' distance. (Only applies for ExhaustiveSearcher.)
- Otherwise: Empty.

See Also createns | KDTreeSearcher | ExhaustiveSearcher

## Purpose

Generate quasi-random point set

## Syntax <br> $X=\operatorname{net}(p, n)$

$X=\operatorname{net}(p, n)$ returns the first $n$ points $X$ from the point set $p$ of the qrandset class. X is n -by- $d$, where $d$ is the dimension of the point set.

Objects p of the @qrandset class encapsulate properties of a specified quasi-random sequence. Values of the point set are not generated and stored in memory until $p$ is accessed using net or parenthesis indexing.

## Examples

Use haltonset to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
    ScrambleMethod : none
```

Use scramble to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
    ScrambleMethod : RR2
```

Use net to generate the first four points:

```
XO = net(p,4)
XO =
    0.0928 0.6950 0.0029
    0.6958 0.2958 0.8269
```

## qrandset.net

| 0.3013 | 0.6497 | 0.4141 |
| :--- | :--- | :--- |
| 0.9087 | 0.7883 | 0.2166 |

Use parenthesis indexing to generate every third point, up to the 11th point:

| 0.0928 | 0.6950 | 0.0029 |
| :---: | :---: | :---: |
| 0.9087 | 0.7883 | 0.2166 |
| 0.3843 | 0.9840 | 0.9878 |
| 0.6831 | 0.7357 | 0.7923 |

## CompactClassificationDiscriminant.nLinearCoeffs

## Purpose Number of nonzero linear coefficients

Syntax<br>Description

## Input <br> Arguments

## Output <br> Arguments

```
ncoeffs = nLinearCoeffs(obj)
ncoeffs = nLinearCoeffs(obj,delta)
```

ncoeffs $=$ nLinearCoeffs (obj) returns the number of nonzero linear coefficients in the linear discriminant model obj.
ncoeffs $=$ nLinearCoeffs(obj, delta) returns the number of nonzero linear coefficients for threshold parameter delta.

## obi

Discriminant analysis classifier, produced using ClassificationDiscriminant.fit.

## delta

Scalar or vector value of the Delta parameter. See "Gamma and Delta" on page 20-1749.

## ncoeffs

Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model obj.

If you call nLinearCoeffs with a delta argument, ncoeffs is the number of nonzero linear coefficients for threshold parameter delta. If delta is a vector, ncoeffs is a vector with the same number of elements.

If obj is a quadratic discriminant model, ncoeffs is the number of predictors in obj.

## Definitions Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, $\gamma$ and $\delta$, that control regularization as follows. cvshrink helps you select appropriate values of the parameters.

## CompactClassificationDiscriminant.nLinearCoeffs

Let $\Sigma$ represent the covariance matrix of the data $X$, and let $\hat{X}$ be the centered data (the data $X$ minus the mean by class). Define

$$
D=\operatorname{diag}\left(\hat{X}^{T} * \hat{X}\right)
$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$
\tilde{\Sigma}=(1-\gamma) \Sigma+\gamma D
$$

Whenever $\gamma \geq$ MinGamma, $\tilde{\Sigma}$ is nonsingular.
Let $\mu_{k}$ be the mean vector for those elements of $X$ in class $k$, and let $\mu_{0}$ be the global mean vector (the mean of the rows of $X$ ). Let $C$ be the correlation matrix of the data $X$, and let $\tilde{C}$ be the regularized correlation matrix:

$$
\tilde{C}=(1-\gamma) C+\gamma I,
$$

where $I$ is the identity matrix.
The linear term in the regularized discriminant analysis classifier for a data point $x$ is

$$
\left(x-\mu_{0}\right)^{T} \tilde{\Sigma}^{-1}\left(\mu_{k}-\mu_{0}\right)=\left[\left(x-\mu_{0}\right)^{T} D^{-1 / 2}\right]\left[\tilde{C}^{-1} D^{-1 / 2}\left(\mu_{k}-\mu_{0}\right)\right] .
$$

The parameter $\delta$ enters into this equation as a threshold on the final term in square brackets. Each component of the vector
$\left[\tilde{C}^{-1} D^{-1 / 2}\left(\mu_{k}-\mu_{0}\right)\right]$ is set to zero if it is smaller in magnitude than the threshold $\delta$. Therefore, for class $k$, if component $j$ is thresholded to zero, component $j$ of $x$ does not enter into the evaluation of the posterior probability.

The DeltaPredictor property is a vector related to this threshold. When $\delta \geq$ DeltaPredictor(i), all classes $k$ have

## CompactClassificationDiscriminant.nLinearCoeffs

$$
\left|\tilde{C}^{-1} D^{-1 / 2}\left(\mu_{k}-\mu_{0}\right)\right| \leq \delta .
$$

Therefore, when $\delta \geq$ DeltaPredictor(i), the regularized classifier does not use predictor i.

## Examples Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier

Find the number of nonzero coefficients in a discriminant analysis classifier for various Delta values.

Create a discriminant analysis classifier from the fishseriris data.

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas,species);
```

Find the number of nonzero coefficients in obj.

```
ncoeffs = nLinearCoeffs(obj)
ncoeffs =
```

4

Find the number of nonzero coefficients for delta $=1,2,4$, and 8.

```
delta = [1 2 4 8];
ncoeffs = nLinearCoeffs(obj,delta)
ncoeffs =
```

    4
    4
    3
    0
    The DeltaPredictor property gives the values of delta where the number of nonzero coefficients changes.

## CompactClassificationDiscriminant.nLinearCoeffs

```
ncoeffs2 = nLinearCoeffs(obj,obj.DeltaPredictor)
ncoeffs2 =
```

    4
    3
    1
    2

## Purpose Nonlinear regression

Syntax<br>Description

```
beta = nlinfit(X,Y,modelfun,betaO)
beta = nlinfit(X,Y,modelfun,betaO,options)
beta = nlinfit(___,Name,Value)
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)
```

## Input Arguments

beta $=$ nlinfit( $\mathrm{X}, \mathrm{Y}$, modelfun, beta0 $)$ returns a vector of estimated coefficients for the nonlinear regression of the responses in $Y$ on the predictors in X using the model specified by modelfun. The coefficients are estimated using iterative least squares estimation, with initial values specified by beta0.
beta $=$ nlinfit $(X, Y$, modelfun, beta0,options) fits the nonlinear regression using the algorithm control parameters in the structure options. You can return any of the output arguments in the previous syntaxes.
beta = nlinfit( __ , Name, Value) uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(__ ) additionally returns the residuals, R, the Jacobian of modelfun, J, the estimated variance-covariance matrix for the estimated coefficients, CovB, an estimate of the variance of the error term, MSE, and a structure containing details about the error model, ErrorModelInfo.

## X - Predictor variables

matrix
Predictor variables for the nonlinear regression function, specified as a matrix. Typically, X is a design matrix of predictor (independent

## nlinfit

variable) values, with one row for each value in $Y$, and one column for each coefficient. However, $X$ can be any array that modelfun can accept.

```
Data Types
single | double
```

## Y - Response values

vector
Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as $X$.

Data Types<br>single | double

## modelfun - Nonlinear regression model function

function handle
Nonlinear regression model function, specified as a function handle. modelfun must accept two input arguments, a coefficient vector and an array X-in that order-and return a vector of fitted response values.

For example, to specify the hougen nonlinear regression function, use the function handle @hougen.

```
Data Types
function_handle
```

## beta0 - Initial coefficient values

vector
Initial coefficient values for the least squares estimation algorithm, specified as a vector.

Note Poor starting values can lead to a solution with large residual error.

Data Types
single | double

## options - Estimation algorithm options

structure created using statset
Estimation algorithm options, specified as a structure you create using statset. The following statset parameters are applicable to nlinfit.

## DerivStep - Relative difference for finite difference gradient eps^(1/3) (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as beta. Use a vector to specify a different relative difference for each coefficient.

## Display - Level of output display

```
'off'(default) | 'iter' | 'final'
```

Level of output display during estimation, specified as one of 'off', 'iter', or 'final'. If you specify 'iter', output is displayed at each iteration. If you specify 'final', output is displayed after the final iteration.

## FunValCheck - Indicator for whether to check for invalid values 'on' (default) | 'off'

Indicator for whether to check for invalid values such as NaN or Inf from the objective function, specified as 'on' or 'off'.

## Maxlter - Maximum number of iterations <br> 100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by MaxIter is reached.

## RobustWgtFun - Weight function

## nlinfit

## string | function handle | []

Weight function for robust fitting, specified as a valid string or function handle.

Note RobustWgtFun must have value [] when you use observation weights, W.

The following table describes the possible string values. Let $r$ denote normalized residuals and $w$ denote robust weights. The indicator function $\mathrm{I}[x]$ is equal to 1 if the expression $x$ is true, and 0 otherwise.

| Weight <br> Function | Equation | Default Tuning <br> Constant |
| :--- | :--- | :--- |
| ' ' (default) | No robust fitting | - |
| 'andrews' | $w=I[\|r\|<\pi] \times \sin (r) / r$ | 1.339 |
| 'bisquare' | $w=I[\|r\|<1] \times\left(1-r^{2}\right)^{2}$ | 4.685 |
| 'cauchy' | $w=1 /\left(1+r^{2}\right)$ | 2.385 |
| 'fair' | $w=1 /(1+\|r\|)$ | 1.400 |

| Weight <br> Function | Equation | Default Tuning <br> Constant |
| :--- | :--- | :--- |
| 'huber' | $w=1 / \max (1,\|r\|)$ | 1.345 |
| 'logistic' | $w=\tanh (r) / r$ | 1.205 |
| 'talwar' | $w=I[\|r\|<1]$ | 2.795 |
| 'welsch' | $w=\exp \left\{-r^{2}\right\}$ | 2.985 |

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a Tune constant.

## Tune - Tuning constant

positive scalar value
Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by RobustWgtFun.
If you use a function handle to specify RobustWgtFun, then you must specify a value for Tune.

## TolFun - Termination tolerance on residual sum of squares 1e-8 (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the

## nlinfit

convergence tolerance, or the maximum number of iterations specified by MaxIter is reached.

## ToIX - Termination tolerance on estimated coefficients

1e-8 (default) | positive scalar value
Termination tolerance on the estimated coefficients, beta, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by MaxIter is reached.

## Robust - Indicator for robust fitting

'off' (default) | 'on'
Indicator for robust fitting, specified as 'off' or 'on'.

Note Robust will be removed in a future software release. Use RobustWgtFun for robust fitting.

## WgtFun - Weight function for robust fitting

## string \| function handle

Weight function for robust fitting, specified as a string indicating a weight function, or a function handle. WgtFun is valid only when Robust has value 'on'.

Note WgtFun will be removed in a future software release. Use RobustWgtFun instead.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can
specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

Example: 'ErrorModel','proportional','ErrorParameters',0.5 specifies a proportional error model, with initial value 0.5 for the error parameter estimation

## 'ErrorModel' - Form of error term

'constant' (default) | 'proportional' | 'combined'
Form of the error term, specified as the comma-separated pair consisting of 'ErrorModel' and one of the following strings indicating the error model. Each model defines the error using a standard mean-zero and unit-variance variable $e$ in combination with independent components: the function value $f$, and one or two parameters $a$ and $b$.

```
'constant' (default)
    \(y=f+a e\)
'proportional'
    \(y=f+b f e\)
combined'
\[
y=f+(a+b|f|) e
\]
```

The only allowed error model when using Weights is 'constant'.

Note options.RobustWgtFun must have value [] when using an error model other than 'constant'.

## 'ErrorParameters' - Initial estimates for error model parameters

1 or [1,1] (default) | scalar value | two-element vector
Initial estimates for the error model parameters in the chosen ErrorModel, specified as the comma-separated pair consisting of 'ErrorParameters' and a scalar value or two-element vector.

## nlinfit

| Error Model | Parameters | Default Values |
| :--- | :--- | :--- |
| 'constant' | $a$ | 1 |
| 'proportional' | $b$ | 1 |
| 'combined' | $a, b$ | $[1,1]$ |

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for $a$ and the starting value 2 for $b$ as follows.

```
Example: 'ErrorParameters',[1,2]
```

You can only use the 'constant' error model when using Weights.

Note options.RobustWgtFun must have value [] when using an error model other than 'constant'.

## Data Types <br> double | single

## 'Weights' - Observation weights

## vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If W is a vector, then it must be the same size as Y .
- If $W$ is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Note options.RobustWgtFun must have value [] when you use observation weights.

## Data Types <br> double | single | function_handle

## Output <br> Arguments

## beta - Estimated regression coefficients

vector
Estimated regression coefficients, returned as a vector. The number of elements in beta equals the number of elements in beta0.

Let $f\left(X_{i}, \mathbf{b}\right)$ denote the nonlinear function specified by modelfun, where $\mathbf{x}_{i}$ are the predictors for observation $i, i=1, \ldots, N$, and $\mathbf{b}$ are the regression coefficients. The vector of coefficients returned in beta minimizes the weighted least squares equation,

$$
\sum_{i=1}^{N} w_{i}\left[y_{i}-f\left(\mathbf{x}_{i}, \mathbf{b}\right)\right]^{2} .
$$

For unweighted nonlinear regression, all of the weight terms are equal to 1 .

## R - Residuals

## vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument Weights, then R contains weighted residuals.
- If you specify an error model other than 'constant' using the name-value pair argument ErrorModel, then you can no longer interpret R as model fit residuals.

## J - Jacobian

## matrix

Jacobian of the nonlinear regression model, modelfun, returned as an $N$-by- $p$ matrix, where $N$ is the number of observations and $p$ is the number of estimated coefficients.

## nlinfit

- If you specify observation weights using the name-value pair argument Weights, then $J$ is the weighted model function Jacobian.
- If you specify an error model other than 'constant' using the name-value pair argument ErrorModel, then you can no longer interpret $J$ as the model function Jacobian.

## CovB - Estimated variance-covariance matrix

matrix
Estimated variance-covariance matrix for the fitted coefficients, beta, returned as a $p$-by- $p$ matrix, where $p$ is the number of estimated coefficients. If the model Jacobian, $J$, has full column rank, then CovB $=$ $\operatorname{inv}(J ' * J) * M S E$, where MSE is the mean squared error.

## MSE - Mean squared error

scalar value
Mean squared error (MSE) of the fitted model, returned as a scalar value. MSE is an estimate of the variance of the error term. If the model Jacobian, J, has full column rank, then MSE $=\left(R^{\prime *} R\right) /(N-p)$, where $N$ is the number of observations, and $p$ is the number of estimated coefficients.

## ErrorModelInfo - Information about error model fit

structure
Information about the error model fit, returned as a structure with the following fields:

ErrorModel Chosen error model
ErrorParameters
Estimated error parameters
ErrorVariance
Function handle that accepts an $N$-by- $p$ matrix, X, and returns an $N$-by- 1 vector of error variances using the estimated error model

| MSE | Mean squared error |
| :--- | :--- |
| ScheffeSimPred | Scheffé parameter for simultaneous <br> prediction intervals when using the <br> estimated error model |
| WeightFunction | Logical with value true if you used a <br> custom weight function previously in <br> nlinfit |
| FixedWeights | Logical with value true if you used fixed <br> weights previously in nlinfit |
| RobustWeightFunction | Logical with value true if you used robust <br> fitting previously in |

## Examples <br> Nonlinear Regression Model Using Default Options

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
betaO = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
beta = nlinfit(X,y,@hougen,betaO)
```

beta $=$

0.1124
1.1914

## Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model

$$
y=b_{1}+b_{2} \exp \left\{-b_{3} x\right\}+\varepsilon
$$

where $b_{1}, b_{2}$, and $b_{3}$ are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1 .

```
modelfun = a(b,x)(b(1)+b(2)*exp(-b(3)*x));
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.

```
betaO = [2;2;2];
beta = nlinfit(x,y,modelfun,beta0,opts)
beta =
```

    1.0041
    3.0997
    2.1483
    
## Nonlinear Regression Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
```

```
betaO = S.beta;
```

Specify a vector of known observation weights.
W = [8 216129121010122108$] ' ;$

Fit the Hougen-Watson model to the rate data using the specified observation weights.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,betaO,'Weights',W);
beta
beta =
    2.2068
    0.1077
    0.0766
    0.1818
    0.6516
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))
ans =
    2.5721
    0.1251
    0.0950
    0.2043
    0.7735
```

## Nonlinear Regression Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
```

## nlinfit

```
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.
[beta,R,J,CovB] = nlinfit(X,y,@hougen,betaO,'Weights', weights); beta
beta $=$
0.8308
0.0409
0.0251
0.0801
1.8261

Display the coefficient standard errors.

```
sqrt(diag(CovB))
```

ans $=$
0.5822
0.0297
0.0197
0.0578
1.2810

## Nonlinear Regression Using Nonconstant Error Model

Load sample data.
S = load('reaction');

```
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error model.

```
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(X,y,@hougen,beta0,'Errorl
``` beta
beta =
1.2526
0.0628
0.0400
0.1124
1.1914

Display the error model information.

\section*{ErrorModelInfo}

\section*{ErrorModelInfo =}

ErrorModel: 'combined'
ErrorParameters: [0.1517 5.6783e-08]
ErrorVariance: @(x)mse*(errorparam(1)+errorparam(2)*abs(mod
MSE: 1.6245
ScheffeSimPred: 6
WeightFunction: 0
FixedWeights: 0
RobustWeightFunction: 0
Tips
- To produce error estimates on predictions, use the optional output arguments R, J, CovB, or MSE as inputs to nlpredci.
- To produce error estimates on the estimated coefficients, beta, use the optional output arguments R, J, CovB, or MSE as inputs to nlparci.
- If you use the robust fitting option, RobustWgtFun, you must use CovB-and might need MSE-as inputs to nlpredci or nlparci to ensure that the confidence intervals take the robust fit properly into account.

\section*{Algorithms}

\section*{Definitions}

\section*{Weighted Residuals}

A weighted residual is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients, \(\mathbf{b}\), the residual for observation \(i\) is
\[
r_{i}=y_{i}-f\left(\mathbf{x}_{i}, \mathbf{b}\right)
\]
where \(y_{i}\) is the observed response and \(f\left(\mathbf{x}_{i}, \mathbf{b}\right)\) is the fitted response at predictors \(\mathbf{x}_{i}\).
When you fit a weighted nonlinear regression with weights \(w_{i}, i=\) \(1, \ldots, N\), nlinfit returns the weighted residuals,
\[
r_{i}^{*}=\sqrt{w_{i}}\left(y_{i}-f\left(\mathbf{x}_{i}, \mathbf{b}\right)\right) .
\]

\section*{Weighted Model Function Jacobian}

The weighted model function Jacobian is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients, \(\mathbf{b}\), the estimated model
Jacobian, \(\mathbf{J}\), for the nonlinear function \(f\left(\mathbf{x}_{i}, \mathbf{b}\right)\) has elements
\[
\mathbf{J}_{i j}=\frac{\partial f\left(\mathbf{x}_{i}, \mathbf{b}\right)}{\partial b_{j}},
\]
where \(b_{j}\) is the \(j\) th element of \(\mathbf{b}\).
When you fit a weighted nonlinear regression with diagonal weights matrix \(\mathbf{W}\), nlinfit returns the weighted Jacobian matrix,
\[
\mathbf{J}^{*}=\mathbf{W}^{1 / 2} \mathbf{J} .
\]

\section*{Purpose Interactive nonlinear regression}
```

Syntax
nlintool (X,y,fun, beta0)
nlintool(X,y,fun, betaO, alpha)
nlintool(X,y,fun, beta0, alpha, 'xname','yname')

```

\section*{Description}

\section*{Examples}
nlintool ( \(X, y\), fun, beta0) is a graphical user interface to the nlinfit function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show \(95 \%\) simultaneous confidence bands for the function.
nlintool(X,y,fun, beta0, alpha) shows 100(1-alpha)\% confidence bands. These are simultaneous confidence bounds for the function value. Using the Bounds menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.
nlintool(X,y,fun, beta0, alpha, 'xname', 'yname') labels the plots using the string matrix 'xname' for the predictors and the string 'yname' for the response.

The data in reaction.mat are partial pressures of three chemical reactants and the corresponding reaction rates. The function hougen implements the nonlinear Hougen-Watson model for reaction rates. The following fits the model to the data:
```

load reaction
nlintool(reactants,rate,@hougen, beta, 0.01,xn,yn)

```

See Also nlinfit | polytool | rstool

- PHI - A 1-by-p vector of model parameters.

\section*{nlmefit}
- XFUN - A \(k\)-by- \(h\) array of predictors, where:
- \(k=1\) if XFUN is a single row of X.
- \(k=n_{i}\) if XFUN contains the rows of X for a single group of size \(n_{i}\).
- \(k=n\) if XFUN contains all rows of X.
- VFUN - Group-specific predictors given by one of:
- A 1-by-g vector corresponding to a single group and a single row of \(V\).
- An \(n\)-by-g array, where the \(j\) th row is \(\mathrm{V}(\mathrm{I},:)\) if the \(j\) th observation is in group I.

If V is empty, nlmefit calls modelfun with only two inputs.
- yfit - A \(k\)-by-1 vector of fitted values

When either PHI or VFUN contains a single row, it corresponds to all rows in the other two input arguments.

Note If modelfun can compute yfit for more than one vector of model parameters per call, use the 'Vectorization' parameter (described later) for improved performance.
beta0 is a \(q\)-by- 1 vector with initial estimates for \(q\) fixed effects. By default, \(q\) is the number of model parameters \(p\).
nlmefit fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:
- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.
[beta, PSI] = nlmefit(X,y,group, V,fun, beta0) also returns PSI, an \(r\)-by- \(r\) estimated covariance matrix for the random effects. By default, \(r\) is equal to the number of model parameters \(p\).
[beta, PSI, stats] = nlmefit(X,y,group, \(V\),fun, beta0) also returns stats, a structure with fields:
- dfe - The error degrees of freedom for the model
- logl - The maximized loglikelihood for the fitted model
- rmse - The square root of the estimated error variance (computed on the log scale for the exponential error model)
- errorparam - The estimated parameters of the error variance model
- aic - The Akaike information criterion, calculated as aic \(=-2 * \log 1\) +2 * numParam, where numParam is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and logl is a field in the stats structure
- bic - The Bayesian information criterion, calculated as bic \(=\) \(-2 * \log 1+\log (M) *\) numParam
- \(M\) is the number of groups.
- numParam and logl are defined as in aic.

Note that some literature suggests that the computation of bic should be, bic \(=-2^{*} \log l+\log (N) *\) numParam, where \(N\) is the number of observations.
- covb - The estimated covariance matrix of the parameter estimates
- sebeta - The standard errors for beta
- ires - The population residuals (y-y_population), where y_population is the individual predicted values
- pres - The population residuals (y-y_population), where y_population is the population predicted values
- iwres - The individual weighted residuals

\section*{nlmefit}
- pwres - The population weighted residuals
- cwres - The conditional weighted residuals
[beta, PSI, stats, \(B\) ] = nlmefit (X, y, group, V, fun, beta0) also returns B, an \(r\)-by- \(m\) matrix of estimated random effects for the \(m\) groups. By default, \(r\) is equal to the number of model parameters \(p\).
[beta,PSI,stats,B] =
nlmefit(X,y,group,V,fun, betaO, 'Name', value) specifies one or more optional parameter name/value pairs. Specify Name inside single quotes.
Use the following parameters to fit a model different from the default. (The default model is obtained by setting both FEConstDesign and REConstDesign to eye ( \(p\) ), or by setting both FEParamsSelect and REParamsSelect to 1:p.) Use at most one parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The nlmefit function requires you to specify at least one fixed effect and one random effect.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline FEParamsSelect & \begin{tabular}{l} 
A vector specifying which elements of the \\
parameter vector PHI include a fixed effect, \\
given as a numeric vector of indices from \\
1 to \(p\) or as a 1-by- \(p\) logical vector. If \(q\) is \\
the specified number of elements, then the \\
model includes \(q\) fixed effects.
\end{tabular} \\
\hline FEConstDesign & \begin{tabular}{l} 
A \(p\)-by- \(q\) design matrix ADESIGN, where \\
ADESIGN*beta are the fixed components of \\
the \(p\) elements of PHI.
\end{tabular} \\
\hline FEGroupDesign & \begin{tabular}{l} 
A \(p\)-by- \(q\)-by- \(m\) array specifying a different \\
\(p-\) by- \(q\) fixed-effects design matrix for each \\
of the \(m\) groups.
\end{tabular} \\
\hline FEObsDesign & \begin{tabular}{l} 
A \(p\)-by- \(q\)-by- \(n\) array specifying a different \\
\(p\)-by- \(q\) fixed-effects design matrix for each \\
of the \(n\) observations.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline REParamsSelect & \begin{tabular}{l} 
A vector specifying which elements of the \\
parameter vector PHI include a random \\
effect, given as a numeric vector of indices \\
from 1 to \(p\) or as a 1-by- \(p\) logical vector. The \\
model includes \(r\) random effects, where \(r\) \\
is the specified number of elements.
\end{tabular} \\
\hline REConstDesign & \begin{tabular}{l} 
A \(p\)-by- \(r\) design matrix BDESIGN, where \\
BDESIGN*B are the random components of \\
the \(p\) elements of PHI.
\end{tabular} \\
\hline REGroupDesign & \begin{tabular}{l} 
A \(p\)-by- \(r\)-by- \(m\) array specifying a different \\
\(p-\) by- random-effects design matrix for \\
each of \(m\) groups.
\end{tabular} \\
\hline REObsDesign & \begin{tabular}{l} 
A \(p\)-by- \(r\)-by- \(n\) array specifying a different \\
\(p\)-by- \(r\) random-effects design matrix for \\
each of \(n\) observations.
\end{tabular} \\
\hline
\end{tabular}

Use the following parameters to control the iterative algorithm for maximizing the likelihood:
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline RefineBeta0 & \begin{tabular}{l} 
Determines whether nlmef it makes an \\
initial refinement of betao by first fitting \\
modelfun without random effects and \\
replacing beta0 with beta. Choices are \\
'on' and 'off'. The default value is 'on '.
\end{tabular} \\
\hline ErrorModel & \begin{tabular}{l} 
A string specifying the form of the error \\
term. Default is 'constant '. Each model \\
defines the error using a standard normal \\
(Gaussian) variable \(e\), the function value \\
\(f\), and one or two parameters \(a\) and \(b\). \\
Choices are:
\end{tabular} \\
- 'constant ' \(: y=f+a^{*} e\)
\end{tabular}

\section*{nlmefit}
\begin{tabular}{|c|c|}
\hline Parameter & Value \\
\hline & \begin{tabular}{l}
- 'proportional': \(y=f+b^{*} f^{*} e\) \\
- 'combined' \(: y=f+\left(a+b^{*} f\right) * e\) \\
- 'exponential': \(y=f^{*} \exp \left(a^{*} e\right)\), or equivalently \(\log (y)=\log (f)+a^{*} e\) \\
If this parameter is given, the output stats.errorparam field has the value \\
- \(a\) for 'constant ' and 'exponential' \\
- \(b\) for 'proportional' \\
- \([a b]\) for 'combined'
\end{tabular} \\
\hline ApproximationType & \begin{tabular}{l}
The method used to approximate the likelihood of the model. Choices are: \\
- 'LME' - Use the likelihood for the linear mixed-effects model at the current conditional estimates of beta and \(B\). This is the default. \\
- 'RELME ' - Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of beta and \(B\). \\
- 'FO' - First-order Laplacian approximation without random effects. \\
- 'FOCE' - First-order Laplacian approximation at the conditional estimates of B.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline Vectorization & \begin{tabular}{l} 
Indicates acceptable sizes for the PHI, \\
XFUN, and VFUN input arguments to \\
modelfun. Choices are:
\end{tabular} \\
& \begin{tabular}{l} 
- 'SinglePhi' - modelfun can only \\
accept a single set of model parameters \\
at a time, so PHI must be a single \\
row vector in each call. nlmefit calls \\
modelfun in a loop, if necessary, with \\
a single PHI vector and with XFUN \\
containing rows for a single observation \\
or group at a time. VFUN may be a single \\
row that applies to all rows of XFUN, or a \\
matrix with rows corresponding to rows
\end{tabular} \\
& in XFUN. This is the default. \\
&
\end{tabular}
- 'SingleGroup' - modelfun can only accept inputs corresponding to a single group in the data, so XFUN must contain rows of \(X\) from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group or a matrix with one row for each observation. VFUN is a single row.
- 'Full' - modelfun can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN or a matrix with rows corresponding to rows in XFUN. This option can improve performance by reducing the number of calls to modelfun, but may require modelfun to perform singleton expansion on PHI or V.

\section*{nlmefit}
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline CovParameterization & \begin{tabular}{l} 
Specifies the parameterization used \\
internally for the scaled covariance matrix. \\
Choices are 'chol' for the Cholesky \\
factorization or 'logm' the matrix \\
logarithm. The default is 'logm'.
\end{tabular} \\
\hline CovPattern & \begin{tabular}{l} 
Specifies an \(r\)-by- \(r\) logical or numeric \\
matrix P that defines the pattern of the \\
random-effects covariance matrix PSI. \\
nlmefit estimates the variances along \\
the diagonal of PSI and the covariances \\
specified by nonzeros in the off-diagonal \\
elements of P. Covariances corresponding \\
to zero off-diagonal elements in P are \\
constrained to be zero. If P does not specify \\
a row-column permutation of a block \\
diagonal matrix, nlmefit adds nonzero \\
elements to P as needed. The default \\
value of P is eye (r), corresponding to \\
uncorrelated random effects.
\end{tabular} \\
Alternatively, P may be a 1-by- \(r\) vector \\
containing values in 1: \(r\), with equal values \\
specifying groups of random effects. In this \\
case, nlmefit estimates covariances only \\
within groups, and constrains covariances \\
across groups to be zero.
\end{tabular}
\begin{tabular}{|c|c|}
\hline Parameter & Value \\
\hline ParamTransform & \begin{tabular}{l}
A vector of \(p\)-values specifying a transformation function \(f()\) for each of the \(P\) parameters: \(X B=\) ADESIGN*BETA + BDESIGN*B PHI \(=f(X B)\). Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI : \\
- \(0: \mathrm{PHI}=\mathrm{XB}\) (default for all parameters) \\
- \(1: \log (\mathrm{PHI})=X B\) \\
- 2: \(\operatorname{probit}(\mathrm{PHI})=X B\) \\
- 3: \(\operatorname{logit}(\mathrm{PHI})=X B\)
\end{tabular} \\
\hline Options & \begin{tabular}{l}
A structure of the form returned by statset. nlmefit uses the following statset parameters: \\
- 'DerivStep' - Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters \(p\). The default is \(\operatorname{eps}^{\wedge}(1 / 3)\). \\
- 'Display' - Level of iterative display during estimation. Choices are: \\
- 'off' (default) - Displays no information \\
- 'final' - Displays information after the final iteration \\
- 'iter' - Displays information at each iteration \\
- 'FunValCheck' - Check for invalid values, such as NaN or Inf, from
\end{tabular} \\
\hline
\end{tabular}

\section*{nlmefit}
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline & \begin{tabular}{l} 
modelfun. Choices are 'on' and 'off '. \\
The default is 'on '.
\end{tabular} \\
& \begin{tabular}{l} 
- MaxIter' - Maximum number of \\
iterations allowed. The default is 200. \\
- OutputFcn' — Function handle \\
specified using @, a cell array with \\
function handles or an empty array \\
(default). The solver calls all output \\
functions after each iteration.
\end{tabular} \\
- 'TolFun' — Termination tolerance on \\
the loglikelihood function. The default \\
is 1e-4. \\
- 'TolX' - Termination tolerance on the \\
estimated fixed and random effects. The \\
default is 1e-4.
\end{tabular}

Examples Display data on the growth of five orange trees:
```

CIRC = [l30 58 87 115 120 142 145;
33 69 111 156 172 203 203;
30 51 75 108 115 139 140;
32 62 112 167 179 209 214;
30 49 81 125 142 174 177];
time = [118 484 664 1004 1231 1372 1582];
h = plot(time,CIRC','o','LineWidth',2);

```
```

xlabel('Time (days)')
ylabel('Circumference (mm)')
title('{\bf Orange Tree Growth}')
legend([repmat('Tree ',5,1),num2str((1:5)')],...
Location','NW')
grid on
hold on

```

Orange Tree Growth

Use an anonymous function to specify a logistic growth model:
```

model=@(PHI,t)(PHI(:,1))./(1+exp(-(t-PHI(:,2))./PHI(:,3)));

```

\section*{nlmefit}

Fit the model using nlmefit with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):
```

TIME = repmat(time,5,1);
NUMS = repmat((1:5)',size(time));
beta0 = [100 100 100];
[beta1,PSI1,stats1] = nlmefit(TIME(:),CIRC(:),NUMS(:),...
[],model,beta0)
beta1 =
191.3189
723.7608
346.2517
PSI1 =
962.1534 0 0
0 0.0000 0
0 0 297.9881
stats1 =
dfe: 28
logl: -131.5457
mse: 59.7882
rmse: 7.9016
errorparam: 7.7323
aic: 277.0913
bic: 274.3574
covb: [3x3 double]
sebeta: [15.2249 33.1579 26.8235]
ires: [35x1 double]
pres: [35x1 double]
iwres: [35x1 double]
pwres: [35\times1 double]
cwres: [35x1 double]

```

The negligible variance of the second random effect, PSI1 \((2,2)\), suggests that it can be removed to simplify the model:
```

[beta2,PSI2,stats2,b2] = nlmefit(TIME(:),CIRC(:),...
NUMS(:),[],model,beta0,'REParamsSelect',[1 3])
beta2 =
191.3194
723.7628
346.2548
PSI2 =
962.2114 0
0 298.3989
stats2 =
dfe: 29
logl: -131.5456
mse: 59.7851
rmse: 7.7640
errorparam: 7.7321
aic: 275.0913
bic: 272.7479
covb: [3\times3 double]
sebeta: [15.2252 33.1572 26.8246]
ires: [35x1 double]
pres: [35x1 double]
iwres: [35x1 double]
pwres: [35x1 double]
cwres: [35x1 double]
b2 =
-28.5250 31.6063 -36.5070 39.0735 -5.6479
10.0097 -0.7638 6.0117 -9.4685 -5.7892

```

\section*{nlmefit}

The loglikelihood logl is unaffected, and both the Akaike and Bayesian information criteria (aic and bic) are reduced, supporting the decision to drop the second random effect from the model.

Use the estimated fixed effects in beta2 and the estimated random effects for each tree in b2 to plot the model through the data:
```

PHI = repmat(beta2,1,5) + ... % Fixed effects
[b2(1,:);zeros(1,5);b2(2,:)]; % Random effects
colors = get(h,'Color');
tplot = 0:0.1:1600;
for I = 1:5
fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I))./ ...
PHI(3,I)));
plot(tplot,fitted_model(tplot),'Color',colors{I}, ...
'LineWidth',2)
end

```

\section*{Purpose}

Fit nonlinear mixed-effects model with stochastic EM algorithm

\section*{Syntax}

\section*{Description}

\section*{Input \\ Arguments}
```

[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETAO)
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETAO,
'Name',Value)

```
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP, V,MODELFUN,BETAO) fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in BETA. By default, nlmefitsa fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The BETA, PSI, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the 'Replicates' parameter to perform multiple simulations.
[BETA,PSI,STATS,B] =
nlmefitsa(X, Y, GROUP, V, MODELFUN, BETAO, 'Name' , Value) accepts one or more comma-separated parameter name/value pairs. Specify Name inside single quotes.

\section*{Definitions:}

In the following list of arguments, the following variable definitions apply:
- \(n\) - number of observations
- \(h\) - number of predictor variables
- \(m\) - number of groups
- \(g\) - number of group-specific predictor variables
- \(p\) - number of parameters

\section*{nlmefitsa}
- \(f\) - number of fixed effects

\section*{X}

An \(n\)-by- \(h\) matrix of \(n\) observations on \(h\) predictor variables.

\section*{Y}

An \(n\)-by- 1 vector of responses.

\section*{GROUP}

A grouping variable indicating to which of \(m\) groups each observation belongs. GROUP can be a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings.

\section*{V}

An \(m\)-by- \(g\) matrix of \(g\) group-specific predictor variables for each of the \(m\) groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of V are ordered according to GRP2IDX (GROUP). Use an \(m\)-by- \(g\) cell array for \(V\) if any of the group-specific predictor values vary in size across groups. Specify [ ] for \(V\) if there are no group predictors.

\section*{MODELFUN}

A handle to a function that accepts predictor values and model parameters, and returns fitted values. MODELFUN has the form YFIT = MODELFUN (PHI, XFUN, VFUN) with input arguments
- PHI - A 1-by-p vector of model parameters.
- XFUN - An \(l\)-by- \(h\) array of predictor variables where
- \(l\) is 1 if XFUN is a single row of \(X\)
- \(l\) is \(n_{i}\) if XFUN contains the rows of X for a single group of size \(n_{i}\)
- \(l\) is \(n\) if XFUN contains all rows of X .
- VFUN - Either
- A 1-by-g vector of group-specific predictors for a single group, corresponding to a single row of V
- An \(n\)-by- \(g\) matrix, where the \(k\)-th row of VFUN is \(\mathrm{V}(i,:)\) if the \(k\)-th observation is in group \(i\).
If \(V\) is empty, nlmefitsa calls MODELFUN with only two inputs. MODELFUN returns an \(l\)-by- 1 vector of fitted values YFIT. When either PHI or VFUN contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the 'Vectorization' parameter name/value pair (described below) if MODELFUN can compute YFIT for more than one vector of model parameters in one call.

\section*{BETAO}

An \(f\)-by- 1 vector with initial estimates for the \(f\) fixed effects. By default, \(f\) is equal to the number of model parameters \(p\). BETAO can also be an \(f\)-by-REPS matrix, and the estimation is repeated REPS times using each column of BETAO as a set of starting values.

\section*{Name-Value Pair Arguments}

By default, nlmefitsa fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an 'FE' prefix and one parameter name with an 'RE' prefix. Note that some choices change the way nlmefitsa calls MODELFUN, as described further below.

\section*{'FEParamsSelect'}

A vector specifying which elements of the model parameter vector PHI include a fixed effect, as a numeric vector with elements in \(1: p\), or as a 1 -by- \(p\) logical vector. The model will include \(f\) fixed effects, where \(f\) is the specified number of elements.

\section*{'FEConstDesign'}

\section*{nlmefitsa}

A \(p\)-by-f design matrix ADESIGN, where ADESIGN*BETA are the fixed components of the \(p\) elements of PHI.

\section*{'FEGroupDesign'}

A \(p\)-by- \(f\)-by- \(m\) array specifying a different \(p\)-by- \(f\) fixed effects design matrix for each of the \(m\) groups.

\section*{'REParamsSelect'}

A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in 1:p, or as a 1-by- \(p\) logical vector. The model will include \(r\) random effects, where \(r\) is the specified number of elements.

\section*{'REConstDesign'}

A \(p\)-by- \(r\) design matrix BDESIGN, where BDESIGN*B are the random components of the \(p\) elements of PHI. This matrix must consist of 0 s and 1 s , with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to eye ( \(p\) ), or to setting both FEParamsSelect and REParamsSelect to 1:p.

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

\section*{'CovPattern'}

Specifies an \(r\)-by-r logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. nlmefitsa computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. nlmefitsa constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and nlmefitsa adds non-zero elements to PAT as needed to produce such a pattern. The
default value of PAT is eye \((r)\), corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by- \(r\) vector containing values in 1:r. In this case, elements of PAT with equal values define groups of random effects, nlmefitsa estimates covariances only within groups, and constrains covariances across groups to be zero.

\section*{'CovO'}

Initial value for the covariance matrix PSI. Must be an \(r\)-by- \(r\) positive definite matrix. If empty, the default value depends on the values of BETAO.

\section*{'ComputeStdErrors'}
true to compute standard errors for the coefficient estimates and store them in the output STATS structure, or false (default) to omit this computation.

\section*{'ErrorModel'}

A string specifying the form of the error term. Default is 'constant '. Each model defines the error using a standard normal (Gaussian) variable \(e\), the function value \(f\), and one or two parameters \(a\) and \(b\). Choices are
- 'constant' \(-y=f+a^{*} e\)
- 'proportional' - \(y=f+b^{*} f^{*} e\)
- 'combined' \(-y=f+\left(a+b^{*} f\right)^{*} e\)
- 'exponential' \(-y=f^{*} \exp \left(a^{*} e\right)\), or equivalently \(\log (y)=\log (f)+a^{*} e\) If this parameter is given, the output STATS.errorparam field has the value
- \(a\) for 'constant' and 'exponential'
- \(b\) for 'proportional'
- \([a b]\) for 'combined'

\section*{nlmefitsa}

\section*{'ErrorParameters'}

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the \(a, b\), or \([a b]\) values depending on the ErrorModel parameter.

\section*{'LogLikMethod'}

Specifies the method for approximating the loglikelihood. Choices are:
- 'is' - Importance sampling
- 'gq' - Gaussian quadrature
- 'lin' - Linearization
- 'none ' - Omit the loglikelihood approximation (default)

\section*{'NBurnIn'}

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5 .

\section*{'NChains'}

Number \(c\) of "chains" simulated. Default is 1 . Setting \(c>1\) causes \(c\) simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

\section*{'Nlterations'}

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

\section*{1 simulated annealing}

2 full step size
3 reduced step size

Default is [150 150 100]. A scalar is distributed across the three phases in the same proportions as the default.

\section*{'NMCMCIterations'}

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

1 full multivariate update
2 single coordinate update
3 multiple coordinate update
Default is [2 2 2]. A scalar value is treated as a three-element vector with all elements equal to the scalar.

\section*{'OptimFun'}

Either 'fminsearch' or 'fminunc ', specifying the optimization function to be used during the estimation process. Default is 'fminsearch'. Use of 'fminunc' requires Optimization Toolbox.

\section*{'Options'}

A structure created by a call to statset. nlmefitsa uses the following statset parameters:
- 'DerivStep' - Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters \(p\). The default is eps^(1/3).
- Display - Level of display during estimation.
- 'off' (default) - Displays no information
- 'final' - Displays information after the final iteration of the estimation algorithm

\section*{nlmefitsa}
- 'iter' - Displays information at each iteration
- FunValCheck
- 'on ' (sdefault) - Check for invalid values (such as NaN or Inf) from MODELFUN
- 'off' - Skip this check
- OutputFcn - Function handle specified using @, a cell array with function handles or an empty array. nlmefitsa calls all output functions after each iteration. See nlmefitoutputfon.m (the default output function for nlmefitsa) for an example of an output function.

\section*{'ParamTransform'}

A vector of \(p\)-values specifying a transformation function \(f()\) for each of the \(p\) parameters:
```

XB = ADESIGN*BETA + BDESIGN*B
PHI = f(XB)

```

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:
- \(0:\) PHI = XB (default for all parameters)
- \(1: \log (\) PHI \()=X B\)
- 2: probit(PHI) = XB
- 3: logit(PHI) = XB

\section*{'Replicates'}

Number REPS of estimations to perform starting from the starting values in the vector BETAO. If BETAO is a matrix, REPS must match the number of columns in BETAO. Default is the number of columns in BETAO.

\section*{'Vectorization'}

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

\section*{nlmefitsa}
- 'SinglePhi' - MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. nlmefitsa calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.
- 'SingleGroup ' - MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of \(X\) from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.
- 'Full' - MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.
The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, nlmefitsa calls MODELFUN with only two inputs.

\section*{Output Arguments}

\section*{BETA}

Estimates of the fixed effects

\section*{PSI}

An \(r\)-by- \(r\) estimated covariance matrix for the random effects. By default, \(r\) is equal to the number of model parameters \(p\).

\section*{STATS}

A structure with the following fields:
- logl - The maximized loglikelihood for the fitted model; empty if the LogLikMethod parameter has its default value of 'none'

\section*{nlmefitsa}
- rmse - The square root of the estimated error variance (computed on the log scale for the exponential error model)
- errorparam - The estimated parameters of the error variance model
- aic - The Akaike information criterion (empty if logl is empty), calculated as aic \(=-2 * \operatorname{logl}+2\) * numParam, where
- logl is the maximized loglikelihood.
- numParam is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.
- bic - The Bayesian information criterion (empty if logl is empty), calculated as bic \(=-2 * \log 1+\log (\mathrm{M}) *\) numParam
- \(M\) is the number of groups.
- logl and numParam are defined as in aic.

Note that some literature suggests that the computation of bic should be , bic \(=-2^{*} \operatorname{logl}+\log (\mathrm{N})\) * numParam, where \(N\) is the number of observations. To adjust the value of the output you can redefine bic as follows: bic = bic - numel(unique(group)) + numel(Y)
- sebeta - The standard errors for BETA (empty if the ComputeStdErrors parameter has its default value of false)
- covb - The estimated covariance of the parameter estimates (empty if ComputeStdErrors is false)
- dfe - The error degrees of freedom
- pres - The population residuals (y-y_population), where y_population is the population predicted values
- ires - The population residuals (y-y_population), where y_population is the individual predicted values
- pwres - The population weighted residuals
- cwres - The conditional weighted residuals
- iwres - The individual weighted residuals

Examples
Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours:
```

load indomethacin
model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t));
phiO = [[1 1 1 1 1 1];
% log transform for 2nd and 4th parameters
xform = [00 1 0 1];
[beta,PSI,stats,br] = nlmefitsa(time,concentration,...
subject,[],model,phi0,'ParamTransform',xform)

```

\section*{nlmefitsa}
```

% Plot the data along with an overall "population" fit
clf
phi = [beta(1), exp(beta(2)), beta(3), exp(beta(4))];
h = gscatter(time,concentration,subject);
xlabel('Time (hours)')
ylabel('Concentration (mcg/ml)')
title('{\bf Indomethacin Elimination}')
xx = linspace(0,8);
line(xx,model(phi,xx),'linewidth',2,'color','k')
% Plot individual curves based on random effect estimates
for j=1:6
phir = [beta(1)+br(1,j), exp(beta(2)+br(2,j)), ...
beta(3)+br(3,j), exp(beta(4)+br(4,j))];
line(xx,model(phir, xx),'color',get(h(j),'color'))
end

```

\section*{Indomethacin Elimination}

\section*{Algorithms}

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form
\[
p\left(y \mid \beta, \sigma^{2}, \Sigma\right)=\int p\left(y \mid \beta, b, \sigma^{2}\right) p(b \mid \Sigma) d b
\]
where
- \(y\) is the response data

\section*{nlmefitsa}
- \(B\) is the vector of population coefficients
- \(\sigma^{2}\) is the residual variance
- \(\sum\) is the covariance matrix for the random effects
- \(b\) is the set of unobserved random effects

Each \(p()\) function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

1 Simulation: Generate simulated values of the random effects \(b\) from the posterior density \(p(b \mid \Sigma)\) given the current parameter estimates.

2 Stochastic approximation: Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.

3 Maximization step: Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.

\section*{gmdistribution.NlogL property}

Purpose Negative of log-likelihood
Description The negative of the log-likelihood of the data.

Note This property applies only to gmdistribution objects constructed with fit.

\section*{ProbDistParametric.NLogL property}
\begin{tabular}{ll} 
Purpose & \begin{tabular}{l} 
Read-only value specifying negative log likelihood for input data to \\
ProbDistParametric object
\end{tabular} \\
Description \(\quad\)\begin{tabular}{l} 
NLogL is a read-only property of the ProbDistParametric class. NLogL \\
is a value specifying the negative log likelihood for input data used to fit \\
a distribution represented by a ProbDistParametric object.
\end{tabular} \\
Values & \begin{tabular}{l} 
The value is a numeric scalar for a distribution fit to input data, that \\
is, a distribution created using the fitdist function. This property is \\
empty for distributions created without fitting to data, that is, by using \\
the ProbDistUnivParam. ProbDistUnivParam constructor. Use this \\
information to view and compare the negative log likelihood for input \\
data supplied to create distributions.
\end{tabular}
\end{tabular}

\section*{ProbDistUnivKernel.NLogL property}

\author{

}

\section*{Purpose Nonlinear regression parameter confidence intervals}
```

Syntax ci = nlparci(beta,resid,'covar',sigma)
ci = nlparci(beta,resid,'jacobian',J)
ci = nlparci(...,'alpha',alpha)

```

\section*{Description}

\section*{Examples}
ci = nlparci(beta, resid,'covar',sigma) returns the \(95 \%\) confidence intervals ci for the nonlinear least squares parameter estimates beta. Before calling nlparci, use nlinfit to fit a nonlinear regression model and get the coefficient estimates beta, residuals resid, and estimated coefficient covariance matrix sigma.
ci = nlparci(beta, resid,'jacobian', J) is an alternative syntax that also computes \(95 \%\) confidence intervals. \(J\) is the Jacobian computed by nlinfit. If the 'robust' option is used with nlinfit, use the 'covar' input rather than the 'jacobian' input so that the required sigma parameter takes the robust fitting into account.
ci = nlparci(...,'alpha',alpha) returns 100(1-alpha)\% confidence intervals.
nlparci treats \(N a N s\) in resid or \(J\) as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of resid exceeds the length of beta and \(J\) has full column rank. When \(J\) is ill-conditioned, confidence intervals may be inaccurate.

\section*{Fit to exponential decay}

Suppose you have data, and want to fit a model of the form
\[
y_{i}=a_{1}+a_{2} \exp \left(-a_{3} x_{i}\right)+\varepsilon_{i} .
\]

Here the \(\alpha_{i}\) are the parameters you want to estimate, \(x_{i}\) are the data points, the \(y_{i}\) are the responses, and the \(\varepsilon_{i}\) are noise terms.

1 Write a function handle that represents the model:
```

$m d l=@(a, x)(a(1)+a(2) * \exp (-a(3) * x)) ;$

```

2 Generate synthetic data with parameters a \(=[1 ; 3 ; 2]\), with the \(x\) data points distributed exponentially with parameter 2 , and normally distributed noise with standard deviation 0.1:
```

rng(9845,'twister') % for reproducibility
a = [1;3;2];
x = exprnd(2,100,1);
epsn = normrnd(0,0.1,100,1);
y = mdl(a,x) + epsn;

```

3 Fit the model to data starting from the arbitrary guess a0 \(=[2 ; 2 ; 2]\) :
aO = [2;2;2];
[ahat,r,J,cov,mse] = nlinfit(x,y,mdl,aO);
ahat
ahat \(=\)
1.0153
3.0229
2.1070

4 Check whether [1;3;2] is in a \(95 \%\) confidence interval using the Jacobian argument in nlparci:
```

ci = nlparci(ahat,r,'Jacobian',J)
ci =
0.9869 1.0438
2.9401 3.1058
1.9963 2.2177

```

5 You can obtain the same result using the covariance argument:
```

ci = nlparci(ahat,r,'covar',cov)
Ci =
0.9869 1.0438

```
```

2.9401
3.1058
1.9963
2.2177

```

See Also nlinfit | nlpredci

\section*{nlpredci}

Purpose Nonlinear regression prediction confidence intervals
```

Syntax
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar', CovB)
[Ypred,delta] =
nlpredci(modelfun, X, beta, R, 'Covar', CovB, Name,
Value)
[Ypred,delta] = nlpredci(modelfun, X, beta, R, 'Jacobian', J)
[Ypred,delta] =
nlpredci(modelfun, X, beta, R, 'Jacobian', J,Name,
Value)

```

\section*{Description}
[Ypred,delta] = nlpredci(modelfun, X, beta, R, 'Covar', CovB) returns predictions, Ypred, and \(95 \%\) confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and variance-covariance matrix, CovB.
[Ypred,delta] =
nlpredci(modelfun, X, beta, R, 'Covar', CovB, Name, Value) uses additional options specified by one or more name-value pair arguments.
[Ypred,delta] = nlpredci(modelfun, X, beta, R, 'Jacobian', J) returns predictions, Ypred, and \(95 \%\) confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and Jacobian, J.

If you use a robust option with nlinfit, then you should use the Covar syntax rather than the Jacobian syntax. The variance-covariance matrix, CovB, is required to properly take the robust fitting into account.
[Ypred,delta] =
nlpredci(modelfun, X, beta, R, 'Jacobian', J,Name, Value) uses additional options specified by one or more name-value pair arguments.

\section*{Input Arguments}

\section*{modelfun - Nonlinear regression model function \\ function handle}

Nonlinear regression model function, specified as a function handle. modelfun must accept two input arguments, a coefficient vector and an array \(X\)-in that order-and return a vector of fitted response values.

For example, to specify the hougen nonlinear regression function, use the function handle @nougen.

Data Types
function_handle

\section*{X - Input values for predictions}

\section*{matrix}

Input values for predictions, specified as a matrix. nlpredci makes a prediction for the covariates in each row of \(X\). There should be a column in \(X\) for each coefficient in the model.
```

Data Types
single | double

```

\section*{beta-Estimated regression coefficients}
vector returned by nlinfit
Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to nlinfit.

Data Types
single | double

\section*{R-Residuals}
vector returned by nlinfit
Residuals for the fitted modelfun, specified as the vector of residuals returned by a previous call to nlinfit.

\section*{CovB - Estimated variance-covariance matrix}
matrix returned by nlinfit

\section*{nlpredci}

Estimated variance-covariance matrix for the fitted coefficients, beta, specified as the variance-covariance matrix returned by a previous call to nlinfit.

\section*{J - Estimated Jacobian}
matrix returned by nlinfit
Estimated Jacobian of the nonlinear regression model, modelfun, specified as the Jacobian matrix returned by a previous call to nlinfit.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Alpha',0.1,'PredOpt','observation' specifies 90\% prediction intervals for new observations.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level for the confidence interval, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range ( 0,1 ). If Alpha has value \(a\), then nlpredci returns intervals with \(100 \times(1-\alpha) \%\) confidence level.

The default confidence level is \(95 \%\) ( \(\alpha=0.05\) ).
Example: 'Alpha', 0.1
Data Types
single | double

\section*{'ErrorModelinfo' - Information about error model fit}
structure returned by nlinfit

Information about the error model fit, specified as the comma-separated pair consisting of 'ErrorModelInfo' and a structure returned by a previous call to nlinfit.
ErrorModelInfo only has an effect on the returned prediction interval when PredOpt has the value 'observation'. If you do not use ErrorModelInfo, then nlpredci assumes the error variance model is 'constant'.

The error model structure returned by nlinfit has the following fields:
\begin{tabular}{ll} 
ErrorModel & Chosen error model \\
ErrorParameters & \begin{tabular}{l} 
Estimated error parameters \\
ErrorVariance
\end{tabular} \\
\begin{tabular}{l} 
Function handle that accepts an \(N\)-by-p \\
matrix, X, and returns an \(N\)-by-1 vector of \\
error variances using the estimated error \\
model
\end{tabular} \\
MSE & \begin{tabular}{l} 
Mean squared error
\end{tabular} \\
ScheffeSimPred & \begin{tabular}{l} 
Scheffé parameter for simultaneous \\
prediction intervals when using the \\
estimated error model
\end{tabular} \\
WeightFunction & \begin{tabular}{l} 
Logical with value true if you used a \\
custom weight function previously in \\
nlinfit
\end{tabular} \\
FixedWeights & \begin{tabular}{l} 
Logical with value true if you used fixed \\
weights previously in nlinfit
\end{tabular} \\
RobustWeightFunction & \begin{tabular}{l} 
Logical with value true if you used robust \\
fitting previously in
\end{tabular}
\end{tabular}

\section*{'MSE' - Mean squared error}

MSE returned by nlinfit
Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of 'MSE' and the MSE value returned by a previous call to nlinfit.

\section*{nlpredci}

If you use a robust option with nlinfit, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then nlpredci computes the MSE from the residuals, R, and does not take the robust fitting into account.

For example, if mse is the MSE value returned by nlinfit, then you can specify 'MSE',mse.

Data Types
single | double

\section*{'PredOpt' - Prediction interval to compute}
'curve' (default) | 'observation'
Prediction interval to compute, specified as the comma-separated pair consisting of 'PredOpt' and either 'curve' or 'observation'.
- If you specify the value 'curve', then nlpredci returns confidence intervals for the estimated curve (function value) at the observations X.
- If you specify the value 'observation', then nlpredci returns prediction intervals for new observations at \(X\).
If you specify 'observation ' after using a robust option with nlinfit, then you must also specify a value for MSE to provide the robust estimate of the mean squared error.

Example: 'PredOpt','observation'

\section*{Data Types \\ char}

\section*{'SimOpt' - Indicator for specifying simultaneous bounds 'off' (default) | 'on'}

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of 'SimOpt' and either 'off' or 'on'. Use the value 'off' to compute nonsimultaneous bounds, and 'on' for simultaneous bounds.

\section*{'Weights' - Observation weights}

\section*{vector | function handle}

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of positive scalar values or a function handle. The default is no weights.
- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in \(X\).
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.
Given weights, W, nlpredci estimates the error variance at observation \(i\) by mse*(1/W(i)), where mse is the mean squared error value specified using MSE.

\section*{Example: 'Weights', @WFun}

Data Types
double | single | function_handle

\section*{Output \\ Arguments}

\section*{Ypred - Predicted responses}
vector
Predicted responses, returned as a vector with the same number of rows as X .

\section*{delta - Confidence interval half-widths}
vector
Confidence interval half-widths, returned as a vector with the same number of rows as X. By default, delta contains the half-widths for nonsimultaneous \(95 \%\) confidence intervals for modelfun at the observations in X. You can compute the lower and upper bounds of the confidence intervals as Ypred-delta and Ypred+delta, respectively.

If 'PredOpt' has value 'observation', then delta contains the half-widths for prediction intervals of new observations at the values in \(X\).

\section*{nlpredci}

\section*{Examples Confidence Interval for Nonlinear Regression Curve}

Load sample data.
```

S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.
[beta, R,J] = nlinfit(X,y, @hougen, beta0);
Obtain the predicted response and \(95 \%\) confidence interval half-width for the value of the curve at average reactant levels.
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
ypred =
5.4622
delta =
0.1921

Compute the \(95 \%\) confidence interval for the value of the curve.
[ypred-delta,ypred+delta]
ans \(=\)
\(5.2702 \quad 5.6543\)

\section*{Prediction Interval for New Observation}

Load sample data.
```

S = load('reaction');
X = S.reactants;
y = S.rate;
betaO = S.beta;

```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.
```

[beta,R,J] = nlinfit(X,y,@hougen,beta0);

```

Obtain the predicted response and \(95 \%\) prediction interval half-width for a new observation with reactant levels [100, 100, 100].
```

[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,..
'PredOpt','observation')

```
ypred =
    1.8346
delta =
    0.5101

Compute the \(95 \%\) prediction interval for the new observation.
[ypred-delta,ypred+delta]
ans \(=\)
\(1.3245 \quad 2.3447\)

\section*{Simultaneous Confidence Intervals for Robust Fit Curve}

Generate sample data from the nonlinear regression model
\[
y=b_{1}+b_{2} \exp \left\{-b_{3} x\right\}+\varepsilon,
\]

\section*{nlpredci}
where \(b_{1}, b_{2}\), and \(b_{3}\) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5 .
```

modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);

```

Fit the nonlinear model using robust fitting options.
```

opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
betaO = [2;2;2];
[beta,R,J,CovB,MSE] = nlinfit(x,y,modelfun,betaO,opts);

```

Plot the fitted regression model and simultaneous \(95 \%\) confidence bounds.
```

xrange = min(x):.01:max(x);
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...
'MSE',MSE,'SimOpt','on');
lower = ypred - delta;
upper = ypred + delta;
figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,[lower;upper],'r--','LineWidth',1.5)

```

\section*{Confidence Interval Using Observation Weights}

Load sample data.
S = load('reaction');
X = S.reactants;
y = S.rate;
betao = S.beta;
Specify a function handle for observation weights, then fit the
Hougen-Watson model to the rate data using the specified observation weights function.
```

a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
[beta,R,J,CovB] = nlinfit(X,y,@hougen,betaO,'Weights',weights);

```

\section*{nlpredci}

Compute the \(95 \%\) prediction interval for a new observation with reactant levels [100, 100, 100] using the observation weight function.
```

[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
'PredOpt','observation','Weights',weights);
[ypred-delta,ypred+delta]
ans =
1.5264 2.1033

```

\section*{Confidence Interval Using Nonconstant Error Model}

Load sample data.
```

S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

```

Fit the Hougen-Watson model to the rate data using the combined error variance model.
[beta,R,J,CovB,MSE,S] = nlinfit(X,y, @hougen, betaO,'ErrorModel','combined'
Compute the \(95 \%\) prediction interval for a new observation with reactant levels [ \(100,100,100\) ] using the fitted error variance model.
```

[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
'PredOpt','observation','ErrorModelInfo',S);
[ypred-delta,ypred+delta]

```
ans =
    \(1.3245 \quad 2.3447\)

\section*{Algorithms}
- nlpredci treats NaN values in the residuals, R, or the Jacobian, J, as missing values, and ignores the corresponding observations.
- If the Jacobian, J, does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, nlpredci tries to construct confidence intervals for estimable predictions, and returns NaN for those that are not.

\section*{Tips}
- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling nlinfit:

1 Define your parameter vector beta as the concatenation of the real and imaginary parts of the original parameter vector.
2 Concatenate the real and imaginary parts of the response vector \(Y\) as a single vector.

3 Modify your model function modelfun to accept \(X\) and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.
With the problem formulated this way, nlinfit computes real estimates, and confidence intervals are feasible.

\section*{Definitions}

\section*{Confidence Intervals for Estimable Predictions}

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, nlpredci still tries to construct confidence intervals for any estimable prediction points.

For example, suppose you fit the linear function
\(f\left(\mathbf{x}_{i}, \beta\right)=\beta_{1} x_{i 1}+\beta_{2} x_{i 2}+\beta_{3} x_{i 3}\) at the points in the design matrix

\section*{nlpredci}
\[
\mathbf{X}=\left(\begin{array}{lll}
1 & 1 & 0 \\
1 & 1 & 0 \\
1 & 1 & 0 \\
1 & 0 & 1 \\
1 & 0 & 1 \\
1 & 0 & 1
\end{array}\right)
\]

The estimated Jacobian at the values in \(\mathbf{X}\) is the design matrix itself, \(\mathbf{J}=\mathbf{X}\). Thus, the Jacobian is not of full rank:
```

rng('default') % For reproducibility
y = randn(6,1);
linfun = @(b,x) x*b;
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];
[beta,R,J] = nlinfit(X,y,linfun,beta0);
Warning: The Jacobian at the solution is ill-conditioned, and
some model parameters may not be estimated well (they are not
identifiable). Use caution in making predictions.
> In nlinfit at 283

```

In this example, nlpredci can only compute prediction intervals at points that satisfy the linear relationship
\[
x_{i 1}=x_{i 2}+x_{i 3} .
\]

If you try to compute confidence intervals for predictions at nonidentifiable points, nlpredci returns NaN for the corresponding interval half-widths:
```

xpred = [$$
\begin{array}{lllllllll}{1}&{1;0 1 -1;2 1 1];}\end{array}
$$]
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)
ypred =

```
```

    \(-0.0035\)
    0.0798
    -0.0047
    delta =
NaN
3.8102
3.8102

```

Here, the first element of delta is NaN because the first row in xpred does not satisfy the required linear dependence, and is therefore not an estimable contrast.

nlinfit | nlparciNonLinearModel |

Purpose Nonnegative matrix factorization
```

Syntax
[W, H] $=\operatorname{nnmf}(A, k)$
[W,H] = nnmf(A,k,param1,val1,param2,val2,...)
[W,H,D] = nnmf(...)

```

\section*{Description}
\([\mathrm{W}, \mathrm{H}]=\operatorname{nnmf}(\mathrm{A}, \mathrm{k})\) factors the nonnegative \(n\)-by- \(m\) matrix A into nonnegative factors W ( \(n\)-by-k) and \(\mathrm{H}(\mathrm{k}-\mathrm{by}-m\) ). The factorization is not exact; \(\mathrm{W} * \mathrm{H}\) is a lower-rank approximation to A . The factors W and H are chosen to minimize the root-mean-squared residual D between \(A\) and W*H:

D = sqrt(norm(A-W*H,'fro')/(N*M))
The factorization uses an iterative method starting with random initial values for \(W\) and \(H\). Because the root-mean-squared residual D may have local minima, repeated factorizations may yield different W and H . Sometimes the algorithm converges to a solution of lower rank than \(k\), which may indicate that the result is not optimal.

W and H are normalized so that the rows of H have unit length. The columns of \(W\) are ordered by decreasing length.
\([\mathrm{W}, \mathrm{H}]=\mathrm{nnmf}(\mathrm{A}, \mathrm{k}\), param1, val1, param2, val2, ...) specifies optional parameter name/value pairs from the following table.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'algorithm' & \begin{tabular}{l} 
Either 'als ' (the default) to use an alternating \\
least-squares algorithm, or 'mult ' to use a \\
multiplicative update algorithm.
\end{tabular} \\
\begin{tabular}{l} 
In general, the 'als ' algorithm converges faster \\
and more consistently. The 'mult ' algorithm is \\
more sensitive to initial values, which makes it a
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline & good choice when using 'replicates' to find \(W\) and \(H\) from multiple random starting values. \\
\hline 'w0' & An \(n\)-by-k matrix to be used as the initial value for \(W\). \\
\hline 'h0' & A k-by- \(m\) matrix to be used as the initial value for H . \\
\hline 'options' & \begin{tabular}{l}
An options structure as created by the statset function. nnmf uses the following fields of the options structure: \\
- Display - Level of display. Choices: \\
- 'off' (default) - No display \\
- 'final' - Display final result \\
- 'iter' - Iterative display of intermediate results \\
- MaxIter - Maximum number of iterations. Default is 100 . Unlike in optimization settings, reaching MaxIter iterations is treated as convergence. \\
- TolFun - Termination tolerance on change in size of the residual. Default is 1e-4. \\
- TolX - Termination tolerance on relative change in the elements of \(W\) and \(H\). Default is 1e-4. \\
- UseParallel - Set to true to compute in parallel. Default is false. \\
- UseSubstreams - Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Parameter & Value \\
\hline & \begin{tabular}{l}
to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. \\
- Streams - A RandStream object or cell array of such objects. If you do not specify Streams, nnmf uses the default stream or streams. If you choose to specify Streams, use a single object except in the case \\
- You have an open MATLAB pool \\
- UseParallel is true \\
- UseSubstreams is false \\
In that case, use a cell array the same size as the MATLAB pool.
\end{tabular} \\
\hline 'replicates' & The number of times to repeat the factorization, using new random starting values for W and H , except at the first replication if 'wo' and 'ho' are given. This is most beneficial with the 'mult' algorithm. The default is 1 . \\
\hline
\end{tabular}

\section*{Examples}

\section*{Example 1}

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data:
```

load fisheriris
[W,H] = nnmf(meas,2);
H
H =

| 0.6852 | 0.2719 | 0.6357 | 0.2288 |
| :--- | :--- | :--- | :--- |
| 0.8011 | 0.5740 | 0.1694 | 0.0087 |

```

The first and third variables in meas (sepal length and petal length, with coefficients 0.6852 and 0.6357 , respectively) provide relatively
strong weights to the first column of W . The first and second variables in meas (sepal length and sepal width, with coefficients 0.8011 and 0.5740 ) provide relatively strong weights to the second column of W .

Create a biplot of the data and the variables in meas in the column space of W:
```

biplot(H','scores',W,'varlabels',{'sl','sw','pl','pw'});
axis([0 1.1 0 1.1])
xlabel('Column 1')
ylabel('Column 2')

```

\section*{Example 2}

Starting from a random array X with rank 20 , try a few iterations at several replicates using the multiplicative algorithm:
\begin{tabular}{|c|c|c|c|}
\hline \multicolumn{4}{|l|}{```
X = rand(100,20)*rand(20,50);
opt = statset('MaxIter',5,'Display','final')
[WO,HO] = nnmf(X,5,'replicates',10,...
    'options',opt,...
    'algorithm','mult');
```} \\
\hline rep & iteration & rms resid & |delta x \\
\hline 1 & 5 & 0.560887 & 0.0245182 \\
\hline 2 & 5 & 0.66418 & 0.0364471 \\
\hline 3 & 5 & 0.609125 & 0.0358355 \\
\hline 4 & 5 & 0.608894 & 0.0415491 \\
\hline 5 & 5 & 0.619291 & 0.0455135 \\
\hline 6 & 5 & 0.621549 & 0.0299965 \\
\hline 7 & 5 & 0.640549 & 0.0438758 \\
\hline 8 & 5 & 0.673015 & 0.0366856 \\
\hline 9 & 5 & 0.606835 & 0.0318931 \\
\hline 10 & 5 & 0.633526 & 0.0319591 \\
\hline
\end{tabular}

Final root mean square residual \(=0.560887\)

Continue with more iterations from the best of these results using alternating least squares:
```

opt = statset('Maxiter',1000,'Display','final');
[W,H] = nnmf(X,5,'wO',WO,'hO',HO,...
'options',opt,...
'algorithm','als');
rep iteration rms resid |delta x|
1 80 0.256914 9.78625e-005
Final root mean square residual = 0.256914

```

\section*{classregtree.nodeclass}

Purpose Class values of nodes of classification tree
```

Syntax
NAME=nodeclass(T)
NAME=nodeclass(T,J)
[ NAME, ID]=nodeclass(. . .)

```

\section*{Description}

See Also

NAME=nodeclass(T) returns an \(n\)-element cell array with the names of the most probable classes in each node of the tree T, where \(n\) is the number of nodes in the tree. Every element of this array is a string equal to one of the class names returned by classname( \(T\) ). For regression trees, nodeclass returns an empty cell array.

NAME=nodeclass \((T, J)\) takes an array \(J\) of node numbers and returns the class names for the specified nodes.
[NAME, ID]=nodeclass(...) also returns a numeric array with the class index for each node. The class index is determined by the order of classes classname returns.
classregtree | classname | numnodes

Purpose
Syntax

Description

\section*{Examples}

Return vector of node errors
e = nodeerr(t)
e = nodeerr(t,nodes)
e = nodeerr(t) returns an \(n\)-element vector e of the errors of the nodes in the tree \(t\), where \(n\) is the number of nodes. For a regression tree, the error \(e(i)\) for node \(i\) is the variance of the observations assigned to node i. For a classification tree, e(i) is the misclassification probability for node i.
e = nodeerr(t, nodes) takes a vector nodes of node numbers and returns the errors for the specified nodes.

The error e is the so-called resubstitution error computed by applying the tree to the same data used to create the tree. This error is likely to under estimate the error you would find if you applied the tree to new data. The test function provides options to compute the error (or cost) using cross-validation or a test sample.

Create a classification tree for Fisher's iris data:
```

load fisheriris;
t = classregtree(meas,species,...
'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

```

\section*{classregtree.nodeerr}

\section*{view(t)}
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline Click to display: |dentity & \(\checkmark\) & Magnification: & 100\% & & Pruning level: & 0 of 4 & \(\wedge\) \\
\hline
\end{tabular}

\[
\begin{aligned}
& \mathrm{e}= \text { nodeerr }(\mathrm{t}) \\
& \mathrm{e}= 0.6667 \\
& 0 \\
& 0.5000 \\
& 0.0926 \\
& 0.0217 \\
& 0.0208
\end{aligned}

}

\section*{classregtree.nodemean}

Purpose Mean values of nodes of regression tree
Syntax
NM = nodemean( T )
NM = nodemean( \(\mathrm{T}, \mathrm{J}\) )

Description \(\quad N M=\) nodemean \((T)\) returns an \(n\)-element numeric array with mean values in each node of the tree \(T\), where \(n\) is the number of nodes in the tree. Every element of this array is computed by averaging true Y values over all observations in the node. For classification trees, nodemean returns an empty numeric array.
\(N M=\) nodemean \((T, J)\) takes an array \(J\) of node numbers and returns the mean values for the specified nodes.

\section*{See Also \\ classregtree | numnodes}

\section*{classregtree.nodeprob}

\section*{Purpose Node probabilities}
```

Syntax
p = nodeprob(t)
p = nodeprob(t,nodes)

```
\(p=\) nodeprob( \(t\) ) returns an \(n\)-element vector \(p\) of the probabilities of the nodes in the tree \(t\), where \(n\) is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. For a classification tree, this proportion is adjusted for any prior probabilities assigned to each class.
\(p\) = nodeprob(t, nodes) takes a vector nodes of node numbers and returns the probabilities for the specified nodes.

\section*{Examples Create a classification tree for Fisher's iris data:}
```

load fisheriris;
t = classregtree(meas,species,...
names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa

}

\section*{classregtree.nodesize}

\section*{Purpose Return node size}
```

Syntax
sizes = nodesize(t)
sizes = nodesize(t,nodes)

```
sizes \(=\) nodesize( t ) returns an \(n\)-element vector sizes of the sizes of the nodes in the tree \(t\), where \(n\) is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.
sizes = nodesize(t, nodes) takes a vector nodes of node numbers and returns the sizes for the specified nodes.

\section*{Examples \\ Create a classification tree for Fisher's iris data:}

\section*{Superclasses \\ categorical}

\section*{Purpose Arrays for nominal categorical data}

Description Nominal arrays are used to store discrete values that are not numeric and that do not have an ordering. A nominal array provides efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values. Nominal arrays are often used as grouping variables.

You can subscript, concatenate, reshape, etc. nominal arrays much like ordinary numeric arrays. You can test equality between elements of two nominal arrays, or between a nominal array and a single string representing a nominal value.

\section*{Construction}

Use the nominal constructor to create a nominal array from a numeric, logical, or character array, or from a cell array of strings.
nominal
Construct nominal categorical array

Methods
Each nominal array carries along a list of possible values that it can store, known as its levels. The list is created when you create a nominal array, and you can access it using the getlevels method, or modify it using the addlevels, mergelevels, or droplevels methods. Assignment to the array will also add new levels automatically if the values assigned are not already levels of the array.

You can change the order of the list of levels for a nominal array using the reorderlevels method, however, that order has no significance for the values in the array. The order is used only for display purposes, or when you convert the nominal array to numeric values using methods such as double or subsindex, or compare two arrays using isequal. If you need to work with values that have a mathematical ordering, you should use an ordinal array instead.

\section*{Inherited Methods}

Methods in the following table are inherited from categorical.
\begin{tabular}{ll} 
addlevels & Add levels to categorical array \\
cat \\
cellstr & \begin{tabular}{l} 
Concatenate categorical arrays \\
Convert categorical array to cell \\
array of strings
\end{tabular} \\
char & \begin{tabular}{l} 
Convert categorical array to \\
character array
\end{tabular} \\
circshift & Shift categorical array circularly \\
ctranspose & Transpose categorical matrix \\
disp & \begin{tabular}{l} 
Display categorical array \\
display
\end{tabular} \\
double & \begin{tabular}{l} 
Convert categorical array to \\
double array
\end{tabular} \\
droplevels & \begin{tabular}{l} 
Drop levels \\
end
\end{tabular} \\
\begin{tabular}{l} 
Last index in indexing expression \\
for categorical array
\end{tabular} \\
flipdim & \begin{tabular}{l} 
Flip categorical array along \\
specified dimension
\end{tabular} \\
fliplr & \begin{tabular}{l} 
Flip categorical matrix in \\
left/right direction
\end{tabular} \\
flipud & \begin{tabular}{l} 
Flip categorical matrix in \\
up/down direction
\end{tabular} \\
getlabels & \begin{tabular}{l} 
Access categorical array labels
\end{tabular} \\
getlevels & \begin{tabular}{l} 
Get categorical array levels
\end{tabular} \\
hist & Plot histogram of categorical data
\end{tabular}
\begin{tabular}{ll} 
horzcat & \begin{tabular}{l} 
Horizontal concatenation for \\
categorical arrays \\
Convert categorical array to \\
signed 16-bit integer array
\end{tabular} \\
int16 & \begin{tabular}{l} 
Convert categorical array to \\

Set difference for categorical \\
arrays
\end{tabular} \\
setdiff & \begin{tabular}{l} 
Label levels
\end{tabular} \\
setlabels & \begin{tabular}{l} 
Set exclusive-or for categorical \\
arrays
\end{tabular} \\
setxor & \begin{tabular}{l} 
Shift dimensions of categorical \\
array
\end{tabular} \\
shiftdim & \begin{tabular}{l} 
Convert categorical array to \\
single array
\end{tabular} \\
single & \begin{tabular}{l} 
Size of categorical array \\
Squeeze singleton dimensions \\
from categorical array
\end{tabular} \\
size & \begin{tabular}{l} 
Subscripted assignment for \\
categorical array
\end{tabular} \\
squeeze & \begin{tabular}{l} 
Subscript index for categorical \\
array
\end{tabular} \\
subsasgn & \begin{tabular}{l} 
Subscripted reference for \\
categorical array
\end{tabular} \\
subsindex & \begin{tabular}{l} 
Summary statistics for categorical \\
array
\end{tabular} \\
subsref & \begin{tabular}{l} 
Product of categorical arrays
\end{tabular} \\
summary &
\end{tabular}
\begin{tabular}{ll} 
transpose & \begin{tabular}{l} 
Transpose categorical matrix \\
uint16
\end{tabular} \\
uint32 & \begin{tabular}{l} 
unsigned 16-bit integers to \\
Convert categorical array to \\
unsigned 32-bit integers
\end{tabular} \\
uint64 & \begin{tabular}{l} 
Convert categorical array to \\
unsigned 64-bit integers
\end{tabular} \\
uint8 & \begin{tabular}{l} 
Convert categorical array to \\
unsigned 8-bit integers
\end{tabular} \\
union & \begin{tabular}{l} 
Set union for categorical arrays
\end{tabular} \\
unique & \begin{tabular}{l} 
Unique values in categorical \\
array
\end{tabular} \\
vertcat & \begin{tabular}{l} 
Vertical concatenation for \\
categorical arrays
\end{tabular} \\
\hline
\end{tabular}

\section*{Properties Inherited Properties}

Properties in the following table are inherited from categorical.
\begin{tabular}{ll} 
labels & Text labels for levels \\
undeflabel & Text label for undefined levels
\end{tabular}

\section*{Copy \\ Semantics}

\section*{Examples}

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

Create a nominal array from string data in a cell array:
```

colors = nominal({'r' 'b' 'g';'g' 'r' 'b';'b' 'r' 'g'},...
{'blue' 'green' 'red'})
% Find elements meeting a criterion
colors == 'red'

```
```

ismember(colors,{'red' 'blue'})
% Compare two nominal arrays
colors2 = fliplr(colors)
colors == colors2

```

See Also histc | ordinal
Purpose \(\quad\)\begin{tabular}{ll} 
Construct nominal categorical array \\
Syntax & \(B=\operatorname{nominal}(A)\) \\
& \(B=n o m i n a l(A, l a b e l s)\) \\
& \(B=n o m i n a l(A, l a b e l s, l e v e l s)\) \\
& \(B=n o m i n a l(A, l a b e l s,[]\), edges \()\)
\end{tabular}

Description
\(B=\) nominal \((A)\) creates a nominal array \(B\) from the array \(A\). A can be numeric, logical, character, categorical, or a cell array of strings. nominal creates the levels of \(B\) from the sorted unique values in \(A\), and creates default labels for them.
\(B=\) nominal(A, labels) labels the levels in B using the character array or cell array of strings labels. nominal assigns labels to levels in B in order according to the sorted unique values in A.
\(B=\) nominal(A, labels, levels) creates a nominal array with possible levels defined by levels. levels is a vector whose values can be compared to those in A using the equality operator. nominal assigns labels to each level from the corresponding elements of labels. If A contains any values not present in levels, the levels of the corresponding elements of \(B\) are undefined.
\(B=\) nominal(A, labels, [], edges) creates a nominal array by binning the numeric array \(A\) with bin edges given by the numeric vector edges. The uppermost bin includes values equal to the right-most edge. nominal assigns labels to each level in B from the corresponding elements of labels. edges must have one more element than labels.

By default, an element of \(B\) is undefined if the corresponding element of \(A\) is \(\operatorname{NaN}\) (when \(A\) is numeric), an empty string (when \(A\) is character), or undefined (when A is categorical). nominal treats such elements as "undefined" or "missing" and does not include entries for them among the possible levels for B. To create an explicit level for such elements instead of treating them as undefined, you must use the levels input, and include NaN , the empty string, or an undefined element.

You may include duplicate labels in labels in order to merge multiple values in A into a single level in \(B\).

Examples Create a nominal array from Fisher's iris data:
```

load fisheriris
species = nominal(species);
summary(species)
setosa versicolor virginica
50 50 50

```

Create a nominal array from characters, and provide explicit labels:
```

colors1 = nominal({'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'},...
{'blue' 'green' 'red'})

```

Create a nominal array from characters, and provide both explicit labels and an explicit order for display:
```

colors2 = nominal({'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}, ...
{'red' 'green' 'blue'},{'r' 'g' 'b'})

```

Create a nominal array from integer data, merging odd and even values into only two nominal levels. Provide explicit labels:
```

toss = nominal(randi([1 4],5,2),{'odd' 'even' 'odd' 'even'},1:4)

```

1 Load patient data from the CSV file hospital. dat and store the information in a dataset array with observation names given by the first column in the data (patient identification):
```

patients = dataset('file','hospital.dat',...
'delimiter',',',...
'ReadObsNames',true);

```

2 Make the \(\{0,1\}\)-valued variable smoke nominal, and change the labels to 'No' and 'Yes':
patients.smoke = nominal(patients.smoke,\{'No','Yes'\});
3 Add new levels to smoke as placeholders for more detailed histories of smokers:
```

patients.smoke = addlevels(patients.smoke,...
{'0-5 Years','5-10 Years','LongTerm'});

```

4 Assuming the nonsmokers have never smoked, relabel the 'No' level:
```

patients.smoke = setlabels(patients.smoke,'Never','No');

```

5 Drop the undifferentiated 'Yes' level from smoke:
patients.smoke = droplevels(patients.smoke,'Yes');
Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.
6 Set each smoker to one of the new levels, by observation name:
```

patients.smoke('YPL-320') = '5-10 Years';

```

\section*{See Also \\ histc | ordinal}
\begin{tabular}{|c|c|}
\hline Purpose & Nonlinear regression model class \\
\hline Description & An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the predict or feval methods. \\
\hline \multirow[t]{12}{*}{Construction} & nlm = NonLinearModel.fit(ds,modelfun,betaO) or nlm = NonLinearModel.fit ( \(X, y\), modelfun, betaO) create a nonlinear model of a dataset array ds, or of the responses y to a data matrix X. For details, see NonLinearModel.fit. \\
\hline & Input Arguments \\
\hline & ds \\
\hline & Dataset array, where by default the last column is the response variable, and all other columns are the predictors. Predictors can be numeric, or can be any grouping variable type, such as logical or categorical (see "Grouping Variables" on page 2-51). The response must be numeric or logical. \\
\hline & To set a different column as the response variable, use the ResponseVar name-value pair. To use a subset of the columns as predictors, use the PredictorVars name-value pair. \\
\hline & X \\
\hline & Matrix of predictor values. Each column of X represents one variable, and each row represents one observation. \\
\hline & \(y\) \\
\hline & Vector of response values with the same number of rows as \(X\). Each entry in \(y\) is the response to the data in the corresponding row of \(X\). \\
\hline & modelfun \\
\hline & Functional form of the model. Either a: \\
\hline & - Function handle @modelfun or \(@(\mathrm{~b}, \mathrm{x})\) modelfun, where \\
\hline
\end{tabular}

\section*{NonLinearModel}
- \(b\) is a coefficient vector with the same number of elements as beta0.
- x is a matrix with the same number of columns as X or the data columns of ds.
modelfun( \(\mathrm{b}, \mathrm{x}\) ) returns a column vector that contains the same number of rows as x. Each row of the vector is the result of evaluating modelfun on the corresponding row of \(x\). In other words, modelfun is a vectorized function, one that operates on all data rows and returns all evaluations in one function call.
- String of the form
'y~f(b1,b2,...,bk,x1,x2, ...,xk)'
\(f\) represents a scalar function of the scalar coefficient variables \(\mathrm{b} 1, \ldots, \mathrm{bk}\) and the scalar data variables \(\mathrm{x} 1, \ldots, \mathrm{xk}\).

\section*{beta0}

Numeric vector of coefficients for the modelfun nonlinear model. NonLinearModel.fit starts its search for optimal coefficients from beta0.

\section*{Properties CoefficientCovariance}

Covariance matrix of coefficient estimates.

\section*{CoefficientNames}

Cell array of strings containing a label for each coefficient.

\section*{Coefficients}

Table of coefficient values in a dataset array. Coefficients has one row for each coefficient and these columns:
- Estimate - Estimated coefficient value
- SE - Standard error of the estimate
- tStat - \(t\) statistic for a test that the coefficient is zero
- pValue - \(p\)-value for the \(t\) statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in mdl the estimated coefficient vector is
beta \(=\) mdl.Coefficients.Estimate
Use coeftest to perform other tests on the coefficients.

\section*{Diagnostics}

Dataset array with diagnostics helpful in finding outliers and influential observations. The structure contains the following fields.
\begin{tabular}{l|l|l}
\hline Field & Meaning & Utility \\
\hline Leverage & \begin{tabular}{l} 
Diagonal elements of \\
HatMatrix
\end{tabular} & \begin{tabular}{l} 
Leverage indicates to what extent the predicted \\
value for an observation is determined by \\
the observed value for that observation. A \\
value close to 1 indicates that the prediction is \\
largely determined by that observation, with \\
little contribution from the other observations. \\
A value close to 0 indicates the fit is largely \\
determined by the other observations. For a \\
model with P coefficients and N observations, \\
the average value of Leverage is P/N. An
\end{tabular} \\
\hline
\end{tabular}

\section*{NonLinearModel}
\begin{tabular}{l|l|l}
\hline Field & Meaning & Utility \\
\hline \multicolumn{2}{|c}{} & \begin{tabular}{l} 
observation with Leverage larger than 2*P/N \\
can be regarded as having high leverage.
\end{tabular} \\
\hline CooksDistance & \begin{tabular}{l} 
Cook's measure of \\
scaled change in \\
fitted values
\end{tabular} & \begin{tabular}{l} 
CooksDistance is a measure of scaled \\
change in fitted values. An observation with \\
CooksDistance larger than three times the \\
mean Cook's distance can be an outlier.
\end{tabular} \\
\hline HatMatrix & \begin{tabular}{l} 
Projection matrix to \\
compute fitted from \\
observed responses
\end{tabular} & \begin{tabular}{l} 
HatMatrix is an N-by-N matrix such that \\
Fitted = HatMatrix*Y, where Y is the response \\
vector and Fitted is the vector of fitted response \\
values.
\end{tabular} \\
\hline
\end{tabular}

\section*{DFE}

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

\section*{Fitted}

Vector of predicted values based on the training data.
NonLinearModel.fit attempts to make Fitted as close as possible to the response data.

\section*{Formula}

Object that represents the mathematical form of the model.

\section*{Iterative}

Structure with information about the fitting process. Fields:
- InitialCoefs - Initial coefficient values (the beta0 vector)
- IterOpts - Options included in the Options name-value pair for NonLinearModel.fit

\section*{LogLikelihood}

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

\section*{ModelCriterion}

AIC and other information criteria for comparing models. A structure with fields:
- AIC - Akaike information criterion
- AICc - Akaike information criterion corrected for sample size
- BIC - Bayesian information criterion
- CAIC - Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model mdl, the AIC value aic is:
aic = mdl.ModelCriterion.AIC

\section*{MSE}

Mean squared error, a scalar that is an estimate of the variance of the error term in the model.

\section*{NumCoefficients}

Number of coefficients in the fitted model, a scalar. NumCoefficients is the same as NumEstimatedCoefficients for NonLinearModel objects. NumEstimatedCoefficients is equal to the degrees of freedom for regression.

\section*{NumEstimatedCoefficients}

Number of estimated coefficients in the fitted model, a scalar. NumEstimatedCoefficients is the same as NumCoefficients for NonLinearModel objects. NumEstimatedCoefficients is equal to the degrees of freedom for regression.

\section*{NumPredictors}

\section*{NonLinearModel}

Number of variables NonLinearModel.fit used as predictors for fitting.

\section*{NumVariables}

Number of variables in the data. NumVariables is the number of variables in the original dataset when the fit is based on a dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

\section*{ObservationInfo}

Dataset with the same number of rows as the input data (ds or X).
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Weights & Observation weights. Default is all 1. \\
\hline Excluded & \begin{tabular}{l} 
Logical value, 1 indicates an observation that \\
you excluded from the fit with the Exclude \\
name-value pair.
\end{tabular} \\
\hline Missing & \begin{tabular}{l} 
Logical value, 1 indicates a missing value in \\
the input. Missing values are not used in the \\
fit.
\end{tabular} \\
\hline Subset & \begin{tabular}{l} 
Logical value, 1 indicates the observation is \\
not excluded or missing, so is used in the fit.
\end{tabular} \\
\hline
\end{tabular}

\section*{ObservationNames}

Cell array of strings containing the names of the observations used in the fit.
- If the fit is based on a dataset containing observation names, ObservationNames uses those names.
- Otherwise, ObservationNames is an empty cell array

\section*{PredictorNames}

Cell array of strings, the names of the predictors used in fitting the model.

\section*{Residuals}

Dataset array containing a table of residuals, with one row for each observation and these variables.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Raw & Observed minus fitted values. \\
\hline Pearson & Raw residuals divided by RMSE. \\
\hline Standardized & \begin{tabular}{l} 
Raw residuals divided by their estimated \\
standard deviation.
\end{tabular} \\
\hline Studentized & \begin{tabular}{l} 
Residual divided by an independent estimate \\
of the residual standard deviation. The \\
residual for observation \(i\) is divided by an \\
estimate of the error standard deviation based \\
on all observations except for observation \(i\).
\end{tabular} \\
\hline
\end{tabular}

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model mdl, the ordinary raw residual vector \(r\) is:
\(r=\) mdl.Residuals.Raw
Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain NaN values.

Rows not used in the fit because of excluded values (in ObservationInfo.Excluded) contain NaN values, with the following exceptions:
- raw contains the difference between the observed and predicted values.
- standardized is the residual, standardized in the usual way.

\section*{NonLinearModel}
- studentized matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

\section*{ResponseName}

String giving naming the response variable.

\section*{RMSE}

Root mean squared error, a scalar that is an estimate of the standard deviation of the error term in the model.

\section*{Robust}

Structure that is empty unless NonLinearModel.fit constructed the model using robust regression.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline WgtFun & \begin{tabular}{l} 
Robust weighting function, such as \\
'bisquare ' (see robustfit)
\end{tabular} \\
\hline Tune & \begin{tabular}{l} 
Value specified for tuning parameter (can be \\
{\([\) ] ) }
\end{tabular} \\
\hline Weights & \begin{tabular}{l} 
Vector of weights used in final iteration of \\
robust fit
\end{tabular} \\
\hline
\end{tabular}

\section*{Rsquared}

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:
```

Rsquared = SSR/SST = 1 - SSE/SST.

```

Rsquared is a structure with two fields:
- Ordinary - Ordinary (unadjusted) R-squared
- Adjusted - R-squared adjusted for the number of coefficients

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R -squared value in mdl is
r2 = mdl.Rsquared.Adjusted

\section*{SSE}

Sum of squared errors (residuals).
The Pythagorean theorem implies
SST = SSE + SSR.

SSR
Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
SST = SSE + SSR.

\section*{SST}

Total sum of squares, the sum of squared deviations of \(y\) from mean(y).

The Pythagorean theorem implies
```

SST = SSE + SSR.

```

\section*{Variablelnfo}

Dataset array containing metadata about Variables. There is one row for each term in the model, and the following columns.

\section*{NonLinearModel}
\begin{tabular}{l|l}
\hline Field & Description \\
\hline Class & String giving variable class, such as 'double '
\end{tabular}

\section*{VariableNames}

Cell array of strings containing names of the variables in the fit.
- If the fit is based on a dataset, this property provides the names of the variables in that dataset.
- If the fit is based on a predictor matrix and response vector, VariableNames is the values in the VarNames name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

\section*{Variables}

Dataset array containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a dataset array, Variables is a copy of that dataset. Otherwise, Variables is a dataset created from the input data matrix \(X\) and response vector \(y\).

\section*{Methods}
\begin{tabular}{ll} 
coefCI & \begin{tabular}{l} 
Confidence intervals of coefficient \\
estimates of nonlinear regression \\
model
\end{tabular} \\
coefTest & \begin{tabular}{l} 
Linear hypothesis test on \\
nonlinear regression model \\
coefficients
\end{tabular} \\
disp & \begin{tabular}{l}

\end{tabular} \\
predict & \begin{tabular}{l} 
Predict response of nonlinear \\
regression model
\end{tabular} \\
random & \begin{tabular}{l} 
Simulate responses for nonlinear \\
regression model
\end{tabular} \\
\hline
\end{tabular}

\section*{Definitions Hat Matrix}

The hat matrix \(H\) is defined in terms of the data matrix \(X\) and the Jacobian matrix \(J\) :
\[
J_{i, j}=\left.\frac{\partial f}{\partial \beta_{j}}\right|_{x_{i}, \beta}
\]

\section*{NonLinearModel}

Here \(f\) is the nonlinear model function, and \(\beta\) is the vector of model coefficients.

The Hat Matrix \(H\) is
\[
H=J\left(J^{T} J\right)^{-1} J^{T} .
\]

The diagonal elements \(H_{i i}\) satisfy
\[
\begin{aligned}
& 0 \leq h_{i i} \leq 1 \\
& \sum_{i=1}^{n} h_{i i}=p
\end{aligned}
\]
where \(n\) is the number of observations (rows of \(X\) ), and \(p\) is the number of coefficients in the regression model.

\section*{Leverage}

The leverage of observation \(i\) is the value of the \(i\) th diagonal term of the hat matrix \(H_{i i}\). Because the sum of the leverage values is \(p\) (the number of coefficients in the regression model), an observation \(i\) can be considered to be an outlier if its leverage substantially exceeds \(p / n\), where \(n\) is the number of observations.

\section*{Cook's Distance}

The Cook's distance \(D_{i}\) of observation \(i\) is
\[
D_{i}=\frac{\sum_{j=1}^{n}\left(\hat{y}_{j}-\hat{y}_{j(i)}\right)^{2}}{p M S E},
\]
where
- \(\hat{y}_{j}\) is the \(j\) th fitted response value.
- \(\hat{y}_{j(i)}\) is the \(j\) th fitted response value, where the fit does not include observation \(i\).
- MSE is the mean squared error.
- \(p\) is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:
\[
D_{i}=\frac{r_{i}^{2}}{p M S E}\left(\frac{h_{i i}}{\left(1-h_{i i}\right)^{2}}\right),
\]
where \(e_{i}\) is the \(i\) th residual.

\section*{Copy Semantics}

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

\section*{Examples}

\section*{Nonlinear Model}

Create a nonlinear model for auto mileage based on the carbig data. Predict the mileage of an average car.

Load the data and create a nonlinear model.
```

load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
mdl =

```
Nonlinear regression model:
    \(y \sim b 1+b 2 * x 1^{\wedge} b 3+b 4 * x 2^{\wedge} b 5\)

\section*{NonLinearModel}
```

Estimated Coefficients:

|  | Estimate | SE | tStat | pValue |
| :--- | ---: | ---: | ---: | ---: |
| b1 | -49.383 | 119.97 | -0.41164 | 0.68083 |
| b2 | 376.43 | 567.05 | 0.66384 | 0.50719 |
| b3 | -0.78193 | 0.47168 | -1.6578 | 0.098177 |
| b4 | 422.37 | 776.02 | 0.54428 | 0.58656 |
| b5 | -0.24127 | 0.48325 | -0.49926 | 0.61788 |

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

```

Find the predicted mileage of an average auto. The data contain some observations with NaN , so compute the mean using nanmean.
```

Xnew = nanmean(X)
Xnew =
1.0e+03 *
0.1051 2.9794
MPGnew = predict(mdl,Xnew)
MPGnew =

```

\section*{Superclasses ToolboxFittableParametricDistribution}

Purpose Normal probability distribution object
Description prob.NormalDistribution is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd = makedist('Normal') creates a normal probability distribution object using the default parameter values.
pd = makedist('Normal','mu',mu,'sigma',sigma) creates a normal distribution object using the specified parameter values.

\section*{Input Arguments}
mu - Mean
0 (default) | scalar value
Mean of the normal distribution, specified as a scalar value.

\section*{Data Types}
single | double

\section*{sigma-Standard deviation}

1 (default) | nonnegative scalar value
Standard deviation of the normal distribution, specified as a nonnegative scalar value.
```

Data Types
single | double

```

\section*{Properties \\ mu}

Mean of the normal distribution, stored as a scalar value.

\section*{prob.NormalDistribution}

\author{
Data Types \\ single | double \\ sigma
}

Standard deviation of the normal distribution, stored as a nonnegative scalar value.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types}
char

\section*{InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

\section*{Data Types}
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types \\ logical}

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterCovariance}

Covariance matrix of the parameter estimates, stored as a \(p\)-by- \(p\) matrix, where \(p\) is the number of parameters in the distribution. The ( \(i, j\) ) element is the covariance between the estimates of the ith parameter and the \(j\) th parameter. The ( \(i, i\) ) element is the estimated variance of the \(i\) th parameter. If parameter \(i\) is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.

\section*{Data Types}
```

single | double

```

\section*{ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{Data Types}
char

\section*{ParameterlsFixed}

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

\section*{Data Types}
logical

\section*{ParameterNames}

\section*{prob.NormalDistribution}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types \\ char}

\section*{ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\section*{Data Types \\ single | double \\ Truncation}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.
```

\section*{Definitions Normal Distribution}

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

The normal distribution uses the following parameters.

\section*{prob.NormalDistribution}
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline mu & Mean & \(-\infty<\mu<\infty\) \\
\hline sigma & \begin{tabular}{l} 
Standard \\
deviation
\end{tabular} & \(\sigma \geq 0\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid \mu, \sigma)=\frac{1}{\sigma \sqrt{2 \pi}} e^{\frac{-(x-\mu)^{2}}{2 \sigma^{2}}} \quad, \quad-\infty<x<\infty .
\]

\section*{Examples Create a Normal Distribution Object Using Default Parameters}

Create a normal distribution object using the default parameter values.
```

pd = makedist('Normal')

```
pd =
NormalDistribution
```

Normal distribution
mu = 0
sigma = 1

```

\section*{Create a Normal Distribution Object Using Specified Parameters}

Create a normal distribution object by specifying the parameter values.
pd = makedist('Normal','mu',75,'sigma', 10)
pd =

NormalDistribution
```

Normal distribution
mu = 75
sigma = 10

```

Compute the interquartile range of the distribution.
```

r = iqr(pd)

```
\(r=\)
13.4898

\section*{Fit a Normal Distribution Object}

Load the sample data. Create a vector containing the first column of students' exam grades data.
load examgrades;
x = grades(:,1);
Create a normal distribution object by fitting it to the data.
```

pd = fitdist(x,'Normal')

```
pd \(=\)

NormalDistribution
```

    Normal distribution
            mu = 75.0083 [73.4321, 76.5846]
        sigma = 8.7202 [7.7391, 9.98843]
    ```

- Property Attributes

Purpose Normal cumulative distribution function
```

Syntax $\quad P=\operatorname{normcdf}(X$, mu, sigma $)$
[P,PLO,PUP] = normcdf(X,mu,sigma,pcov,alpha)

```

\section*{Description}
\(P=\operatorname{normcdf}(X, m u\), sigma \()\) computes the normal cdf at each of the values in X using the corresponding mean mu and standard deviation sigma. \(X\), mu, and sigma can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in sigma must be positive.
[P,PLO,PUP] = normcdf(X,mu,sigma,pcov,alpha) produces confidence bounds for \(P\) when the input parameters mu and sigma are estimates. pcov is the covariance matrix of the estimated parameters. alpha specifies \(100(1-a l p h a) \%\) confidence bounds. The default value of alpha is 0.05 . PLO and PUP are arrays of the same size as P containing the lower and upper confidence bounds.

The function normdf computes confidence bounds for P using a normal approximation to the distribution of the estimate
\[
\frac{X-\hat{\mu}}{\hat{\sigma}}
\]
and then transforming those bounds to the scale of the output P. The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and pcov from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The normal cdf is
\[
p=F(x \mid \mu, \sigma)=\frac{1}{\sigma \sqrt{2 \pi}} \int_{-\infty}^{x} e^{\frac{-(t-\mu)^{2}}{2 \sigma^{2}}} d t
\]

The result, \(p\), is the probability that a single observation from a normal distribution with parameters \(\mu\) and \(\sigma\) will fall in the interval \((-\infty x]\).

The standard normal distribution has \(\mu=0\) and \(\sigma=1\).
Examples What is the probability that an observation from a standard normal distribution will fall on the interval [-1 1]?
```

p = normcdf([-1 1]);
p(2)-p(1)
ans =
0.6827

```

More generally, about \(68 \%\) of the observations from a normal distribution fall within one standard deviation, \(\sigma\), of the mean, \(\mu\).

How To
- "Normal Distribution" on page B-96

\section*{Purpose Normal parameter estimates}
```

Syntax
[muhat,sigmahat] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)
[...] = normfit(data,alpha,censoring)
[...] = normfit(data,alpha,censoring,freq)
[...] = normfit(data,alpha,censoring,freq,options)

```

\section*{Description}
[muhat, sigmahat] = normfit(data) returns an estimate of the mean \(\mu\) in muhat, and an estimate of the standard deviation \(\sigma\) in sigmahat, of the normal distribution given the data in data.
[muhat,sigmahat,muci,sigmaci] = normfit(data) returns 95\% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays muci and sigmaci, respectively. The first row of muci contains the lower bounds of the confidence intervals for \(\mu\) the second row contains the upper bounds. The first row of sigmaci contains the lower bounds of the confidence intervals for \(\sigma\), and the second row contains the upper bounds.
[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha) returns 100(1-alpha) \% confidence intervals for the parameter estimates, where alpha is a value in the range [ 0 1] specifying the width of the confidence intervals. By default, alpha is 0.05 , which corresponds to \(95 \%\) confidence intervals.
[...] = normfit(data, alpha, censoring) accepts a Boolean vector, censoring, of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. data must be a vector in order to pass in the argument censoring.
[...] = normfit(data,alpha, censoring,freq) accepts a frequency vector, freq, of the same size as data. Typically, freq contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for alpha, censoring, or freq to use their default values.
[...] = normfit(data,alpha,censoring,freq,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The normal fit function accepts an options structure which you can create using the function statset. Enter statset('normfit') to see the names and default values of the parameters that normfit accepts in the options structure. See the reference page for statset for more information about these options.

Note With no censoring, normfit computes muhat using the sample mean and sigmahat using the square root of the unbiased estimator of the variance. With censoring, both muhat and sigmahat are the maximum likelihood estimates.
```

Examples In this example the data is a two-column random normal matrix. Both columns have $\mu=10$ and $\sigma=2$. Note that the confidence intervals below contain the "true values."
data = normrnd(10,2,100,2);
[mu,sigma,muci,sigmaci] = normfit(data)
mu =
10.1455 10.0527
sigma =
1.9072 2.1256
muci =
9.7652 9.6288
10.5258 10.4766
sigmaci =
1.6745 1.8663
2.2155 2.4693

```

How To . "Normal Distribution" on page B-96

\section*{norminv}

Purpose Normal inverse cumulative distribution function
```

Syntax }X==\mathrm{ norminv( P,mu,sigma)
[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)

```
\(X=\) norminv( \(P\), mu, sigma) computes the inverse of the normal cdf using the corresponding mean mu and standard deviation sigma at the corresponding probabilities in P. P, mu, and sigma can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in sigma must be positive, and the values in \(P\) must lie in the interval [01].
[X,XLO,XUP] = norminv(P,mu,sigma, pcov,alpha) produces confidence bounds for \(X\) when the input parameters mu and sigma are estimates. pcov is the covariance matrix of the estimated parameters. alpha specifies \(100(1\) - alpha) \(\%\) confidence bounds. The default value of alpha is 0.05 . XLO and XUP are arrays of the same size as X containing the lower and upper confidence bounds.

The function norminv computes confidence bounds for P using a normal approximation to the distribution of the estimate
\[
\hat{\mu}+\hat{\sigma} q
\]
where \(q\) is the Pth quantile from a normal distribution with mean 0 and standard deviation 1 . The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and pcov from large samples, but in smaller samples other methods of computing the confidence bounds may be more accurate.

The normal inverse function is defined in terms of the normal cdf as
\[
x=F^{-1}(p \mid \mu, \sigma)=\{x: F(x \mid \mu, \sigma)=p\}
\]
where
\[
p=F(x \mid \mu, \sigma)=\frac{1}{\sigma \sqrt{2 \pi}} \int_{-\infty}^{x} e^{\frac{-(t-\mu)^{2}}{2 \sigma^{2}}} d t
\]

The result, \(x\), is the solution of the integral equation above where you supply the desired probability, \(p\).

\section*{Examples}

How To

\section*{See Also}

Find an interval that contains \(95 \%\) of the values from a standard normal distribution.
```

x = norminv([0.025 0.975],0,1)
x =
-1.9600 1.9600

```

Note that the interval \(x\) is not the only such interval, but it is the shortest.
```

xl = norminv([0.01 0.96],0,1)
xl =
-2.3263 1.7507

```

The interval xl also contains \(95 \%\) of the probability, but it is longer than \(x\).

\section*{normlike}
Purpose Normal negative log-likelihood
Syntax nlogL = normlike(params,data)

[nlogL,AVAR] = normlike(params,data)

[...] = normlike(param,data, censoring)

[...] = normlike(param,data,censoring,freq)

\section*{Description}

How To
nlogL \(=\) normlike(params, data) returns the negative of the normal log-likelihood function. params (1) is the mean, mu, and params (2) is the standard deviation, sigma.
[nlogL,AVAR] = normlike(params,data) also returns the inverse of Fisher's information matrix, AVAR. If the input parameter values in params are the maximum likelihood estimates, the diagonal elements of AVAR are their asymptotic variances. AVAR is based on the observed Fisher's information, not the expected information.
[...] = normlike(param,data, censoring) accepts a Boolean vector, censoring, of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.
[...] = normlike(param,data, censoring,freq) accepts a frequency vector, freq, of the same size as data. The vector freq typically contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for censoring to use its default value.
normlike is a utility function for maximum likelihood estimation.

- "Normal Distribution" on page B-96

\section*{Purpose Normal probability plot}
\[
\text { Syntax } \quad h=\operatorname{normplot}(X)
\]

Description \(\quad \mathrm{h}=\) normplot \((\mathrm{X})\) displays a normal probability plot of the data in X . For matrix X , normplot displays a line for each column of X . h is a handle to the plotted lines.
The plot has the sample data displayed with the plot symbol ' + '. Superimposed on the plot is a line joining the first and third quartiles of each column of X (a robust linear fit of the sample order statistics.) This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

The purpose of a normal probability plot is to graphically assess whether the data in X could come from a normal distribution. If the data are normal the plot will be linear. Other distribution types will introduce curvature in the plot. normplot uses midpoint probability plotting positions. Use probplot when the data included censored observations.

\section*{Examples Generate a normal sample and a normal probability plot of the data.}
```

x = normrnd(10,1, 25,1);
normplot(x)

Purpose Normal density plot between specifications
```

Syntax normspec(specs)
normspec(specs,mu,sigma)
normspec(specs,mu,sigma,region)
p = normspec(...)
[p,h] = normspec(...)

```

\section*{Description}

Examples
normspec (specs) plots the standard normal density, shading the portion inside the specification limits given by the two-element vector specs. Set specs(1) to - Inf if there is no lower limit; set specs(2) to Inf if there is no upper limit.
normspec (specs, mu, sigma) shades the portion inside the specification limits of a normal density with parameters mu and sigma. The defaults are mu \(=0\) and sigma \(=1\).
normspec(specs,mu,sigma, region) shades the region either 'inside' or 'outside' the specification limits. The default is 'inside'.
\(\mathrm{p}=\) normspec (...) also returns the probability, p , of the shaded area.
\([p, h]=\) normspec (...) also returns a handle \(h\) to the line objects.

A production process fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces ( \(2 / 128\) gallons). What is the probability that cans will be filled under specification by 3 or more ounces?
```

p = normspec([1-3/128,Inf],1,2/128,'outside')
p =
0.0668

```

Probability Less than Lower Bound is 0.066807

\(\begin{array}{ll}\text { See Also } & \text { capaplot | histfit } \\ \text { How To } & \text {. "Normal Distribution" on page B-96 }\end{array}\)

Purpose Normal mean and variance
\[
\text { Syntax } \quad[M, V]=\text { normstat }(m u, \text { sigma })
\]

Description \([M, V]=\) normstat (mu, sigma) returns the mean of and variance for the normal distribution using the corresponding mean mu and standard deviation sigma. mu and sigma can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \(M\) and \(V\). A scalar input for mu or sigma is expanded to a constant array with the same dimensions as the other input.

The mean of the normal distribution with parameters \(\mu\) and \(\sigma\) is \(\mu\), and the variance is \(\sigma^{2}\).

\section*{dataset.ObsNames property}

Purpose Cell array of nonempty, distinct strings giving names of observations in data set

\section*{Description}

A cell array of nonempty, distinct strings giving the names of the observations in the data set. This property may be empty, but if not empty, the number of strings must equal the number of observations.

\section*{Purpose}

Syntax

Description

\section*{Input Arguments}

Optimal leaf ordering for hierarchical clustering
```

leafOrder = optimalleaforder(tree,D)
leafOrder = optimalleaforder(tree,D,Name,Value)

```
leafOrder = optimalleaforder(tree, D) returns an optimal leaf ordering for the hierarchical binary cluster tree, tree, using the distances, D. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.
leafOrder = optimalleaforder(tree, D,Name, Value) returns the optimal leaf ordering using one or more name-value pair arguments.

\section*{tree - Hierarchical binary cluster tree}
matrix returned by linkage
Hierarchical binary cluster tree, specified as an ( \(M-1\) )-by-3 matrix that you generate using linkage, where \(M\) is the number of leaves.

\section*{D - Distances}
matrix | vector
Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using pdist.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Criteria', 'group', 'Transformation','inverse' specifies that the sum of similarities be maximized between every leaf

\section*{optimalleaforder}
and all other leaves in adjacent clusters, using an inverse similarity transformation.

\section*{'Criteria' - Optimization criterion}
'adjacent' (default) | 'group'
Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of 'criteria' and one of these strings:
\begin{tabular}{ll} 
'adjacent' & \begin{tabular}{l} 
Maximize the sum of similarities between adjacent \\
leaves.
\end{tabular} \\
'group ' & \begin{tabular}{l} 
Maximize the sum of similarities between every leaf \\
and all other leaves in the adjacent clusters at the \\
same level of the dendrogram.
\end{tabular}
\end{tabular}

Example: 'Criteria','group'

\section*{Data Types}
char

\section*{'Transformation' - Method for transforming distances to similarities}
```

'linear' (default) | 'inverse' | function handle

```

Method for transforming distances to similarities, specified as the comma-separated pair consisting of 'Transformation' and one of 'linear', 'inverse', or a function handle.

Let \(d_{i, j}\) and \(\operatorname{Sim}_{i, j}\) denote the distance and similarity between leaves \(i\) and \(j\), respectively. The included similarity transformations are:
\[
\begin{array}{ll}
\text { 'linear' } & \operatorname{Sim}_{i, j}=\max _{i, j}\left(d_{i, j}\right)-d_{i, j} \\
\text { 'inverse' } & \operatorname{Sim}_{i, j}=1 / d_{i, j}
\end{array}
\]

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, \(D\), and returns a matrix of similarities, S . The function should be monotonic decreasing in the
range of distance values. S must have the same size as \(D\), with \(S(i, j)\) being the similarity computed based on \(D(i, j)\).

Example: 'Transformation', @myTransform

\section*{Data Types}
char | function_handle

\section*{Output Arguments}

\section*{leafOrder - Optimal leaf order \\ vector}

Optimal leaf order, returned as a length- \(M\) vector, where \(M\) is the number of leaves. leafOrder is a permutation of the vector \(1: \mathrm{M}\), giving an optimal leaf ordering based on the specified distances and similarity transformation.

\section*{Examples}

\section*{Plot Dendrogram With Optimal Leaf Order}

Create a hierarchical binary cluster tree using linkage. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.
```

rng('default') % For reproducibility
X = rand(10,2);

```

Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.
```

D = pdist(X);
tree = linkage(D,'average');
leafOrder = optimalleaforder(tree,D);

```

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.
figure()
subplot (2,1,1)
dendrogram(tree)
```

title('Default Leaf Order')
subplot(2,1,2)
dendrogram(tree,'reorder',leafOrder)
title('Optimal Leaf Order')

```

Optimal Leaf Order

The order of the leaves in the bottom figure corresponds to the elements in leafOrder.
leafOrder

\section*{leafOrder =}

\section*{Optimal Leaf Order Using Inverse Distance Similarity}

Generate sample data.
```

rng('default') % For reproducibility
X = rand(10,2);

```

Create a distance vector and a hierarchical binary clustering tree.
```

D = pdist(X);
tree = linkage(D,'average');

```

Use the inverse distance similarity transformation to determine an optimal leaf order.
leafOrder = optimalleaforder(tree, D,'Transformation','inverse')
leafOrder =
\begin{tabular}{llllllllll}
1 & 4 & 9 & 10 & 2 & 5 & 8 & 3 & 7 & 6
\end{tabular}

\section*{ClassificationBaggedEnsemble.oobEdge}

Purpose Out-of-bag classification edge

Description edge = oobEdge(ens) returns out-of-bag classification edge for ens.
edge = oobEdge(ens,Name, Value) computes classification edge with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

\section*{Input \\ Arguments}

\section*{ens}

A classification bagged ensemble, constructed with fitensemble.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NTrained

\section*{'mode'}

String representing the meaning of the output L:
- 'ensemble' - L is a scalar value, the loss for the entire ensemble.

\section*{ClassificationBaggedEnsemble.oobEdge}
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - \(L\) is a vector in which element \(J\) is obtained by using learners \(1: J\) from the input list of learners.

Default: 'ensemble'

\section*{Output Arguments}

\section*{Definitions}

\section*{edge}

Classification edge, a weighted average of the classification margin.

\section*{Edge}

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in ens. Prior.

\section*{Margin}

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix ens. X .

\section*{Out of Bag}

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, fitensemble generates many bootstrap replicas of the dataset and grows decision trees on these replicas. fitensemble obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where \(N\) is the dataset size. To find the predicted response of a trained ensemble, predict take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average \(37 \%(1 / e)\) of observations for each decision tree. These are "out-of-bag" observations. For each observation, oobLoss estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed

\section*{ClassificationBaggedEnsemble.oobEdge}
prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.
```

Examples Find the out-of-bag edge for a bagged ensemble from the Fisher iris data:
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
'Tree','type','classification');
edge = oobEdge(ens)
edge =
0.8730

```

See Also oobMargin | oobPredict | oobLoss

\section*{TreeBagger.oobError}
\begin{tabular}{|c|c|}
\hline Purpose & Out-of-bag error \\
\hline Syntax & ```
err = oobError(B)
err = oobError(B,'param1',val1,'param2',val2,...)
``` \\
\hline Description & \begin{tabular}{l}
err \(=\) oobError(B) computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger \(B\). err is a vector of length NTrees, where NTrees is the number of trees in the ensemble. \\
err = oobError(B,'param1',val1,'param2', val2,...) specifies optional parameter name/value pairs: \\
'mode ' \\
String indicating how oobError computes errors. If set to 'cumulative' (default), the method computes cumulative errors and err is a vector of length NTrees, where the first element gives error from trees (1), second element gives error from trees(1:2) etc, up to trees ( \(1:\) NTrees). If set to 'individual', err is a vector of length NTrees, where each element is an error from each tree in the ensemble. If set to 'ensemble', err is a scalar showing the cumulative error for the entire ensemble.
\end{tabular} \\
\hline & \begin{tabular}{l}
'trees' \\
Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the
\end{tabular} \\
\hline
\end{tabular}

\section*{TreeBagger.oobError}
first element gives error from trees(1), the second element gives error from trees (1:2) etc.
'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. oobError uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

CompactTreeBagger.error

\section*{TreeBagger.OOBIndices property}

\author{
Purpose Indicator matrix for out-of-bag observations \\ Description The 00BIndices property is a logical array of size Nobs-by-NTrees where Nobs is the number of observations in the training data and NTrees is the number of trees in the ensemble. The ( \(I, J\) ) element is true if observation I is out-of-bag for tree \(J\) and false otherwise. In other words, a true value means observation I was not selected for the training data used to grow tree J .
}

\author{
See Also \\ classregtree
}

\section*{TreeBagger.OOBInstanceWeight property}

Purpose Count of out-of-bag trees for each observation
Description The 00BInstanceWeight property is a numeric array of size Nobs-by-1 containing the number of trees used for computing out-of-bag response for each observation. Nobs is the number of observations in the training data used to create the ensemble.

\section*{ClassificationBaggedEnsemble.oobLoss}
\begin{tabular}{ll} 
Purpose & Out-of-bag classification error \\
Syntax & L \(=\) oobloss(ens) \\
& L \(=\) oobloss(ens, Name, Value)
\end{tabular}

Description \(L=\) oobloss(ens) returns the classification error for ens computed for out-of-bag data.

L = oobloss(ens, Name, Value) computes error with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ,NameN,ValueN.

\section*{Input \\ Arguments}
ens
A classification bagged ensemble, constructed with fitensemble.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to NTrained. oobLoss uses only these learners for calculating loss.

Default: 1:NTrained

\section*{'lossfun'}

Function handle or string representing a loss function. Built-in loss functions:
- 'binodeviance' - See "Loss Functions" on page 20-1911
- 'classiferror' - Fraction of misclassified data

\section*{ClassificationBaggedEnsemble.oobLoss}
- 'exponential' - See "Loss Functions" on page 20-1911

You can write your own loss function in the syntax described in "Loss Functions" on page 20-1911.

Default: 'classiferror'

\section*{'mode'}

String representing the meaning of the output L:
- 'ensemble' - L is a scalar value, the loss for the entire ensemble.
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - \(L\) is a vector in which element \(J\) is obtained by using learners \(1: J\) from the input list of learners.

Default: 'ensemble'

\section*{Output}

Arguments

\section*{Definitions}

L
Classification error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

\section*{Out of Bag}

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, fitensemble generates many bootstrap replicas of the dataset and grows decision trees on these replicas. fitensemble obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where \(N\) is the dataset size. To find the predicted response of a trained ensemble, predict take an average over predictions from individual trees.

\section*{ClassificationBaggedEnsemble.oobLoss}

Drawing N out of N observations with replacement omits on average \(37 \%(1 / e)\) of observations for each decision tree. These are "out-of-bag" observations. For each observation, oobLoss estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

\section*{Loss Functions}

The built-in loss functions are:
- 'binodeviance' - For binary classification, assume the classes \(y_{n}\) are -1 and 1 . With weight vector \(w\) normalized to have sum 1 , and predictions of row \(n\) of data \(X\) as \(f\left(X_{n}\right)\), the binomial deviance is
\[
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
\]
- 'classiferror' - Fraction of misclassified data, weighted by \(w\).
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is
\[
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
\]

To write your own loss function, create a function file of the form
```

function loss = lossfun(C,S,W,COST)

```
- \(N\) is the number of rows of \(X\).
- K is the number of classes in tree, represented in tree.ClassNames.
- \(C\) is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in tree.ClassNames.

\section*{ClassificationBaggedEnsemble.oobLoss}
- \(S\) is an N -by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.
- \(W\) is a numeric vector with \(N\) elements, the observation weights.
- COST is a K-by-K numeric matrix of misclassification costs. The default 'classiferror' cost function uses a cost of 0 for correct classification, and 1 for misclassification. In other words, 'classiferror' uses COST=ones(K)-eye(K).
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.
```

Examples Find the out-of-bag error for a bagged ensemble from the Fisher iris
data:
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
'Tree','type', 'classification');
L = oobLoss(ens)
L =
0.0467

```
```

\section*{RegressionBaggedEnsemble.oobLoss}
\begin{tabular}{ll} 
Purpose & Out-of-bag regression error \\
Syntax & L \(=\) oobLoss(ens) \\
& L \(=00 b L o s s(e n s\), Name, Value)
\end{tabular}

\section*{Description}

\section*{Input} Arguments
\(\mathrm{L}=\) oobLoss(ens) returns the mean squared error for ens computed for out-of-bag data.

L = oobLoss(ens,Name, Value) computes error with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

\section*{ens}

A regression bagged ensemble, constructed with fitensemble.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to NTrained. oobLoss uses only these learners for calculating loss.

Default: 1:NTrained

\section*{'lossfun'}

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle fun, oobLoss calls it as

FUN(Y,Yfit,W)

\section*{RegressionBaggedEnsemble.oobLoss}
re \(Y\), Yfit, and \(W\) are numeric vectors of the same length. \(Y\) is the observed response, Yfit is the predicted response, and \(W\) is the observation weights.

Default: 'mse'

\section*{'mode'}

String representing the meaning of the output L:
- 'ensemble' - L is a scalar value, the loss for the entire ensemble.
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - L is a vector in which element J is obtained by using learners \(1: J\) from the input list of learners.

Default: 'ensemble'

\section*{Output}

Arguments

\section*{Definitions}

L
Mean squared error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

\section*{Out of Bag}

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, fitensemble generates many bootstrap replicas of the dataset and grows decision trees on these replicas. fitensemble obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where \(N\) is the dataset size. To find the predicted response of a trained ensemble, predict take an average over predictions from individual trees.

Drawing \(N\) out of \(N\) observations with replacement omits on average \(37 \%\) (1/e) of observations for each decision tree. These are "out-of-bag"

\section*{RegressionBaggedEnsemble.oobLoss}

\section*{Examples Compute the out-of-bag error for the carsmall data:}
```

load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
'type','regression');
L = oobLoss(ens)
L =
17.0665

```

CompactTreeBagger.meanMargin

\section*{TreeBagger.OOBPermutedVarCountRaiseMargin property}

Purpose Variable importance for raising margin
Description
The 00BPermutedVarCountRaiseMargin property is a numeric array of size 1-by-Nvars containing a measure of variable importance for each predictor. For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

\section*{TreeBagger.OOBPermutedVarDeltaError property}

Purpose Variable importance for prediction error
Description The OOBPermutedVarDeltaError property is a numeric array of size 1-by-Nvars containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

\section*{TreeBagger.OOBPermutedVarDeltaMeanMargin property}

Purpose Variable importance for classification margin
Description
The OOBPermutedVarDeltaMeanMargin property is a numeric array of size 1-by-Nvars containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

\section*{ClassificationBaggedEnsemble.oobPredict}

\section*{Purpose}

Predict out-of-bag response of ensemble

\section*{Syntax}

Description

Input Arguments
```

[label,score] = oobPredict(ens)

```
[label,score] = oobPredict(ens,Name,Value)
[label, score] = oobPredict(ens) returns class labels and scores for ens for out-of-bag data.
[label, score] = oobPredict(ens,Name, Value) computes labels and scores with additional options specified by one or more Name, Value pair arguments.

\section*{ens}

A classification bagged ensemble, constructed with fitensemble.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NTrained

\section*{Output \\ Arguments}

\section*{label}

Classification labels of the same data type as the training data Y . There are \(N\) elements or rows, where \(N\) is the number of training observations. The label is the class with the highest score. In case of a tie, the label is earliest in ens.ClassNames.

\section*{score}

\section*{ClassificationBaggedEnsemble.oobPredict}

An N-by-K numeric matrix for N observations and K classes. A high score indicates that an observation is likely to come from this class. Scores are in the range 0 to 1 .

\section*{Definitions}

\section*{Out of Bag}

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, fitensemble generates many bootstrap replicas of the dataset and grows decision trees on these replicas. fitensemble obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where \(N\) is the dataset size. To find the predicted response of a trained ensemble, predict take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average \(37 \%\) ( \(1 / e\) ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, oobLoss estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

\section*{Score (ensemble)}

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:
- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
- Bag scores range from 0 to 1 .

\section*{ClassificationBaggedEnsemble.oobPredict}
```

Examples Find the out-of-bag predictions and scores for the Fisher iris data. Find
the scores in the range ( $0.2,0.8$ ); these are the scores where there is
notable uncertainty in the resulting classifications.
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
'Tree','type', 'classification');
[label score] = oobPredict(ens);

See Also oobMargin | oobPredict | oobLoss | oobEdge | predict

```

\section*{RegressionBaggedEnsemble.oobPredict}

\section*{Output Arguments}

\section*{ens}

A regression bagged ensemble, constructed with fitensemble.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to NTrained. oobLoss uses only these learners for calculating loss.

Default: 1:NTrained

Yfit
A vector of predicted responses for out-of-bag data. Yfit has size(ens.X,1) elements.
You can find the indices of out-of-bag observations for weak learner \(L\) with the command
~ens.UseObsForLearner(: , L)

\section*{RegressionBaggedEnsemble.oobPredict}

\section*{Definitions Out of Bag}

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, fitensemble generates many bootstrap replicas of the dataset and grows decision trees on these replicas. fitensemble obtains each bootstrap replica by randomly selecting \(N\) observations out of \(N\) with replacement, where \(N\) is the dataset size. To find the predicted response of a trained ensemble, predict take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average \(37 \%\) (1/e) of observations for each decision tree. These are "out-of-bag" observations. For each observation, oobLoss estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

\section*{Examples}

Compute out-of-bag predictions for the carsmall data. Look at the first three terms of the fit:
```

load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
'type','regression');
Yfit = oobPredict(ens);
Yfit(1:3) % first three terms
ans =
15.7964
14.7162
14.8062

```

See Also oobLoss | predict

\section*{TreeBagger.oobPredict}

Purpose Ensemble predictions for out-of-bag observations
```

Syntax
Y = oobPredict(B)
Y = oobPredict(B,'param1',val1,'param2',val2,...)

```

Description \(\quad Y=\) oobPredict \((B)\) computes predicted responses using the trained bagger B for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned Y is a cell array of strings for classification and a numeric array for regression.

Y = oobPredict(B,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:
\begin{tabular}{ll} 
'trees' & \begin{tabular}{l} 
Array of tree indices to use for computation of \\
responses. Default is 'all'.
\end{tabular} \\
'treeweights ' & \begin{tabular}{l} 
Array of NTrees weights for weighting votes from \\
the specified trees.
\end{tabular}
\end{tabular}

See Also CompactTreeBagger.predict | OOBIndices

\section*{Superclasses categorical}

\section*{Purpose Arrays for ordinal categorical data}

Description Ordinal arrays are used to store discrete values that have an ordering but are not numeric. An ordinal array provides efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values. Ordinal arrays are often used as grouping variables.

Like a numerical array, an ordinal array can have any size or dimension. You can subscript, concatenate, reshape, sort, etc. ordinal arrays, much like ordinary numeric arrays. You can make comparisons between elements of two ordinal arrays, or between an ordinal array and a single string representing a ordinal value.

\section*{Construction}

Use the ordinal constructor to create an ordinal array from a numeric, logical, or character array, or from a cell array of strings.
\[
\begin{array}{ll}
\text { ordinal } & \begin{array}{l}
\text { Construct ordinal categorical } \\
\text { array }
\end{array}
\end{array}
\]

\section*{Methods}

Each ordinal array carries along a list of possible values that it can store, known as its levels. The list is created when you create an ordinal array, and you can access it using the getlevels method, or modify it using the addlevels, mergelevels, or droplevels methods. Assignment to the array will also add new levels automatically if the values assigned are not already levels of the array. The ordering on values stored in an ordinal array is defined by the order of the list of levels. You can change that order using the reorderlevels method.

The following table lists operations available for ordinal arrays.
\begin{tabular}{ll} 
ismember & Test for membership \\
mergelevels & Merge levels
\end{tabular}
sort

\begin{tabular}{rl} 
Purpose & Construct ordinal categorical array \\
Syntax & \(B=\operatorname{ordinal}(A)\) \\
& \(B=\operatorname{ordinal}(A\), labels \()\) \\
& \(B=\operatorname{ordinal}(A\), labels, levels \()\) \\
& \(B=\operatorname{ordinal}(A, l a b e l s,[]\), edges \()\)
\end{tabular}

Description
\(B=\) ordinal \((A)\) creates an ordinal array \(B\) from the array \(A\). \(A\) can be numeric, logical, character, categorical, or a cell array of strings. ordinal creates the levels of B from the sorted unique values in A, and creates default labels for them.

B = ordinal(A, labels) labels the levels in B using the character array or cell array of strings labels. ordinal assigns labels to levels in B in order according to the sorted unique values in A .
\(B=o r d i n a l(A, l a b e l s, l e v e l s)\) creates an ordinal array with possible levels defined by levels. levels is a vector whose values can be compared to those in A using the equality operator. ordinal assigns labels to each level from the corresponding elements of labels. If A contains any values not present in levels, the levels of the corresponding elements of \(B\) are undefined. Use [ ] for labels to allow ordinal to create default labels.
\(B=\) ordinal(A, labels, [], edges) creates an ordinal array by binning the numeric array \(A\), with bin edges given by the numeric vector edges. The uppermost bin includes values equal to the right-most edge. ordinal assigns labels to each level in B from the corresponding elements of labels. edges must have one more element than labels.

By default, an element of \(B\) is undefined if the corresponding element of A is NaN (when A is numeric), an empty string (when A is character), or undefined (when A is categorical). ordinal treats such elements as "undefined" or "missing" and does not include entries for them among the possible levels for \(B\). To create an explicit level for such elements instead of treating them as undefined, you must use the levels input, and include NaN , the empty string, or an undefined element.

You may include duplicate labels in labels in order to merge multiple values in A into a single level in B.

\section*{Examples}

Create an ordinal array from integer data, and provide explicit labels:
```

quality1 = ordinal([1 2 3; 3 2 1; 2 1 3],...
{'low' 'medium' 'high'})

```

Create an ordinal array from integer data, and provide both explicit labels and an explicit order:
```

quality2 = ordinal([1 2 3; 3 2 1; 2 1 3],...
{'high' 'medium' 'low'},[3 2 1])

```

Create an ordinal array by binning floating point values:
```

size = ordinal(rand(5,2),{'small' 'medium' 'large'},...
[],[0 1/3 2/3 1])

```

Create an ordinal array from the measurements in Fisher's iris data, ignoring decimal lengths:
```

load fisheriris
m = floor(min(meas(:)));
M = floor(max(meas(:)));
labels = num2str((m:M)');
edges = m:M+1;
cms = ordinal(meas,labels,[],edges)
meas(1:5,:)
ans =

| 5.1000 | 3.5000 | 1.4000 | 0.2000 |
| :--- | :--- | :--- | :--- |
| 4.9000 | 3.0000 | 1.4000 | 0.2000 |

```
\begin{tabular}{cccc}
4.7000 & 3.2000 & 1.3000 & 0.2000 \\
4.6000 & 3.1000 & 1.5000 & 0.2000 \\
5.0000 & 3.6000 & 1.4000 & 0.2000 \\
cms \((1.5,:)\) & & & \\
ans \(=\) & & & \\
5 & 3 & 1 & 0 \\
4 & 3 & 1 & 0 \\
4 & 3 & 1 & 0 \\
4 & 3 & 1 & 0 \\
5 & 3 & 1 & 0
\end{tabular}

Create an age group ordinal array from the data in hospital.mat:
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','\%d'),\{'s'\});
AgeGroup = ordinal(hospital.Age,labels,[],edges);
hospital.Age(1:5)
ans \(=\)
38
43
38
40
49
AgeGroup(1:5)
ans =
30s
40s
30s
40s
40s

\section*{CompactTreeBagger.outlierMeasure}
\begin{tabular}{|c|c|}
\hline Purpose & Outlier measure for data \\
\hline Syntax & ```
out = outlierMeasure(B,X)
out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)
``` \\
\hline \multirow[t]{4}{*}{Description} & out = outlierMeasure \((B, X)\) computes outlier measures for predictors \(X\) using trees in the ensemble \(B\). The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. outlierMeasure then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier. \\
\hline & \begin{tabular}{l}
You can supply the proximity matrix directly by using the 'data' parameter. \\
out = outlierMeasure (B, X,'param1', val1,'param2', val2,...) specifies optional parameter name/value pairs:
\end{tabular} \\
\hline & \begin{tabular}{l}
'data' \\
Flag indicating how to treat the X input argument. If set to 'predictors' (default), the method assumes \(X\) is a matrix of predictors and uses it for computation of the proximity matrix. If set to 'proximity', the method treats X as a proximity matrix returned by the proximity method. If you do not supply the proximity matrix, outlierMeasure computes it internally. If you use the proximity method to compute a proximity matrix, supplying it as input to outlierMeasure reduces computing time.
\end{tabular} \\
\hline & \begin{tabular}{l}
'labels' \\
Vector of true class labels. True class labels can be either a numeric vector, character matrix, or cell array of strings. When you supply this parameter, the method performs the outlier calculation for any observations using only other observations from the same class. This parameter must specify one label for each observation (row) in \(X\).
\end{tabular} \\
\hline
\end{tabular}

\title{
CompactTreeBagger.outlierMeasure
}

\section*{TreeBagger.OutlierMeasure property}

Purpose Measure for determining outliers
Description \(\begin{aligned} & \text { The OutlierMeasure property is a numeric array of size Nobs-by-1, } \\ & \text { where Nobs is the number of observations in the training data, } \\ & \text { containing outlier measures for each observation. }\end{aligned}\)
See Also CompactTreeBagger.outlierMeasure

Parallel coordinates plot
```

parallelcoords(X)
parallelcoords(X,...,'Standardize','on')
parallelcoords(X,...,'Standardize','PCA')
parallelcoords(X,...,'Standardize','PCAStd')
parallelcoords(X,...,'Quantile',alpha)
parallelcoords(X,...,'Group',group)
parallelcoords(X,...,'Labels',labels)
parallelcoords(X,...,PropertyName,PropertyValue,...)
h = parallelcoords(X,...)
parallelcoords(axes,...)

```
parallelcoords (X) creates a parallel coordinates plot of the multivariate data in the \(n\)-by- \(p\) matrix X . Rows of X correspond to observations, columns to variables. A parallel coordinates plot is a tool for visualizing high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices. parallelcoords treats NaNs in X as missing values and does not plot those coordinate values.
parallelcoords(X, ...,'Standardize', 'on') scales each column of X to have mean 0 and standard deviation 1 before making the plot.
parallelcoords(X, .., 'Standardize', 'PCA') creates a parallel coordinates plot from the principal component scores of \(X\), in order of decreasing eigenvalues. parallelcoords removes rows of \(X\) containing missing values ( NaNs ) for principal components analysis (PCA) standardization.
parallelcoords(X,...,'Standardize', 'PCAStd') creates a parallel coordinates plot using the standardized principal component scores.
parallelcoords(X, ...,'Quantile', alpha) plots only the median and the alpha and 1-alpha quantiles of \(f(t)\) at each value of \(t\). This is useful if \(X\) contains many observations.
parallelcoords(X,..., 'Group', group) plots the data in different groups with different colors. Groups are defined by group, a numeric

\section*{parallelcoords}
array containing a group index for each observation. group can also be a categorical variable, character matrix, or cell array of strings, containing a group name for each observation.
parallelcoords(X, ..., 'Labels', labels) labels the coordinate tick marks along the horizontal axis using labels, a character array or cell array of strings.
parallelcoords(X, ...,PropertyName,PropertyValue,...) sets properties to the specified property values for all line graphics objects created by parallelcoords.
\(h=\) parallelcoords \((X, \ldots)\) returns a column vector of handles to the line objects created by parallelcoords, one handle per row of \(X\). If you use the 'Quantile' input argument, \(h\) contains one handle for each of the three lines objects created. If you use both the 'Quantile' and the 'Group ' input arguments, h contains three handles for each group.
parallelcoords(axes,...) plots into the axes with handle axes.

\section*{Examples}
```

% Make a grouped plot of the raw data
load fisheriris
labels = {'Sepal Length','Sepal Width',...
'Petal Length','Petal Width'};
parallelcoords(meas,'group',species,'labels',labels);
% Plot only the median and quartiles of each group
parallelcoords(meas,'group',species,'labels',labels,...
'quantile',.25);

```

How To . "Grouping Variables" on page 2-51

\section*{ProbDistUnivParam.paramci}

\section*{Purpose}

Return parameter confidence intervals of ProbDistUnivParam object
Syntax
CI = paramci(PD)
CI = paramci(PD, Alpha)

CI = paramci(PD) returns CI, a 2 -by-N array containing \(95 \%\) confidence intervals for the parameters of the ProbDistUnivParam object PD. \(N\) is the number of parameters in the distribution. When you create PD by specifying parameters (such as using the ProbDistUnivParam.ProbDistUnivParam constructor or using the fitdist function and specifying a 'binomial' or 'generalized pareto' distribution) rather than by fitting to data, the confidence intervals have a width of 0 because the parameters are viewed as estimates of an unknown parameter.

CI = paramci(PD, Alpha) returns 100*(1 - Alpha)\% confidence intervals. Default Alpha is 0.05 , which specifies \(95 \%\) confidence intervals.

Note If you create PD with a distribution that does not support confidence intervals, then CI contains NaN values.

\section*{Input \\ Arguments}

Output
Arguments

PD
Alpha

An object of the class ProbDistUnivParam.
A value between 0 and 1 that specifies a confidence interval. Default is 0.05 , which specifies \(95 \%\) confidence intervals.

A 2 -by-N array containing 100*(1-Alpha) \(\%\) confidence intervals for the parameters of the ProbDistUnivParam object PD. \(N\) is the number of parameters in the distribution.

\section*{ProbDistUnivParam.paramci}

See Also fitdist

\title{
prob.ToolboxFittableParametricDistribution.paramci
}

\section*{Purpose}

Confidence intervals for probability distribution parameters
ci = paramci(pd)
ci \(=\) paramci(pd,Name, Value)

Input
Arguments
\(\mathrm{ci}=\) paramci(pd) returns the array ci containing the lower and upper boundaries of the \(95 \%\) confidence interval for each parameter in probability distribution pd.
ci = paramci(pd,Name, Value) returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

\section*{pd - Probability distribution}
probability distribution object
Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, create a probability distribution object by fitting it to data using fitdist or dfittool.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Alpha', 0.01 specifies a \(99 \%\) confidence interval.

\section*{'Alpha' - Alpha level}
0.05 (default) | scalar value in the range \((0,1)\)

Alpha level for the confidence interval, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\). The default value 0.05 corresponds to a \(95 \%\) confidence interval.

\section*{prob.ToolboxFittableParametricDistribution.paramci}

\section*{Example: 'Alpha',0.01}

\section*{Data Types}
single | double

\section*{'Parameter' - Parameter list}
vector | cell array of strings
Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of 'Parameter' and a vector or a cell array of strings containing the parameter names. By default, paramci computes confidence intervals for all distribution parameters.
Example: 'Parameter', 'mu'

\section*{Data Types \\ char}

\section*{'Type' - Computation method}
```

'exact' | 'Wald' | 'lr'

```

Computation method for the confidence intervals, specified as the comma-separated pair consisting of 'Type' and 'exact', 'Wald', or 'lr'.
'exact ' computes the confidence intervals using an exact method, and is available for the following distributions.
\[
\begin{array}{ll}
\text { Binomial } & \begin{array}{l}
\text { Compute using the Clopper-Pearson method } \\
\text { based on exact probability calculations. This } \\
\text { method does not provide exact coverage } \\
\text { probabilities. }
\end{array} \\
\text { Exponential } & \begin{array}{l}
\text { Compute using a method based on a chi-square } \\
\text { distribution. This method provides exact coverage } \\
\text { for complete and Type } 2 \text { censored samples. }
\end{array}
\end{array}
\]
\begin{tabular}{cl} 
Normal & \begin{tabular}{l} 
Computation method based on \(t\) and chi-square \\
distributions for uncensored samples provides \\
exact coverage for uncensored samples. For \\
censored samples, paramci uses the Wald method \\
if Type is exact.
\end{tabular} \\
Lognormal & \begin{tabular}{l} 
Computation method based on \(t\) and chi-square \\
distributions for uncensored samples provides \\
exact coverage. For censored samples, paramci \\
uses the Wald method if Type is exact.
\end{tabular} \\
Poisson & \begin{tabular}{l} 
Computation method based on a chi-square \\
distribution provides exact coverage. For \\
large degrees of freedom, the chi-square is \\
approximated by a normal distribution for \\
numerical efficiency.
\end{tabular} \\
Rayleigh & \begin{tabular}{l} 
Computation method based on a chi-square \\
distribution provides exact coverage probabilities.
\end{tabular}
\end{tabular}
'exact' is the default when it is available. Alternatively, you can specify 'Wald' to compute the confidence intervals using the Wald method, or ' lr' to compute the confidence intervals using the likelihood radio method.

\section*{Example: 'Type','Wald'}

\section*{'LogFlag' - Boolean flag for log scale vector}

Boolean flag for the log scale, specified as the comma-separated pair consisting of 'LogFlag' and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.
```

Example: 'LogFlag',[0,1]

```

\section*{Data Types}
logical

\section*{prob.ToolboxFittableParametricDistribution.paramci}

\section*{Output \\ Arguments}

\section*{ci-Confidence interval}
array
Confidence interval, returned as a \(p\)-by- 2 array containing the lower and upper bounds of the ( 1 - Alpha) \% confidence interval for each distribution parameter. \(p\) is the number of distribution parameters.

\section*{Examples Parameter Confidence Intervals}

Load the sample data. Create a vector containing the first column of students' exam grade data.
```

load examgrades;
x = grades(:,1);

```

Fit a normal distribution object to the data.
```

pd = fitdist(x,'Normal')
pd =
NormalDistribution

```
```

Normal distribution

```
Normal distribution
            mu = 75.0083 [73.4321, 76.5846]
            mu = 75.0083 [73.4321, 76.5846]
    sigma = 8.7202 [7.7391, 9.98843]
```

    sigma = 8.7202 [7.7391, 9.98843]
    ```

Compute the \(95 \%\) confidence interval for the distribution parameters.
ci \(=\) paramci(pd)
ci =
    \(73.4321 \quad 7.7391\)
    \(76.5846 \quad 9.9884\)

\section*{prob.ToolboxFittableParametricDistribution.paramci}

Column 1 of ci contains the lower and upper \(95 \%\) confidence interval boundaries for the mu parameter, and column 2 contains the boundaries for the sigma parameter.

\section*{Change Parameter Confidence Intervals}

Load the sample data. Create a vector containing the first column of students' exam grade data.
```

load examgrades;
x = grades(:,1);

```

Fit a normal distribution object to the data.
```

pd = fitdist(x,'Normal')
pd =

```

NormalDistribution
```

Normal distribution
mu = 75.0083 [73.4321, 76.5846]
sigma = 8.7202 [7.7391, 9.98843]

```

Compute the \(99 \%\) confidence interval for the distribution parameters.
```

ci = paramci(pd,'Alpha',.01)

```
ci =
    \(72.9245 \quad 7.4627\)
    77.092210 .4403

Column 1 of ci contains the lower and upper \(99 \%\) confidence interval boundaries for the mu parameter, and column 2 contains the boundaries for the sigma parameter.

\section*{ProbDistParametric.ParamCov property}
\begin{tabular}{ll} 
Purpose & \begin{tabular}{l} 
Read-only covariance matrix of parameter estimates of \\
ProbDistParametric object
\end{tabular} \\
Description \(\quad\)\begin{tabular}{l} 
ParamCov is a read-only property of the ProbDistParametric class. \\
ParamCov is a covariance matrix containing the parameter estimates of \\
a distribution represented by a ProbDistParametric object. ParamCov \\
has a size of NumParams-by-NumParams.
\end{tabular} \\
Values & \begin{tabular}{l} 
This covariance matrix includes estimates for both the specified \\
parameters and parameters that are fit to the data. For specified \\
parameters, the covariance is 0, indicating the parameter is known \\
exactly. Use this information to view and compare the descriptions of \\
parameters supplied to create distributions.
\end{tabular}
\end{tabular}

\section*{ProbDistParametric.ParamDescription property}
\begin{tabular}{ll} 
Purpose & \begin{tabular}{l} 
Read-only cell array specifying descriptions of parameters of \\
ProbDistParametric object
\end{tabular} \\
Description \(\quad\)\begin{tabular}{l} 
ParamDescription is a read-only property of the ProbDistParametric \\
class. ParamDescription is a cell array of strings specifying the \\
descriptions or meanings of the parameters of a distribution represented \\
by a ProbDistParametric object. ParamDescription has a length of \\
NumParams.
\end{tabular} \\
Values & \begin{tabular}{l} 
This cell array includes a brief description of the meaning of both \\
the specified parameters and parameters that are fit to the data. \\
The description is the same as the parameter name when no further \\
description information is available. Use this information to view and \\
compare the descriptions of parameters used to create distributions.
\end{tabular}
\end{tabular}

\section*{ProbDistParametric.ParamlsFixed property}
\begin{tabular}{ll} 
Purpose & \begin{tabular}{l} 
Read-only logical array specifying fixed parameters of \\
ProbDistParametric object
\end{tabular} \\
Description & \begin{tabular}{l} 
ParamIsFixed is a read-only property of the ProbDistParametric class. \\
ParamIsFixed is a logical array specifying the fixed parameters of a \\
distribution represented by a ProbDistParametric object. ParamIsFixed \\
has a length of NumParams.
\end{tabular} \\
Values & \begin{tabular}{l} 
This array specifies a 1 (true) for fixed parameters, and a 0 (false) \\
for parameters that are estimated from the input data. Use this \\
information to view and compare the fixed parameters used to create \\
distributions.
\end{tabular}
\end{tabular}

\section*{ProbDistParametric.ParamNames property}
\begin{tabular}{ll} 
Purpose & \begin{tabular}{l} 
Read-only cell array specifying names of parameters of \\
ProbDistParametric object
\end{tabular} \\
Description \(\quad\)\begin{tabular}{l} 
ParamNames is a read-only property of the ProbDistParametric class. \\
ParamNames is a cell array of strings specifying the names of the \\
parameters of a distribution represented by a ProbDistParametric \\
object. ParamNames has a length of NumParams.
\end{tabular} \\
Values & \begin{tabular}{l} 
This cell array includes the names of both the specified parameters and \\
parameters that are fit to the data. Use this information to view and \\
compare the names of parameters used to create distributions.
\end{tabular}
\end{tabular}

\section*{NaiveBayes.Params property}

\section*{Purpose Parameter estimates}

\section*{Description}

The Params property is an NClasses-by-NDims cell array containing the parameter estimates, excluding the class priors. Params(i,j) contains the parameter estimates for the \(j\) th feature in the ith class. Params ( \(i, j\) ) is an empty cell if the ith class is empty.

The entry in Params ( \(i, j\) ) depends on the distribution type used for the \(j\) th feature, as follows:
\begin{tabular}{|c|c|}
\hline 'normal' & A vector of length two. The first element is the mean, and the second element is standard deviation \\
\hline 'kernel' & A ProbDistUnivKernel object \\
\hline 'mvmn' & A vector containing the probability for each possible value of the \(j\) th feature in the ith class. The order of the probabilities is decided by the sorted order of all the unique values of the \(j\) th feature. \\
\hline 'mn' & A scalar representing the probability the \(j\) th token appearing in the ith class, Prob(token j | class i). It is estimated as (1 + the number of occurrence of token \(J\) in class I)/(NDims + the total number of token occurrence in class I). \\
\hline
\end{tabular}

\section*{ProbDistParametric.Params property}
\begin{tabular}{ll} 
Purpose & \begin{tabular}{l} 
Read-only array specifying values of parameters of ProbDistParametric \\
object
\end{tabular} \\
Description \(\quad\)\begin{tabular}{l} 
Params is a read-only property of the ProbDistParametric class. \\
Params is an array of values specifying the values of the parameters of \\
a distribution represented by a ProbDistParametric object. Params \\
has a length of NumParams.
\end{tabular} \\
Values & \begin{tabular}{l} 
This array includes the values of both the specified parameters and \\
parameters that are fit to the data. Use this information to view and \\
compare the values of parameters used to create distributions.
\end{tabular}
\end{tabular}

\section*{classregtree.parent}

Purpose Parent node
Syntax
p = parent(t)
p = parent(t, nodes)

Description
\(p=\) parent ( \(t\) ) returns an \(n\)-element vector \(p\) containing the number of the parent node for each node in the tree \(t\), where \(n\) is the number of nodes. The parent of the root node is 0 .
\(p\) = parent(t, nodes) takes a vector nodes of node numbers and returns the parent nodes for the specified nodes.

Examples Create a classification tree for Fisher's iris data:
```

load fisheriris;

```
t = classregtree(meas,species,...
    'names',\{'SL' 'SW' 'PL' 'PW'\})
t \(=\)
Decision tree for classification
1 if PL<2.45 then node 2 else node 3
2 class = setosa
3 if PW<1.75 then node 4 else node 5
4 if PL<4.95 then node 6 else node 7
5 class = virginica
6 if PW<1. 65 then node 8 else node 9
7 class = virginica
8 class = versicolor
9 class = virginica
view(t)

Properties

\section*{Copy Semantics}

\author{
How To
}
- "Generalized Pareto Distribution" on page B-50

\section*{Purpose \\ Syntax \\ Description}

Construct Pareto tails object
obj = paretotails(x,pl,pu)
obj = paretotails(x,pl,pu,cdffun)
obj = paretotails( \(\mathrm{x}, \mathrm{pl}, \mathrm{pu}\) ) creates an object obj defining a distribution consisting of the empirical distribution of \(x\) in the center and Pareto distributions in the tails. \(x\) is a real-valued vector of data values whose extreme observations are fit to generalized Pareto distributions (GPDs). pl and pu identify the lower- and upper-tail cumulative probabilities such that 100*pl and 100*(1-pu) percent of the observations in \(x\) are, respectively, fit to a GPD by maximum likelihood. If pl is 0 , or if there are not at least two distinct observations in the lower tail, then no lower Pareto tail is fit. If pu is 1 , or if there are not at least two distinct observations in the upper tail, then no upper Pareto tail is fit.
obj \(=\) paretotails(x, pl, pu,cdffun) uses cdffun to estimate the cdf of \(x\) between the lower and upper tail probabilities. cdffun may be any of the following:
- 'ecdf' - Uses an interpolated empirical cdf, with data values as the midpoints in the vertical steps in the empirical cdf, and computed by linear interpolation between data values. This is the default.
- 'kernel' - Uses a kernel-smoothing estimate of the cdf.
- @fun - Uses a handle to a function of the form [p,xi] = fun (x) that accepts the input data vector \(x\) and returns a vector \(p\) of cdf values and a vector xi of evaluation points. Values in xi must be sorted and distinct but need not equal the values in \(x\).
cdffun is used to compute the quantiles corresponding to pl and pu by inverse interpolation, and to define the fitted distribution between these quantiles.
The output object obj is a Pareto tails object with methods to evaluate the cdf, inverse cdf, and other functions of the fitted distribution. These methods are well-suited to copula and other Monte Carlo simulations.

The pdf method in the tails is the GPD density, but in the center it is computed as the slope of the interpolated cdf.
The paretotails class is a subclass of the piecewisedistribution class, and many of its methods are derived from that class.

\section*{Examples}

Fit Pareto tails to a \(t\) distribution at cumulative probabilities 0.1 and 0.9:
```

t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj);
x = linspace(-5,5);
plot(x,cdf(obj,x),'b-','LineWidth', 2)
hold on
plot(x,tcdf(x,3),'r:','LineWidth',2)
plot(q,p,'bo','LineWidth',2,'MarkerSize',5)
legend('Pareto Tails Object','t Distribution',...
'Location','NW')

```

\section*{partialcorr}

Purpose
Linear or rank partial correlation coefficients
Syntax
RHO = partialcorr (X)
RHO = partialcorr (X,Z)
RHO = partialcorr(X,Y,Z)
[RHO,PVAL] = partialcorr(...)
[...] = partialcorr(...,param1,val1,param2,val2,...)

\section*{Description}

RHO = partialcorr (X) returns the sample linear partial correlation coefficients between pairs of variables in X , controlling for the remaining variables in X . X is an \(n\)-by- \(p\) matrix, with rows corresponding to observations, and columns corresponding to variables. RHO is a symmetric \(p\)-by-p matrix, where the \((i, j)\)-th entry is the sample linear partial correlation between the \(i\)-th and \(j\)-th columns in X .
RHO = partialcorr ( \(X, Z\) ) returns the sample linear partial correlation coefficients between pairs of variables in \(X\) controlling for the variables in \(\mathrm{Z} . \mathrm{X}\) is an \(n\)-by- \(p\) matrix, and Z is an \(n\)-by- \(q\) matrix with rows corresponding to observations, and columns corresponding to variables. The output, RHO, is a symmetric \(p\)-by- \(p\) matrix.

RHO = partialcorr (X,Y,Z) returns the sample linear partial correlation coefficients between pairs of variables between \(X\) and Y , controlling for the variables in Z . X is an \(n\)-by- \(p_{1}\) matrix, Y an \(n\)-by- \(p_{2}\) matrix, and \(Z\) is an \(n\)-by- \(q\) matrix, with rows corresponding to observations, and columns corresponding to variables. RHO is a \(p_{1}\)-by- \(p_{2}\) matrix, where the \((i, j)\) th entry is the sample linear partial correlation between the \(i\) th column in X and the \(j\) th column in Y .

If the covariance matrix of \([X, Z]\) is
\[
S=\left(\begin{array}{cc}
S_{11} & S_{12} \\
S_{12}^{T} & S_{22}
\end{array}\right)
\]
then the partial correlation matrix of X, controlling for Z, can be defined formally as a normalized version of the covariance matrix \(S_{x y}=S_{11}\) \(-\left(S_{12} S_{22}{ }^{-1} S_{12}{ }^{T}\right)\)
[RHO,PVAL] = partialcorr(...) also returns PVAL, a matrix of \(p\)-values for testing the hypothesis of no partial correlation against the alternative that there is a nonzero partial correlation. Each element of PVAL is the \(p\) value for the corresponding element of RHO. If PVAL ( \(\mathrm{I}, \mathrm{J})\) is small, say less than 0.05 , then the partial correlation, \(\mathrm{RHO}(\mathrm{I}, \mathrm{J})\), is significantly different from zero.
[...] = partialcorr(...,param1,val1,param2,val2,...) specifies additional parameters and their values. Valid parameter/value pars are listed in the following table.
\begin{tabular}{|c|c|}
\hline Parameter & Values \\
\hline 'type' & \begin{tabular}{l}
- 'Pearson' - To compute Pearson (linear) partial correlations. This is the default. \\
- 'Spearman ' - To compute Spearman (rank) partial correlations.
\end{tabular} \\
\hline 'rows ' & \begin{tabular}{l}
- 'all' - To use all rows regardless of missing ( NaN ) values. This is the default. \\
- 'complete ' - To use only rows with no missing values. \\
- 'pairwise' - To compute RHO (I , J) using rows with no missing values in column I or \(J\).
\end{tabular} \\
\hline \begin{tabular}{l}
'tail' \\
The alternative hypothesis against which to compute \(p\)-values for testing the hypothesis of no partial correlation.
\end{tabular} & \begin{tabular}{l}
- 'both' (the default) - the correlation is not zero. \\
- 'right ' - the correlation is greater than zero. \\
- 'left' - the correlation is less than zero.
\end{tabular} \\
\hline
\end{tabular}

\section*{partialcorr}

A 'pairwise' value for the rows parameter can produce a RHO that is not positive definite. A 'complete' value always produces a positive definite RHO, but when data is missing, the estimates will be based on fewer observations, in general.
partialcorr computes \(p\)-values for linear and rank partial correlations using a Student's \(t\) distribution for a transformation of the correlation. This is exact for linear partial correlation when \(X\) and \(Z\) are normal, but is a large-sample approximation otherwise.

\section*{See Also}
corr | tiedrank | corrcoef

\section*{Purpose}

Principal component analysis of raw data

\section*{Syntax}
```

coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca(___)
[coeff,score,latent,tsquared] = pca(

```
[coeff,score,latent,tsquared,explained,mu] = pca(__)

Description
coeff \(=p c a(X)\) returns the principal component coefficients for the \(n\)-by- \(p\) data matrix X. Rows of X correspond to observations and columns correspond to variables. The coefficient matrix is \(p\)-by- \(p\). Each column of coeff contains coefficients for one principal component, and the columns are in descending order of component variance. By default, pca centers the data and uses the singular value decomposition (SVD) algorithm.
coeff \(=p c a(X\), Name, Value \()\) returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more Name, Value pair arguments.

For example, you can specify the number of principal components pca returns or an algorithm other than SVD to use.
[coeff,score,latent] = pca(__ ) also returns the principal component scores in score and the principal component variances in latent. You can use any of the input arguments in the previous syntaxes.

Principal component scores are the representations of \(X\) in the principal component space. Rows of score correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of X .
[coeff,score, latent,tsquared] = pca(__ ) also returns the Hotelling's T-squared statistic for each observation in X.
[coeff, score, latent,tsquared, explained, mu] = pca(__ ) also returns explained, the percentage of the total variance explained by each principal component and mu, the estimated mean of each variable in \(X\).

\section*{Input \\ Arguments}

X - Input data
matrix
Input data for which to compute the principal components, specified as an \(n\)-by- \(p\) matrix. Rows of X correspond to observations and columns to variables.

\section*{Data Types \\ single | double}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{Example:}
'Algorithm', 'eig', 'Centered',false,'Rows', 'all', 'NumComponents', 3 specifies that pca uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

\section*{'Algorithm' - Principal component algorithm}

\section*{'svd' (default) | 'eig' | 'als'}

Principal component algorithm that pca uses to perform the principal component analysis, specified as the comma-separated pair consisting of 'Algorithm' and one of the following.
\begin{tabular}{l|l}
\hline 'svd' & Default. Singular value decomposition (SVD) of X. \\
\hline 'eig' & \begin{tabular}{l} 
Eigenvalue decomposition (EIG) of the covariance matrix. \\
The EIG algorithm is faster than SVD when the number \\
of observations, \(n\), exceeds the number of variables, \(p\), \\
but is less accurate because the condition number of the \\
covariance is the square of the condition number of X.
\end{tabular} \\
\hline 'als' & \begin{tabular}{l} 
Alternating least squares (ALS) algorithm. This algorithm \\
finds the best rank- \(k\) approximation by factoring X into \\
a \(n\)-by- \(k\) left factor matrix, L, and a \(p\)-by- \(k\) right factor \\
matrix, R, where \(k\) is the number of principal components. \\
The factorization uses an iterative method starting with \\
random initial values.ALS is designed to better handle \\
missing values. It is preferable to pairwise deletion \\
('Row', , 'apirwise ') and deals with missing values \\
without listwise deletion ('Rows ', 'complete '). It can work \\
well for data sets with a small percentage of missing data \\
at random, but might not perform well on sparse data sets.
\end{tabular} \\
\hline
\end{tabular}

Example: 'Algorithm', 'eig'

\section*{Data Types}
char

\section*{'Centered' - Indicator for centering columns}
true (default) | false
Indicator for centering the columns, specified as the comma-separated pair consisting of 'Centered' and one of these logical expressions.
\begin{tabular}{l|l}
\hline true & \begin{tabular}{l} 
Default. pca centers \(X\) by subtracting column means before \\
computing singular value decomposition or eigenvalue \\
decomposition. If X contains NaN missing values, nanmean \\
is used to find the mean with any available data. You can \\
reconstruct the centered data using score*coeff \({ }^{\prime}\).
\end{tabular} \\
\hline false & \begin{tabular}{l} 
In this case pca does not center the data. You can \\
reconstruct the original data using score*coeff \({ }^{\prime}\).
\end{tabular} \\
\hline
\end{tabular}

\section*{Example: 'Centered',false}

\section*{Data Types}
logical

\section*{'Economy' - Indicator for economy size output \\ true (default) | false}

Indicator for the economy size output when the degrees of freedom, \(d\), is smaller than the number of variables, \(p\), specified as the comma-separated pair consisting of 'Economy ' and one of these logical expressions.
\begin{tabular}{l|l}
\hline true & \begin{tabular}{l} 
Default. pca returns only the first \(d\) elements of latent \\
and the corresponding columns of coeff and score. \\
This option can be significantly faster when the number of \\
variables \(p\) is much larger than \(d\).
\end{tabular} \\
\hline false & \begin{tabular}{l} 
pca returns all elements of latent. The columns of coeff \\
and score corresponding to zero elements in latent are \\
zeros.
\end{tabular} \\
\hline
\end{tabular}

Note that when \(d<p\), score (: \(\mathrm{d}+1: \mathrm{p}\) ) and latent \((\mathrm{d}+1: \mathrm{p})\) are necessarily zero, and the columns of coeff (:, \(\mathrm{d}+1: \mathrm{p}\) ) define directions that are orthogonal to \(X\).

\section*{Example: 'Economy',false}

\section*{Data Types}
logical

\section*{'NumComponents' - Number of components requested \\ number of variables (default) | scalar integer}

Number of components requested, specified as the comma-separated pair consisting of 'NumComponents' and a scalar integer \(k\) satisfying \(0<\) \(k \leq p\), where \(p\) is the number of original variables in X . When specified, pca returns the first \(k\) columns of coeff and score.

\footnotetext{
Example: 'NumComponents',3
}

\section*{Data Types \\ single | double \\ 'Rows' - Action to take for NaN values}
'complete' (default) | 'pairwise' | 'all'
Action to take for NaN values in the data matrix X, specified as the comma-separated pair consisting of 'Rows' and one of the following.
\begin{tabular}{ll}
\hline ' complet®Default. Observations with NaN values are removed before \\
calculation. Rows of NaNs are reinserted into score and \\
tsquared at the corresponding locations.
\end{tabular}

Example: 'Rows','pairwise'

\section*{Data Types}
char

\section*{'Weights' - Observation weights}
ones (default) | row vector
Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length \(n\) containing all positive elements.

\author{
Data Types \\ single | double
}

\section*{'VariableWeights' - Variable weights}
row vector | 'variance'
Variable weights, specified as the comma-separated pair consisting of 'VariableWeights ' and one of the following.

Vector of length \(p\) containing all positive elements.
The string 'variance'. The variable weights are the inverse of sample variance. If you also assign weights to observations using 'Weights ', then the variable weights become the inverse of weighted sample variance.

If 'Centered' is set to true at the same time, the data matrix \(X\) is centered and standardized. In this case, pca returns the principal components based on the correlation matrix.

Example: 'VariableWeights', 'variance'
```

Data Types
single | double | char

```

\section*{'Coeff0' - Initial value for coefficients}
matrix of random values (default) | \(p\)-by- \(k\) matrix
Initial value for the coefficient matrix coeff, specified as the comma-separated pair consisting of 'Coeffo' and a \(p\)-by- \(k\) matrix, where \(p\) is the number of variables, and \(k\) is the number of principal components requested.

Note You can use this name-value pair only when 'algorithm' is 'als'.

\section*{Data Types \\ single | double \\ 'Score0' - Initial value for scores}
matrix of random values (default) | \(k\)-by- \(m\) matrix
Initial value for scores matrix score, specified as a comma-separated pair consisting of 'Score 0 ' and an \(n\)-by- \(k\) matrix, where \(n\) is the number of observations and \(k\) is the number of principal components requested.

Note You can use this name-value pair only when 'algorithm' is 'als'.

\section*{Data Types}
single | double

\section*{'Options' - Options for iterations}
structure
Options for the iterations, specified as a comma-separated pair consisting of 'Options' and a structure created by the statset function. pca uses the following fields in the options structure.
\begin{tabular}{l|l}
\hline 'Display' & \begin{tabular}{l} 
Level of display output. Choices are 'off ', \\
'final', and 'iter'.
\end{tabular} \\
\hline 'MaxIter' & \begin{tabular}{l} 
Maximum number steps allowed. The default is \\
100. Unlike in optimization settings, reaching the \\
MaxIter value is regarded as convergence.
\end{tabular} \\
\hline 'TolFun' & \begin{tabular}{l} 
Positive number giving the termination tolerance \\
for the cost function. The default is 1e-6.
\end{tabular} \\
\hline 'TolX' & \begin{tabular}{l} 
Positive number giving the convergence threshold \\
for the relative change in the elements of the left \\
and right factor matrices, L and R, in the ALS \\
algorithm. The default is 1e-6.
\end{tabular} \\
\hline
\end{tabular}

Note You can use this name-value pair only when 'algorithm' is 'als'.

\section*{Output} Arguments

\section*{coeff - Principal component coefficients}
matrix
Principal component coefficients, returned as a \(p\)-by-p matrix. Each column of coeff contains coefficients for one principal component. The columns are in the order of descending component variance, latent.

\section*{score - Principal component scores}
matrix
Principal component scores, returned as a matrix. Rows of score correspond to observations, and columns to components.

\section*{latent - Principal component variances}
column vector
Principal component variances, that is the eigenvalues of the covariance matrix of \(X\), returned as a column vector.

\section*{tsquared - Hotelling's T-squared statistic}

\section*{column vector}
"Hotelling's T-Squared Statistic" on page 20-1992, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

\section*{explained - Percentage of total variance explained column vector}

Percentage of the total variance explained by each principal component, returned as a column vector.

\section*{mu - Estimated means}
row vector
Estimated means of the variables in X, returned as a row vector. When 'algorithm' is 'als', this is estimated by ALS algorithm. When 'algorithm' is not 'als', mu is equal to the sample mean of X .

\section*{Examples Principal Components of a Data Set}

Load the sample data set.
load hald

The ingredients data has 13 observations for 4 variables.
Find the principal components for the ingredients data.
```

coeff = pca(ingredients)
coeff =

| -0.0678 | -0.6460 | 0.5673 | 0.5062 |
| ---: | ---: | ---: | ---: |
| -0.6785 | -0.0200 | -0.5440 | 0.4933 |
| 0.0290 | 0.7553 | 0.4036 | 0.5156 |
| 0.7309 | -0.1085 | -0.4684 | 0.4844 |

```

The rows of coeff contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

\section*{PCA in the Presence of Missing Data}

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.
load imports-85
Data matrix X has 13 continuous variables in columns 3 to 15 : wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform principal component analysis.
coeff = pca(X(:,3:15));
By default, pca performs the action specified by the 'Rows ' , 'complete' name-value pair argument. This option removes the observations with NaN values before calculation. Rows of NaNs are reinserted into score and tsquared at the corresponding locations, namely rows 56 to 59 , 131 , and 132.

Use 'pairwise' to perform the principal component analysis.
coeff \(=\operatorname{pca}(X(:, 3: 15)\), 'Rows','pairwise');
In this case, pca computes the \((i, j)\) element of the covariance matrix using the rows with no NaN values in the columns \(i\) or \(j\) of \(X\). Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm pca uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, pca sets it to 'eig'. If you require 'svd' as the algorithm, with the 'pairwise' option, then pca returns a warning message, sets the algorithm to 'eig' and continues.

If you use the 'Rows ' , 'all' name-value pair argument, pca terminates because this option assumes there are no missing values in the data set.
coeff \(=\operatorname{pca}\left(X(:, 3: 15),{ }^{\prime}\right.\) Rows', 'all');
```

Error using pca (line 180)

```
Raw data contains NaN missing value while 'Rows' option is set to 'al

\section*{Weighted PCA}

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.
```

load hald

```

Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.
```

    [wcoeff,~,latent,~,explained] = pca(ingredients,...
    ```
'VariableWeights', 'variance')
```

wcoeff =

```
\begin{tabular}{rrrr}
-2.7998 & 2.9940 & -3.9736 & 1.4180 \\
-8.7743 & -6.4411 & 4.8927 & 9.9863 \\
2.5240 & -3.8749 & -4.0845 & 1.7196 \\
9.1714 & 7.5529 & 3.2710 & 11.3273
\end{tabular}
latent =
    2.2357
    1.5761
    0.1866
    0.0016
explained =
    55.8926
    39.4017
    4.6652
    0.0406

Note that the coefficient matrix, wcoeff, is not orthonormal.
Calculate the orthonormal coefficient matrix.
```

coefforth = inv(diag(std(ingredients)))* wcoeff
coefforth =

| -0.4760 | 0.5090 | -0.6755 | 0.2411 |
| ---: | ---: | ---: | ---: |
| -0.5639 | -0.4139 | 0.3144 | 0.6418 |
| 0.3941 | -0.6050 | -0.6377 | 0.2685 |
| 0.5479 | 0.4512 | 0.1954 | 0.6767 |

```

Check orthonormality of the new coefficient matrix, coefforth.
```

coefforth*coefforth'

```
ans =
\begin{tabular}{rrrr}
1.0000 & 0.0000 & -0.0000 & -0.0000 \\
0.0000 & 1.0000 & -0.0000 & -0.0000 \\
-0.0000 & -0.0000 & 1.0000 & 0 \\
-0.0000 & -0.0000 & 0 & 1.0000
\end{tabular}

\section*{PCA Using ALS for Missing Data}

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.
load hald
The ingredients data has 13 observations for 4 variables.
Perform principal component analysis using the ALS algorithm and display the component coefficients.
```

[coeff,score,latent,tsquared,explained] = pca(ingredients);
coeff

```
```

coeff =

| -0.0678 | -0.6460 | 0.5673 | 0.5062 |
| ---: | ---: | ---: | ---: |
| -0.6785 | -0.0200 | -0.5440 | 0.4933 |
| 0.0290 | 0.7553 | 0.4036 | 0.5156 |
| 0.7309 | -0.1085 | -0.4684 | 0.4844 |

```

Introduce missing values randomly.
```

y = ingredients;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.30;
y(ix) = NaN
y =

```
\begin{tabular}{rrrr}
7 & 26 & 6 & NaN \\
1 & 29 & 15 & 52 \\
NaN & NaN & 8 & 20 \\
11 & 31 & NaN & 47 \\
7 & 52 & 6 & 33 \\
NaN & 55 & NaN & NaN \\
NaN & 71 & NaN & 6 \\
1 & 31 & NaN & 44 \\
2 & NaN & NaN & 22 \\
21 & 47 & 4 & 26 \\
NaN & 40 & 23 & 34 \\
11 & 66 & 9 & NaN \\
10 & 68 & 8 & 12
\end{tabular}

Approximately 30\% of the data has missing values now, indicated by NaN .

Perform principal component analysis using the ALS algorithm and display the component coefficients.
[coeff1,score1,latent,tsquared,explained,mu1] \(=p c a(y, \ldots\) 'algorithm', 'als');
```

coeff1

```
coeff1 =
\begin{tabular}{rrrr}

-0.6831 & -0.0998 & 0.1828 & 0.6999 \\
0.0169 & 0.5575 & 0.8215 & -0.1185 \\
0.7292 & -0.0657 & 0.1261 & 0.6694
\end{tabular}

Display the estimated mean.
mu1
mu1 =
\[
\begin{array}{llll}
8.9956 & 47.9088 & 9.0451 & 28.5515
\end{array}
\]

Reconstruct the observed data.
```

t = score1*coeff1' + repmat(mu1,13,1)
t =

```
\begin{tabular}{rrrr}
7.0000 & 26.0000 & 6.0000 & 51.5250 \\
1.0000 & 29.0000 & 15.0000 & 52.0000 \\
10.7819 & 53.0230 & 8.0000 & 20.0000 \\
11.0000 & 31.0000 & 13.5500 & 47.0000 \\
7.0000 & 52.0000 & 6.0000 & 33.0000 \\
10.4818 & 55.0000 & 7.8328 & 17.9362 \\
3.0982 & 71.0000 & 11.9491 & 6.0000 \\
1.0000 & 31.0000 & -0.5161 & 44.0000 \\
2.0000 & 53.7914 & 5.7710 & 22.0000 \\
21.0000 & 47.0000 & 4.0000 & 26.0000 \\
21.5809 & 40.0000 & 23.0000 & 34.0000 \\
11.0000 & 66.0000 & 9.0000 & 5.7078 \\
10.0000 & 68.0000 & 8.0000 & 12.0000
\end{tabular}

The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.
subspace(coeff, coeff1)
ans \(=\)

\subsection*{2.2925e-16}

This is a small value. It indicates that the results if you use pca with 'Rows', 'complete' name-value pair argument when there is no missing data and if you use pca with 'algorithm', 'als' name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using 'Rows ', 'complete' name-value pair argument and display the component coefficients.
```

[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
coeff2

```
coeff2 \(=\)
\begin{tabular}{rrr}
-0.2054 & 0.8587 & 0.0492 \\
-0.6694 & -0.3720 & 0.5510 \\
0.1474 & -0.3513 & -0.5187 \\
0.6986 & -0.0298 & 0.6518
\end{tabular}

In this case, pca removes the rows with missing values, and \(y\) has only four rows with no missing values. pca returns only three principal components. You cannot use the 'Rows', 'pairwise' option because the covariance matrix is not positive semidefinite and pca returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when 'Rows', 'complete').
```

subspace(coeff(:,1:3),coeff2)
ans =
0.3576

```

The angle between the two spaces is substantially larger. This indicates that these two results are differ.

Display the estimated mean.
mu2
mu2 \(=\)
\[
\begin{array}{llll}
7.8889 & 46.9091 & 9.8750 & 29.6000
\end{array}
\]

In this case, the mean is just the sample mean of \(y\).
Reconstruct the observed data.
```

score2*coeff2'

```
ans =
\begin{tabular}{rrrr}
NaN & NaN & NaN & NaN \\
-7.5162 & -18.3545 & 4.0968 & 22.0056 \\
NaN & NaN & NaN & NaN \\
NaN & NaN & NaN & NaN \\
-0.5644 & 5.3213 & -3.3432 & 3.6040 \\
NaN & NaN & NaN & NaN \\
NaN & NaN & NaN & NaN \\
NaN & NaN & NaN & NaN \\
NaN & NaN & NaN & NaN \\
12.8315 & -0.1076 & -6.3333 & -3.7758 \\
NaN & NaN & NaN & NaN \\
NaN & NaN & NaN & NaN \\
1.4680 & 20.6342 & -2.9292 & -18.0043
\end{tabular}

This shows that deleting rows containing NaN values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

\section*{Principal Component Coefficients, Scores, and Variances}

Find the coefficients, scores, and variances of the principal components.
Load the sample data set.

\section*{load hald}

The ingredients data has 13 observations for 4 variables.
Find the principal component coefficients, scores, and variances of the components for the ingredients data.
```

[coeff,score,latent] = pca(ingredients)
coeff =

| -0.0678 | -0.6460 | 0.5673 | 0.5062 |
| ---: | ---: | ---: | ---: |
| -0.6785 | -0.0200 | -0.5440 | 0.4933 |
| 0.0290 | 0.7553 | 0.4036 | 0.5156 |
| 0.7309 | -0.1085 | -0.4684 | 0.4844 |

29.6073 & 4.6109 & -2.2476 & -0.3958 \\
-12.9818 & -4.2049 & 0.9022 & -1.1261 \\
23.7147 & -6.6341 & 1.8547 & -0.3786 \\
-0.5532 & -4.4617 & -6.0874 & 0.1424 \\
-10.8125 & -3.6466 & 0.9130 & -0.1350 \\
-32.5882 & 8.9798 & -1.6063 & 0.0818 \\
22.6064 & 10.7259 & 3.2365 & 0.3243 \\
-9.2626 & 8.9854 & -0.0169 & -0.5437 \\
-3.2840 & -14.1573 & 7.0465 & 0.3405
\end{tabular}
\begin{tabular}{rrrr}
9.2200 & 12.3861 & 3.4283 & 0.4352 \\
-25.5849 & -2.7817 & -0.3867 & 0.4468 \\
-26.9032 & -2.9310 & -2.4455 & 0.4116
\end{tabular}
```

latent =

```
517.7969
    67.4964
    12.4054
    0.2372

Each column of score corresponds to one principal component. The vector, latent, stores the variances of the four principal components.

Reconstruct the centered ingredients data.
Xcentered = score*coeff'

Xcentered =
\begin{tabular}{rrrr}
-0.4615 & -22.1538 & -5.7692 & 30.0000 \\
-6.4615 & -19.1538 & 3.2308 & 22.0000 \\
3.5385 & 7.8462 & -3.7692 & -10.0000 \\
3.5385 & -17.1538 & -3.7692 & 17.0000 \\
-0.4615 & 3.8462 & -5.7692 & 3.0000 \\
3.5385 & 6.8462 & -2.7692 & -8.0000 \\
-4.4615 & 22.8462 & 5.2308 & -24.0000 \\
-6.4615 & -17.1538 & 10.2308 & 14.0000 \\
-5.4615 & 5.8462 & 6.2308 & -8.0000 \\
13.5385 & -1.1538 & -7.7692 & -4.0000 \\
-6.4615 & -8.1538 & 11.2308 & 4.0000 \\
3.5385 & 17.8462 & -2.7692 & -18.0000 \\
2.5385 & 19.8462 & -3.7692 & -18.0000
\end{tabular}

The new data in Xcentered is the original ingredients data centered by subtracting the column means from corresponding columns.

\section*{T-Squared Statistic}

Find the Hotelling's T-squared statistic values.
Load the sample data set.
```

load hald

```

The ingredients data has 13 observations for 4 variables.
Perform the principal component analysis and request the T-squared values.
```

[coeff,score,latent,tsquared] = pca(ingredients);
tsquared
tsquared =
5.6803
3.0758
6.0002
2.6198
3.3681
0.5668
3.4818
3.9794
2.6086
7.4818
4.1830
2.2327
2.7216

```

Request only the first two principal components and compute the T -squared values in the reduced space of requested principal components.
```

[coeff,score,latent,tsquared] = pca(ingredients,'NumComponents',2);
tsquared

```
tsquared \(=\)
\[
\begin{aligned}
& 5.6803 \\
& 3.0758 \\
& 6.0002 \\
& 2.6198 \\
& 3.3681 \\
& 0.5668 \\
& 3.4818 \\
& 3.9794 \\
& 2.6086 \\
& 7.4818 \\
& 4.1830 \\
& 2.2327 \\
& 2.7216
\end{aligned}
\]

Note that even when you specify a reduced component space, pca computes the T -squared values in the full space, using all four components.

The T-squared value in the reduced space corresponds to the Mahalanobis distance in the reduced space.
```

tsqreduced = mahal(score,score)
tsqreduced =
3.3179
2.0079
0.5874
1.7382
0.2955
0.4228
3.2457
2.6914
1.3619
2.9903

```
2.4371
1.3788
1.5251

Calculate the T-squared values in the discarded space by taking the difference of the T-squared values in the full space and Mahalanobis distance in the reduced space.
```

tsqdiscarded = tsquared - tsqreduced
tsqdiscarded =
2.3624
1.0679
5.4128
0.8816
3.0726
0.1440
0.2362
1.2880
1.2467
4.4915
1.7459
0.8539
1.1965

```

\section*{Percent Variability Explained by Principal Components}

Find the percent variability explained by the principal components.
Load the sample data set.
load imports-85
Data matrix X has 13 continuous variables in columns 3 to 15 : wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.
```

[coeff,score,latent,tsquared,explained] = pca(X(:,3:15));
explained
explained =
64.3429
35.4484
0.1550
0.0379
0.0078
0.0048
0 . 0 0 1 3
0.0011
0.0005
0.0002
0.0002
0.0000
0.0000

```

The first two components explain \(99.79 \%\) of all variability.
To skip any of the outputs, you can use ~instead in the corresponding element. For example, if you don't want to get the T-squared values, specify
```

[coeff,score,latent,~,explained] = pca(X(:,3:15));

```

\section*{Definitions Hotelling's \(\mathbf{T}\)-Squared Statistic}

Hotelling's T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, pca uses all principal components to compute the T-squared statistic
(computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:
- For the T-squared statistic in the reduced space, use mahal(score, score).
- For the T-squared statistic in the discarded space, first compute the T-squared statistic using [coeff, score, latent, tsquared] = pca( X, 'NumComponents ' \(, \mathrm{k}, \ldots\) ), compute the T-squared statistic in the reduced space using tsqreduced \(=\) mahal(score, score), and then take the difference: tsquared - tsqreduced.

\section*{Degrees of Freedom}

The degrees of freedom, \(d\), is equal to \(n-1\), if data is centered and \(n\) otherwise, where:
- \(n\) is the number of rows without any NaNs if you use 'Rows', 'complete'.
- \(n\) is the number of rows without any NaNs in the column pair that has the maximum number of rows without NaNs if you use 'Rows', 'pairwise'.

\section*{Variable Weights}

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called varwei, and the principal component coefficients vector pca returned is wcoeff. You can then calculate the orthonormal coefficients using the transformation diag(sqrt(varwei))*wcoeff.

\section*{Purpose}

Residuals from principal component analysis

\section*{Syntax}
```

residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)

```
residuals \(=\) pcares \((X\), ndim) returns the residuals obtained by retaining ndim principal components of the n-by-p matrix \(X\). Rows of \(X\) correspond to observations, columns to variables. ndim is a scalar and must be less than or equal to p. residuals is a matrix of the same size as \(X\). Use the data matrix, not the covariance matrix, with this function.
pcares does not normalize the columns of \(X\). To perform the principal components analysis based on standardized variables, that is, based on correlations, use pcares(zscore(X), ndim). You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using pcacov.
[residuals, reconstructed] \(=\) pcares(X, ndim) returns the reconstructed observations; that is, the approximation to \(X\) obtained by retaining its first ndim principal components.

\section*{Examples}

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.
```

\section*{Purpose \\ Syntax \\ Description}

Probabilistic principal component analysis
[coeff,score,pcvar] = ppca(Y,K)
[coeff,score,pcvar] = ppca(Y,K,Name,Value)
[coeff,score,pcvar,mu] = ppca(__ )
[coeff,score, pcvar,mu, v, S] = ppca(__ )
[coeff,score, pcvar] = ppca(Y,K) returns the principal component coefficients for the \(n\)-by- \(p\) data matrix \(Y\) based on a probabilistic principal component analysis (PPCA). It also returns the principal component scores, which are the representations of \(Y\) in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of \(Y\), in pcvar.

Each column of coeff contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of score correspond to observations, and columns correspond to components. Rows of \(Y\) correspond to observations and columns correspond to variables.

Probabilistic principle component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.
[coeff,score,pcvar] = ppca(Y,K,Name,Value) returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more Name, Value pair arguments.

For example, you can introduce initial values for the residual variance, \(v\), or change the termination criteria.
[coeff, score, pcvar, mu] = ppca(__ ) also returns the estimated mean of each variable in Y. You can use any of the input arguments in the previous syntaxes.
[coeff, score, pcvar, mu, v, S] = ppca(__) also returns the isotropic residual variance in \(v\) and the final results at convergence in structure \(S\).

\section*{Input Arguments}

\section*{\(\mathbf{Y}\) - Input data}
\(n\)-by- \(p\) matrix
Input data for which to compute the principal components, specified as an \(n\)-by- \(p\) matrix. Rows of \(Y\) correspond to observations and columns correspond to variables.
```

Data Types
single | double

```

\section*{K - Number of principal components}
positive integer value less than rank
Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is \(\min (n, p)\), where \(n\) is the number of observations and \(p\) is the number of variables. However, if the data is correlated, the rank might be smaller than \(\min (n, p)\).
ppca orders the components based on their variance.
If K is \(\min (n, p)\), ppca sets K equal to \(\min (n, p)-1\), and ' WO ' is truncated to \(\min (p, n)-1\) columns if you specify a \(p\)-by- \(p\) W0 matrix.
For example, you can request only the first three components, based on the component variance as follows.

Example: coeff \(=\) ppca( \(\mathrm{Y}, 3\) )
Data Types
single | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'WO', init,'Options',opt specifies that the initial values for 'WO' are in matrix init and ppca uses the options defined by opt.

\section*{'W0' - Initial value of W}
matrix of random values (default) | \(p\)-by- \(k\) matrix
Initial value of \(W\) in the probabilistic principal component analysis algorithm, specified as a comma-separated pair consisting of 'WO' and a \(p\)-by- \(k\) matrix.
Data Types
single | double

\section*{'v0' - Initial value of residual variance}
random number (default) | positive scalar value
Initial value of residual variance, specified as the comma-separated pair consisting of 'v0' and a positive scalar value.

\section*{Data Types}
single | double

\section*{'Options' - Options for iterations}
structure
Options for the iterations, specified as a comma-separated pair 'Options' and a structure created by the statset function. ppca uses the following fields in the options structure.
\begin{tabular}{l|l}
\hline 'Display' & \begin{tabular}{l} 
Level of display output. Choices are 'off ', \\
'final', and 'iter'.
\end{tabular} \\
\hline 'MaxIter' & \begin{tabular}{l} 
Maximum number of steps allowed. The default is \\
1000. Unlike in optimization settings, reaching the \\
MaxIter value is regarded as convergence.
\end{tabular} \\
\hline 'TolFun' & \begin{tabular}{l} 
Positive integer stating the termination tolerance \\
for the cost function. The default is 1e-6.
\end{tabular} \\
\hline 'TolX' & \begin{tabular}{l} 
Positive integer stating the convergence threshold \\
for the relative change in the elements of \(W\). The \\
default is 1e-6.
\end{tabular} \\
\hline
\end{tabular}

You can change the values of these fields and specify the new structure in ppca using the 'Options' name-value pair argument.

Example: opt = statset('ppca'); opt.MaxIter = 2000; coeff = ppca(Y,3,'Options',opt);

\section*{Data Types}
struct

\section*{Output Arguments}

\section*{coeff - Principal component coefficients}
\(p\)-by- \(k\) matrix
Principal component coefficients, returned as a \(p\)-by- \(k\) matrix. Each column of coeff contains coefficients for one principal component. The columns are in the order of descending component variance, pcvar.

\section*{score - Principal component scores}
\(n\)-by-k matrix
Principal component scores, returned as an \(n\)-by- \(k\) matrix. Rows of score correspond to observations, and columns correspond to components.

\section*{pcvar - Principal component variances}
column vector

Principal component variances, which are the eigenvalues of the covariance matrix of Y , returned as a column vector.

\section*{mu - Estimated mean}
row vector
Estimated mean of each variable in Y , returned as a row vector.

\section*{v- Isotropic residual variance}
scalar value
Isotropic residual variance, returned as a scalar value.

\section*{S-Final results at convergence}

\section*{structure}

Final results at convergence, returned as a structure containing the following fields.
\begin{tabular}{l|l}
\hline W & \(W\) at convergence. \\
\hline Xexp & \begin{tabular}{l} 
Conditional expectation of the estimated latent \\
variable \(x\).
\end{tabular} \\
\hline Recon & \begin{tabular}{l} 
Reconstructed observations using \(k\) principle \\
components. This is a low dimension \\
approximation of the input data \(Y\), and is equal \\
to mu + score*coeff \('\).
\end{tabular} \\
\hline v & Residual variance. \\
\hline RMSResid & Root mean square of residuals. \\
\hline NumIter & Number of iteration counts. \\
\hline nloglk & Negative loglikelihood function value. \\
\hline
\end{tabular}

\section*{Examples Perform Probabilistic Principal Component Analysis}

Load the sample data.
load fisheriris

The double matrix meas consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.
```

y = meas;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.20;
y(ix) = NaN;

```

Now, approximately \(20 \%\) of the data is missing, indicated by NaN.
Perform probabilistic principal component analysis and request the component coefficients and variances.
```

[coeff,score,pcvar,mu] = ppca(y,3);

```
coeff
coeff =
\begin{tabular}{rrr}
0.3562 & 0.6709 & -0.5518 \\
-0.0765 & 0.7121 & 0.6332 \\
0.8592 & -0.1596 & 0.0596 \\
0.3592 & -0.1318 & 0.5395
\end{tabular}
pcvar
pcvar =
4.0912
0.2126
0.0617

Perform principal component analysis using the alternating least squares algorithm.
```

[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',...
'NumComponents',3);

```
```

coeff2
coeff2 =

| 0.3376 | 0.4955 | 0.7404 |
| ---: | ---: | ---: |
| -0.0731 | 0.8607 | -0.4479 |
| 0.8657 | -0.1169 | -0.1231 |
| 0.3623 | -0.0087 | -0.4859 |

pcvar2
pcvar2 =
4.0734
0.2651
0.1221

```

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.
```

subspace(coeff,coeff2)

```
ans =
0.0881

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.

\section*{Change the Termination Criteria for Probabilistic Principal Component Analysis}

Load the sample data set.
load imports-85

Data matrix X has 13 continuous variables in columns 3 to 15 : wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.
```

[coeff,score,pcvar] = ppca(X(:,3:15),3);
Warning: Maximum number of iterations 1000 reached'.
> In ppca at 249

```

Change the termination tolerance for the cost function to 0.01 .
```

opt = statset('ppca');
opt.TolFun = 0.01;

```

Perform probabilistic principal component analysis.
[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);
ppca now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

\section*{Reconstruct Observations}

Load the sample data.
```

load hald
y = ingredients;

```

The ingredients data has 13 observations for 4 variables.
Introduce missing values to the data.
\(y(2: 16: e n d)=N a N ;\)

Every 16th value is NaN. This corresponds to \(7.69 \%\) of the data.
Find the first three principal components of data using PPCA and display the reconstructed observations.
\begin{tabular}{|c|c|c|c|}
\hline \multicolumn{4}{|l|}{ans =} \\
\hline 6.8533 & 25.8675 & 5.8388 & 59.8755 \\
\hline 1.0431 & 28.9690 & 14.9652 & 51.9758 \\
\hline 11.5770 & 56.5080 & 8.6352 & 20.5062 \\
\hline 11.0833 & 31.0707 & 8.0920 & 47.0764 \\
\hline 7.0684 & 52.2539 & 6.0753 & 33.0597 \\
\hline 11.0486 & 55.0442 & 9.0534 & 22.0410 \\
\hline 2.8494 & 70.8719 & 16.8338 & 5.8624 \\
\hline 1.0331 & 31.0267 & 19.6906 & 44.0321 \\
\hline 2.0401 & 54.0364 & 18.0440 & 22.0337 \\
\hline 20.7823 & 46.8096 & 3.7603 & 25.8075 \\
\hline 0.9540 & 39.9590 & 22.9495 & 31.1540 \\
\hline 10.8251 & 65.8498 & 8.8072 & 11.8420 \\
\hline 9.9174 & 67.9309 & 7.9087 & 11.9230 \\
\hline
\end{tabular}

You can also reconstruct the observations using the principle components and the estimated mean.
```

t = score*coeff' + repmat(mu,13,1);

```

\section*{Results at Convergence}

Load the sample data.
load hald

Here, ingredients is a real-valued matrix of predictor variables.

Perform the probabilistic principal components analysis and display coefficients.
```

[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);
coeff
coeff =

| -0.0693 | -0.6459 | 0.5673 |
| ---: | ---: | ---: |
| -0.6786 | -0.0184 | -0.5440 |
| 0.0308 | 0.7552 | 0.4036 |
| 0.7306 | -0.1102 | -0.4684 |

```

Display the algorithm results at convergence of the PPCA.
S
S =
```

                    W: [4x3 double]
            Xexp: [13x3 double]
            Recon: [13x4 double]
            v: 0.2372
                NumIter: 1000
    RMSResid: 0.2340
nloglk: 149.3388

```

Display the matrix W.
S.W
ans =
\begin{tabular}{rrr}
0.5624 & 2.0279 & 5.4075 \\
4.8320 & -10.3894 & 5.9202 \\
-3.7521 & -3.0555 & -4.1552 \\
-1.5144 & 11.7122 & -7.2564
\end{tabular}

Orthogonalizing W recovers the coefficients.
```

orth(S.W)
ans =

| -0.0693 | 0.6459 | 0.5673 |
| ---: | ---: | ---: |
| -0.6786 | 0.0184 | -0.5440 |
| 0.0308 | -0.7552 | 0.4036 |
| 0.7306 | 0.1102 | -0.4684 |

```

\section*{Definitions \\ Probabilistic Principal Component Analysis}

Probabilistic principle component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a \(p\)-dimensional observation vector \(y\) to a corresponding \(k\)-dimensional vector of latent (or unobserved) variable \(x\), which is normal with mean zero and covariance \(\mathrm{I}(k)\). The relationship is
\[
y^{T}=W * x^{T}+\mu+\varepsilon,
\]
where \(y\) is the row vector of observed variable, \(x\) is the row vector of latent variables, and \(\varepsilon\) is the isotropic error term. \(\varepsilon\) is Gaussian with mean zero and covariance of \(v^{*} \mathrm{I}(k)\), where \(v\) is the residual variance. Here, \(k\) needs to be smaller than the rank for the residual variance to be greater than \(0(v>0)\). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables, \(y\), are conditionally independent given the values of the latent variables, \(x\). So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular \(y_{i}\). The \(p\)-by- \(k\) matrix \(W\) relates the latent and observation variables, and the vector \(\mu\) permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.

Under this model,
\[
y \sim N\left(\mu, W * W^{T}+v^{*} I(k)\right) .
\]

There is no closed-form analytical solution for \(W\) and \(v\), so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of \(W\) spans the subspace, but they are not orthonormal. ppca obtains the orthonormal coefficients, coeff, for the components by orthogonalization of \(W\).

\section*{gmdistribution.PComponents property}

\author{
Purpose Input vector of mixing proportions \\ Description Optional input vector of mixing proportions p , or its default value.
}

Purpose Probability density functions
Syntax \(\quad \begin{aligned} Y & =\operatorname{pdf}(\text { name }, X, A) \\ Y & =\operatorname{pdf}(\text { name }, X, A, B) \\ & Y\end{aligned}\)

\section*{Description}
\(Y=\operatorname{pdf}(\) name \(, X, A)\) computes the probability density function for the one-parameter family of distributions specified by name. Parameter values for the distribution are given in A. Densities are evaluated at the values in X and returned in Y .

If \(X\) and \(A\) are arrays, they must be the same size. If \(X\) is a scalar, it is expanded to a constant matrix the same size as \(A\). If \(A\) is a scalar, it is expanded to a constant matrix the same size as \(X\).
\(Y\) is the common size of \(X\) and \(A\) after any necessary scalar expansion.
\(Y=p d f(\) name \(, X, A, B)\) computes the probability density function for two-parameter families of distributions, where parameter values are given in \(A\) and \(B\).

If \(X, A\), and \(B\) are arrays, they must be the same size. If \(X\) is a scalar, it is expanded to a constant matrix the same size as A and B. If either A or B are scalars, they are expanded to constant matrices the same size as \(X\).
\(Y\) is the common size of \(X, A\), and \(B\) after any necessary scalar expansion.
\(Y=p d f(\) name \(, X, A, B, C)\) computes the probability density function for three-parameter families of distributions, where parameter values are given in \(A, B\), and \(C\).

If \(X, A, B\), and \(C\) are arrays, they must be the same size. If \(X\) is a scalar, it is expanded to a constant matrix the same size as \(A, B\), and \(C\). If any of A, B or C are scalars, they are expanded to constant matrices the same size as \(X\).
\(Y\) is the common size of \(X, A, B\) and \(C\) after any necessary scalar expansion.

Examples Compute the pdf of the normal distribution with mean 0 and standard deviation 1 at inputs \(-2,-1,0,1,2\) :
```

p1 = pdf('Normal',-2:2,0,1)
p1 =
0.0540}00.2420 0.3989 0.2420 0.0540

```

The order of the parameters is the same as for normpdf.
Compute the pdfs of Poisson distributions with rate parameters \(0,1, \ldots\), 4 at inputs \(1,2, \ldots, 5\), respectively:
p2 = pdf('Poisson', \(0: 4,1: 5)\)
```

p2 =
0.3679

```

The order of the parameters is the same as for poisspdf.
See Also
cdf | icdf | mle | random

\section*{gmdistribution.pdf}

Purpose Probability density function for Gaussian mixture distribution

\section*{Syntax \\ y = pdf(obj, X\()\)}

Description
\(y=\operatorname{pdf}(o b j, X)\) returns a vector \(y\) of length \(n\) containing the values of the probability density function (pdf) for the gmdistribution object obj, evaluated at the \(n\)-by- \(d\) data matrix X , where \(n\) is the number of observations and \(d\) is the dimension of the data. obj is an object created by gmdistribution or fit. y(I) is the pdf of observation I.

Examples Create a gmdistribution object defining a two-component mixture of bivariate Gaussian distributions:

MU = [1 2;-3-5];
SIGMA = cat(3,[2 0;0 .5],[1 0;0 1]);
\(p=\operatorname{ones}(1,2) / 2 ;\)
obj = gmdistribution(MU,SIGMA, p);
ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])

See Also
gmdistribution | fit | cdf | mvnpdf

\section*{piecewisedistribution.pdf}

Purpose Probability density function for piecewise distribution

\section*{Syntax \(\quad P=\operatorname{pdf}(o b j, x)\)}

Description \(P=\operatorname{pdf}(o b j, X)\) returns an array \(P\) of values of the probability density function for the piecewise distribution object obj, evaluated at the values in the array \(X\).

Note For a Pareto tails object, the pdf is computed using the generalized Pareto distribution in the tails. In the center, the pdf is computed using the slopes of the cdf, which are interpolated between a set of discrete values. Therefore the pdf in the center is piecewise constant. It is noisy for a cdffun specified in paretotails via the 'ecdf ' option, and somewhat smoother for the 'kernel' option, but generally not a good estimate of the underlying density of the original data.

Examples \(\quad\) Fit Pareto tails to a \(t\) distribution at cumulative probabilities 0.1 and 0.9:
```

t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
0.1000
0.9000
q =
-1.7766
1.8432
pdf(obj,q)
ans =
0.2367
0.1960

```

See Also paretotails | cdf

\section*{ProbDist.pdf}

Purpose
Return probability density function (PDF) for ProbDist object
Syntax \(\quad Y=\operatorname{pdf}(P D, X)\)
Description
\(Y=\operatorname{pdf}(P D, X)\) returns \(Y\), an array containing the probability density function (PDF) for the ProbDist object \(P D\), evaluated at values in \(X\).

\section*{Input \\ Arguments}
\(x\)

Y

\section*{Output Arguments}

\section*{See Also \\ pdf}

An object of the class ProbDistUnivParam or ProbDistUnivKernel.

A numeric array of values where you want to evaluate the PDF.

An array containing the probability density function (PDF) for the ProbDist object PD.

\section*{Purpose}

Syntax \(\quad y=\operatorname{pdf}(p d, x)\)

Input Arguments

\section*{Output} Arguments

\section*{Examples}

Probability density function of probability distribution object
\(y=p d f(p d, x)\) returns the probability density function (pdf) of the continuous probability distribution \(p d\) at the values in \(x\). For discrete distributions, pdf returns the probability mass function.

\author{
pd - Probability distribution \\ probability distribution object
}

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using fitdist or dfittool.

\section*{\(\mathbf{x}\) - Values at which to calculate pdf array}

Values at which to calculate pdf, specified as an array.

Purpose Pairwise distance between pairs of objects
Syntax \(\quad \begin{aligned} D & =\operatorname{pdist}(X) \\ & D=\operatorname{pdist}(X, \text { distance })\end{aligned}\)
Description
\(\mathrm{D}=\mathrm{pdist}(\mathrm{X})\) computes the Euclidean distance between pairs of objects in \(m\)-by- \(n\) data matrix \(X\). Rows of \(X\) correspond to observations, and columns correspond to variables. D is a row vector of length \(m(m-1) / 2\), corresponding to pairs of observations in X. The distances are arranged in the order \((2,1),(3,1), \ldots,(m, 1),(3,2), \ldots,(m, 2), \ldots\), ( \(m, m-1\) )). D is commonly used as a dissimilarity matrix in clustering or multidimensional scaling.

To save space and computation time, D is formatted as a vector. However, you can convert this vector into a square matrix using the squareform function so that element \(i, j\) in the matrix, where \(i<j\), corresponds to the distance between objects \(i\) and \(j\) in the original data set.
\(\mathrm{D}=\) pdist(X, distance) computes the distance between objects in the data matrix, X , using the method specified by distance, which can be any of the following character strings.
\begin{tabular}{l|l}
\hline Metric & Description \\
\hline 'euclidean' & Euclidean distance (default). \\
\hline 'seuclidean' & \begin{tabular}{l} 
Standardized Euclidean distance. Each \\
coordinate difference between rows in X is \\
scaled by dividing by the corresponding \\
element of the standard deviation \\
S=nanstd (X). To specify another value for \\
S, use D=pdist (X, 'seuclidean ' , S).
\end{tabular} \\
\hline 'cityblock' & \begin{tabular}{l} 
City block metric.
\end{tabular} \\
\hline 'minkowski' & \begin{tabular}{l} 
Minkowski distance. The default exponent is \\
2. To specify a different exponent, use D \(=\) \\
pdist (X, 'minkowski' , P), where P is a scalar
\end{tabular} \\
\hline
\end{tabular} positive value of the exponent.
\(\left.\begin{array}{l|l}\hline \text { Metric } & \text { Description } \\ \hline \text { 'chebychev' } & \begin{array}{l}\text { Chebychev distance (maximum coordinate } \\ \text { difference). }\end{array} \\ \hline \text { 'mahalanobis' } & \begin{array}{l}\text { Mahalanobis distance, using the sample } \\ \text { covariance of X as computed by nancov. To } \\ \text { compute the distance with a different covariance, } \\ \text { use D = pdist (X, 'mahalanobis ' , C), where } \\ \text { the matrix C is symmetric and positive definite. }\end{array} \\ \hline \text { 'cosine' } & \begin{array}{l}\text { One minus the cosine of the included angle } \\ \text { between points (treated as vectors). }\end{array} \\ \hline \text { 'correlation' } & \begin{array}{l}\text { One minus the sample correlation between } \\ \text { points (treated as sequences of values). }\end{array} \\ \hline \text { 'spearman' } & \begin{array}{l}\text { One minus the sample Spearman's rank } \\ \text { correlation between observations (treated as } \\ \text { sequences of values). }\end{array} \\ \hline \text { 'hamming' } & \begin{array}{l}\text { Hamming distance, which is the percentage of } \\ \text { coordinates that differ. }\end{array} \\ \hline \text { 'jaccard' } & \begin{array}{l}\text { One minus the Jaccard coefficient, which is the } \\ \text { percentage of nonzero coordinates that differ. }\end{array} \\ \hline \begin{array}{l}\text { custom distance } \\ \text { function }\end{array} & \begin{array}{l}\text { A distance function specified using @: } \\ \mathrm{D}=\text { pdist (X, @distfun) } \\ \text { A distance function must be of form }\end{array} \\ \hline \text { d2 = distfun (XI, XJ) }\end{array}\right\}\)

\section*{pdist}

The output D is arranged in the order of \(((2,1),(3,1), \ldots\), ( \(m, 1\) ),(3,2),...( \(m, 2\) ),.....( \(m, m-1\) )), i.e. the lower left triangle of the full \(m\)-by- \(m\) distance matrix in column order. To get the distance between the \(i\) th and \(j\) th observations \((i<j\) ), either use the formula \(D\left((i-1)^{*}(m-i / 2)+j-i\right)\), or use the helper function \(Z=\) squareform \((\mathrm{D})\), which returns an \(m\)-by- \(m\) square symmetric matrix, with the ( \(i, j\) ) entry equal to distance between observation \(i\) and observation \(j\).

\section*{Metrics}

Given an \(m\)-by- \(n\) data matrix X , which is treated as \(m\) (1-by- \(n\) ) row vectors \(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{m}\), the various distances between the vector \(\mathrm{x}_{s}\) and \(\mathrm{x}_{t}\) are defined as follows:
- Euclidean distance
\[
d_{s t}^{2}=\left(x_{s}-x_{t}\right)\left(x_{s}-x_{t}\right)^{\prime}
\]

Notice that the Euclidean distance is a special case of the Minkowski metric, where \(\mathrm{p}=2\).
- Standardized Euclidean distance
\[
d_{s t}^{2}=\left(x_{s}-x_{t}\right) V^{-1}\left(x_{s}-x_{t}\right)^{\prime}
\]
where V is the \(n\)-by- \(n\) diagonal matrix whose \(j\) th diagonal element is \(S(j)^{2}\), where \(S\) is the vector of standard deviations.
- Mahalanobis distance
\[
d_{s t}^{2}=\left(x_{s}-x_{t}\right) C^{-1}\left(x_{s}-x_{t}\right)^{\prime}
\]
where C is the covariance matrix.
- City block metric
\[
d_{s t}=\sum_{j=1}^{n}\left|x_{s j}-x_{t j}\right|
\]

Notice that the city block distance is a special case of the Minkowski metric, where \(\mathrm{p}=1\).
- Minkowski metric
\[
d_{s t}=\sqrt[p]{\sum_{j=1}^{n}\left|x_{s j}-x_{t j}\right|^{p}}
\]

Notice that for the special case of \(p=1\), the Minkowski metric gives the city block metric, for the special case of \(p=2\), the Minkowski metric gives the Euclidean distance, and for the special case of \(p=\infty\), the Minkowski metric gives the Chebychev distance.
- Chebychev distance
\[
d_{s t}=\max _{j}\left\{\left|x_{s j}-x_{t j}\right|\right\}
\]

Notice that the Chebychev distance is a special case of the Minkowski metric, where \(p=\infty\).
- Cosine distance
\[
d_{s t}=1-\frac{x_{s} x_{t}^{\prime}}{\sqrt{\left(x_{s} x_{s}^{\prime}\right)\left(x_{t} x_{t}^{\prime}\right)}}
\]
- Correlation distance
\[
d_{s t}=1-\frac{\left(x_{s}-\bar{x}_{s}\right)\left(x_{t}-\bar{x}_{t}\right)^{\prime}}{\sqrt{\left(x_{s}-\bar{x}_{s}\right)\left(x_{s}-\bar{x}_{s}\right)^{\prime}} \sqrt{\left(x_{t}-\bar{x}_{t}\right)\left(x_{t}-\bar{x}_{t}\right)^{\prime}}}
\]
where
\(\bar{x}_{s}=\frac{1}{n} \sum_{j} x_{s j}\) and \(\bar{x}_{t}=\frac{1}{n} \sum_{j} x_{t j}\)
- Hamming distance
\[
d_{s t}=\left(\#\left(x_{s j} \neq x_{t j}\right) / n\right)
\]
- Jaccard distance
\[
d_{s t}=\frac{\#\left[\left(x_{s j} \neq x_{t j}\right) \cap\left(\left(x_{s j} \neq 0\right) \cup\left(x_{t j} \neq 0\right)\right)\right]}{\#\left[\left(x_{s j} \neq 0\right) \cup\left(x_{t j} \neq 0\right)\right]}
\]
- Spearman distance
\[
d_{s t}=1-\frac{\left(r_{s}-\bar{r}_{s}\right)\left(r_{t}-\bar{r}_{t}\right)^{\prime}}{\sqrt{\left(r_{s}-\bar{r}_{s}\right)\left(r_{s}-\bar{r}_{s}\right)^{\prime}} \sqrt{\left(r_{t}-\bar{r}_{t}\right)\left(r_{t}-\bar{r}_{t}\right)^{\prime}}}
\]
where
- \(r_{s j}\) is the rank of \(x_{s j}\) taken over \(x_{1 j}, x_{2 j}, \ldots x_{m j}\), as computed by tiedrank
- \(r_{s}\) and \(r_{t}\) are the coordinate-wise rank vectors of \(x_{s}\) and \(x_{t}\), i.e., \(r_{s}=\left(r_{s 1}, r_{s 2}, \ldots r_{s n}\right)\)
- \(\quad \bar{r}_{s}=\frac{1}{n} \sum_{j} r_{s j}=\frac{(n+1)}{2}\)
- \(\bar{r}_{t}=\frac{1}{n} \sum_{j} r_{t j}=\frac{(n+1)}{2}\)

Generate random data and find the unweighted Euclidean distance and then find the weighted distance using two different methods:
```

% Compute the ordinary Euclidean distance.
X = randn(100, 5);
D = pdist(X,'euclidean'); % euclidean distance
% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation.

```
```

Dstd = pdist(X,'seuclidean');
% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1]; % coordinate weights
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist(X, @(Xi,Xj) weuc(Xi,Xj,Wgts));

```

[D,I] = pdist2(X,Y,distance,'Largest',K)

```

\section*{Description}

D = pdist2 \((X, Y)\) returns a matrix \(D\) containing the Euclidean distances between each pair of observations in the \(m x\)-by- \(n\) data matrix X and \(m y\)-by- \(n\) data matrix Y . Rows of X and Y correspond to observations, columns correspond to variables. D is an \(m x\)-by- \(m y\) matrix, with the \((i, j)\) entry equal to distance between observation \(i\) in X and observation \(j\) in Y . The \((i, j)\) entry will be NaN if observation \(i\) in X or observation \(j\) in Y contain NaNs.
\(\mathrm{D}=\) pdist2(X,Y,distance) computes D using distance. Choices are:
\begin{tabular}{|c|c|}
\hline Metric & Description \\
\hline 'euclidean' & Euclidean distance (default). \\
\hline 'seuclidean' & Standardized Euclidean distance. Each coordinate difference between rows in \(X\) and \(Y\) is scaled by dividing by the corresponding element of the standard deviation computed from X , \(S=\) nanstd \((X)\). To specify another value for \(S\), use \(D=\) PDIST2 ( \(\mathrm{X}, \mathrm{Y}\), ' seuclidean ' S ). \\
\hline 'cityblock' & City block metric. \\
\hline 'minkowski' & Minkowski distance. The default exponent is 2. To compute the distance with a different exponent, use D = pdist2(X,Y,'minkowski', P), where the exponent \(P\) is a scalar positive value. \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Metric & Description \\
\hline 'chebychev' & \begin{tabular}{l}

D = pdist2(X,Y, @distfun). \\
A distance function must be of the form
\end{tabular} \\
\hline function D2 = distfun (ZI, ZJ)
\end{tabular}

\section*{Metric \(\quad\) Description}

If your data is not sparse, generally it is faster to use a built-in distance than to use a function handle.
\(\mathrm{D}=\) pdist2( \(\mathrm{X}, \mathrm{Y}\), distance, 'Smallest', K ) returns a K-by-my matrix \(D\) containing the \(K\) smallest pairwise distances to observations in \(X\) for each observation in Y. pdist2 sorts the distances in each column of \(D\) in ascending order. \(\mathrm{D}=\) pdist2(X,Y,distance, 'Largest', K ) returns the \(K\) largest pairwise distances sorted in descending order. If \(K\) is greater than \(m x\), pdist2 returns an \(m x\)-by- \(m y\) distance matrix. For each observation in Y , pdist2 finds the K smallest or largest distances by computing and comparing the distance values to all the observations in \(X\).
[ \(\mathrm{D}, \mathrm{I}]=\) pdist2(X,Y,distance, 'Smallest', K) returns a K -by-my matrix I containing indices of the observations in X corresponding to the K smallest pairwise distances in D . \([\mathrm{D}, \mathrm{I}]=\) pdist2(X,Y, distance, 'Largest', K) returns indices corresponding to the \(K\) largest pairwise distances.

\section*{Metrics}

Given an \(m x\)-by- \(n\) data matrix X , which is treated as \(m x\) (1-by- \(n\) ) row vectors \(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{m \mathrm{x}}\), and \(m y\)-by- \(n\) data matrix Y , which is treated as \(m y\) (1-by- \(n\) ) row vectors \(\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{m y}\), the various distances between the vector \(\mathrm{x}_{s}\) and \(\mathrm{y}_{t}\) are defined as follows:
- Euclidean distance
\[
d_{s t}^{2}=\left(x_{s}-y_{t}\right)\left(x_{s}-y_{t}\right)^{\prime}
\]

Notice that the Euclidean distance is a special case of the Minkowski metric, where \(\mathrm{p}=2\).

\[
d_{s t}=1-\frac{\left(x_{s}-\bar{x}_{s}\right)\left(y_{t}-\bar{y}_{t}\right)^{\prime}}{\sqrt{\left(x_{s}-\bar{x}_{s}\right)\left(x_{s}-\bar{x}_{s}\right)^{\prime}} \sqrt{\left(y_{t}-\bar{y}_{t}\right)\left(y_{t}-\bar{y}_{t}\right)^{\prime}}}
\]
where
\[
\begin{gathered}
\bar{x}_{s}=\frac{1}{n} \sum_{j} x_{s j} \text { and } \\
\bar{y}_{t}=\frac{1}{n} \sum_{j} y_{t j}
\end{gathered}
\]
- Hamming distance
\[
d_{s t}=\left(\#\left(x_{s j} \neq y_{t j}\right) / n\right)
\]
- Jaccard distance
\[
d_{s t}=\frac{\#\left[\left(x_{s j} \neq y_{t j}\right) \cap\left(\left(x_{s j} \neq 0\right) \cup\left(y_{t j} \neq 0\right)\right)\right]}{\#\left[\left(x_{s j} \neq 0\right) \cup\left(y_{t j} \neq 0\right)\right]}
\]
- Spearman distance
\[
d_{s t}=1-\frac{\left(r_{s}-\bar{r}_{s}\right)\left(r_{t}-\bar{r}_{t}\right)^{\prime}}{\sqrt{\left(r_{s}-\bar{r}_{s}\right)\left(r_{s}-\bar{r}_{s}\right)^{\prime}} \sqrt{\left(r_{t}-\bar{r}_{t}\right)\left(r_{t}-\bar{r}_{t}\right)^{\prime}}}
\]
where
- \(r_{s j}\) is the rank of \(x_{s j}\) taken over \(x_{1 j}, x_{2 j}, \ldots x_{m x, j}\), as computed by tiedrank
- \(r_{t j}\) is the rank of \(y_{t j}\) taken over \(y_{1 j}, y_{2 j}, \ldots y_{m y, j}\), as computed by tiedrank
- \(r_{s}\) and \(r_{t}\) are the coordinate-wise rank vectors of \(x_{s}\) and \(y_{t}\), i.e. \(r_{s}=\) \(\left(r_{s 1}, r_{s 2}, \ldots r_{s n}\right)\) and \(r_{t}=\left(r_{t 1}, r_{t 2}, \ldots r_{t n}\right)\)
- \(\quad \bar{r}_{s}=\frac{1}{n} \sum_{j} r_{s j}=\frac{(n+1)}{2}\)
- \(\bar{r}_{t}=\frac{1}{n} \sum_{j} r_{t j}=\frac{(n+1)}{2}\)

\section*{Examples}

Generate random data and find the unweighted Euclidean distance, then find the weighted distance using two different methods:
```

% Compute the ordinary Euclidean distance
X = randn(100, 5);
Y = randn(25, 5);
D = pdist2(X,Y,'euclidean'); % euclidean distance
% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation
Dstd = pdist2(X,Y,'seuclidean');
% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist2(X,Y, @(Xi,Xj) weuc(Xi,Xj,Wgts));

```

Purpose Pearson system random numbers
```

Syntax $\quad r=$ pearsrnd(mu, sigma, skew, kurt, m, n)
$r=$ pearsrnd(mu,sigma,skew,kurt)
$r=$ pearsrnd(mu,sigma,skew,kurt,m,n,...)
$r$ = pearsrnd(mu, sigma, skew, kurt, [m, n, ...])
[r,type] = pearsrnd(...)
[r,type,coefs] = pearsrnd(...)

```

\section*{Description}
\(r=\) pearsrnd(mu, sigma, skew, kurt, \(m, n\) ) returns an m-by-n matrix of random numbers drawn from the distribution in the Pearson system with mean mu, standard deviation sigma, skewness skew, and kurtosis kurt. The parameters mu, sigma, skew, and kurt must be scalars.

Note Because \(r\) is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.
pearsrnd uses the definition of kurtosis for which a normal distribution has a kurtosis of 3 . Some definitions of kurtosis subtract 3 , so that a normal distribution has a kurtosis of 0 . The pearsrnd function does not use this convention.

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3 .
\(r=\) pearsrnd(mu, sigma, skew, kurt) returns a scalar value.
\(r=p e a r s r n d(m u, s i g m a, s k e w, k u r t, m, n, \ldots)\) or \(r=\) pearsrnd(mu, sigma, skew, kurt, [m,n,...]) returns an m-by-n-by-... array.
[ \(r\), type] \(=\) pearsrnd (...) returns the type of the specified distribution within the Pearson system. type is a scalar integer from 0
to 7 . Set m and n to 0 to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:
- 0 - Normal distribution
- 1 - Four-parameter beta distribution
- 2 - Symmetric four-parameter beta distribution
- 3 - Three-parameter gamma distribution
- 4 - Not related to any standard distribution. The density is proportional to:
\[
\left(1+((x-a) / b)^{2}\right)^{-c} \exp (-d \arctan ((x-a) / b))
\]
- 5 - Inverse gamma location-scale distribution
- \(6-F\) location-scale distribution
- 7 - Student's \(t\) location-scale distribution
[r,type,coefs] = pearsrnd(...) returns the coefficients coefs of the quadratic polynomial that defines the distribution via the differential equation
\[
\frac{d}{d x} \log (p(x))=\frac{-(a+x)}{c(0)+c(1) x+c(2) x^{2}} .
\]

\section*{Examples}

Generate random values from the standard normal distribution:
```

r = pearsrnd(0,1,0,3,100,1); % Equivalent to randn(100,1)

```

Determine the distribution type:
```

[r,type] = pearsrnd(0,1,1,4,0,0);
r =

```

\section*{Description}

Compute Receiver Operating Characteristic (ROC) curve or other performance curve for classifier output
[ \(\mathrm{X}, \mathrm{Y}\) ] = perfcurve(labels, scores, posclass) computes a ROC curve for a vector of classifier predictions scores given true class labels, labels. labels can be a numeric vector, logical vector, character matrix, cell array of strings or categorical vector. scores is a numeric vector of scores returned by a classifier for some data. posclass is the positive class label (scalar), either numeric (for numeric labels), logical (for logical labels), or char. The returned values \(X\) and \(Y\) are coordinates for the performance curve and can be visualized with plot ( \(\mathrm{X}, \mathrm{Y}\) ). For more information on labels, scores, and posclass, see "Input Arguments" on page 20-2045 . For more information on \(X\) and Y, see "Output Arguments" on page 20-2049.
[ \(\mathrm{X}, \mathrm{Y}\) ] = perfcurve(labels,scores, posclass,'Name', value) specifies one or more optional parameter name/value pairs, with Name in single quotes. See "Input Arguments" on page 20-2045 for a list of inputs, parameter name/value pairs, and respective explanations.

See "Grouping Variables" on page 2-51 for more information on grouping variables.
```

[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] =
perfcurve(labels,scores,posclass) returns:

```
- An array of thresholds on classifier scores for the computed values of \(X\) and \(Y(T)\).
- The area under curve (AUC) for the computed values of \(X\) and \(Y\).
- The optimal operating point of the ROC curve (OPTROCPT).
- An array of \(Y\) values for negative subclasses (SUBY).

\section*{perfcurve}
- A cell array of negative class names (SUBYNAMES).

For more information on each output, see "Output Arguments" on page 20-2049.
[ \(\mathrm{X}, \mathrm{Y}, \mathrm{T}, \mathrm{AUC}]=\) perfcurve(labels,scores, posclass) also returns pointwise confidence bounds for the computed values \(\mathrm{X}, \mathrm{Y}, \mathrm{T}\), and AUC if you supply cell arrays for labels and scores or set NBoot (see "Input Arguments" on page 20-2045 ) to a positive integer. To compute the confidence bounds, perfcurve uses either vertical averaging (VA) or threshold averaging (TA). The returned values \(Y\) are an \(m\)-by- 3 array in which the 1st element in every row gives the mean value, the 2nd element gives the lower bound and the 3rd element gives the upper bound. The returned AUC is a row-vector with 3 elements following the same convention. For VA, the returned values T are an \(m\)-by- 3 array and X is a column-vector. For TA, the returned values X are an \(m\)-by- 3 matrix and \(T\) is a column-vector.
perfcurve computes confidence bounds using either cross validation or bootstrap. If you supply cell arrays for labels and scores, perfcurve uses cross validation and treats elements in the cell arrays as cross validation folds. labels can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of strings or categorical vectors. All elements in labels must have the same type. scores is a cell array of numeric vectors. The cell arrays for labels and scores must have the same number of elements, and the number of labels in cell \(k\) must be equal to the number of scores in cell \(k\) for any \(k\) in the range from 1 to the number of elements in scores.

If you set NBoot to a positive integer, perfcurve generates nboot bootstrap replicas to compute pointwise confidence bounds. You cannot supply cell arrays for labels and scores and set NBoot to a positive integer at the same time.
perfcurve returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

If you use 'XCrit' or 'YCrit' options described below to set the criterion for \(X\) or \(Y\) to an anonymous function, perfcurve can only compute confidence bounds by bootstrap.
\begin{tabular}{ll} 
Input \\
Arguments & labels \\
scores & \begin{tabular}{l} 
labels can be a numeric vector, logical vector, \\
character matrix, cell array of strings or \\
categorical vector.
\end{tabular} \\
posclass & \begin{tabular}{l} 
scores is a numeric vector of scores returned by a \\
classifier for some data. This vector must have as \\
many elements as labels does.
\end{tabular} \\
\begin{tabular}{l} 
posclass is the positive class label (scalar), \\
either numeric (for numeric labels) or char. The \\
specified positive class must be in the array of \\
input labels.
\end{tabular}
\end{tabular}

\section*{Name-Value Pair Arguments}

\section*{Name}
negClass
xCrit

\section*{Value and Description}

List of negative classes. Can be either a numeric array or an array of chars or a cell array of strings. By default, negClass is set to 'all' and all classes found in the input array of labels that are not the positive class are considered negative. If negClass is a subset of the classes found in the input array of labels, instances with labels that do not belong to either positive or negative classes are discarded.

Criterion to compute for X . This criterion must be a monotone function of the positive class score. perfcurve supports the following criteria:
- TP - Number of true positive instances.
- FN - Number of false negative instances.
- FP - Number of false positive instances.
- TN - Number of true negative instances.
- TP+FP - Sum of TP and FP.

\section*{Name}

\section*{Value and Description}
- RPP - Rate of positive predictions. RPP \(=(T P+F P) /(T P+F N+F P+T N)\)
- RNP - Rate of negative predictions. RNP \(=(T N+F N) /(T P+F N+F P+T N)\)
- accu - Accuracy. accu \(=(T P+T N) /(T P+F N+F P+T N)\)
- TPR, sens, reca - True positive rate, sensitivity, recall. TPR, sens, reca \(=\) TP/(TP+FN)
- FNR, miss - False negative rate, miss. FNR, miss=FN / (TP+FN)
- FPR, fall - False positive rate, fallout. FPR,fall=FP/(TN+FP)
- TNR, spec - True negative rate, specificity. TNR, spec=TN/ (TN+FP)
- PPV, prec - Positive predictive value, precision. PPV, prec=TP/(TP+FP)
- NPV - Negative predictive value. NPV=TN/(TN+FN)
- ecost - Expected cost. ecost \(=(T P * \operatorname{COST}(P \mid P)+F N * \operatorname{COST}(N \mid P)+F P *\) \(\operatorname{COST}(P \mid N)+T N * \operatorname{COST}(N \mid N)) /(T P+F N+F P+T N)\)

In addition, you can define an arbitrary criterion by supplying an anonymous function of three arguments, (C, scale, cost), where \(C\) is a 2 -by- 2 confusion matrix, scale is a 2 -by- 1 array of class scales, and cost is a 2 -by- 2 misclassification cost matrix.

Caution Some of these criteria return NaN values at one of the two special thresholds, 'reject all' and 'accept all'.

\section*{Name}
yCrit

XVals

TVals

UseNearest

\section*{Value and Description}

Criterion to compute for Y. perfcurve supports the same criteria as for \(X\). This criterion does not have to be a monotone function of the positive class score.
Values for the X criterion. The default value for XVals is 'all' and perfcurve computes \(X\) and \(Y\) values for all scores. If the value for xVals is not 'all', it must be a numeric array. In this case, perfcurve computes \(X\) and \(Y\) only for the specified \(X V a l s\).

Thresholds for the positive class score. By default, TVals is unset and perfcurve computes \(X\), Y , and T values for all scores. You can set TVals to either 'all' or a numeric array. If TVals is set to 'all' or unset and XVals is unset, perfcurve returns X, Y , and T values for all scores and computes pointwise confidence bounds for \(Y\) and \(X\) using threshold averaging. If TVals is set to a numeric array, perfcurve returns \(X, Y\), and \(T\) values for the specified thresholds and computes pointwise confidence bounds for \(Y\) and \(X\) at these thresholds using threshold averaging. You cannot set XVals and TVals at the same time.
'on' to use nearest values found in the data instead of the specified numeric XVals or TVals and 'off' otherwise. If you specify numeric XVals and set UseNearest to 'on', perfcurve returns nearest unique values \(X\) found in the data, as well as corresponding values of \(Y\) and \(T\). If you specify numeric XVals and set UseNearest to 'off', perfcurve returns these XVals sorted. By default this parameter is set to 'on'. If you compute confidence bounds by cross validation or bootstrap, this parameter is always 'off'.

Name
ProcessNaN

Prior

Cost

Alpha

Weights

\section*{Value and Description}

Specifies how perfcurve processes NaN scores. The default value is 'ignore' and perfcurve removes observations with NaN scores from the data. If you set the parameter to 'addtofalse ', perfcurve adds instances with NaN scores to false classification counts in the respective class. That is, perfcurve always counts instances from the positive class as false negative (FN), and always counts instances from the negative class as false positive (FP).
Either string or array with two elements. It represents prior probabilities for the positive and negative class, respectively. Default is 'empirical', that is, perfcurve derives prior probabilities from class frequencies. If set to 'uniform', perfcurve sets all prior probabilities equal.

A 2-by-2 matrix of misclassification costs [C(P|P) C(N|P); \(C(P \mid N) C(N \mid N)]\) where \(C(I \mid J)\) is the cost of misclassifying class \(J\) as class I. By default set to [0 0.5; 0.5 0].
A numeric value between 0 and 1 . perfcurve returns 100*(1-Alpha) percent pointwise confidence bounds for X, Y, T and AUC. By default set to 0.05 for \(95 \%\) confidence interval.
A numeric vector of nonnegative observation weights. This vector must have as many elements as scores or labels do. If you supply cell arrays for scores and labels and you need to supply weights, you must supply them as a cell array too. In this case, every element in weights must be a numeric vector with as many elements as the corresponding element in scores: numel (weights \(\{1\}\) ) \(==\) numel ( scores \(\{1\}\) ) etc. To compute \(X\), Y and T or to compute confidence bounds by cross validation, perfcurve uses these observation weights instead of observation counts. To compute confidence bounds by bootstrap, perfcurve samples \(N\) out of \(N\) with replacement using these weights as multinomial sampling probabilities.

\section*{Name}

NBoot

BootType

BootArg

\section*{Value and Description}

Number of bootstrap replicas for computation of confidence bounds. Must be a positive integer. By default this parameter is set to zero, and bootstrap confidence bounds are not computed. If you supply cell arrays for labels and scores, this parameter must be set to zero because perfcurve cannot use both cross validation and bootstrap to compute confidence bounds.
Confidence interval type bootci uses to compute confidence bounds. You can specify any type supported by bootci. By default set to 'bca'.

Optional input arguments for bootci used to compute confidence bounds. You can specify all arguments bootci supports. Empty by default.

\section*{Output \(x\) \\ Arguments}
\(Y \quad y\)-coordinates for the performance curve. By default, Y is true positive rate, TPR, (equivalently, recall, or sensitivity). To change this output, use the 'yCrit' input. For accepted criterion, see 'xCrit' in "Input Arguments" on page 20-2045 for more information.

T

AUC The area under curve (AUC) for the computed values of \(X\) and Y. If you set \(x\) Vals to 'all' (the default), perfcurve computes AUC using the returned \(X\) and \(Y\) values. If \(x\) Vals is a numeric array, perfcurve computes AUC using \(X\) and \(Y\) values found from all distinct scores in the interval specified by the smallest and largest elements of xVals. More precisely, perfcurve finds \(X\) values for all distinct thresholds as if XVals were set to 'all', then uses a subset of these (with corresponding \(Y\) values) between min(xVals) and max (xVals) to compute AUC. The function uses trapezoidal approximation to estimate the area. If the first or last value of \(X\) or \(Y\) are NaNs , perfcurve removes them to allow calculation of AUC. This takes care of criteria that produce NaNs for the special 'reject all' or 'accept all' thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).

OPTROCPT The optimal operating point of the ROC curve as an array of size 1-by- 2 with FPR and TPR values for the optimal ROC operating point. perfcurve computes optrocpt only for the standard ROC curve and sets to NaNs otherwise. To obtain the optimal operating point for the ROC curve, perfcurve first finds the slope, S , using
 of class \(J\) to class \(I\), and \(P=T P+F N\) and \(N=T N+F P\) are the total instance counts in the positive and negative class, respectively. perfcurve then finds the optimal operating point by moving the straight line with slope \(S\) from the upper left corner of the ROC plot (FPR=0, TPR=1) down and to the right until it intersects the ROC curve.
SUBY An array of \(Y\) values for negative subclasses. If you only specify one negative class, SUBY is identical to Y . Otherwise SUBY is a matrix of size \(M\)-by- \(K\), where \(M\) is the number of returned values for \(X\) and \(Y\), and \(K\) is the number of negative classes. perfcurve computes \(Y\) values by summing counts over all negative classes. SUBY gives values of the \(Y\) criterion for each negative class separately. For each negative class, perfcurve places a new column in SUBY and fills it with \(Y\) values for TN and FP counted just for this class.

SUBYNAMES A cell array of negative class names. If you provide an input array, negClass, of negative class names, perfcurve copies it into SUBYNAMES. If you do not provide negClass, perfcurve extracts SUBYNAMES from input labels. The order of SUBYNAMES is the same as the order of columns in \(\operatorname{SUBY}\), that is, \(\operatorname{SUBY}(:, 1)\) is for negative class SUBYNAMES \(\{1\}\) etc.

Examples Plot the ROC curve for classification by logistic regression:
```

load fisheriris
x = meas(51:end,1:2);
% iris data, 2 classes and 2 features
y = (1:100)'>50;
% versicolor=0, virginica=1
b = glmfit(x,y,'binomial');
% logistic regression
p = glmval(b,x,'logit');
% fit probabilities for scores
[X,Y,T,AUC] = perfcurve(species(51:end,:),p,'virginica');
plot(X,Y)
xlabel('False positive rate'); ylabel('True positive rate')
title('ROC for classification by logistic regression')

```

Obtain errors on TPR by vertical averaging
```

[X,Y] = perfcurve(species(51:end,:),p,'virginica',...
'nboot',1000,'xvals','all');
% plot errors

```
\(\operatorname{errorbar}(X, Y(:, 1), Y(:, 2)-Y(:, 1), Y(:, 3)-Y(:, 1)) ;\)

\section*{Purpose Enumeration of permutations}

\section*{Syntax \(\quad P=\operatorname{perms}(v)\)}

Description \(\quad P=\) perms \((v)\), where \(v\) is a row vector of length \(n\), creates a matrix whose rows consist of all possible permutations of the \(n\) elements of \(v\). The matrix P contains \(n!\) rows and \(n\) columns.
perms is only practical when \(n\) is less than about 11 (for \(n=11\), the output takes over 3 gigabytes).

\section*{Examples}
perms([2 46 6])
ans =
\(6 \quad 4 \quad 2\)
\(6 \quad 2 \quad 4\)
\(4 \quad 6 \quad 2\)
\(4 \quad 26\)
246
\(2 \quad 6 \quad 4\)

\section*{Purpose Permute dimensions of categorical array}
Syntax
B = permute(A,order)

Description
\(B=\) permute \((A\), order \()\) rearranges the dimensions of the categorical array A so that they are in the order specified by the vector order. The array produced has the same values as A but the order of the subscripts needed to access any particular element are rearranged as specified by order. The elements of order must be a rearrangement of the numbers from 1 to \(n\).

\section*{prob.PiecewiseLinearDistribution}

Superclasses ParametricTruncatableDistribution
Purpose Piecewise linear probability distribution object
Description prob.PiecewiseLinearDistribution is an object consisting of a model description for a piecewise linear probability distribution. Create a probability distribution object with specified parameters using makedist.

Construction
pd = makedist('PiecewiseLinear') creates a piecewise linear probability distribution object using the default parameter values.
pd = makedist('PiecewiseLinear','x', x, 'Fx', Fx) creates a piecewise linear probability distribution object using the specified values.

\section*{Input Arguments}

\section*{x - Data values}

1 (default) | vector of scalar values
Data values at which the cumulative distribution function (cdf) changes slope, specified as a vector of scalar values.

\author{
Data Types \\ single | double
}

\section*{Fx - cdf value}

1 (default) | vector of scalar values
cdf value at each value in \(X\), specified as a vector of scalar values. \(x\) and \(F x\) must be the same size. The first value in the vector \(F x\) must be 0 , and the last element must be 1 . Fx increases linearly between \(\mathrm{x}(j)\) and \(\mathrm{x}(j+1)\), for all \(j\).

\author{
Data Types \\ single | double
}

\section*{Properties}

\section*{\(\mathbf{x}\)}

Data values at which the cumulative distribution function (cdf) changes slope, stored as a vector of scalar values.
```

Data Types
single | double

```
Fx
cdf value at each value in \(x\), stored as a vector of scalar values.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types \\ char}

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types}

\section*{Definitions Piecewise Linear Distribution}

The piecewise linear distribution is a nonparametric probability distribution created using a piecewise linear representation of the cumulative distribution function (cdf). The options specified for the piecewise linear distribution specify the form of the cdf. The probability density function (pdf) is a step function.

\section*{Examples Create a Piecewise Linear Distribution Object Using Default Parameters}

Create a piecewise linear distribution object using the default parameter values.
```

pd = makedist('PiecewiseLinear')

```

\section*{prob.PiecewiseLinearDistribution}
```

pd =
PiecewiseLinearDistribution
F(0) = 0
F(1) = 1

```

\section*{Create a Piecewise Linear Distribution Object Using Specified Parameters}

Load the sample data. Visualize the patient weight data using a histogram.
load hospital;
hist(hospital.Weight)

The histogram shows that the data has two modes, one for female patients and one for male patients.

Compute the empirical cumulative distribution function (ecdf) for the data.
[f,x] = ecdf(hospital.Weight);
Construct a piecewise linear approximation to the ecdf and plot both functions.
```

f = f(1:5:end); % keep a less dense grid of points
x = x(1:5:end);
figure;
ecdf(hospital.Weight)
hold on
plot(x,f,'ro','MarkerFace','r') % overlay grid
plot(x,f,'k') % show interpolation

```

Create a piecewise linear probability distribution object using the piecewise approximation of the ecdf.
```

pd = makedist('PiecewiseLinear','x',x,'Fx',f)
pd =

```
    PiecewiseLinearDistribution
\(F(111)=0\)
\(F(118)=0.05\)
\(F(124)=0.13\)
\(F(130)=0.25\)
\(F(135)=0.37\)
\(F(142)=0.5\)
\(F(163)=0.55\)
\(F(171)=0.61\)
\(F(178)=0.7\)
\(F(183)=0.82\)
\(F(189)=0.94\)
\(F(202)=1\)

Generate 100 random numbers from the distribution.
```

rw = random(pd,100,1);

```

Plot the random numbers to visually compare their distribution to the original data.
figure;
hist(rw)

\section*{prob.PiecewiseLinearDistribution}

The random numbers generated from the piecewise linear distribution have the same bimodal distribution as the original data.

\section*{Purpose}

Scatter plot or added variable plot of linear model
Syntax
plot(mdl)
h = plot(mdl)

Input
Arguments

\section*{Output}

Arguments

\section*{Definitions}
plot (mdl) creates a plot of the fitted linear model. The plot type depends on the number of predictor variables.
- If there is just one predictor variable, plot creates a scatter plot of the data along with a fitted curve and confidence bounds.
- If there are multiple predictor variables, plot creates an added variable plot.
- If there are no predictors, plot creates a histogram of the residuals.
\(\mathrm{h}=\mathrm{plot}(\mathrm{mdl})\) returns handles to the lines in the plot.
mdl
Linear model, as constructed by LinearModel.fit or LinearModel.stepwise.

\section*{h}

Vector of handles to lines or patches in the plot.
Added Variable Plot, Adjusted Response
An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

\section*{LinearModel.plot}

\section*{Examples Create an Added Variable Plot}

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the carsmall data.
```

load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = LinearModel.fit(ds,'MPG ~ Year + Weight^2');

```

Create an added variable plot.
plot(mdl)

The plot illustrates that the model is significant-a horizontal line does not fit between the confidence bounds.
Alternatives Use plotAdded to select particular predictors for an added variable plot.
See AlsoLinearModel | plotAdded
How To - "Linear Regression" on page 9-11

\section*{LinearModel.plotAdded}
Purpose Added variable plot or leverage plot for linear model
Syntax plotAdded(mdl)
plotAdded(mdl, coef)

h = plotAdded(mdl,...)

h = plotAdded(mdl, coef,Name, Value)

\section*{Description}

\section*{Tips}

\section*{Input}

Arguments
plotAdded (mdl) produces a generalized added variable plot for all terms in mdl except the constant term.
plotAdded(mdl, coef) produces an added variable plot for the coef terms in mdl, after adjusting for all other terms.
\(\mathrm{h}=\mathrm{plotAdded}(\mathrm{mdl}, \ldots)\) returns handles to the lines in the plot.
h = plotAdded(mdl, coef, Name, Value) plots with additional options specified by one or more Name, Value pair arguments.
- For many plots, the Data Cursor tool in the figure window displays the \(x\) and \(y\) values for any data point, along with the observation name or number.

\section*{mdl}

Linear model, as constructed by LinearModel.fit or LinearModel.stepwise.

\section*{coef}

Coefficients in mdl. Represent as:
- String giving a single coefficient name
- Vector of coefficient numbers in the mdl. CoefficientNames property

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can

\section*{LinearModel.plotAdded}
specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Note The plot property name-value pairs apply to the first returned handle h(1).

\section*{'Color'}

Color of the line or marker, a string or ColorSpec specification. For details, see linespec.

\section*{'LineStyle'}

Type of line, a string or lineseriesproperties specification. For details, see linespec.

\section*{'LineWidth'}

Width of the line or edges of filled area, in points, a positive scalar. One point is \(1 / 72\) inch.

Default: 0.5

\section*{'MarkerEdgeColor'}

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerFaceColor'}

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerSize'}

Size of the marker in points, a strictly positive scalar. One point is \(1 / 72\) inch.

\section*{LinearModel.plotAdded}

\section*{LinearModel.plotAdjustedResponse}

Note The plot property name-value pairs apply to the first returned handle h(1).

\section*{'Color'}

Color of the line or marker, a string or ColorSpec specification. For details, see linespec.

\section*{'LineStyle'}

Type of line, a string or lineseriesproperties specification. For details, see linespec.

\section*{'LineWidth'}

Width of the line or edges of filled area, in points, a positive scalar. One point is \(1 / 72\) inch.

Default: 0.5

\section*{'MarkerEdgeColor'}

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerFaceColor'}

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerSize'}

Size of the marker in points, a strictly positive scalar. One point is \(1 / 72\) inch.

\section*{Output h}

Vector of handles to lines or patches in the plot.

\section*{LinearModel.plotAdjustedResponse}

\section*{Definitions}

\section*{Adjusted Response Plot}

The adjusted response plot shows the fitted response as a function of var, with the other predictors averaged out by averaging the fitted values over the data used in the fit. Adjusted data points are computed by adding the residual to the adjusted fitted value for each observation.

\section*{Examples Plot Adjusted Responses}

Plot the adjusted responses of a fitted linear model.
Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.
```

load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = LinearModel.fit(ds,'MPG ~ Year + Weight^2');

```

Plot the effect of 'Weight' averaged over Year values.
plotAdjustedResponse(mdl,'Weight')

Plot the effect of Year averaged over 'Weight' values. Include the h output.
h = plotAdjustedResponse(mdl,'Year');

\section*{LinearModel.plotAdjustedResponse}

Change the adjusted data to black x instead of red o .
set(h(1),'Marker','x','Color','k')

\end{tabular}
\end{tabular}

Description

Tips

Input
Arguments
plotDiagnostics(mdl) plots diagnostics from the mdl linear model using leverage as the plot type.
plotDiagnostics(mdl,plottype) plots diagnostics from the mdl generalized linear model in a plot of type plottype.
\(\mathrm{h}=\) plotDiagnostics(...) returns handles to the lines in the plot.
h = plotDiagnostics(mdl,plottype,Name, Value) plots with additional options specified by one or more Name, Value pair arguments.
- For many plots, the Data Cursor tool in the figure window displays the \(x\) and \(y\) values for any data point, along with the observation name or number.

\section*{mdl}

Generalized linear model, as constructed by GeneralizedLinearModel.fit or GeneralizedLinearModel.stepwise.

\section*{plottype}

String specifying the type of plot:
\begin{tabular}{ll} 
'contour' & \begin{tabular}{l} 
Residual vs. leverage with overlayed \\
Cook's contours
\end{tabular} \\
'cookd ' & Cook's distance \\
'leverage ' & Leverage (diagonal of Hat matrix)
\end{tabular}

\section*{GeneralizedLinearModel.plotDiagnostics}

Default: 'leverage'

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Note The plot property name-value pairs apply to the first returned handle h(1).

\section*{'Color'}

Color of the line or marker, a string or ColorSpec specification. For details, see linespec.

\section*{'LineStyle'}

Type of line, a string or lineseriesproperties specification. For details, see linespec.

\section*{'LineWidth'}

Width of the line or edges of filled area, in points, a positive scalar. One point is \(1 / 72\) inch.

Default: 0.5

\section*{'MarkerEdgeColor'}

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerFaceColor'}

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{GeneralizedLinearModel.plołDiagnostics}

\section*{'MarkerSize'}

Size of the marker in points, a strictly positive scalar. One point is \(1 / 72\) inch.

\section*{Output \\ Arguments \\ h}

\section*{Definitions}

Vector of handles to lines or patches in the plot.

\section*{Hat Matrix}

The hat matrix \(H\) is defined in terms of the data matrix \(X\) and a diagonal weight matrix \(W\) :
\[
H=X\left(X^{T} W X\right)^{-1} X^{T} W^{T}
\]
\(W\) has diagonal elements \(w_{i}\) :
\[
w_{i}=\frac{g^{\prime}\left(\mu_{i}\right)}{\sqrt{V\left(\mu_{i}\right)}}
\]
where
- \(g\) is the link function mapping \(y_{i}\) to \(x_{i} b\).
- \(g^{\prime}\) is the derivative of the link function \(g\).
- \(V\) is the variance function.
- \(\mu_{i}\) is the \(i\) th mean.

The diagonal elements \(H_{i i}\) satisfy
\[
\begin{aligned}
& 0 \leq h_{i i} \leq 1 \\
& \sum_{i=1}^{n} h_{i i}=p,
\end{aligned}
\]

\section*{GeneralizedLinearModel.plotDiagnostics}
where \(n\) is the number of observations (rows of \(X\) ), and \(p\) is the number of coefficients in the regression model.

\section*{Leverage}

The leverage of observation \(i\) is the value of the \(i\) th diagonal term of the hat matrix \(H_{i i}\). Because the sum of the leverage values is \(p\) (the number of coefficients in the regression model), an observation \(i\) can be considered to be an outlier if its leverage substantially exceeds \(p / n\), where \(n\) is the number of observations.

\section*{Cook's Distance}

The Cook's distance \(D_{i}\) of observation \(i\) is
\[
D_{i}=w_{i} \frac{e_{i}^{2}}{p \hat{\varphi}} \frac{h_{i i}}{\left(1-h_{i i}\right)^{2}},
\]
where
- \(\hat{\varphi}\) is the dispersion parameter (estimated or theoretical).
- \(e_{i}\) is the linear predictor residual, \(g\left(y_{i}\right)-x_{i} \hat{\beta}\), where
- \(g\) is the link function.
- \(y_{i}\) is the observed response.
- \(x_{i}\) is the observation.
- \(\hat{\beta}\) is the estimated coefficient vector.
- \(p\) is the number of coefficients in the regression model.
- \(h_{i i}\) is the \(i\) th diagonal element of the Hat Matrix \(H\).

\section*{Examples Diagnostic Plots for Generalized Linear Models}

Create leverage and Cook's distance plots of a fitted generalized linear model.

\section*{GeneralizedLinearModel.plołDiagnostics}

Generate artificial data for the model, Poisson random numbers with two underlying predictors \(X(1)\) and \(X(2)\).
rng('default') \% for reproducibility
rndvars = randn \((100,2)\);
X = [2+rndvars(:,1), rndvars(:,2)];
mu \(=\exp (1+X *[1 ; 2])\);
y = poissrnd(mu);
Create a generalized linear regression model of Poisson data.
```

mdl = GeneralizedLinearModel.fit(X,y,...
'y ~ x1 + x2','distr','poisson');

```

Create a leverage plot.
plotDiagnostics(mdl)

\section*{GeneralizedLinearModel.plołDiagnostics}

Create a contour plot with Cook's distance.
plotDiagnostics(mdl,'contour')

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerSize'}

Size of the marker in points, a strictly positive scalar. One point is \(1 / 72\) inch.

\section*{Output \\ h}

Arguments

\section*{Definitions}

\section*{Hat Matrix}

The hat matrix \(H\) is defined in terms of the data matrix \(X\) :
\[
H=X\left(X^{T} X\right)^{-1} X^{T} .
\]

The diagonal elements \(H_{i i}\) satisfy
\[
\begin{aligned}
& 0 \leq h_{i i} \leq 1 \\
& \sum_{i=1}^{n} h_{i i}=p,
\end{aligned}
\]
where \(n\) is the number of observations (rows of \(X\) ), and \(p\) is the number of coefficients in the regression model.

\section*{Leverage}

The leverage of observation \(i\) is the value of the \(i\) th diagonal term of the hat matrix \(H_{i i}\). Because the sum of the leverage values is \(p\) (the

\section*{LinearModel.plotDiagnostics}
number of coefficients in the regression model), an observation \(i\) can be considered to be an outlier if its leverage substantially exceeds \(p / n\), where \(n\) is the number of observations.

\section*{Cook's Distance}

Cook's distance is the scaled change in fitted values. Each element in CooksDistance is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance, \(D_{i}\), of observation \(i\) is
\[
D_{i}=\frac{\sum_{j=1}^{n}\left(\hat{y}_{j}-\hat{y}_{j(i)}\right)^{2}}{p M S E}
\]
where
- \(\hat{y}_{j}\) is the \(j\) th fitted response value.
- \(\hat{y}_{j(i)}\) is the \(j\) th fitted response value, where the fit does not include observation \(i\).
- \(M S E\) is the mean squared error.
- \(p\) is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:
\[
D_{i}=\frac{r_{i}^{2}}{p M S E}\left(\frac{h_{i i}}{\left(1-h_{i i}\right)^{2}}\right)
\]
where \(r_{i}\) is the \(i\) th residual, and \(h_{i i}\) is the \(i\) th leverage value.
CooksDistance is an \(n\)-by- 1 column vector in the Diagnostics dataset array of the LinearModel object.

\section*{LinearModel.plotDiagnostics}

\section*{Examples Leverage Plot of Linear Model}

Plot the leverage values of observations in a fitted model.
Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.
```

load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = LinearModel.fit(ds,'MPG ~ Year + Weight^2');

```

Plot the leverage values.
plotDiagnostics(mdl)

\section*{LinearModel.plotDiagnostics}

Plot the Cook's distance.
plotDiagnostics(mdl, 'cookd')

Case order plot of Cook's distance

The two diagnostic plots give different results.

Default: 0.5

\section*{'MarkerEdgeColor'}

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerFaceColor'}

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see linespec.

\section*{'MarkerSize'}

\section*{NonLinearModel.plotDiagnostics}

Size of the marker in points, a strictly positive scalar. One point is \(1 / 72\) inch.

\section*{Output}

Arguments

\section*{Definitions}

\section*{h}

Vector of handles to lines or patches in the plot.

\section*{Hat Matrix}

The hat matrix \(H\) is defined in terms of the data matrix \(X\) and the Jacobian matrix \(J\) :
\[
J_{i, j}=\left.\frac{\partial f}{\partial \beta_{j}}\right|_{x_{i}, \beta}
\]

Here \(f\) is the nonlinear model function, and \(\beta\) is the vector of model coefficients.

The Hat Matrix \(H\) is
\[
H=J\left(J^{T} J\right)^{-1} J^{T}
\]

The diagonal elements \(H_{i i}\) satisfy
\[
\begin{aligned}
& 0 \leq h_{i i} \leq 1 \\
& \sum_{i=1}^{n} h_{i i}=p
\end{aligned}
\]
where \(n\) is the number of observations (rows of \(X\) ), and \(p\) is the number of coefficients in the regression model.

\section*{Leverage}

The leverage of observation \(i\) is the value of the \(i\) th diagonal term of the hat matrix \(H_{i i}\). Because the sum of the leverage values is \(p\) (the number of coefficients in the regression model), an observation \(i\) can be considered to be an outlier if its leverage substantially exceeds \(p / n\), where \(n\) is the number of observations.

\section*{NonLinearModel.plotDiagnostics}

\section*{Cook's Distance}

The Cook's distance \(D_{i}\) of observation \(i\) is
\[
D_{i}=\frac{\sum_{j=1}^{n}\left(\hat{y}_{j}-\hat{y}_{j(i)}\right)^{2}}{p M S E}
\]
where
- \(\hat{y}_{j}\) is the \(j\) th fitted response value.
- \(\hat{y}_{j(i)}\) is the \(j\) th fitted response value, where the fit does not include observation \(i\).
- \(M S E\) is the mean squared error.
- \(p\) is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:
\[
D_{i}=\frac{r_{i}^{2}}{p M S E}\left(\frac{h_{i i}}{\left(1-h_{i i}\right)^{2}}\right),
\]
where \(e_{i}\) is the \(i\) th residual.

\section*{Examples Nonlinear Model Leverage Plot}

Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.
```

load reaction
mdl = NonLinearModel.fit(reactants,...
rate,@hougen,[1 .05 .02 .1 2]);

```

\section*{NonLinearModel.plotDiagnostics}

Create a leverage plot of the fitted model.
plotDiagnostics(mdl)

To examine the observation with high leverage, activate the Data Cursor and click the observation.

\section*{NonLinearModel.plotDiagnostics}

Alternatively, find the high-leverage observation at the command line.
```

find(mdl.Diagnostics.Leverage > 0.8)

```
ans =
6

\section*{LinearModel.plotEffects}
Purpose Plot main effects of each predictor in linear regression model
SyntaxplotEffects(mdl)h = plotEffects(mdl)
DescriptionplotEffects(mdl) produces an effects plot for the predictors in the mdlregression model. The plot shows the estimated effect on the responsefrom changing each predictor value, averaging out the effects of theother predictors. plotEffects chooses values to produce a relativelylarge effect on the response.
\(\mathrm{h}=\) plotEffects(mdl) returns handles to the lines in the plot.- For many plots, the Data Cursor tool in the figure window displaysthe \(x\) and \(y\) values for any data point, along with the observationname or number.
InputArguments
Output
Arguments
Examples Effects Plot
Plot the effects of two predictors in a fitted linear model.Load the carsmall data and fit a linear model of the mileage as afunction of model year, weight, and weight squared.
```

load carsmall
ds = dataset(MPG,Weight);

```
```

ds.Year = ordinal(Model_Year);
mdl = LinearModel.fit(ds,'MPG ~ Year + Weight^2');
Create an effects plot.
plotEffects(mdl)

```

The width of each horizontal line in the figure shows a confidence interval for the effect on the response of the listed change in each predictor. The estimated effect of changing Year from 70 to 82 is an increase of about 8 , and is between 6 and 10 with \(95 \%\) confidence.

\section*{Alternatives}

Use plotInteraction for an effects plot of the interactions of two specified variables.

\section*{LinearModel.plotEffects}

\author{
See Also LinearModel | plotAdjustedResponse | plotInteraction \\ Tułorials . "Plots to Understand Predictor Effects" on page 9-29 \\ How To • "Linear Regression" on page 9-11
}

\section*{LinearModel.plotInteraction}

\section*{Purpose}

Plot interaction effects of two predictors in linear regression model
plotInteraction(mdl, var1, var2) plotInteraction(mdl, var1, var2, ptype) h = plotInteraction(...)

\section*{Description}

Tips

\section*{Input Arguments}
plotInteraction(mdl, var1, var2) creates a plot of the interaction effects of the predictors var1 and var2 in mdl. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. The plot also shows the estimated effect with the other predictor fixed at certain values. plotInteraction chooses values to produce a relatively large effect on the response. The plot lets you examine whether the effect of one predictor depends on the value of the other predictor.
plotInteraction(mdl, var1, var2, ptype) returns a plot of the type specified in ptype.
\(\mathrm{h}=\) plotInteraction(...) returns handles to the lines in the plot.
- For many plots, the Data Cursor tool in the figure window displays the \(x\) and \(y\) values for any data point, along with the observation name or number.

\section*{mdl}

Linear model, as constructed by LinearModel.fit or LinearModel.stepwise.

\section*{var 1}

String naming the variable for plot. plotInteraction chooses values of var1 to create relatively large changes in the response. When you set ptype = 'predictions', the plot shows curves as a function of var2 with various fixed values of var1.

\section*{var2}

String naming the variable for plot. plotInteraction chooses values of var2 to create relatively large changes in the response.

\section*{LinearModel.plotInteraction}

When you set ptype = 'predictions', the plot shows curves as a function of var2 various fixed values of var1.

\section*{ptype}

String naming the plot type.
- 'effects' - The plot shows each effect as a circle, with a horizontal bar showing the confidence interval for the estimated effect. plotInteraction computes the effect values from the adjusted response curve, as shown by the plotAdjustedResponse function.
- 'predictions' - The plot shows the adjusted response curve as a function of var2, with var1 fixed at certain values.

Default: 'effects'

\section*{Output \\ Arguments}

\section*{Examples}
h
Vector of handles to lines or patches in the plot.

\section*{Interaction Plot}

Create a model of car mileage as a function of weight and model year. Then create a plot to see if the predictors have interactions.

Create a linear model of mileage from the carsmall data.
```

load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = LinearModel.fit(ds,'MPG ~ Year * Weight^2');

```

Create an interaction plot.
plotInteraction(mdl, var1, var2)

The plot might show an interaction, because the groups of points are not perfectly vertical. But the error bars seem large enough that a vertical line could pass within all of the confidence intervals for each group, possibly indicating no interaction.

\section*{Prediction Curve Interaction Plot}

Create a model of car mileage as a function of weight and model year. Then create an interaction curve plot to see if the predictors have interactions.

Create a linear model of mileage from the carsmall data.
```

load carsmall

```

\section*{LinearModel.plotInteraction}
```

ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = LinearModel.fit(ds,'MPG ~ Year * Weight^2');

```

Create an interaction plot with type 'predictions'.
plotInteraction(mdl,var1,var2,'predictions')

The curves are not parallel. This indicates interactions between the predictors. The effect is subtle enough not to definitively indicate a interaction.

\section*{LinearModel.plotInteraction}
Alternatives Use plotEffects for an effects plot showing separate effects for all predictors.
See Also LinearModel | plotAdjustedResponse | plotEffects
Tutorials - "Plots to Understand Predictor Effects" on page 9-29
How To - "Linear Regression" on page 9-11

\section*{GeneralizedLinearModel.plotResiduals}
```

Purpose Plot residuals of generalized linear regression model
Syntax plotResiduals(mdl)
plotResiduals(mdl,plottype)
h = plotResiduals(...)
h = plotResiduals(mdl,plottype,Name,Value)

```

Description

Tips

Input
Arguments
plotResiduals(mdl) gives a histogram plot of the residuals of the mdl nonlinear model.
plotResiduals(mdl, plottype) plots residuals in a plot of type plottype.
\(\mathrm{h}=\) plotResiduals(...) returns handles to the lines in the plot.
\(\mathrm{h}=\) plotResiduals(mdl, plottype, Name, Value) plots with additional options specified by one or more Name, Value pair arguments.
- For many plots, the Data Cursor tool in the figure window displays the \(x\) and \(y\) values for any data point, along with the observation name or number.

\section*{mdl}

Generalized linear model, as constructed by GeneralizedLinearModel.fit or GeneralizedLinearModel.stepwise.

\section*{plottype}

String specifying the type of plot:
\begin{tabular}{ll} 
'caseorder' & Residuals vs. case (row) order \\
'fitted' & Residuals vs. fitted values \\
'histogram' & Histogram \\
'lagged ' & \begin{tabular}{l} 
Residuals vs. lagged residual \((r(t)\) vs. \\
\(r(t-1))\)
\end{tabular}
\end{tabular}

\section*{Output \\ Arguments \\ h}

\section*{Definitions}

Vector of handles to lines or patches in the plot.

\section*{Deviance}

Deviance is twice the log likelihood of the model. Because this overall log likelihood is a sum of log likelihoods for each observation, the residual plot of deviance type shows the log likelihood per observation.

\section*{GeneralizedLinearModel.plotResiduals}

\section*{Examples Residual Plots for Generalized Linear Models}

Create residual plots of a fitted generalized linear model.
Generate artificial data for the model, Poisson random numbers with two underlying predictors \(\mathrm{X}(1)\) and \(\mathrm{X}(2)\).
```

rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);

```

Create a generalized linear regression model of Poisson data.
```

mdl = GeneralizedLinearModel.fit(X,y,...
'y ~ x1 + x2','distr','poisson');

```

Create a default residuals plot.
plotResiduals(mdl)

\section*{GeneralizedLinearModel.plotResiduals}

Histogram of residuals

Create a probability plot.
plotResiduals(mdl,'probability')

\section*{GeneralizedLinearModel.plotResiduals}

The residuals do not match a normal distribution in the tails-they are more spread out.

Create a plot of the fitted residuals of Anscombe type.

Purpose & Plot of slices through fitted linear regression surface \\
Syntax & \begin{tabular}{l} 
plotSlice \((\mathrm{mdl})\) \\
\(\mathrm{h}=\) plotSlice \((\mathrm{mdl})\)
\end{tabular}
\end{tabular}

Description

Tips

\section*{Input \\ Arguments}

\section*{Output \\ Arguments}

\section*{Examples}
plotSlice (mdl) creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by mdl. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.
\(\mathrm{h}=\) plotSlice \((\mathrm{mdl})\) returns handles to the lines in the plot.
- If there are more than eight predictors, plotSlice selects the first five for plotting. Use the Predictors menu to control which predictors are plotted.
- The Bounds menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

\section*{mdl}

Linear model, as constructed by LinearModel.fit or LinearModel.stepwise.

\section*{h}

Vector of handles to lines or patches in the plot.

\section*{Slice Plot}

Plot the slices through a fitted linear model.
Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.
```

load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);

```

\section*{LinearModel.plotSlice}
```

mdl = LinearModel.fit(ds,'MPG ~ Year + Weight^2');

```

Create a slice plot.
plotSlice(mdl)

Drag the Weight prediction line to the right and observe the change in the predicted MPG and the response curve for Year.

Purpose
Syntax

Description
Partial least-squares regression
```

[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = PLSREGRESS(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y, ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(...,param1,val1,
param2,val2,...)
[XL,YL,XS,YS,BETA, PCTVAR,MSE,stats] = PLSREGRESS(X,Y,ncomp,
...)

```
\([\mathrm{XL}, \mathrm{YL}]=\mathrm{pl}\) sregress \((\mathrm{X}, \mathrm{Y}, \mathrm{ncomp})\) computes a partial least-squares (PLS) regression of \(Y\) on \(X\), using ncomp PLS components, and returns the predictor and response loadings in XL and YL , respectively. X is an \(n\)-by- \(p\) matrix of predictor variables, with rows corresponding to observations and columns to variables. Y is an \(n\)-by- \(m\) response matrix. XL is a \(p\)-by-ncomp matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables. YL is an \(m\)-by-ncomp matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.
\([\mathrm{XL}, \mathrm{YL}, \mathrm{XS}]=\mathrm{plsregress}(\mathrm{X}, \mathrm{Y}, \mathrm{ncomp})\) returns the predictor scores XS , that is, the PLS components that are linear combinations of the variables in X. XS is an \(n\)-by-ncomp orthonormal matrix with rows corresponding to observations and columns to components.
[XL, YL, XS, YS] = plsregress(X,Y, ncomp) returns the response scores YS, that is, the linear combinations of the responses with which the PLS components XS have maximum covariance. YS is an \(n\)-by-ncomp matrix with rows corresponding to observations and columns to components. YS is neither orthogonal nor normalized.
plsregress uses the SIMPLS algorithm, first centering \(X\) and \(Y\) by subtracting off column means to get centered variables XO and YO.

However, it does not rescale the columns. To perform PLS with standardized variables, use zscore to normalize \(X\) and \(Y\).
If ncomp is omitted, its default value is min \((\operatorname{size}(X, 1)-1, \operatorname{size}(X, 2))\).
The relationships between the scores, loadings, and centered variables XO and YO are:
\(X L=(X S \backslash X O)^{\prime}=X O^{\prime *} X S\),
\(Y L=(X S \backslash Y O)^{\prime}=Y O^{\prime *} X S\),
\(X L\) and \(Y L\) are the coefficients from regressing \(X O\) and \(Y O\) on \(X S\), and \(X S * X L '\) and \(X S * Y L '\) are the PLS approximations to \(X 0\) and YO.
plsregress initially computes YS as:
YS = YO*YL = YO*YO'*XS,
By convention, however, plsregress then orthogonalizes each column of YS with respect to preceding columns of XS, so that XS' *YS is lower triangular.
[XL, YL, XS, YS, BETA] = PLSREGRESS(X,Y, ncomp, ...) returns the PLS regression coefficients BETA. BETA is a ( \(p+1\) )-by- \(m\) matrix, containing intercept terms in the first row:
```

Y = [ones(n,1),X]*BETA + Yresiduals,

```

YO = XO*BETA(2:end,:) + Yresiduals. Here Yresiduals is the vector of response residuals.
[XL, YL, XS, YS, BETA, PCTVAR] = plsregress (X, Y, ncomp) returns a 2-by-ncomp matrix PCTVAR containing the percentage of variance explained by the model. The first row of PCTVAR contains the percentage of variance explained in X by each PLS component, and the second row contains the percentage of variance explained in \(Y\).
[ \(\mathrm{XL}, \mathrm{YL}, \mathrm{XS}, \mathrm{YS}, \mathrm{BETA}, \mathrm{PCTVAR}, \mathrm{MSE}\) ] = plsregress ( \(\mathrm{X}, \mathrm{Y}, \mathrm{ncomp}\) ) returns a 2 -by-(ncomp+1) matrix MSE containing estimated mean-squared errors for PLS models with 0 : ncomp components. The first row of MSE contains mean-squared errors for the predictor variables in \(X\), and the second row contains mean-squared errors for the response variable(s) in Y .
\[
\begin{aligned}
& {[\mathrm{XL}, \mathrm{YL}, \mathrm{XS}, \mathrm{YS}, \mathrm{BETA}, \mathrm{PCTVAR}, \mathrm{MSE}]=} \\
& \text { plsregress }(. . ., \text { param1, val1, param2, val2,...) specifies optional } \\
& \text { parameter name/value pairs from the following table to control the } \\
& \text { calculation of MSE. }
\end{aligned}
\]
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'cv' & \begin{tabular}{l} 
The method used to compute MSE. \\
- When the value is a positive integer k, plsregress uses k-fold \\
cross-validation. \\
- When the value is an object of the cvpartition class, other forms of \\
cross-validation can be specified. \\
- When the value is 'resubstitution ', plsregress uses \(X\) and \(Y\) both \\
to fit the model and to estimate the mean-squared errors, without \\
cross-validation.
\end{tabular} \\
\hline 'mcreps' & \begin{tabular}{l} 
The default is 'resubstitution'.
\end{tabular} \\
\hline opositive integer indicating the number of Monte-Carlo repetitions for \\
cross-validation. The default value is 1. The value must be 1 if the value of \\
'cv' is 'resubstitution'.
\end{tabular}
[XL, YL, XS , YS , BETA, PCTVAR,MSE, stats] = PLSREGRESS ( \(X, Y\), ncomp, ...) returns a structure stats with the following fields:
- W - A p-by-ncomp matrix of PLS weights so that \(\mathrm{XS}=\mathrm{XO} * \mathrm{~W}\).
- T2 - The \(T^{2}\) statistic for each point in XS.
- Xresiduals - The predictor residuals, that is, XO-XS*XL'.
- Yresiduals - The response residuals, that is, YO-XS*YL'.

\section*{Examples}

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings:
load spectra
X = NIR;
y = octane;
Perform PLS regression with ten components:
\([\mathrm{XL}, \mathrm{yl}, \mathrm{XS}, \mathrm{YS}\), beta, PCTVAR] = plsregress \((\mathrm{X}, \mathrm{y}, 10)\);
Plot the percent of variance explained in the response variable as a function of the number of components:
```

plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');
xlabel('Number of PLS components');
ylabel('Percent Variance Explained in y');

```

Compute the fitted response and display the residuals:
```

yfit = [ones(size(X,1),1) X]*beta;
residuals = y-yfit;
stem(residuals)
xlabel('Observation');
ylabel('Residual');

```

\section*{sobolset.PointOrder property}

\section*{Purpose Point generation method}

Description The PointOrder property contains a string that specifies the order in which the Sobol sequence points are produced. The property value must be one of 'standard' or 'graycode'. When set to 'standard' the points produced match the original Sobol sequence implementation. When set to 'graycode', the sequence is generated using an implementation that uses the Gray code of the index instead of the index itself.

\section*{qrandstream.PointSet property}

Purpose Point set from which stream is drawn
Description
The PointSet property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

\section*{Examples}
```

Q = qrandstream('sobol', 5, 'Skip', 8);
% Create a new stream based on the same sequence as that in Q
Q2 = qrandstream(Q.PointSet);
u1 = qrand(Q, 10)
u2 = qrand(Q2, 10) % contains exactly the same values as u1

```

\section*{Purpose Poisson cumulative distribution function}
\[
\text { Syntax } \quad P=\operatorname{poisscdf}(X, \text { lambda })
\]

Description
\(P=\) poisscdf( \(X\), lambda) computes the Poisson cdf at each of the values in \(X\) using the corresponding mean parameters in lambda. \(X\) and lambda can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in lambda must be positive.

The Poisson cdf is
\[
p=F(x \mid \lambda)=e^{-\lambda} \sum_{i=0}^{\text {floor }(x)} \frac{\lambda^{i}}{i!}
\]

\section*{Examples}

For example, consider a Quality Assurance department that performs random tests of individual hard disks. Their policy is to shut down the manufacturing process if an inspector finds more than four bad sectors on a disk. What is the probability of shutting down the process if the mean number of bad sectors ( \(\Lambda\) ) is two?
```

probability = 1-poisscdf(4,2)
probability =
0.0527

```

About 5\% of the time, a normally functioning manufacturing process produces more than four flaws on a hard disk.

Suppose the average number of flaws ( \(\lambda\) ) increases to four. What is the probability of finding fewer than five flaws on a hard drive?
```

probability = poisscdf(4,4)
probability =
0.6288

```

This means that this faulty manufacturing process continues to operate after this first inspection almost \(63 \%\) of the time.

[lambdahat, lambdaci] \(=\) poissfit(data) \\
\\
\end{tabular} [lambdahat, lambdaci] \(=\) poissfit(data, alpha)
\end{tabular}

\section*{Description}
lambdahat = poissfit(data) returns the maximum likelihood estimate (MLE) of the parameter of the Poisson distribution, \(\lambda\), given the data data.
[lambdahat,lambdaci] = poissfit(data) also gives 95\% confidence intervals in lamdaci.
[lambdahat,lambdaci] = poissfit(data,alpha) gives \(100(1-\) alpha) \(\%\) confidence intervals. For example alpha \(=0.001\) yields \(99.9 \%\) confidence intervals.

The sample mean is the MLE of \(\lambda\).

How To . "Poisson Distribution" on page B-102

Superclasses ToolboxFittableParametricDistribution
Purpose Poisson probability distribution object
Description prob.PoissonDistribution is an object consisting of parameters, a model description, and sample data for a Poisson probability distribution.

Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd = makedist('Poisson') creates a Poisson probability distribution object using the default parameter values.
pd = makedist('Poisson','lambda',lambda) creates a Poisson distribution object using the specified parameter value.

\section*{Input Arguments}

\section*{lambda-Mean}

1 (default) | nonnegative scalar value
Mean of the Poisson distribution, specified as a nonnegative scalar value.

\section*{Data Types}
single | double

\section*{Properties}

\section*{lambda}

Mean of the Poisson distribution, stored as a nonnegative scalar value.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{prob.PoissonDistribution}

\section*{Data Types \\ char \\ InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

\section*{Data Types}
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types \\ single | double \\ ParameterCovariance}

Covariance matrix of the parameter estimates, stored as a \(p\)-by- \(p\) matrix, where \(p\) is the number of parameters in the distribution. The ( \(\mathrm{i}, \mathrm{j}\) ) element is the covariance between the estimates of the ith parameter and the \(j\) th parameter. The ( \(i, i\) ) element is the
estimated variance of the ith parameter. If parameter \(i\) is fixed rather than estimated by fitting the distribution to data, then the ( \(\mathrm{i}, \mathrm{i}\) ) elements of the covariance matrix are 0 . This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{Data Types}
char

\section*{ParameterlsFixed}

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

\section*{Data Types}
logical

\section*{ParameterNames}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types \\ char \\ ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\author{
Data Types \\ single | double \\ Truncation
}

\section*{prob.PoissonDistribution}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

\section*{Definitions Poisson Distribution}

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

The Poisson distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline lambda & Mean & \(\lambda \geq 0\) \\
\hline
\end{tabular}

The probability density function of the Poisson distribution is
\[
f(x \mid \lambda)=\frac{\lambda^{x}}{x!} e^{-\lambda} \quad ; \quad x=0,1,2, \ldots, \infty .
\]

\section*{Examples Create a Poisson Distribution Object Using Default Parameters}

\section*{Purpose}

\section*{Syntax}

Description

Examples

Poisson probability density function

Y = poisspdf(X,lambda)
\(Y=\) poisspdf( \(X\), lambda) computes the Poisson pdf at each of the values in \(X\) using mean parameters in lambda. \(X\) and lambda can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in lambda must all be positive.

The Poisson pdf is
\[
y=f(x \mid \lambda)=\frac{\lambda^{x}}{x!} e^{-\lambda} I_{(0,1, \ldots)}(x)
\]
where \(x\) can be any nonnegative integer. The density function is zero unless \(x\) is an integer.

A computer hard disk manufacturer has observed that flaws occur randomly in the manufacturing process at the average rate of two flaws in a 4 GB hard disk and has found this rate to be acceptable. What is the probability that a disk will be manufactured with no defects?

In this problem, \(\lambda=2\) and \(x=0\).

How To . "Poisson Distribution" on page B-102

Purpose Poisson random numbers
Syntax \(\quad \begin{aligned} R & =\text { poissrnd (lambda) } \\ R & =\operatorname{poissrnd}(\text { lambda }, m, n, \ldots) \\ R & =\operatorname{poissrnd}(\text { lambda },[m, n, \ldots])\end{aligned}\)

\section*{Description}
\(R=\) poissrnd(lambda) generates random numbers from the Poisson distribution with mean parameter lambda. lambda can be a vector, a matrix, or a multidimensional array. The size of \(R\) is the size of lambda.
\(R=\) poissrnd(lambda, \(m, n, \ldots\) ) or \(R=\)
poissrnd(lambda, \([m, n, \ldots])\) generates an m-by-n-by-... array. The lambda parameter can be a scalar or an array of the same size as R.

\section*{Examples}

Generate a random sample of 10 pseudo-observations from a Poisson distribution with \(\lambda=2\).
```

lambda = 2;

```
random_sample1 = poissrnd(lambda,1,10)
random_sample1 =
    \(\begin{array}{llllllllll}1 & 0 & 1 & 2 & 1 & 3 & 4 & 2 & 0 & 0\end{array}\)
random_sample2 = poissrnd(lambda,[10])
random_sample2 =
    \(\begin{array}{llllllllll} & -1 & 1 & 5 & 0 & 3 & 2 & 2 & 3 & 4\end{array}\)
random_sample3 \(=\) poissrnd(lambda(ones(1,10)))
random_sample3 =
    \(\begin{array}{llllllllll}3 & 2 & 1 & 1 & 0 & 0 & 4 & 0 & 2 & 0\end{array}\)

How To - "Poisson Distribution" on page B-102

Purpose
Polynomial confidence intervals

\section*{Syntax}
\(Y=\operatorname{polyconf}(p, X)\)
[Y,DELTA] = polyconf( \(p, X, S\) )
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)

\section*{Description}
\(Y=\) polyconf \((p, X)\) evaluates the polynomial \(p\) at the values in \(X . p\) is
a vector of coefficients in descending powers.
[ \(\mathrm{Y}, \mathrm{DELTA}\) ] = polyconf( \(\mathrm{p}, \mathrm{X}, \mathrm{S}\) ) takes outputs p and S from polyfit and generates \(95 \%\) prediction intervals \(Y\) - DELTA for new observations at the values in X .
[Y, DELTA] = polyconf( \(\mathrm{p}, \mathrm{X}, \mathrm{S}\), param1, val1, param2, val2, \(\ldots\) ) specifies optional parameter name/value pairs chosen from the following list.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline ' alpha' & \begin{tabular}{l} 
A value between 0 and 1 specifying a confidence level \\
of 100*(1-alpha)\%. The default is 0.05.
\end{tabular} \\
\hline 'mu ' & \begin{tabular}{l} 
A two-element vector containing centering and \\
scaling parameters. With this option, polyconf uses \\
(X-mu(1)) /mu (2) in place of X.
\end{tabular} \\
\hline 'predopt' & \begin{tabular}{l} 
Either 'observation' (the default) to compute \\
prediction intervals for new observations at the \\
values in X, or 'curve ' to compute confidence \\
intervals for the fit evaluated at the values in X. See \\
below.
\end{tabular} \\
\hline 'simopt' & \begin{tabular}{l} 
Either 'off' (the default) for nonsimultaneous \\
bounds, or 'on' for simultaneous bounds. See below.
\end{tabular} \\
\hline
\end{tabular}

The 'predopt' and 'simopt ' parameters can be understood in terms of the following functions:
- \(p(x)\) - the unknown mean function estimated by the fit
- \(l(x)\) - the lower confidence bound
- \(u(x)\) - the upper confidence bound

Suppose you make a new observation \(y_{n+1}\) at \(x_{n+1}\), so that
\[
y_{n+1}\left(x_{n+1}\right)=p\left(x_{n+1}\right)+\varepsilon_{n+1}
\]

By default, the interval \(\left[l_{n+1}\left(x_{n+1}\right), u_{n+1}\left(x_{n+1}\right)\right]\) is a \(95 \%\) confidence bound on \(y_{n+1}\left(x_{n+1}\right)\).
The following combinations of the 'predopt' and 'simopt' parameters allow you to specify other bounds.
\begin{tabular}{l|l|l}
\hline 'simopt & 'predopt' & Bounded Quantity \\
\hline 'off' & 'observation' & \(y_{n+1}\left(x_{n+1}\right)\) (default) \\
\hline 'off' & 'curve' & \(p\left(x_{n+1}\right)\) \\
\hline 'on' & 'observation' & \(y_{n+1}(x)\), for all \(x\) \\
\hline 'on' & 'curve' & \(p(x)\), for all \(x\) \\
\hline
\end{tabular}

In general, 'observation' intervals are wider than 'curve' intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors \(x\).

This example uses code from the documentation example function polydemo, and calls the documentation example function polystr to convert the coefficient vector \(p\) into a string for the polynomial expression displayed in the figure title. It combines the functions polyfit, polyval, roots, and polyconf to produce a formatted display of data with a polynomial fit.

Note Statistics Toolbox documentation example files are located in the \help\toolbox\stats \(\backslash\) examples subdirectory of your MATLAB root folder (matlabroot). This subdirectory is not on the MATLAB path at installation. To use the files in this subdirectory, either add the subdirectory to the MATLAB path (addpath) or make the subdirectory your current working folder (cd).

Display simulated data with a quadratic trend, a fitted quadratic polynomial, and \(95 \%\) prediction intervals for new observations:
```

xdata = -5:5;
ydata = x.^2 - 5*x - 3 + 5*randn(size(x));
degree = 2; % Degree of the fit
alpha = 0.05; % Significance level
% Compute the fit and return the structure used by
% POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);
% Compute the real roots and determine the extent of the
% data.
r = roots(p)'; % Roots as a row vector.
real_r = r(imag(r) == 0); % Real roots.
% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));
% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);

```
```

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);
% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);
hroots = plot(real_r,zeros(size(real_r)),...
'bo','MarkerSize',5,...
'LineWidth',2,...
'MarkerFaceColor','b');
grid on
plot(xfit,zeros(size(xfit)),'k-','LineWidth',2)
axis([mx-sx Mx+sx my-sy My+sy])
% Add prediction intervals to the plot.
[Y,DELTA] = polyconf(p,xfit,S,'alpha',alpha);
hconf = plot(xfit,Y+DELTA,'b--');
plot(xfit,Y-DELTA,'b--')
% Display the polynomial fit and the real roots.
approx_p = round(100*p)/100; % Round for display.
htitle = title(['{\bf Fit: }',...
texlabel(polystr(approx_p))]);
set(htitle,'Color','b')
approx_real_r = round(100*real_r)/100; % Round for display.
hxlabel = xlabel(['{\bf Real Roots: }',...
num2str(approx_real_r)]);
set(hxlabel,'Color','b')
% Add a legend.

Purpose Interactive polynomial fitting
```

Syntax polytool
polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha, xname, yname)
h = polytool(...)

```

\section*{Description}

\section*{Examples}
polytool
polytool ( \(\mathrm{x}, \mathrm{y}\) ) fits a line to the vectors x and y and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.
polytool ( \(x, y, n\) ) initially fits a polynomial of degree \(n\). The default is 1 , which produces a linear fit.
polytool(x,y,n,alpha) initially plots 100(1-alpha)\% confidence intervals on the predicted values. The default is 0.05 which results in \(95 \%\) confidence intervals.
polytool( \(x, y, n\), alpha, xname, yname) labels the \(x\) and \(y\) values on the graphical interface using the strings xname and yname. Specify \(n\) and alpha as [] to use their default values.
\(\mathrm{h}=\) polytool(...) outputs a vector of handles, h , to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

\section*{Interactive polynomial fitting}

This example shows how to start an interactive fitting session with polytool.

Generate data from a quadratic curve with added noise.
```

rng('default') % for reproducibility
x = -5:5;

```
```

y = x.^2 - 5*x - 3 + 5*randn(size(x));

```

Fit a quadratic (degree-2) model with 0.90 confidence intervals.
```

n = 2;
alpha = 0.1;
polytool(x,y,n,alpha)

```

Purpose Posterior probabilities of components
\(\begin{array}{ll}\text { Syntax } & P=\text { posterior }(o b j, X) \\ & {[P, n l o g l]=\operatorname{posterior}(o b j, X)}\end{array}\)
Description \(\quad P=\) posterior \((o b j, X)\) returns the posterior probabilities of each of the \(k\) components in the Gaussian mixture distribution defined by obj for each observation in the data matrix X . X is \(n\)-by- \(d\), where \(n\) is the number of observations and \(d\) is the dimension of the data. obj is an object created by gmdistribution or fit. P is \(n\)-by- \(k\), with \(\mathrm{P}(\mathrm{I}, \mathrm{J})\) the probability of component \(J\) given observation I.
posterior treats NaN values as missing data. Rows of X with NaN values are excluded from the computation.
[P, nlogl] = posterior(obj, X) also returns nlogl, the negative log-likelihood of the data.

\section*{Examples}

Generate data from a mixture of two bivariate Gaussian distributions using the mvnrnd function:
```

MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];
scatter(X(:,1),X(:,2),10,'.')
hold on

```

Fit a two-component Gaussian mixture model:
```

obj = gmdistribution.fit(X,2);
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);

```

\section*{gmdistribution.posterior}

Compute posterior probabilities of the components:
```

P = posterior(obj,X);
delete(h)
scatter(X(:,1),X(:,2),10,P(:,1),'.')
hb = colorbar;
ylabel(hb,'Component 1 Probability')

```

\section*{NaiveBayes.posterior}

\section*{Purpose Compute posterior probability of each class for test data}

\author{
Syntax \\ \section*{Description}
}
post = posterior(nb,test)
[post,cpre] = posterior(nb,test)
[post,cpre,logp] = posterior(nb,test)
[...] = posterior(..., 'HandleMissing',val)
post = posterior(nb,test) returns the posterior probability of the observations in test according to the NaiveBayes object nb. test is a \(N\)-by-nb.ndims matrix, where \(N\) is the number of observations in the test data. Rows of test correspond to points, columns of test correspond to features. post is a N -by-nb.nclasses matrix containing the posterior probability of each observation for each class. post (i, \(j\) ) is the posterior probability of point I belonging to class j . Classes are ordered the same as nb.clevels, i.e., column \(j\) of post corresponds to the \(j\) th class in nb.clevels. The posterior probabilities corresponding to any empty classes are NaN.
[post, cpre] = posterior(nb,test) returns cpre, an N-by-1 vector, containing the class to which each row of test has been assigned. cpre has the same type as nb.CLevels.
[post, cpre, logp] = posterior(nb,test) returns logp, an N-by-1 vector containing estimates of the log of the probability density function (PDF). \(\log (i)\) is the \(\log\) of the PDF of point \(i\). The PDF value of point \(i\) is the sum of \(\operatorname{Prob}(\) point \(\mathrm{I} \mid\) class J) * \(\operatorname{Pr}\{\) class J\} taken over all classes.
[...] = posterior(..., 'HandleMissing', val) specifies how posterior treats NaN (missing values). val can be one of the following:
\begin{tabular}{ll} 
'off' \\
(default) & \begin{tabular}{l} 
Observations with NaN in any of the columns are not \\
classified into any class. The corresponding rows in \\
post and logp are NaN. The corresponding rows in \\
cpre are NaN (if obj.clevels is numeric or logical), \\
empty strings (if obj.clevels is char or cell array of \\
strings) or (if obj.clevels is categorical).
\end{tabular} \\
'on' & \begin{tabular}{l} 
For observations having NaN in some (but not all) \\
columns, post and cpre are computed using the \\
columns with non-NaN values. Corresponding logp \\
values are NaN.
\end{tabular}
\end{tabular}

See Also NaiveBayes | fit | predict

\section*{prctile}

\section*{Purpose Percentiles of a data set}
Syntax \(\quad\)\begin{tabular}{rl}
\(Y\) & \(=\operatorname{prctile}(X, p)\) \\
\(Y\) & \(=\operatorname{prctile}(X, p, \operatorname{dim})\)
\end{tabular}

Description

Arguments
\(Y=\operatorname{prctile}(X, p)\) returns percentiles of the values in a data vector or matrix \(X\) for the percentages \(p\) in the interval \([0,100]\).
- If \(X\) is a vector, then \(Y\) is a scalar or a vector with the same length as the number of percentiles required (length \((\mathrm{p})\) ). \(\mathrm{Y}(\mathrm{i})\) contains the \(p(i)\) percentile.
- If \(X\) is a matrix, then \(Y\) is a row vector or a matrix, where the number of rows of \(Y\) is equal to the number of percentiles required (length \((p)\) ). The ith row of \(Y\) contains the \(p(i)\) percentiles of each column of \(X\).
- For multidimensional arrays, prctile operates along the first nonsingleton dimension of \(X\).
\(Y=p r c t i l e(X, p, d i m)\) returns percentiles along dimension dim.

\section*{X - Input data}
vector | array
Input data, specified as a vector or array.
Data Types
double | single
p - Percentages
scalar | vector
Percentages for which to compute percentiles, returned as a scalar or vector of scalars from 0 to 100 .

Example: 25
Example: [25, 50, 75]

\section*{Data Types \\ double | single \\ dim - Dimension \\ 1 (default) | positive integer}

Dimension along which the percentiles of \(X\) are required, specified as a positive integer. For example, for a matrix \(X\), when dim \(=1\), prctile returns the quantile(s) of the columns of \(X\) and when dim \(=2\), quantile returns the quantile(s) of the rows of \(X\). For a multidimensional array \(X\), the length of the dimth dimension of \(Y\) is equal to the length of \(p\).

\section*{Data Types \\ double}

\section*{Output \\ Arguments \\ Y - Percentiles \\ scalar | array}

Percentiles of a data vector or array, specified as a scalar or array for one or more percentage values.
- If \(X\) is a vector, then \(Y\) is a scalar or a vector with the same length as the number of percentiles required (length ( \(p\) )). \(Y(i)\) contains the \(\mathrm{p}(\mathrm{i})\) th percentile.
- If \(X\) is a matrix, then \(Y\) is a vector or a matrix with the length of the dimth dimension equal to the number percentiles required (length \((p)\) ). When dim \(=1\), for example, the ith row of \(Y\) contains the \(p(i)\) th percentiles of columns of \(X\).
- If X is an array of dimension \(d\), then Y is an array with the length of the dimth dimension equal to the number of percentiles required (length(p)).

\section*{Definitions Multidimensional Array}

A multidimensional array is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a 3-D array.

\section*{Nonsingleton Dimension}

A first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if X is a 1 -by- 2 -by- 3 -by- 4 array, then the second dimension is the first nonsingleton dimension of X .

\section*{Linear Interpolation}

Linear interpolation uses linear polynomials to find \(y_{i}=\mathrm{f}\left(x_{i}\right)\), the values of the underlying function \(Y=\mathrm{f}(X)\) at the points in the vector or array \(x\). Given the data points \(\left(x_{1}, y_{1}\right)\) and \(\left(x_{2}, y_{2}\right)\), where \(y_{1}=\mathrm{f}\left(x_{1}\right)\) and \(y_{2}=\) \(\mathrm{f}\left(x_{2}\right)\), linear interpolation finds \(y=\mathrm{f}(x)\) for a given \(x\) between \(x_{1}\) and \(x_{2}\) as follows:
\[
y=f(x)=y_{1}+\frac{\left(x-x_{1}\right)}{\left(x_{2}-x_{1}\right)}\left(y_{2}-y_{1}\right)
\]

Similarly, if the \(100(1.5 / n)\) th percentile is \(y_{1.5 / n}\) and the \(100(2.5 / n)\) th percentile is \(y_{2.5 / n}\), then linear interpolation finds the \(100(2.3 / n)\) th percentile, \(y_{2.3 / n}\) as:
\[
y_{\frac{2.3}{n}}=y_{\frac{1.5}{n}}+\frac{\left(\frac{2.3}{n}-\frac{1.5}{n}\right)}{\left(\frac{2.5}{n}-\frac{1.5}{n}\right)}\left(y_{\frac{2.5}{n}}-y_{\frac{1.5}{n}}\right)
\]

\section*{Algorithms}

For an \(n\)-element vector X , prctile returns percentiles as follows:
1 The sorted values in X are taken as the \(100(0.5 / n)\) th, \(100(1.5 / n)\) th, \(\ldots\), \(100([n-0.5] / n)\) th percentiles. For example:
- For a data vector of five elements such as \(\{6,3,2,10,1\}\), the sorted elements \(\{1,2,3,6,10\}\) respectively correspond to the 10th, 30 th, 50 th, 70th, and 90th percentiles.
- For a data vector of six elements such as \(\{6,3,2,10,8,1\}\), the sorted elements \(\{1,2,3,6,8,10\}\) respectively correspond to the
(50/6)th, (150/6)th, (250/6)th, (350/6)th, (450/6)th, and (550/6)th percentiles.

2 prctile uses linear interpolation to compute percentiles for percentages between \(100(0.5 / n)\) and \(100([n-0.5] / n)\).

3 prctile assigns the minimum or maximum values in \(X\) to the percentiles corresponding to the percentages outside that range.
prctile treats NaNs as missing values and removes them.

\section*{Examples Percentiles of a Data Vector}

Generate a data set of size 10 .
```

rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
x =
6.0753 8.6678 0.4823 6.7243 5.6375 2.3846 4.132

```

Calculate the 42 nd percentile.
\(Y=\operatorname{prctile}(X, 42)\)
\(Y=\)
5.6709

\section*{Percentiles of a Data Matrix}

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.
\(X=(1: 5)^{\prime *}(2: 6)\)

X =

\section*{prctile}
\begin{tabular}{rrrrr}
2 & 3 & 4 & 5 & 6 \\
4 & 6 & 8 & 10 & 12 \\
6 & 9 & 12 & 15 & 18 \\
8 & 12 & 16 & 20 & 24 \\
10 & 15 & 20 & 25 & 30
\end{tabular}

Calculate the 25th, 50th, and 75 th percentiles along the columns of X .
```

Y = prctile(X,[25 50 75],1)

```
\(Y=\)
\begin{tabular}{rrrrr}
3.5000 & 5.2500 & 7.0000 & 8.7500 & 10.5000 \\
6.0000 & 9.0000 & 12.0000 & 15.0000 & 18.0000 \\
8.5000 & 12.7500 & 17.0000 & 21.2500 & 25.5000
\end{tabular}

The rows of \(Y\) correspond to the percentiles of columns of \(X\). For example, the 25 th, 50 th , and 75 th percentiles of the third column of \(X\) with elements \((4,8,12,16,20)\) are 7,12 , and 17 , respectively. \(Y=\) prctile ( \(\mathrm{X},\left[\begin{array}{ll}25 & 50 \\ 75\end{array}\right]\) ) returns the same percentile matrix.

Calculate the 25 th, 50 th, and 75 th percentiles along the rows of \(x\).
\(Y=\operatorname{prctile}(X,[255075], 2)\)
\(Y=\)
\begin{tabular}{rrr}
2.7500 & 4.0000 & 5.2500 \\
5.5000 & 8.0000 & 10.5000 \\
8.2500 & 12.0000 & 15.7500 \\
11.0000 & 16.0000 & 21.0000 \\
13.7500 & 20.0000 & 26.2500
\end{tabular}

The rows of \(Y\) correspond to the percentiles of rows of \(X\). For example, the 25 th, 50 th, and 75 th percentiles of the first row of \(X\) with elements \((2,3,4,5,6)\) are \(2.75,4\), and 5.25 , respectively.

}

\section*{ClassificationKNN.predict}

Purpose Predict \(k\)-nearest neighbor classification
Syntax label = predict(mdl, Xnew)
[label,score] = predict(mdl,Xnew)
[label,score,cost] = predict(mdl,Xnew)

Description

Input
Arguments
mdl
label \(=\) predict(mdl, Xnew) returns a vector of predicted class labels for a matrix Xnew, based on mdl, a ClassificationKNN model.
[label, score] = predict(mdl,Xnew) returns a matrix of scores, indicating the likelihood that a label comes from a particular class.
[label, score, cost] = predict(mdl, Xnew) returns a matrix of costs; label is the vector of minimal costs for each row of cost
\(k\)-nearest neighbor classifier, created by ClassificationKNN.fit.

\section*{Xnew}

Points at which mdl predicts classifications. Each row of Xnew is one point. The number of columns in Xnew must equal the number of predictors in mdl.

\section*{Output \\ label} Arguments

Predicted class labels for the points in Xnew, a vector with length equal to the number of rows of Xnew. The label is the class with minimal expected cost. See "Predicted Class Label" on page 20-2181.

\section*{score}

Numeric matrix of size N -by-K, where N is the number of observations (rows) in Xnew, and \(K\) is the number of classes (in mdl.ClassNames). score ( \(\mathrm{i}, \mathrm{j}\) ) is the posterior probability that row i of Xnew is of class j. See "Posterior Probability" on page 20-2181.

\section*{cost}

\section*{ClassificationKNN.predict}

Matrix of expected costs of size N -by-K, where N is the number of observations (rows) in Xnew, and \(K\) is the number of classes (in mdl. ClassNames). cost ( \(i, j\) ) is the cost of classifying row \(i\) of \(X\) as class j. See "Expected Cost" on page 20-2182.

\section*{Definitions}

\section*{Predicted Class Label}
predict classifies so as to minimize the expected classification cost:
\[
\hat{y}=\underset{y=1, \ldots, K}{\arg \min } \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),
\]
where
- \(\hat{y}\) is the predicted classification.
- \(K\) is the number of classes.
- \(\hat{P}(k \mid x)\) is the posterior probability of class \(k\) for observation \(x\).
- \(C(y \mid k)\) is the cost of classifying an observation as \(y\) when its true class is \(k\).

\section*{Posterior Probability}

For a vector (single query point) Xnew and model mdl, let:
- \(K\) be the number of nearest neighbors used in prediction, mdl. NumNeighbors
- nbd (mdl, Xnew) be the K nearest neighbors to Xnew in mdl. X
- \(Y(n b d)\) be the classifications of the points in nbd (mdl, Xnew), namely mdl.Y(nbd)
- \(W\) (nbd) be the weights of the points in nbd(mdl, Xnew)
- prior be the priors of the classes in mdl. Y

\section*{ClassificationKNN.predict}

If there is a vector of prior probabilities, then the observation weights \(W\) are normalized by class to sum to the priors. This might involve a calculation for the point Xnew, because weights can depend on the distance from Xnew to the points in mdl. X .

The posterior probability \(p(j \mid \mathrm{Xnew})\) is
\[
p(j \mid \text { Xnew })=\frac{\sum_{i \in \mathrm{nbd}} W(i) 1_{Y(X(i)=j)}}{\sum_{i \in \mathrm{nbd}} W(i)}
\]

Here, \(1_{Y(X(i)=j)}\) means 1 when mdl. \(Y(i)=j\), and 0 otherwise.

\section*{True Misclassification Cost}

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.
You can set the true misclassification cost per class in the Cost name-value pair when you run ClassificationKNN.fit. Cost(i,j) is the cost of classifying an observation into class \(j\) if its true class is i. By default, \(\operatorname{Cost}(i, j)=1\) if \(i \sim=j\), and \(\operatorname{cost}(i, j)=0\) if \(i=j\). In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

\section*{Expected Cost}

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of predict is the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier mdl. Suppose you have K classes. You place the observations into a matrix Xnew with one observation per row. The command
[label,score, cost] = predict(mdl,Xnew)

\section*{ClassificationKNN.predict}
returns, among other outputs, a cost matrix of size Nobs-by-K. Each row of the cost matrix contains the expected (average) cost of classifying the observation into each of the \(K\) classes. cost \((n, k)\) is
\[
\sum_{i=1}^{K} \hat{P}(i \mid X n e w(n)) C(k \mid i)
\]
where
- \(K\) is the number of classes.
- \(\hat{P}(i \mid \operatorname{Xnew}(n))\) is the posterior probability of class \(i\) for observation Xnew(n).
- \(C(k \mid i)\) is the true misclassification cost of classifying an observation as \(k\) when its true class is \(i\).

\section*{Examples KNN Classification Predictions}

Construct a \(k\)-nearest neighbor classifier for the Fisher iris data, where \(k=5\). Evaluate some model predictions on new data.

Load the data.
load fisheriris
X = meas;
\(Y\) = species;

Construct a classifier for 5-nearest neighbors.
```

mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5);

```

Predict the classifications for flowers with minimum, mean, and maximum characteristics.
```

Xnew = [min(X);mean(X);max(X)];
[label,score,cost] = predict(mdl,Xnew)

```

\section*{ClassificationKNN.predict}
```

label =
setosa'
'versicolor'
virginica'
score =
1 0 0
0}1
0 0
cost =
0}
1 0 1
1 1 0

```

The classifications have binary values for the score and cost matrices, meaning all five nearest neighbors of each of the three points have identical classifications.

\section*{See Also ClassificationknN I}

\section*{Related \\ - "Predict Classification Based on a KNN Classifier" on page 15-27 \\ Examples}

\section*{Concepts \\ - "Classification Using Nearest Neighbors" on page 15-9}

\section*{CompactClassificationDiscriminant.predict}

\section*{Purpose Predict classification}

Syntax label \(=\operatorname{predict}(o b j, x)\)
[label,score] = predict(obj, X)
[label,score,cost] = predict(obj,X)

Description

Input Arguments

\section*{Output Arguments}
label \(=\) predict \((\mathrm{obj}, \mathrm{X})\) returns a vector of predicted class labels for a matrix \(X\), based on obj, a trained full or compact classifier.
[label,score] = predict(obj,X) returns a matrix of scores (posterior probabilities).
[label, score, cost] = predict(obj,X) returns a matrix of costs; label is the vector of minimal costs for each row of cost.

\section*{obi}

Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with ClassificationDiscriminant.fit.

\section*{X}

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in obj.

\section*{label}

Vector of class labels of the same type as the response data used in training obj. Each entry of labels corresponds to a predicted class label for the corresponding row of X ; see "Predicted Class Label" on page 20-2187.

\section*{score}

Numeric matrix of size N -by-K, where N is the number of observations (rows) in \(X\), and \(K\) is the number of classes (in

\section*{CompactClassificationDiscriminant.predict}
obj.ClassNames). score ( \(i, j\) ) is the posterior probability that row \(i\) of \(X\) is of class \(j\); see "Posterior Probability" on page 20-2186.

\section*{cost}

Matrix of expected costs of size N-by-K. cost (i,j) is the cost of classifying row i of \(X\) as class j. See "Cost" on page 20-2187.

\section*{Definitions}

\section*{Posterior Probability}

The posterior probability that a point \(z\) belongs to class \(j\) is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean \(\mu_{j}\) and covariance \(\Sigma_{j}\) at a point \(z\) is
\[
P(x \mid k)=\frac{1}{\left(2 \pi\left|\Sigma_{k}\right|\right)^{1 / 2}} \exp \left(-\frac{1}{2}\left(x-\mu_{k}\right)^{T} \Sigma_{k}^{-1}\left(x-\mu_{k}\right)\right),
\]
where \(\left|\Sigma_{k}\right|\) is the determinant of \(\Sigma_{k}\), and \(\Sigma_{k}^{-1}\) is the inverse matrix.
Let \(P(k)\) represent the prior probability of class \(k\). Then the posterior probability that an observation \(x\) is of class \(k\) is
\[
\hat{P}(k \mid x)=\frac{P(x \mid k) P(k)}{P(x)}
\]
where \(P(x)\) is a normalization constant, the sum over \(k\) of \(P(x \mid k) P(k)\).

\section*{Prior Probability}

The prior probability is one of three choices:
- 'uniform' - The prior probability of class k is one over the total number of classes.
- 'empirical' - The prior probability of class \(k\) is the number of training samples of class \(k\) divided by the total number of training samples.

\section*{CompactClassificationDiscriminant.predict}
- Custom - The prior probability of class k is the kth element of the prior vector. See ClassificationDiscriminant.fit.

After creating a classifier obj, you can set the prior by dot addressing:
```

obj.Prior = v;

```
where \(v\) is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

\section*{Cost}

The matrix of expected costs per observation is defined in "Cost" on page 14-8.

\section*{Predicted Class Label}
predict classifies so as to minimize the expected classification cost:
\[
\hat{y}=\underset{y=1, \ldots, K}{\arg \min } \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),
\]
where
- \(\hat{y}\) is the predicted classification.
- \(K\) is the number of classes.
- \(\hat{P}(k \mid x)\) is the posterior probability of class \(k\) for observation \(x\).
- \(C(y \mid k)\) is the cost of classifying an observation as \(y\) when its true class is \(k\).

\section*{Examples Examine predictions for a few rows in the Fisher iris data:}
```

load fisheriris
obj = ClassificationDiscriminant.fit(meas,species);
X = meas(99:102,:); % take four rows

```

\section*{CompactClassificationDiscriminant.predict}
```

[label score cost] = predict(obj,X)
label =
'versicolor'
'versicolor'
'virginica'
'virginica'
score =
0.0000 1.0000 0.0000
0.0000 0.9999 0.0001
0.0000 0.0000 1.0000
0.0000 0.0011 0.9989
cost =
1.0000 0.0000 1.0000
1.0000 0.0001 0.9999
1.0000 1.0000 0.0000
1.0000 0.9989 0.0011

```

\section*{CompactClassificationEnsemble.predict}

\section*{Purpose Predict classification}
```

Syntax labels = predict(ens,X)
[labels,score] = predict(ens,X)
[labels,...] = predict(ens,X,Name,Value)

```

\section*{Description}

Input
Arguments
labels \(=\) predict (ens, \(X\) ) returns a vector of predicted class labels for a matrix \(X\), based on ens, a trained full or compact classification ensemble.
[labels, score] = predict(ens, X) also returns scores for all classes.
[labels,...] = predict(ens,X,Name,Value) predicts classifications with additional options specified by one or more Name, Value pair arguments.

\section*{ens}

A classification ensemble created by fitensemble, or a compact classification ensemble created by compact.

\section*{X}

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in ens.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'learners'}

Indices of weak learners predict uses for computation of responses, a numeric vector.

\section*{CompactClassificationEnsemble.predict}

Default: \(1: T\), where \(T\) is the number of weak learners in ens

\section*{'UseObsForLearner'}

A logical matrix of size N -by-T, where:
- \(N\) is the number of rows of \(X\).
- T is the number of weak learners in ens.

When UseObsForLearner ( \(\mathrm{i}, \mathrm{j}\) ) is true, learner j is used in predicting the class of row i of \(X\).

Default: \(\operatorname{true}(\mathrm{N}, \mathrm{T})\)

\section*{Output \\ labels}

Arguments

\section*{Definitions}

Vector of classification labels. labels has the same data type as the labels used in training ens.

\section*{score}

A matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. predict averages these scores over all trees in the ensemble.

\section*{Score (ensemble)}

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:
- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
- Bag scores range from 0 to 1 .

\section*{CompactClassificationEnsemble.predict}
```

Examples Train a boosting ensemble for the ionosphere data, and predict the
classification of the mean of the data:
load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
Xbar = mean(X);
[ypredict score] = predict(ada,Xbar)
ypredict =
'g'
score =
-2.9460 2.9460
See Also margin | edge | loss

```

\section*{CompactClassificationTree.predict}
\begin{tabular}{|c|c|}
\hline Purpose & Predict classification \\
\hline \multirow[t]{5}{*}{Syntax} & label = predict(tree, X ) \\
\hline & [label, score] = predict(tree, X) \\
\hline & [label, score, node] = predict(tree, X) \\
\hline & [label, score, node, cnum] = predict(tree, X) \\
\hline & [label,...] = predict(tree, X, Name, Value) \\
\hline
\end{tabular}

Description

Input Arguments
label \(=\) predict(tree, \(X\) ) returns a vector of predicted class labels for a matrix X , based on tree, a trained full or compact classification tree.
[label,score] = predict(tree, X) returns a matrix of scores, indicating the likelihood that a label comes from a particular class.
[label, score, node] = predict(tree, X) returns a vector of predicted node numbers for the classification, based on tree.
[label, score, node, cnum] = predict(tree, X) returns a vector of predicted class number for the classification, based on tree.
[label,...] = predict(tree, X,Name, Value) returns labels with additional options specified by one or more Name, Value pair arguments.

\section*{tree}

A classification tree created by ClassificationTree.fit, or a compact classification tree created by compact.

\section*{X}

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in tree.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can

\section*{CompactClassificationTree.predict}
specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

\section*{'subtrees'}

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the subtrees name-value pair, tree must include a pruning sequence as created by the ClassificationTree.fit or prune methods. If subtrees has \(T\) elements, and X has N rows, then labels is an N -by- T matrix. The ith column of labels contains the fitted values produced by the subtrees (I) subtree. Similarly, score is an N-by-K-by-T array, and node and cnum are N -by-T matrices. subtrees must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use prune to prune the tree.)

Default: 0

\section*{Output Arguments}

\section*{label}

Vector of class labels of the same type as the response data used in training tree. Each entry of label corresponds to the class with minimal expected cost for the corresponding row of X. See "Predicted Class Label" on page 20-2194.

\section*{score}

Numeric matrix of size N -by-K, where N is the number of observations (rows) in \(X\), and \(K\) is the number of classes (in tree.ClassNames). score ( \(\mathrm{i}, \mathrm{j}\) ) is the posterior probability that row \(i\) of \(X\) is of class \(j\).
node
Numeric vector of node numbers for the predicted classes. Each entry corresponds to the predicted node in tree for the corresponding row of X .

\section*{cnum}

\section*{CompactClassificationTree.predict}

Numeric vector of class numbers corresponding to the predicted labels. Each entry of cnum corresponds to a predicted class number for the corresponding row of \(X\).

\section*{Definitions}

\section*{Predicted Class Label}
predict classifies so as to minimize the expected classification cost:
\[
\hat{y}=\underset{y=1, \ldots, K}{\arg \min } \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),
\]
where
- \(\hat{y}\) is the predicted classification.
- \(K\) is the number of classes.
- \(\hat{P}(k \mid x)\) is the posterior probability of class \(k\) for observation \(x\).
- \(C(y \mid k)\) is the cost of classifying an observation as \(y\) when its true class is \(k\).

\section*{Score (tree)}

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor \(X\) as true when \(X<0.15\) or \(X>0.95\), and \(X\) is false otherwise.

Generate 100 random points and classify them:
rng(0,'twister') \% for reproducibility
\(X=\operatorname{rand}(100,1)\);

\section*{CompactClassificationTree.predict}
```

Y = (abs(X - . 55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')

```

2
Prune the tree:
```

tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')

```

\section*{CompactClassificationTree.predict}

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than .15 should be about \(.05 / .85=.06\) for true, and about \(.8 / .85=.94\) for false.

3
Compute the prediction scores for the first 10 rows of X :
[~,score] = predict(tree1, X(1:10));
[score X(1:10,:)]
ans =
\begin{tabular}{rrr}
0.9059 & 0.0941 & 0.8147 \\
0.9059 & 0.0941 & 0.9058 \\
0 & 1.0000 & 0.1270 \\
0.9059 & 0.0941 & 0.9134 \\
0.9059 & 0.0941 & 0.6324 \\
0 & 1.0000 & 0.0975 \\
0.9059 & 0.0941 & 0.2785
\end{tabular}

\section*{CompactClassificationTree.predict}
\begin{tabular}{lll}
0.9059 & 0.0941 & 0.5469 \\
0.9059 & 0.0941 & 0.9575 \\
0.9059 & 0.0941 & 0.9649
\end{tabular}

Indeed, every value of \(X\) (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of \(X\) have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in \(X\) in the range \((.95,1)\) instead of the expected 5 observations.

\section*{True Misclassification Cost}

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the Cost name-value pair when you create the classifier using the ClassificationTree.fit method. Cost (i,j) is the cost of classifying an observation into class \(j\) if its true class is \(i\). By default, Cost ( \(i, j\) )=1 if \(i \sim=j\), and Cost ( \(i, j\) ) \(=0\) if \(i=j\). In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

\section*{Expected Cost}

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier. Suppose you have K classes. You place the observations into a matrix Xnew with one observation per row.

The expected cost matrix CE has size Nobs-by-K. Each row of CE contains the expected (average) cost of classifying the observation into each of the \(K\) classes. \(C E(n, k)\) is

\section*{CompactClassificationTree.predict}
\(\sum_{i=1}^{K} \hat{P}(i \mid \operatorname{Xnew}(n)) C(k \mid i)\),
where
- \(K\) is the number of classes.
- \(\hat{P}(i \mid X n e w(n))\) is the posterior probability of class \(i\) for observation Xnew(n).
- \(C(k \mid i)\) is the true misclassification cost of classifying an observation as \(k\) when its true class is \(i\).

\section*{Predictive Measure of Association}

The predictive measure of association between the optimal split on variable \(i\) and a surrogate split on variable \(j\) is:
\[
\lambda_{i, j}=\frac{\min \left(P_{L}, P_{R}\right)-\left(1-P_{L_{i} L_{j}}-P_{R_{i} R_{j}}\right)}{\min \left(P_{L}, P_{R}\right)} .
\]

Here
- \(P_{L}\) and \(P_{R}\) are the node probabilities for the optimal split of node \(i\) into Left and Right nodes respectively.
- \(P_{L_{i} L_{j}}\) is the probability that both (optimal) node \(i\) and (surrogate) node \(j\) send an observation to the Left.
- \(P_{R_{i} R_{j}}\) is the probability that both (optimal) node \(i\) and (surrogate) node \(j\) send an observation to the Right.

Clearly, \(\lambda_{i, j}\) lies from \(-\infty\) to 1 . Variable \(j\) is a worthwhile surrogate split for variable \(i\) if \(\lambda_{i, j}>0\).

\section*{CompactClassificationTree.predict}

\section*{Algorithms}

See Also
predict generates predictions by following the branches of tree until it reaches a leaf node or a missing value. If predict reaches a leaf node, it returns the classification of that node.

If predict reaches a node with a missing value for a predictor, its behavior depends on the setting of the Surrogate name-value pair when ClassificationTree.fit constructs tree.
- Surrogate \(=\) 'off' \((\) default \()\) - predict returns the label with the largest number of training samples that reach the node.
- Surrogate = 'on' - predict uses the best surrogate split at the node. If all surrogate split variables with positive predictive measure of association are missing, predict returns the label with the largest number of training samples that reach the node. For a definition, see "Predictive Measure of Association" on page 20-2198.

\text { Regression ensemble created by fitensemble, or by the compact } \\
\text { Arguments }
\end{array}
\end{array}
\]

\section*{Xdata}

Numeric array with the same number of columns as the array used for creating ens. Each row of Xdata corresponds to one data point, and each column corresponds to one predictor.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'learners'}

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NTrained

\section*{'UseObsForLearner'}

\section*{CompactRegressionEnsemble.predict}
gical matrix of size N -by-NTrained, where N is the number of observations in ens. \(X\), and NTrained is the number of weak learners. When UseObsForLearner ( \(I, J\) ) is true, predict uses learner \(J\) in predicting observation I.

Default: true(N,NTrained)

\section*{Output Arguments}

Examples Find the predicted mileage for a four-cylinder car, with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs , based on the carsmall data:
```

load carsmall
X = [Cylinders Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Mileage = predict(rens,[4 200 150 3000])
Mileage =
20.4982

```
See Also loss | fitensemble

\section*{CompactRegressionTree.predict}

Purpose Predict response of regression tree
```

Syntax Yfit = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata,Name,Value)

```

\section*{Description}

\section*{Input}

Arguments

Yfit \(=\) predict(tree, Xdata) returns predicted responses to the data in Xdata, based on the tree regression tree.
[Yfit, node] = predict(tree,Xdata) returns the predicted node numbers of tree in response to Xdata.
[Yfit, node] = predict(tree,Xdata, Name, Value) predicts response with additional options specified by one or more Name, Value pair arguments.

\section*{tree}

Regression tree created by RegressionTree.fit, or by the compact method.

\section*{Xdata}

Numeric array with the same number of columns as the array used for creating tree. Each row of Xdata corresponds to one data point, and each column corresponds to one predictor.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'subtrees'}

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the subtrees name-value pair, tree must include a pruning sequence as created by the

\section*{CompactRegressionTree.predict}

RegressionTree.fit or prune methods. If subtrees has T elements, and \(X\) has \(N\) rows, then \(Y f i t\) is an \(N\)-by-T matrix. The ith column of Yfit contains the fitted values produced by the subtrees (I) subtree. Similarly, node is an N-by-T matrix. subtrees must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use prune to prune the tree.)

Default: 0

\section*{Output Arguments}
Examples

Find the predicted mileage for a car with 200 cubic inch engine
 displacement, 150 horsepower, weighing 3000 lbs , based on the
 carsmall data:
```

load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
Mileage = predict(tree,[200 150 3000])
Mileage =
21.9375

```See Also

\section*{Yfit}

A numeric column vector with the same number of rows as Xdata. Each row of Yfit gives the predicted response to the

\section*{node}

Numeric vector of node numbers for the predictions. Each entry corresponds to the predicted leaf node in tree for the corresponding row of Xdata.
```

RegressionTree.fit | compact | loss

``` corresponding row of Xdata, based on the tree regression model.

\section*{CompactTreeBagger.predict}

\section*{Purpose Predict response}

Syntax
```

YFIT = predict(B,X)
[YFIT,stdevs] = predict(B,X)
[YFIT,scores] = predict(B,X)
[YFIT,scores,stdevs] = predict(B,X)
Y = predict(B,X,'param1',val1,'param2',val2,...)

```

\section*{Description}

YFIT \(=\) predict \((\mathrm{B}, \mathrm{X})\) computes the predicted response of the trained ensemble B for predictors X. By default, predict takes a democratic (nonweighted) average vote from all trees in the ensemble. In X, rows represent observations and columns represent variables. YFIT is a cell array of strings for classification and a numeric array for regression.

For regression, [YFIT, stdevs] = predict \((B, X)\) also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, [YFIT, scores] = predict (B,X) returns scores for all classes. scores is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. predict averages these scores over all trees in the ensemble.
[YFIT, scores, stdevs] = predict ( \(\mathrm{B}, \mathrm{X}\) ) also returns standard deviations of the computed scores for classification. stdevs is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

Y = predict(B,X,'param1',val1,'param2', val2,...) specifies optional parameter name/value pairs:

\section*{CompactTreeBagger.predict}
\begin{tabular}{ll} 
'trees' & \begin{tabular}{l} 
Array of tree indices to use for computation of \\
responses. Default is 'all'.
\end{tabular} \\
'treeweights' & \begin{tabular}{l} 
Array of NTrees weights for weighting votes from \\
the specified trees.
\end{tabular} \\
'useifort' & \begin{tabular}{l} 
Logical matrix of size Nobs-by-NTrees indicating \\
which trees to use to make predictions for each \\
observation. By default all trees are used for all \\
observations.
\end{tabular}
\end{tabular}

\section*{See Also}
classregtree.eval | TreeBagger.predict

\section*{GeneralizedLinearModel.predict}

\section*{Description}

Tips

Input
Arguments
```

Purpose Predict response of generalized linear regression model
Syntax $\quad$ ypred $=$ predict $(m d l$, Xnew $)$
[ypred,yci] = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew,Name,Value)
Predict response of generalized linear regression model
ypred = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew,Name,Value)

```
ypred \(=\) predict(mdl,Xnew) returns the predicted response of the mdl generalized linear regression model to the points in Xnew.
[ypred,yci] = predict(mdl,Xnew) returns confidence intervals for the true mean responses.
[ypred,yci] = predict(mdl,Xnew,Name,Value) predicts responses with additional options specified by one or more Name, Value pair arguments.
- For predictions with added noise, use random.
- For a syntax that can be easier to use with models created from dataset arrays, try feval.

\section*{mdl}

Generalized linear model, as constructed by GeneralizedLinearModel.fit or GeneralizedLinearModel.stepwise.

\section*{Xnew}

Points at which mdl predicts responses.
- If Xnew is a dataset array, it must contain the predictor names in mdl.
- If Xnew is a numeric matrix, it must have the same number of variables (columns) as was used to create mdl. Furthermore, all variables used in creating mdl must be numeric.

\section*{GeneralizedLinearModel.predict}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'alpha'}

Positive scalar from 0 to 1 . Confidence level of yci is 100(1 - alpha)\%.

Default: 0.05 , meaning a \(95 \%\) confidence interval.

\section*{'BinomialSize'}

Value of the binomial \(n\) parameter for each row in the training data. BinomialSize can be a vector the same length as Xnew, or a scalar that applies to each row. The default value 1 produces ypred values that are predicted proportions. Use BinomialSize only if mdl is fit to a binomial distribution.

Default: 1

\section*{'Offset'}

Value of the offset for each row in Xnew. Offset can be a vector the same length as Xnew, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1 . In other words, if \(b\) is the fitted coefficient vector, and link is the link function,
link(ypred) \(=\) Offset + Xnew * b.
Default: zeros(size(Xnew, 1))

\section*{'Simultaneous'}

\section*{GeneralizedLinearModel.predict}

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (true), or hold for each individual predictor value (false). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see polyconf.
Default: false

\section*{Output ypred \\ Arguments \\ Vector of predicted mean values at Xnew.}

\section*{yci}

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

\section*{Examples Generalized Linear Model Predictions}

Create a generalized linear model, and predict its response to new data.
Generate artificial data for the model using Poisson random numbers with two underlying predictors \(X(1)\) and \(X(2)\).
```

rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);

```

Create a generalized linear regression model of Poisson data.
```

mdl = GeneralizedLinearModel.fit(X,y,...
'y ~ x1 + x2','distr','poisson');

```

Create points for prediction.

\section*{GeneralizedLinearModel.predict}
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2); Xnew = [Xtest1(:),Xtest2(:)];

Predict responses at the new points.
ypred = predict(mdl,Xnew);
Plot the predictions.
surf(Xtest1,Xtest2, reshape(ypred,9,9))

Create confidence intervals on the predictions.
[ypred yci] = predict(mdl,Xnew);

\section*{GeneralizedLinearModel.predict}
Alternatives feval gives the same predictions, but uses separate input arrays foreach predictor, instead of one input array containing all predictors.random predicts with added noise.
See Also GeneralizedLinearModel | random |

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can

\section*{LinearModel.predict}
specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, Valuen.

\section*{'alpha'}

Positive scalar from 0 to 1 . Confidence level of yci is 100(1 - alpha)\%.

Default: 0.05, meaning a \(95 \%\) confidence interval.

\section*{'Prediction'}

String specifying the type of prediction:
- 'curve' - predict predicts confidence bounds for the fitted mean values.
- 'observation' - predict predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see polyconf.
Default: 'curve'

\section*{'Simultaneous'}

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (true), or hold for each individual predictor value (false). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see polyconf.
Default: false

\section*{Output ypred}

Vector of predicted mean values at Xnew.

\section*{yci}

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

\section*{Examples Predict Response to Data}

Create a model of car mileage as a function of weight, and predict the response.

Create a quadratic model of car mileage as a function of weight from the carsmall data.
```

load carsmall
X = Weight;
y = MPG;
mdl = LinearModel.fit(X,y,'quadratic');

```

Create predicted responses to the data.
Xnew = X;
ypred \(=\) predict(mdl,Xnew);

Plot the original responses and the predicted responses to see how they differ.
plot(X,y,'o',Xnew,ypred,'x')
legend('Data','Predictions')

\footnotetext{
Alternatives
feval gives the same predictions, but uses multiple input arrays with one component in each input argument. feval can be simpler to use with a model created from a dataset array ds. feval does not give confidence intervals on its predictions.
random predicts with added noise.

\section*{NaiveBayes.predict}

\section*{Purpose Predict class label for test data}
```

Syntax

```
Description
(default)
'on ' For observations having NaN in some (but not all) columns, post and predict computes cpre using the columns with non-NaN values. Corresponding logp values are NaN.

See Also NaiveBayes | fit | posterior

\section*{Purpose}

Predict response of nonlinear regression model
Syntax
ypred \(=\) predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew, Name, Value)

Description

Tips

Input
Arguments
ypred \(=\) predict(mdl, Xnew) returns the predicted response of the mdl nonlinear regression model to the points in Xnew.
[ypred,yci] = predict(mdl,Xnew) returns confidence intervals for the true mean responses.
[ypred,yci] = predict(mdl,Xnew,Name, Value) predicts responses with additional options specified by one or more Name, Value pair arguments.
- For predictions with added noise, use random.
- For a syntax that can be easier to use with models created from dataset arrays, try feval.
mdl
Nonlinear regression model, constructed by NonLinearModel.fit.

\section*{Xnew}

Points at which mdl predicts responses.
- If Xnew is a dataset array, it must contain the predictor names in mdl.
- If Xnew is a numeric matrix, it must have the same number of variables (columns) as was used to create mdl. Furthermore, all variables used in creating mdl must be numeric.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can

\section*{NonLinearModel.predict}
specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, Valuen.

\section*{'alpha'}

Positive scalar from 0 to 1. Confidence level of yci is 100(1 - alpha)\%.

Default: 0.05, meaning a \(95 \%\) confidence interval.

\section*{'Prediction'}

String specifying the type of prediction:
- 'curve' — predict predicts confidence bounds for the fitted mean values.
- 'observation' - predict predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see polyconf.
Default: 'curve'

\section*{'Simultaneous'}

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (true), or hold for each individual predictor value (false). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.
For details, see polyconf.
Default: false

\section*{'Weights'}

Vector of real, positive value weights or a function handle.
- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in Xnew.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W , predict estimates the error variance at observation \(i\) by MSE*(1/W(i)), where MSE is the mean squared error.

Default: No weights

\section*{Output Arguments}

\section*{ypred}

Vector of predicted mean values at Xnew.

\section*{yci}

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

\section*{Examples}

\section*{Predict Responses}

Create a nonlinear model of car mileage as a function of weight, and predict the response.

Create an exponential model of car mileage as a function of weight from the carsmall data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.
```

load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';

```

\section*{NonLinearModel.predict}
```

betaO = [1 1 1 1];
mdl = NonLinearModel.fit(X,y,modelfun,betaO);

```

Create predicted responses to the data.
Xnew = X;
ypred = predict(mdl,Xnew);
Plot the original responses and the predicted responses to see how they differ.
```

plot(X,y,'o',X,ypred,'x')
legend('Data','Predicted')

```

\section*{Confidence Intervals for Predictions}

Create a nonlinear model of car mileage as a function of weight, and examine confidence intervals of some responses.

Create an exponential model of car mileage as a function of weight from the carsmall data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.
```

load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
betaO = [1 1 1];
mdl = NonLinearModel.fit(X,y,modelfun,betaO);

```

Create predicted responses to the smallest, mean, and largest data points.
```

Xnew = [min(X);mean(X);max(X)];
[ypred,yci] = predict(mdl,Xnew)
ypred =
34.9469
22.6868
10.0617
yci =
32.5212 37.3726
21.4061 23.9674
7.0148 13.1086

```

\section*{Simultaneous Confidence Intervals for Robust Fit Curve}

Generate sample data from the nonlinear regression model
\[
y=b_{1}+b_{2} \exp \left\{-b_{3} x\right\}+\varepsilon,
\]

\section*{NonLinearModel.predict}
where \(b_{1}, b_{2}\), and \(b_{3}\) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5 .
```

modelfun = a(b,x)(b(1)+b(2)*exp(-b(3)*x));
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);

```

Fit the nonlinear model using robust fitting options.
```

opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
bO = [2;2;2];
mdl = NonLinearModel.fit(x,y,modelfun,bo,'Options',opts);

```

Plot the fitted regression model and simultaneous \(95 \%\) confidence bounds.
```

xrange = [min(x):.01:max(x)]';
[ypred,yci] = predict(mdl,xrange,'Simultaneous',true);
figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,yci','r--','LineWidth',1.5)

```

\section*{Confidence Interval Using Observation Weights}

Load sample data.
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
Specify a function handle for observation weights, then fit the
Hougen-Watson model to the rate data using the specified observation weights function.
\(\mathrm{a}=1\); \(\mathrm{b}=1\);
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
mdl = NonLinearModel.fit(X,y,@hougen, betaO, 'Weights', weights);

\section*{NonLinearModel.predict}

Compute the \(95 \%\) prediction interval for a new observation with reactant levels [100, 100, 100] using the observation weight function.
```

[ypred,yci] = predict(mdl,[100,100,100],'Prediction','observation',...
'Weights',weights)

```
```

ypred =

```
    1.8149
yci =
    \(1.5264 \quad 2.1033\)

```

Description
\(Y=p r e d i c t(B, X)\) computes predicted response of the trained ensemble \(B\) for data \(X\). The output has one prediction for each row of \(X\). The returned \(Y\) is a cell array of strings for classification and a numeric array for regression.

For regression, \([\mathrm{Y}, \mathrm{stdevs}]=\) predict \((\mathrm{B}, \mathrm{X})\) also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, [ Y, scores] = predict \((\mathrm{B}, \mathrm{X})\) returns scores for all classes. scores is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. predict averages these scores over all trees in the ensemble.
[ Y, scores,stdevs] = predict \((\mathrm{B}, \mathrm{X})\) also returns standard deviations of the computed scores for classification. stdevs is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

Y = predict(B,X,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

\section*{TreeBagger.predict}

\hline
\end{tabular}

\section*{CompactClassificationEnsemble.predictorImportance}

\section*{Definitions}

\section*{Predictor Importance}
predictor Importance computes estimates of predictor importance for ens by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. If ens is grown without surrogate splits, this sum is taken over best splits found at each branch node. If ens is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train ens. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

\section*{Impurity and Node Error}

ClassificationTree splits nodes based on either impurity or node error. Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair:
- Gini's Diversity Index (gdi) - The Gini index of a node is
\[
1-\sum_{i} p^{2}(i),
\]
where the sum is over the classes \(i\) at the node, and \(p(i)\) is the observed fraction of classes with class \(i\) that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.
- Deviance ('deviance') — With \(p(i)\) defined as for the Gini index, the deviance of a node is
\[
-\sum_{i} p(i) \log p(i)
\]

A pure node has deviance 0 ; otherwise, the deviance is positive.
- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let \(L(i)\) denote the fraction of members of class \(i\) in the left child node after a

\section*{CompactClassificationEnsemble.predictorImportance}
split, and \(R(i)\) denote the fraction of members of class \(i\) in the right child node after a split. Choose the split criterion to maximize
\[
P(L) P(R)\left(\sum_{i}|L(i)-R(i)|\right)^{2},
\]
where \(P(L)\) and \(P(R)\) are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.
- Node error - The node error is the fraction of misclassified classes at a node. If \(j\) is the class with largest number of training samples at a node, the node error is
\[
1-p(j)
\]

\section*{Predictive Measure of Association}

The predictive measure of association between the optimal split on variable \(i\) and a surrogate split on variable \(j\) is:
\[
\lambda_{i, j}=\frac{\min \left(P_{L}, P_{R}\right)-\left(1-P_{L_{i} L_{j}}-P_{R_{i} R_{j}}\right)}{\min \left(P_{L}, P_{R}\right)}
\]

Here
- \(P_{L}\) and \(P_{R}\) are the node probabilities for the optimal split of node \(i\) into Left and Right nodes respectively.
- \(P_{L_{i} L_{j}}\) is the probability that both (optimal) node \(i\) and (surrogate) node \(j\) send an observation to the Left.
- \(P_{R_{j} R_{j}}\) is the probability that both (optimal) node \(i\) and (surrogate) node \(j\) send an observation to the Right.

\section*{CompactClassificationEnsemble.predictorImportance}

Clearly, \(\lambda_{i, j}\) lies from \(-\infty\) to 1 . Variable \(j\) is a worthwhile surrogate split for variable \(i\) if \(\lambda_{i, j}>0\).
Element ma( \(\mathrm{i}, \mathrm{j})\) is the predictive measure of association averaged over surrogate splits on predictor \(j\) for which predictor \(i\) is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor \(j\) and dividing by the total number of optimal splits on predictor \(i\), including splits for which the predictive measure of association between predictors \(i\) and \(j\) is negative.

\section*{Examples}

Estimate the predictor importance for all variables in the Fisher iris data:
```

load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
imp = predictorImportance(ens)
imp =
0.0001 0.0005 0.0384 0.0146

```

The first two predictors are not very important in ens.

Estimate the predictor importance for all variables in the Fisher iris data for an ensemble where the trees contain surrogate splits:
```

load fisheriris
surrtree = ClassificationTree.template('Surrogate','on');
ens2 = fitensemble(meas,species,'AdaBoostM2',100,surrtree);
[imp2,ma] = predictorImportance(ens2)
imp2 =
0.0224 0.0142 0.0525 0.0508
ma =
1.0000 0}00.0001 0.0001
0.0115 1.0000 0.0023 0.0054

```

\section*{CompactClassificationEnsemble.predictorImportance}
\begin{tabular}{llll}
0.2810 & 0.1747 & 1.0000 & 0.5372 \\
0.0789 & 0.0463 & 0.2339 & 1.0000
\end{tabular}

The first two predictors show much more importance than in the previous example.

\author{
See Also \\ predictorImportance
}

\section*{CompactClassificationTree.predictorImportance}
\begin{tabular}{ll} 
Purpose & Estimates of predictor importance \\
Syntax & imp = predictorImportance(tree)
\end{tabular}

Description

Input
Arguments

\section*{Output} Arguments

\section*{Definitions}
imp \(=\) predictorImportance(tree) computes estimates of predictor importance for tree by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes.

\section*{tree}

A classification tree created by ClassificationTree.fit, or by the compact method.
imp
A row vector with the same number of elements as the number of predictors (columns) in tree. X. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

\section*{Predictor Importance}
predictorImportance computes estimates of predictor importance for tree by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. If tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train tree. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.
If you use surrogate splits, predictor Importance computes estimates before the tree is reduced by pruning or merging leaves. If you do not

\section*{CompactClassificationTree.predictorImportance}
use surrogate splits, predictor Importance computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

\section*{Impurity and Node Error}

ClassificationTree splits nodes based on either impurity or node error. Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair:
- Gini's Diversity Index (gdi) - The Gini index of a node is
\[
1-\sum_{i} p^{2}(i)
\]
where the sum is over the classes \(i\) at the node, and \(p(i)\) is the observed fraction of classes with class \(i\) that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.
- Deviance ('deviance') — With \(p(i)\) defined as for the Gini index, the deviance of a node is
\[
-\sum_{i} p(i) \log p(i)
\]

A pure node has deviance 0 ; otherwise, the deviance is positive.
- Twoing rule ('twoing') - Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let \(L(i)\) denote the fraction of members of class \(i\) in the left child node after a split, and \(R(i)\) denote the fraction of members of class \(i\) in the right child node after a split. Choose the split criterion to maximize
\[
P(L) P(R)\left(\sum_{i}|L(i)-R(i)|\right)^{2},
\]

\section*{CompactClassificationTree.predictorImportance}
where \(P(L)\) and \(P(R)\) are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.
- Node error - The node error is the fraction of misclassified classes at a node. If \(j\) is the class with largest number of training samples at a node, the node error is
\[
1-p(j) .
\]

\section*{Examples}

Estimate the predictor importance for all variables in the Fisher iris data:
```

load fisheriris
tree = ClassificationTree.fit(meas,species);
imp = predictorImportance(tree)
imp =

```
    \(\begin{array}{llll}0 & 0 & 0.0403 & 0.0303\end{array}\)

The first two elements of imp are zero. Therefore, the first two predictors do not enter into tree calculations for classifying irises.

Estimate the predictor importance for all variables in the Fisher iris data for a tree grown with surrogate splits:
```

tree2 = ClassificationTree.fit(meas,species,...
'Surrogate','on');
imp2 = predictorImportance(tree2)
imp2 =
0.0287 0.0136 0.0560 0.0556

```

In this case, all predictors have some importance. As you expect by comparing to the first example, the first two predictors are less important than the final two.

\section*{CompactClassificationTree.predictorImportance}

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits. For example, permute the order of the data columns in the previous example:
```

load fisheriris
meas3 = meas(:,[4 1 3 2]);
tree3 = ClassificationTree.fit(meas3,species);
imp3 = predictorImportance(tree2)
imp3 =
0.0674 0 0.0033 0

```

The estimates of predictor importance are not a permutation of imp from the first example.

Estimate the predictor importance using surrogate splits.
```

tree4 = ClassificationTree.fit(meas3,species,...
'Surrogate','on');
imp4 = predictorImportance(tree4)
imp4 =
0.0556 0.0287 0.0560 0.0136

```
imp4 is a permutation of imp2, demonstrating that estimates of predictor importance do not depend on the order of predictors with surrogate splits.

Description

\section*{Input}

Arguments

\section*{Output Arguments}

\section*{Definitions}

\section*{Predictor Importance}
predictor Importance computes estimates of predictor importance for tree by summing changes in the mean squared error (MSE) due to

\section*{CompactRegressionEnsemble.predictorImportance}
splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

\section*{Predictive Measure of Association}

The predictive measure of association between the optimal split on variable \(i\) and a surrogate split on variable \(j\) is:
\[
\lambda_{i, j}=\frac{\min \left(P_{L}, P_{R}\right)-\left(1-P_{L_{i} L_{j}}-P_{R_{i} R_{j}}\right)}{\min \left(P_{L}, P_{R}\right)}
\]

Here
- \(P_{L}\) and \(P_{R}\) are the node probabilities for the optimal split of node \(i\) into Left and Right nodes respectively.
- \(P_{L_{i} L_{j}}\) is the probability that both (optimal) node \(i\) and (surrogate) node \(j\) send an observation to the Left.
- \(P_{R_{i} R_{j}}\) is the probability that both (optimal) node \(i\) and (surrogate) node \(j\) send an observation to the Right.

Clearly, \(\lambda_{i, j}\) lies from \(-\infty\) to 1 . Variable \(j\) is a worthwhile surrogate split for variable \(i\) if \(\lambda_{i, j}>0\).
Element ma( \(\mathrm{i}, \mathrm{j})\) is the predictive measure of association averaged over surrogate splits on predictor j for which predictor \(i\) is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor \(j\) and dividing by the total number of

\section*{CompactRegressionEnsemble.predictorImportance}
optimal splits on predictor \(i\), including splits for which the predictive measure of association between predictors \(i\) and \(j\) is negative.

\section*{Examples}

Estimate the predictor importance for all numeric variables in the carsmall data:
```

load carsmall
X = [Acceleration Cylinders Displacement ...
Horsepower Model_Year Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
imp = predictorImportance(ens)
imp =
0.0082 0

```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0 ; this means the number of cylinders has no impact on predictions made with ens.

Estimate the predictor importance for all variables in the carsmall data for an ensemble where the trees contain surrogate splits:
```

load carsmall
surrtree = RegressionTree.template('Surrogate','on');
X = [Acceleration Cylinders Displacement ...
Horsepower Model_Year Weight];
ens2 = fitensemble(X,MPG,'LSBoost',100,surrtree);
[imp2,ma] = predictorImportance(ens2)
imp2 =
0.0725 0.1342
0.1425
0.1397 0.1380
0.1855
ma =

| 1.0000 | 0.0414 | 0.0607 | 0.0782 | 0.0102 | 0.0322 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 1.0000 | 0 | 0 | 0 | 0 |
| 0.0441 | 0.0704 | 1.0000 | 0.0883 | 0.0175 | 0.0913 |
| 0.0944 | 0.1166 | 0.1400 | 1.0000 | 0.0390 | 0.1308 |

```

\section*{CompactRegressionEnsemble.predictorImportance}
\begin{tabular}{llllll}
0.0121 & 0.0139 & 0.0127 & 0.0127 & 1.0000 & 0.0113 \\
0.0818 & 0.1317 & 0.2072 & 0.1878 & 0.0340 & 1.0000
\end{tabular}

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) is essentially tied for third most important predictor.

\author{

}

\section*{CompactRegressionTree.predictorImportance}

Purpose Estimates of predictor importance
Syntax imp = predictorImportance (tree)

Description

\section*{Input \\ Arguments}

\section*{Output Arguments}

\section*{Definitions}

\section*{Predictor Importance}
predictor Importance computes estimates of predictor importance for tree by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.
Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

\section*{CompactRegressionTree.predictorImportance}

\section*{Examples}

If you use surrogate splits, predictorImportance computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, predictorImportance computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

Find predictor importance for the carsmall data. Use just the numeric predictors:
```

load carsmall
X = [Acceleration Cylinders Displacement ...
Horsepower Model_Year Weight];
tree = RegressionTree.fit(X,MPG);
imp = predictorImportance(tree)
imp =
0.0315 0 0.1082 0.0686 0.1629 1.2924

```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0 ; this means the number of cylinders has no impact on predictions made with tree.

Estimate the predictor importance for all variables in the carsmall data for a tree grown with surrogate splits:
```

load carsmall
X = [Acceleration Cylinders Displacement ...
Horsepower Model_Year Weight];
tree2 = RegressionTree.fit(X,MPG,...
'Surrogate','on');
imp2 = predictorImportance(tree2)
imp2 =
0.5287 1.1977 1.2400 0.7059 1.0677 1.4106

```

\section*{CompactRegressionTree.predictorImportance}

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) as the third most important predictor.

See Also predictorImportance

\section*{Purpose}

Principal component analysis (PCA) on data

\section*{Syntax}

Description
[COEFF,SCORE] = princomp(X)
[COEFF,SCORE, latent] = princomp(X)
[COEFF,SCORE,latent,tsquare] = princomp(X)
[...] = princomp(X,'econ')
COEFF = princomp (X) performs principal components analysis (PCA)
on the \(n\)-by- \(p\) data matrix X , and returns the principal component coefficients, also known as loadings. Rows of X correspond to observations, columns to variables. COEFF is a \(p\)-by- \(p\) matrix, each column containing coefficients for one principal component. The columns are in order of decreasing component variance.
princomp centers \(X\) by subtracting off column means, but does not rescale the columns of \(X\). To perform principal components analysis with standardized variables, that is, based on correlations, use princomp (zscore(X)). To perform principal components analysis directly on a covariance or correlation matrix, use pcacov.
[COEFF,SCORE] = princomp(X) returns SCORE, the principal component scores; that is, the representation of \(X\) in the principal component space. Rows of SCORE correspond to observations, columns to components.
[COEFF, SCORE, latent] = princomp(X) returns latent, a vector containing the eigenvalues of the covariance matrix of \(X\).
[COEFF,SCORE, latent,tsquare] = princomp(X) returns tsquare, which contains Hotelling's \(\mathrm{T}^{2}\) statistic for each data point.
The scores are the data formed by transforming the original data into the space of the principal components. The values of the vector latent are the variance of the columns of SCORE. Hotelling's \(\mathrm{T}^{2}\) is a measure of the multivariate distance of each observation from the center of the data set.

When \(n<=p, \operatorname{SCORE}(:, n: p)\) and latent \((n: p)\) are necessarily zero, and the columns of \(\operatorname{COEFF}(:, n: p)\) define directions that are orthogonal to X .

\section*{princomp}
[...] = princomp(X,'econ') returns only the elements of latent that are not necessarily zero, and the corresponding columns of COEFF and SCORE, that is, when \(n<=p\), only the first \(n-1\). This can be significantly faster when \(p\) is much larger than \(n\).

\section*{Examples}

Compute principal components for the ingredients data in the Hald data set, and the variance accounted for by each component.
```

load hald;
[pc,score,latent,tsquare] = princomp(ingredients);
pc,latent
pc =
0.0678 -0.6460 0.5673-0.5062
0.6785 -0.0200 -0.5440-0.4933
-0.0290 0.7553 0.4036 -0.5156
-0.7309 -0.1085 -0.4684 -0.4844
latent =
517.7969
67.4964
12.4054
0.2372

```

The following command and plot show that two components account for \(98 \%\) of the variance:
```

cumsum(latent)./sum(latent)
ans =
0.86597
0.97886
0.9996
1
biplot(pc(:,1:2),'Scores',score(:,1:2),'VarLabels',...
{'X1' 'X2' 'X3' 'X4'})

```

For a more detailed example and explanation of this analysis method, see "Principal Component Analysis (PCA)" on page 12-78.

\section*{ProbDistUnivKernel}

\section*{Purpose Construct ProbDistUnivKernel object}

Syntax \(\quad P D=\operatorname{ProbDistUnivKernel~}(X)\)
\(P D=\) ProbDistUnivKernel(X, param1, val1, param2, val2, ...)

\section*{Description}

Tip Although you can use this constructor function to create a ProbDistUnivKernel object, using the fitdist function is an easier way to create the ProbDistUnivKernel object.
\(P D=\) ProbDistUnivKernel \((X)\) creates PD, a ProbDistUnivKernel object, which represents a nonparametric probability distribution, based on a normal kernel smoothing function.
\(P D=\) ProbDistUnivKernel(X, param1, val1, param2, val2, \(\ldots\)...) specifies optional parameter name/value pairs, as described in the Parameter/Values table. Parameter and value names are case insensitive.

\section*{Input \(x\) \\ Arguments \\ A column vector of data.}

Note Any NaN values in \(X\) are ignored by the fitting calculations.

\section*{ProbDistUnivKernel}
\begin{tabular}{l|l}
\hline Parameter & Values \\
\hline 'censoring & \begin{tabular}{l} 
A Boolean vector the same size as \(X\), containing 1s when \\
the corresponding elements in \(X\) are right-censored \\
observations and 0s when the corresponding elements \\
are exact observations. Default is a vector of 0s.
\end{tabular} \\
\hline 'frequency & \begin{tabular}{l} 
Note Any NaN values in this censoring vector are \\
ignored by the fitting calculations.
\end{tabular} \\
\begin{tabular}{l} 
A vector the same size as \(X\), containing nonnegative \\
integers specifying the frequencies for the corresponding \\
elements in \(X\). Default is a vector of 1s.
\end{tabular} \\
\hline 'kernel' & \begin{tabular}{l} 
Note Any NaN values in this frequency vector are \\
ignored by the fitting calculations. \\
A string specifying the type of kernel smoother to use. \\
Choices are: \\
- 'normal' (default) \\
- 'box' \\
- 'triangle ' \\
- 'epanechnikov'
\end{tabular} \\
\hline
\end{tabular}

\section*{ProbDistUnivKernel}
\begin{tabular}{l|l}
\hline Parameter & Values \\
\hline 'support' & \begin{tabular}{l} 
Any of the following to specify the support: \\
- 'unbounded' — Default. If the density can extend \\
over the whole real line. \\
\(-~ ' p o s i t i v e ~ ' ~ — ~ T o ~ r e s t r i c t ~ i t ~ t o ~ p o s i t i v e ~ v a l u e s . ~\) \\
- A two-element vector giving finite lower and upper \\
limits for the support of the density.
\end{tabular} \\
\hline 'width' & \begin{tabular}{l} 
A value specifying the bandwidth of the kernel \\
smoothing window. The default is optimal for \\
estimating normal densities, but you may want to \\
choose a smaller value to reveal features such as \\
multiple modes.
\end{tabular} \\
\hline
\end{tabular}

\section*{Output Arguments \\ \(P D\)}

How To \\ - Appendix B, "Distribution Reference"
}
\begin{tabular}{ll} 
Purpose & Construct ProbDistUnivParam object \\
Syntax & \(P D=\) ProbDistUnivParam(DistName, Params)
\end{tabular}

Description \(\quad P D=\) ProbDistUnivParam(DistName, Params) creates \(P D\), a ProbDistUnivParam object, which represents a probability distribution. This distribution is defined by the parametric distribution specified by DistName, with parameters specified by the numeric vector Params.

Input \(\quad\) DistName \(\quad\) A string specifying a distribution. Choices are:
Arguments
- 'beta'
- 'binomial'
- 'birnbaumsaunders'
- 'exponential'
- 'extreme value' or ev'
- 'gamma'
- 'generalized extreme value' or 'gev'
- 'generalized pareto' or 'gp'
- 'inversegaussian'
- 'logistic'
- 'loglogistic'
- 'lognormal'
- 'nakagami'
- 'negative binomial' or 'nbin'
- 'normal'
- 'poisson'

\section*{ProbDistUnivParam}
- 'rayleigh'
- 'rician'
- 'tlocationscale'
- 'weibull' or 'wbl'
For more information on these parametric
distributions, see Appendix B, "Distribution
\begin{tabular}{l} 
Reference".
\end{tabular}
\begin{tabular}{l} 
Numeric vector of distribution parameters. \\
The number and type of parameters \\
depends on the distribution you specify with \\
DistName. For information on parameters \\
for each distribution type, see Appendix B, \\
"Distribution Reference".
\end{tabular}

\section*{Output \(\quad P D\) \\ Arguments}

An object in the ProbDistUnivParam class, which is derived from the ProbDist class. It represents a parametric probability distribution.

Examples 1 Create an object representing a normal distribution with a mean of 100 and a standard deviation of 10 .
pd = ProbDistUnivParam('normal',[100 10])
pd \(=\)
normal distribution
mu \(=100\)
sigma \(=10\)

2 Generate a 4-by- 5 matrix of random values from this distribution.
random(pd,4,5)
ans \(=\)
\begin{tabular}{rrrrr}
105.3767 & 103.1877 & 135.7840 & 107.2540 & 98.7586 \\
118.3389 & 86.9231 & 127.6944 & 99.3695 & 114.8970 \\
77.4115 & 95.6641 & 86.5011 & 107.1474 & 114.0903 \\
108.6217 & 103.4262 & 130.3492 & 97.9503 & 114.1719
\end{tabular}

\section*{See Also fitdist}

How To - Appendix B, "Distribution Reference"

\section*{probplot}

Purpose Probability plots
```

Syntax probplot(Y)
probplot(distribution,Y)
probplot(Y,cens,freq)
probplot(ax,Y)
probplot(...,'noref')
probplot(ax,PD)
probplot(ax,fun,params)
h = probplot(...)

```

\section*{Description}
probplot \((\mathrm{Y})\) produces a normal probability plot comparing the distribution of the data \(Y\) to the normal distribution. \(Y\) can be a single vector, or a matrix with a separate sample in each column. The plot includes a reference line useful for judging whether the data follow a normal distribution.
probplot uses midpoint probability plotting positions. The \(i^{\text {th }}\) sorted value from a sample of size \(N\) is plotted against the midpoint in the jump of the empirical CDF on the \(y\) axis. With uncensored data, that midpoint is \((i-0.5) / N\). With censored data (see below), the \(y\) value is more complicated to compute.
probplot(distribution, Y ) creates a probability plot for the distribution specified by distribution. Acceptable strings for distribution are:
- 'exponential' - Exponential probability plot (nonnegative values)
- 'extreme value' - Extreme value probability plot (all values)
- 'lognormal' - Lognormal probability plot (positive values)
- 'normal' - Normal probability plot (all values)
- 'rayleigh' - Rayleigh probability plot (positive values)
- 'weibull' - Weibull probability plot (positive values)

The \(y\) axis scale is based on the selected distribution. The \(x\) axis has a log scale for the Weibull and lognormal distributions, and a linear scale for the others.

Not all distributions are appropriate for all data sets, and probplot will error when asked to create a plot with a data set that is inappropriate for a specified distribution. Appropriate data ranges for each distribution are given parenthetically in the list above.
probplot(Y,cens,freq) or probplot(distname, \(Y\), cens,freq) requires a vector \(Y\). cens is a vector of the same size as \(Y\) and contains 1 for observations that are right-censored and 0 for observations that are observed exactly. freq is a vector of the same size as Y , containing integer frequencies for the corresponding elements in Y .
probplot (ax, Y ) takes a handle ax to an existing probability plot, and adds additional lines for the samples in Y . ax is a handle for a set of axes.
probplot(...,'noref') omits the reference line.
probplot (ax, PD) takes a probability distribution object, PD, and adds a fitted line to the axes specified by ax to represent the probability distribution specified by PD. PD is a ProbDist object of the ProbDistUnivParam class or ProbDistUnivKernel class.
probplot (ax, fun, params) takes a function fun and a set of parameters, params, and adds fitted lines to the axes of an existing probability plot specified by ax. fun is a function handle to a cdf function, specified with @ (for example, @wblcdf). params is the set of parameters required to evaluate fun, and is specified as a cell array or vector. The function must accept a vector of \(X\) values as its first argument, then the optional parameters, and must return a vector of cdf values evaluated at \(X\).
\(\mathrm{h}=\mathrm{probplot}(\ldots)\) returns handles to the plotted lines.

\section*{Examples}

\section*{Example 1}

The following plot assesses two samples, one from a Weibull distribution and one from a Rayleigh distribution, to see if they may have come from a Weibull population.
```

x1 = wblrnd(3,3,100,1);
x2 = raylrnd(3,100,1);
probplot('weibull',[x1 x2])
legend('Weibull Sample','Rayleigh Sample','Location','NW')

```

Probability plot for Weibull distribution

\section*{Example 2}

Consider the following data, with about \(20 \%\) outliers:
```

left_tail = -exprnd(1,10,1);
right_tail = exprnd(5,10,1);
center = randn(80,1);

```
```

data = [left_tail;center;right_tail];

```

Neither a normal distribution nor a \(t\) distribution fits the tails very well:
```

probplot(data);
p = mle(data,'dist','tlo');
t = @(data,mu,sig,df)cdf('tlocationscale',data,mu,sig,df);
h = probplot(gca,t,p);
set(h,'color','r','linestyle','-')
title('{\bf Probability Plot}')
legend('Data','Normal','t','Location','NW')

```

Probability Plot

\section*{probplot}

See Also normplot | ecdf | wblplot
```

Purpose Procrustes analysis
Syntax d = procrustes(X,Y)
[d,Z] = procrustes(X,Y)
[d,Z,transform] = procrustes(X,Y)
[...] = procrustes(...,'scaling',flag)
[...] = procrustes(...,'reflection',flag)

```

Description
\(\mathrm{d}=\) procrustes \((\mathrm{X}, \mathrm{Y})\) determines a linear transformation (translation, reflection, orthogonal rotation, and scaling) of the points in matrix \(Y\) to best conform them to the points in matrix \(X\). The goodness-of-fit criterion is the sum of squared errors. procrustes returns the minimized value of this dissimilarity measure in \(d\). \(d\) is standardized by a measure of the scale of \(X\), given by:
```

sum(sum((X-repmat(mean(X,1),size(X,1),1)).^2,1))

```

That is, the sum of squared elements of a centered version of \(X\). However, if \(X\) comprises repetitions of the same point, the sum of squared errors is not standardized.
\(X\) and \(Y\) must have the same number of points (rows), and procrustes matches \(Y(i)\) to \(X(i)\). Points in \(Y\) can have smaller dimension (number of columns) than those in \(X\). In this case, procrustes adds columns of zeros to \(Y\) as necessary.
\([d, Z]=\) procrustes \((X, Y)\) also returns the transformed \(Y\) values.
[d, \(Z\), transform] = procrustes \((X, Y)\) also returns the transformation that maps \(Y\) to \(Z\). transform is a structure array with fields:
- c - Translation component
- T - Orthogonal rotation and reflection component
- b - Scale component

That is:
```

c = transform.c;
T = transform.T;

```
b = transform.b;
\(Z=b * Y * T+c ;\)
[...] = procrustes(...,'scaling',flag), when flag is false, allows you to compute the transformation without a scale component (that is, with b equal to 1). The default flag is true.
[...] = procrustes(...,'reflection',flag), when flag is false, allows you to compute the transformation without a reflection component (that is, with \(\operatorname{det}(T)\) equal to 1 ). The default flag is 'best', which computes the best-fitting transformation, whether or not it includes a reflection component. A flag of true forces the transformation to be computed with a reflection component (that is, with \(\operatorname{det}(T)\) equal to -1 )

\section*{Examples}

This example creates some random points in two dimensions, then rotates, scales, translates, and adds some noise to those points. It uses procrustes to conform \(Y\) to \(X\), then plots the original \(X\) and \(Y\) with the transformed \(Y\).
```

n = 10;
X = normrnd(0,1,[n 2]);
S = [0.5 -sqrt(3)/2; sqrt(3)/2 0.5];
Y = normrnd(0.5*X*S+2,0.05,n,2);
[d,Z,tr] = procrustes(X,Y);
plot(X(:,1),X(:,2),'rx',...
Y(:,1),Y(:,2),'b.',...
Z(:,1),Z(:,2),'bx');

```

\section*{prob.ToolboxFittableParametricDistribution.proflik}
\begin{tabular}{|c|c|}
\hline Purpose & Profile likelihood function for probability distribution object \\
\hline \multirow[t]{4}{*}{Syntax} & [ll, param] = proflik(pd, pnum) \\
\hline & [ll, param] = proflik(pd, pnum, 'Display',display) \\
\hline & [ll, param] = proflik(pd,pnum,setparam) \\
\hline & \begin{tabular}{l}
[ll, param] = proflik(pd,pnum, setparam,'Display',display) \\
[ll param, other] = proflik( )
\end{tabular} \\
\hline
\end{tabular}

Description

Input
Arguments
[ll, param] = proflik(pd,pnum) returns a vector ll of loglikelihood values and a vector param of corresponding parameter values for the parameter in the position indicated by pnum.
[ll,param] = proflik(pd,pnum,'Display',display) returns the loglikelihood values and corresponding parameter values, and plots the profile likelihood overlaid on an approximation of the loglikelihood.
[ll, param] = proflik(pd, pnum, setparam) returns the loglikelihood values and corresponding parameter values as specified by setparam.
[ll, param] = proflik(pd, pnum, setparam,'Display', display) returns the loglikelihood values and corresponding parameter values as specified by setparam, and plots the profile likelihood overlaid on an approximation of the loglikelihood.
[ll, param,other] = proflik( __ ) also returns a matrix other containing the values of the other parameters that maximize the likelihood, using any of the input arguments from the previous syntaxes.

\author{
pd - Probability distribution
}
probability distribution object
Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, create a probability distribution object by fitting it to data using fitdist or dfittool.

\section*{pnum - Parameter number}
positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector \{'A', 'B'\}, so specify pnum as 2 to compute the profile likelihood for \(B\).

\section*{Data Types}
single | double

\section*{setparam - Parameter value restriction}
scalar value | vector of scalar values
Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify setparam, proflik chooses the values for output vector param based on the default confidence interval method for the probability distribution pd. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use setparam to specify valid values.

\section*{Example: [3, 3.5,4]}

\section*{display - Display toggle}
'off' (default) | 'on'
Display toggle, specified as either 'on' or 'off'. Specify 'on' to display a plot of the profile loglikelihood overlaid on an approximation of the loglikelihood. Specify 'off' to omit the display. The approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position pnum or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of \(95 \%\) confidence intervals.

\section*{prob.ToolboxFittableParametricDistribution.proflik}

\section*{Output \\ Arguments}

\section*{Examples}

\section*{II - Loglikelihood values}
vector
Loglikelihood values, returned as a vector. The loglikelihood is the value of the likelihood with the parameter in position pnum set to the values in param, maximized over the remaining parameters.

\section*{param - Parameter values}
vector
Parameter values corresponding to the loglikelihood values in ll, returned as a vector. If you specify parameter values using setparam, then param is equal to setparam.

\section*{other - Other parameter values}
matrix
Other parameter values that maximize the likelihood, returned as a matrix. Each row of other contains the values for all parameters except the parameter in position pnum.

\section*{Profile Likelihood of a Distribution Parameter}

Load the sample data. Create a probability distribution object by fitting a Weibull distribution to the miles per gallon (MPG) data.
```

load carsmall;
pd = fitdist(MPG,'Weibull')
pd =

```
    WeibullDistribution
    Weibull distribution
        \(A=26.5079 \quad[24.8333,28.2954]\)
        \(B=3.27193 \quad[2.79441,3.83104]\)

View the parameter names for the distribution.
pd.ParameterNames
'A' 'B'

For the Weibull distribution, A is in position 1, and B is in position 2.
Compute the profile likelihood for B , which is in position pnum \(=2\).
[ll,param] = proflik(pd,2);
Display the loglikelihood values for the estimated values of B.
```

[ll',param']
ans =

```
\begin{tabular}{ll}
-329.9688 & 2.7132 \\
-329.4312 & 2.7748 \\
-328.9645 & 2.8365 \\
-328.5661 & 2.8981 \\
-328.2340 & 2.9597 \\
-327.9658 & 3.0213 \\
-327.7596 & 3.0830 \\
-327.6135 & 3.1446 \\
-327.5256 & 3.2062 \\
-327.4943 & 3.2678 \\
-327.5178 & 3.3295 \\
-327.5946 & 3.3911 \\
-327.7233 & 3.4527 \\
-327.9023 & 3.5143 \\
-328.1303 & 3.5760 \\
-328.4060 & 3.6376 \\
-328.7281 & 3.6992 \\
-329.0956 & 3.7608 \\
-329.5071 & 3.8224 \\
-329.9617 & 3.8841 \\
-330.4583 & 3.9457
\end{tabular}

\section*{prob.ToolboxFittableParametricDistribution.proflik}

These results show that the profile loglikelihood is maximized between the estimated B values of 3.2678 and 3.3295 , which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of \(B\) is 3.27193 , which is in this interval as expected.

\section*{Profile Likelihood With Restricted Parameter Values}

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.
```

load carsmall;
pd = fitdist(MPG,'GeneralizedExtremeValue')
pd =

```

GeneralizedExtremeValueDistribution
Generalized Extreme Value distribution
            \(k=-0.207765 \quad[-0.381674,-0.0338564]\)
        sigma \(=7.49674 \quad[6.31755,8.89603]\)
            \(\mathrm{mu}=20.6233 \quad[18.8859,22.3606]\)

View the parameter names for the distribution.
pd.ParameterNames
ans =
'k' 'sigma' 'mu'
For the generalized extreme value distribution, k is in position 1, sigma is in position 2 , and mu is in position 3.

Compute the profile likelihood for mu, which is in position pnum \(=3\). Restrict the computation to parameter values from 20 to 22 , and display the plot.
```

[ll,param,other] = proflik(pd,3,20:.1:22,'display','on');

```

The plot shows the estimated value for the parameter mu that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of mu, and the values of the other distribution parameters that maximize the corresponding loglikelihood.
[ll', param',other]
ans =

\section*{CompactTreeBagger.proximity}

\section*{Purpose Proximity matrix for data}

\section*{Syntax \\ prox = proximity (B, X)}

Description
prox \(=\) proximity \((B, X)\) computes a numeric matrix of size Nobs-by-Nobs of proximities for data \(X\), where Nobs is the number of observations (rows) in X. Proximity between any two observations in the input data is defined as a fraction of trees in the ensemble \(B\) for which these two observations land on the same leaf. This is a symmetric matrix with ones on the diagonal and off-diagonal elements ranging from 0 to 1 .

\section*{TreeBagger.Proximity property}

Purpose Proximity matrix for observations
Description
The Proximity property is a numeric matrix of size Nobs-by-Nobs, where Nobs is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1 s on the diagonal and off-diagonal elements ranging from 0 to 1 .

\section*{TreeBagger.Prune property}

Purpose Flag to prune trees
Description \(\quad \begin{aligned} & \text { The Prune property is true if decision trees are pruned and false if they } \\ & \text { are not. Pruning decision trees is not recommended for ensembles. The } \\ & \text { default value is false. }\end{aligned}\)
See Also classregtree.prune

Purpose Pruning levels for decision tree nodes
Syntax \(\quad P=\operatorname{prunelist}(T)\)
P = prunelist( \(\mathrm{T}, \mathrm{J}\) )
Description \(\quad P=\) prunelist \((T)\) returns an \(n\)-element numeric vector with the pruning levels in each node of the tree \(T\), where \(n\) is the number of nodes. When you call prune(T,'level',level), nodes with the pruning levels below level are pruned, and nodes with the pruning levels greater or equal to level are not pruned.
\(P=p r u n e l i s t(T, J)\) takes an array \(J\) of node numbers and returns the pruning levels for the specified nodes.

\section*{qrandstream.qrand}

\section*{Purpose Generate quasi-random points from stream}
Syntax
\(x=q \operatorname{rand}(q)\)
\(X=q r a n d(q, n)\)

Description
\(x=q \operatorname{rand}(q)\) returns the next value \(x\) in the quasi-random number stream \(q\) of the qrandstream class. \(x\) is a 1-by- \(d\) vector, where \(d\) is the dimension of the stream. The command sets \(q\). State to the index in the underlying point set of the next value to be returned.
\(\mathrm{X}=\mathrm{qrand}(\mathrm{q}, \mathrm{n})\) returns the next n values X in an n -by- \(d\) matrix.
Objects q of the qrandstream class encapsulate properties of a specified quasi-random number stream. Values of the stream are not generated and stored in memory until \(q\) is accessed using qrand.

\section*{Examples}

Use qrandstream to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:
```

q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
Halton quasi-random stream in 3 dimensions
Point set properties:
Skip : 1000
Leap : 100
ScrambleMethod : none
nextIdx = q.State
nextIdx =
1

```

Use qrand to generate two samples of size four:
```

X1 = qrand(q,4)
X1 =

| 0.0928 | 0.3475 | 0.0051 |
| :--- | :--- | :--- |
| 0.6958 | 0.2035 | 0.2371 |
| 0.3013 | 0.8496 | 0.4307 |

```
```

    0.9087 0.5629 0.6166
    nextIdx = q.State
nextIdx =
5
X2 = qrand(q,4)
X2 =
0.2446 0.0238 0.8102
0.5298 0.7540 0.0438
0.3843 0.5112 0.2758
0.8335 0.2245 0.4694
nextIdx = q.State
nextIdx =
9

```

Use reset to reset the stream, then generate another sample:
```

reset(q)
nextIdx = q.State
nextIdx =
1

```
\(X=\) qrand \((q, 4)\)
\(\mathrm{X}=\)
\begin{tabular}{lll}

}
}

\section*{Purpose Construct quasi-random number stream}
```

Syntax $\quad q=$ qrandstream (type, $d$ )
q = qrandstream(type,d,prop1,val1,prop2,val2,...)
$q$ = qrandstream(p)

```

\section*{Description}

\section*{Examples}
\(\mathrm{q}=\mathrm{qrandstream}(\) type, d\()\) constructs a d-dimensional quasi-random number stream \(q\) of the qrandstream class, of type specified by the string type. type is either 'halton' or 'sobol', and q is based on a point set from either the haltonset class or sobolset class, respectively, with default property settings.
q = qrandstream(type,d,prop1,val1,prop2,val2,...) specifies property name/value pairs for the point set on which the stream is based. Applicable properties depend on type.
\(q=q r a n d s t r e a m(p)\) constructs a stream based on the specified point set \(p\). \(p\) must be a point set from either the haltonset class or sobolset class.

Construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:
```

q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
Halton quasi-random stream in 3 dimensions
Point set properties:
Skip : 1000
Leap : 100
ScrambleMethod : none
nextIdx = q.State
nextIdx =
1

```

Use qrand to generate two samples of size four:
\(X 1=\operatorname{qrand}(q, 4)\)

\section*{qrandstream}
```

X1 =
0.0928 0.3475 0.0051
0.6958 0.2035 0.2371
0.3013 0.8496 0.4307
0.9087 0.5629 0.6166
nextIdx = q.State
nextIdx =
5
X2 = qrand(q,4)
x2 =
0.2446 0.0238 0.8102
0.5298 0.7540 0.0438
0.3843 0.5112 0.2758
0.8335 0.2245 0.4694
nextIdx = q.State
nextIdx =
9

```

Use reset to reset the stream, and then generate another sample:
```

reset(q)
nextIdx = q.State
nextIdx =
1

```
\(X=\) qrand \((q, 4)\)
\(\mathrm{X}=\)
\begin{tabular}{lll}
0.0928 & 0.3475 & 0.0051 \\
0.6958 & 0.2035 & 0.2371 \\
0.3013 & 0.8496 & 0.4307 \\
0.9087 & 0.5629 & 0.6166
\end{tabular}

\section*{Purpose}

Quantile-quantile plot
Syntax
```

qqplot(X)
qqplot(X,Y)
qqplot(X,PD)
qqplot(X,Y,pvec)
h = qqplot(X,Y,pvec)

```

\section*{Description}
qqplot( \(X\) ) displays a quantile-quantile plot of the sample quantiles of \(X\) versus theoretical quantiles from a normal distribution. If the distribution of \(X\) is normal, the plot will be close to linear.
qqplot ( \(\mathrm{X}, \mathrm{Y}\) ) displays a quantile-quantile plot of two samples. If the samples do come from the same distribution, the plot will be linear.
qqplot ( \(X, P D\) ) makes an empirical quantile-quantile plot of the quantiles of the data in the vector \(X\) versus the quantiles of the distribution specified by PD, a ProbDist object of the ProbDistUnivParam class or ProbDistUnivKernel class.

For matrix \(X\) and \(Y\), qqplot displays a separate line for each pair of columns. The plotted quantiles are the quantiles of the smaller data set.

The plot has the sample data displayed with the plot symbol ' + '. Superimposed on the plot is a line joining the first and third quartiles of each distribution (this is a robust linear fit of the order statistics of the two samples). This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

Use qqplot ( \(\mathrm{X}, \mathrm{Y}, \mathrm{pvec}\) ) to specify the quantiles in the vector pvec.
\(h=q q p l o t(X, Y, p v e c)\) returns handles to the lines in \(h\).

\section*{Examples}

The following example shows a quantile-quantile plot of two samples from Poisson distributions. The solid line joins the first and third quartiles. The dashed line extrapolates the solid line.
```

x = poissrnd(10,50,1);
y = poissrnd(5,100,1);
qqplot(x,y);

```

How To
- normplot

\section*{Purpose}

Quantiles of a data set

\section*{Syntax}
```

Y = quantile(X,p)
Y = quantile(X,p,dim)
Y = quantile(X,N)
Y = quantile(X,N,dim)

```

Description
\(Y=\) quantile \((X, p)\) returns quantiles of the values in data vector or matrix \(X\) for the cumulative probability or probabilities \(p\) in the interval [0,1].
- If \(X\) is a vector, then \(Y\) is a scalar or a vector having the same length as \(p\).
- If \(X\) is a matrix, then \(Y\) is a row vector or a matrix where the number of rows of \(Y\) is equal to the length of \(p\).
- For multidimensional arrays, quantile operates along the first nonsingleton dimension of \(X\).
\(Y=\) quantile( \(X, p\), dim) returns quantiles along dimension dim.
\(Y=\) quantile \((X, N)\) returns quantiles for \(N\) evenly spaced cumulative probabilities \((1 /(N+1), 2 /(N+1), \ldots, N /(N+1))\) for integer \(N>1\).
- If \(X\) is a vector, then \(Y\) is a scalar or a vector with length \(N\).
- If \(X\) is a matrix, then \(Y\) is a matrix where the number of rows of \(Y\) is equal to N .
- For multidimensional arrays, quantile operates along the first nonsingleton dimension of \(X\).
\(\mathrm{Y}=\) quantile \((\mathrm{X}, \mathrm{N}, \mathrm{dim})\) returns quantiles at the N evenly-spaced cumulative probabilities \((1 /(N+1), 2 /(N+1), \ldots, N /(N+1))\) for integer \(N>1\) along dimension dim.

\section*{quantile}

\section*{Input Arguments}

\section*{X - Input data}
vector | array
Input data, specified as a vector or array.

\author{
Data Types \\ double | single
}

\section*{p-Cumulative probabilities}
scalar | vector
Cumulative probabilities, for which to compute the quantiles, specified as a scalar or vector of scalars from 0 to 1 .

Example: 0.3
Example: [0.25, 0.5, 0.75]
Example: (0:0.25:1)
Data Types
double | single

\section*{N - Number of quantiles}
positive integer
Number of quantiles to compute, specified as a positive integer. quantile returns \(N\) quantiles that divide the data set into evenly distributed \(N+1\) segments.

Data Types
double | single

\section*{dim - Dimension}

1 (default) | positive integer
Dimension along which the quantiles of a matrix \(X\) are required, specified as a positive integer. For example, for a matrix \(X\), when dim \(=1\), quantile returns the quantile(s) of the columns of \(X\) and when \(\operatorname{dim}=2\), quantile returns the quantile(s) of the rows of \(X\). For a multidimensional array \(X\), the length of the dimth dimension of \(Y\) is same as length of \(p\).

\section*{Output Arguments}

\section*{Y - Quantiles}
scalar \| array
Quantiles of a data vector or matrix, returned as a scalar or array for one or multiple values of cumulative probabilities.
- If \(X\) is a vector, then \(Y\) is a scalar or a vector with the same length as the number of quantiles required ( N or length \((\mathrm{p})\) ). \(\mathrm{Y}(\mathrm{i})\) contains the \(p(i)\) quantile.
- If X is a matrix, then Y is a vector or a matrix with the length of dimth dimension equal to the number of quantiles required ( N or length \((p)\) ). When dim \(=1\), for example, the ith row of \(Y\) contains the \(p(i)\) quantiles of columns of \(x\).
- If \(X\) is an array of dimension \(d\), then \(Y\) is an array with the length of dimth dimension equal to the number of quantiles required ( N or length (p)).

\section*{Definitions}

\section*{Multidimensional Array}

A multidimensional array is an array with more than two dimensions. For example, if X is a 1-by-3-by- 4 array, then X is a 3-D array.

\section*{First Nonsingleton Dimension}

A first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if X is a 1 -by- 2 -by- 3 -by- 4 array, then the second dimension is the first nonsingleton dimension of X .

\section*{Linear Interpolation}

Linear interpolation uses linear polynomials to find \(y_{i}=\mathrm{f}\left(x_{i}\right)\), the values of the underlying function \(Y=\mathrm{f}(X)\) at the points in the vector or array \(x\). Given the data points \(\left(x_{1}, y_{1}\right)\) and \(\left(x_{2}, y_{2}\right)\), where \(y_{1}=\mathrm{f}\left(x_{1}\right)\) and \(y_{2}=\) \(\mathrm{f}\left(x_{2}\right)\), linear interpolation finds \(y=\mathrm{f}(x)\) for a given \(x\) between \(x_{1}\) and \(x_{2}\) as follows:
\[
y=f(x)=y_{1}+\frac{\left(x-x_{1}\right)}{\left(x_{2}-x_{1}\right)}\left(y_{2}-y_{1}\right)
\]

Similarly, if the \(1.5 / n\) quantile is \(y_{1.5 / n}\) and the \(2.5 / n\) quantile is \(y_{2.5 / n}\), then linear interpolation finds the \(2.3 / n\) quantile \(y_{2.3 / n}\) as
\[
y_{\frac{2.3}{n}}=y_{\frac{1.5}{n}}+\frac{\left(\frac{2.3}{n}-\frac{1.5}{n}\right)}{\left(\frac{2.5}{n}-\frac{1.5}{n}\right)}\left(y_{\frac{2.5}{n}}-y_{\frac{1.5}{n}}\right)
\]

\section*{Algorithms}

For an \(n\)-element vector X , quantile computes quantiles as follows:
1 The sorted values in X are taken as the \((0.5 / n),(1.5 / n), \ldots,([n-0.5] / n)\) quantiles. For example:
- For a data vector of five elements such as \(\{6,3,2,10,1\}\), the sorted elements \(\{1,2,3,6,10\}\) respectively correspond to the \(0.1,0.3,0.5\), 0.7, 0.9 quantiles.
- For a data vector of six elements such as \(\{6,3,2,10,8,1\}\), the sorted elements \(\{1,2,3,6,8,10\}\) respectively correspond to the (0.5/6), (1.5/6), (2.5/6), (3.5/6), (4.5/6), (5.5/6) quantiles.

2 quantile uses Linear interpolation to compute quantiles for probabilities between \((0.5 / n)\) and \(([n-0.5] / n)\).

3 For the quantiles corresponding to the probabilities outside that range, quantile assigns the minimum or maximum values in \(X\).
quantile treats NaNs as missing values and removes them.

\section*{Examples Quantiles for Given Probabilities}

Calculate the quantiles of a data set for specified probabilities.
Generate a data set of size 10 .
rng('default'); \% for reproducibility
\(x=\operatorname{normrnd}(0,1,1,10)\)
\(\mathrm{x}=\)
0.5377
1.8339
\(-2.2588\)
0.8622
0.3188
\(-1.3077\)
0.4336

Calculate the 0.3 quantile.
```

y = quantile(x,0.30)
y =
-0.0574

```

Calculate the quantiles for the cumulative probabilities \(0.025,0.25\), \(0.5,0.75\), and 0.975 .
```

y = quantile(x,[0.025 0.25 0.50 0.75 0.975])
y =
-2.2588 -0.4336 0.4401 1.8339 3.5784

```

\section*{Quantiles of a Matrix for Given Probabilities}

Calculate the quantiles along the columns and rows of a data matrix for specified probabilities.

Generate a 4-by-6 data matrix.
```

rng('default'); % for reproducibility
X = normrnd(0,1,4,6)
X =

| 0.5377 | 0.3188 | 3.5784 | 0.7254 | -0.1241 | 0.6715 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 1.8339 | -1.3077 | 2.7694 | -0.0631 | 1.4897 | -1.2075 |
| -2.2588 | -0.4336 | -1.3499 | 0.7147 | 1.4090 | 0.7172 |
| 0.8622 | 0.3426 | 3.0349 | -0.2050 | 1.4172 | 1.6302 |

```

Calculate the 0.3 quantile for each column of \(X(\operatorname{dim}=1)\).
\(y=q u a n t i l e(x, 0.3,1)\)

\section*{quantile}
```

y =
-0.3013 -0.6958 1.5336 -0.1056 0.9491 0.1078

```
quantile returns a row vector \(y\) when calculating one quantile for each column of a matrix. For example, -0.3013 is the 0.3 quantile of the first column of X with elements ( \(0.5377,1.8339,-2.2588,0.8622\) ). \(\mathrm{y}=\) quantile \((X, 0.3)\) returns the same answer because the default value of dim is 1 .

Calculate the 0.3 quantile for each row of \(X(\operatorname{dim}=2)\).
```

y = quantile(x,0.3,2)
y =
0.3844
-0.8642
-1.0750
0.4985

```
quantile returns a column vector y when calculating one quantile for each row of a matrix. For example 0.3844 is the 0.3 quantile of the first row of \(X\) with elements \((0.5377,0.3188,3.5784,0.7254,-0.1241,0.6715)\).

\section*{Quantiles for \(\mathbf{N}\) Evenly Spaced Cumulative Probabilities}

Calculate the quantiles of a data set for a given number of quantiles.
Generate a data set of size 10 .
```

rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
x =
0.5377 1.8339 -2.2588 0.8622 0.3188 -1.3077 -0.4336

```

Calculate four evenly spaced quantiles.
```

y = quantile(x,4)

```
\(\mathrm{y}=\)
\(\begin{array}{llll}-0.8706 & 0.3307 & 0.6999 & 2.3017\end{array}\)

Using \(y=q u a n t i l e(x,[0.2,0.4,0.6,0.8])\) is another way to return the four evenly spaced quantiles.

\section*{Quantiles of a Matrix for Given Number of Quantiles}

Calculate the N evenly spaced quantiles along the columns and rows of a data matrix.

Generate a 6-by-10 data matrix.
```

rng('default'); % for reproducibility
X = unidrnd(10,6,7)
X =

```
\begin{tabular}{rrrrrrr}
9 & 3 & 10 & 8 & 7 & 8 & 7 \\
10 & 6 & 5 & 10 & 8 & 1 & 4 \\
2 & 10 & 9 & 7 & 8 & 3 & 10 \\
10 & 10 & 2 & 1 & 4 & 1 & 1 \\
7 & 2 & 5 & 9 & 7 & 1 & 5 \\
1 & 10 & 10 & 10 & 2 & 9 & 4
\end{tabular}

Calculate three evenly spaced quantiles for each column of \(X(\operatorname{dim}=1)\).
```

y = quantile(X,3,1)
y =

```
\begin{tabular}{rrrrrrr}
2.0000 & 3.0000 & 5.0000 & 7.0000 & 4.0000 & 1.0000 & 4.0000 \\
8.0000 & 8.0000 & 7.0000 & 8.5000 & 7.0000 & 2.0000 & 4.5000 \\
10.0000 & 10.0000 & 10.0000 & 10.0000 & 8.0000 & 8.0000 & 7.0000
\end{tabular}

Each column of matrix y corresponds to the three evenly spaced quantiles of each column of matrix \(X\). For example, the first column of y with elements \((2,8,10)\) has the quantiles for the first column of X

\section*{quantile}
with elements \((9,10,2,10,7,1)\). y = quantile \((X, 3)\) returns the same answer because the default value of dim is 1 .

Calculate three evenly spaced quantiles for each row of \(X(\operatorname{dim}=2)\).
y = quantile( \(\mathrm{X}, 3,2\) )
\(y=\)
\begin{tabular}{rrr}
7.0000 & 8.0000 & 8.7500 \\
4.2500 & 6.0000 & 9.5000 \\
4.0000 & 8.0000 & 9.7500 \\
1.0000 & 2.0000 & 8.5000 \\
2.7500 & 5.0000 & 7.0000 \\
2.5000 & 9.0000 & 10.0000
\end{tabular}

Each row of matrix y corresponds to the three evenly spaced quantiles of each row of matrix \(X\). For example, the first row of \(y\) with elements \((7,8,8.75)\) has the quantiles for the first column of \(X\) with elements \((9,3,10,8,7,8,7)\).

\section*{Median and Quartiles for Even Number of Data Elements}

Find median and quartiles of a vector, x , with even number of elements.
Enter the data.
```

x = [2 5 5 6 10 11 13]
x =
2 5 5 6 10

```

Calculate the median of \(x\).
\(y=q u a n t i l e(x, 0.50)\)
y \(=\)
    8

Calculate the quartiles of \(x\).
```

y = quantile(x,[0.25, 0.5, 0.75])
y =
5 8 11

```

Using \(y\) = quantile \((x, 3)\) is another way to compute the quartiles of \(x\).
These results might be different than the textbook definitions because quantile uses linear interpolation to find the median and quartiles.

\section*{Median and Quartiles for Odd Number of Data Elements}

Find median and quartiles of a vector, x , with odd number of elements.
Enter the data.
```

x = [2 4 4 6 8 10 12 14]

```
x =
\begin{tabular}{lllllll}
2 & 4 & 6 & 8 & 10 & 12 & 14
\end{tabular}

Find the median of x .
```

y = quantile(x,0.50)
y =
8

```

Find the quartiles of \(x\).
```

y = quantile(x,[0.25, 0.5, 0.75])
y =
4.5000 8.0000 11.5000

```

Using \(y\) = quantile \((x, 3)\) is another way to compute the quartiles of \(x\).

These results might be different than the textbook definitions because quantile uses linear interpolation to find the median and quartiles.

```
Purpose Generate quasi-random points from stream
Syntax rand

rand (q, n)

rand (q)

rand (q,m,n)

\(\operatorname{rand}(q,[m, n])\)

\(\operatorname{rand}(q, m, n, p, \ldots)\)

\(\operatorname{rand}(q,[m, n, p, \ldots])\)

\section*{Description}

\section*{Examples Generate the first 256 points from a 5-D Sobol sequence:}
```

q = qrandstream('sobol',5);
X = rand(q,256,5);

```

See Also qrandstream | qrand \| rand

Purpose Gamma random numbers with unit scale

\author{
Syntax \\ \section*{Description}
}
\(Y=r a n d g\)
\(Y=\operatorname{randg}(A)\)
\(Y=\operatorname{randg}(A, m)\)
\(Y=\operatorname{randg}(A, m, n, p, \ldots)\)
\(Y=\operatorname{randg}(A,[m, n, p, \ldots])\)
\(Y\) = randg returns a scalar random value chosen from a gamma distribution with unit scale and shape.
\(Y=r a n d g(A)\) returns a matrix of random values chosen from gamma distributions with unit scale. Y is the same size as A , and randg generates each element of \(Y\) using a shape parameter equal to the corresponding element of A .
\(Y=\operatorname{randg}(A, m)\) returns an \(m\)-by- \(m\) matrix of random values chosen from gamma distributions with shape parameters A. A is either an \(m\)-by-m matrix or a scalar. If A is a scalar, randg uses that single shape parameter value to generate all elements of \(Y\).
\(Y=r a n d g(A, m, n, p, \ldots)\) or \(Y=r a n d g(A,[m, n, p, \ldots])\) returns an m-by-n-by-p-by-... array of random values chosen from gamma distributions with shape parameters A. A is either an m-by-n-by-p-by-... array or a scalar.
randg produces pseudo-random numbers using the MATLAB functions rand and randn. The sequence of numbers generated is determined by the settings of the uniform random number generator that underlies rand and randn. Control that shared random number generator using rng. See the rng documentation for more information.

Note To generate gamma random numbers and specify both the scale and shape parameters, you should call gamrnd.

\section*{Examples Example 1}

Generate a 100-by-1 array of values drawn from a gamma distribution with shape parameter 3 .
\(r=\operatorname{randg}(3,100,1) ;\)

\section*{Example 2}

Generate a 100-by-2 array of values drawn from gamma distributions with shape parameters 3 and 2 .
\(A=[\operatorname{ones}(100,1) * 3\), ones \((100,1) * 2] ;\)
\(r=r a n d g(A,[100,2]) ;\)

\section*{Example 3}

To create reproducible output from randg, reset the random number generator used by rand and randn to its default startup settings. This way randg produces the same random numbers as if you restarted MATLAB.
```

rng('default')
randg(3,1,5)
ans =
6.9223 4.3369 1.0505 3.2662 11.3269

```

\section*{Example 4}

Save the settings for the random number generator used by rand and randn, generate 5 values from randg, restore the settings, and repeat those values.
```

s = rng; % Obtain the current state of the random stream
r1 = randg(10,1,5)
r1 =

| 9.4719 | 9.0433 | 15.0774 | 14.7763 | 6.3775 |
| :--- | :--- | :--- | :--- | :--- |

```
rng(s); \% Reset the stream to the previous state r2 \(=\operatorname{randg}(10,1,5)\)
r2 =
\[
\begin{array}{lllll}
9.4719 & 9.0433 & 15.0774 & 14.7763 & 6.3775
\end{array}
\]
\(r 2\) contains exactly the same values as \(r 1\).

\section*{Example 5}

Reinitialize the random number generator used by rand and randn with a seed based on the current time. randg returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session.
```

rng('shuffle');
randg(2,1,5);

```

\section*{Purpose Random numbers}

\section*{Syntax \(\quad Y=\operatorname{random}(\) name,\(A)\)}
\(Y=\) random(name, \(A, B)\)
\(Y=\) random(name, \(A, B, C)\)
Y = random(name, \(A, m, n, \ldots\) )
\(Y=\) random(name, \(A,[m, n, \ldots])\)
\(Y=\) random(name, \(A, B, m, n, \ldots\) )
\(Y=\) random(name, \(A, B,[m, n, \ldots])\)
\(Y=\) random(name, \(A, B, C, m, n, \ldots)\)
\(Y=\operatorname{random}(\) name \(, A, B, C,[m, n, \ldots])\)

\section*{Description}
\(\mathrm{Y}=\) random(name, A\()\) where name is the name of a distribution that takes a single parameter, returns random numbers \(Y\) from the one-parameter family of distributions specified by name. Parameter values for the distribution are given in \(A\).

Y is the same size as A .
\(Y=\) random(name, \(A, B\) ) returns random numbers \(Y\) from a two-parameter family of distributions. Parameter values for the distribution are given in \(A\) and \(B\).

If \(A\) and \(B\) are arrays, they must be the same size. If either \(A\) or \(B\) are scalars, they are expanded to constant matrices of the same size.
\(Y=\) random(name, \(A, B, C)\) returns random numbers \(Y\) from a three-parameter family of distributions. Parameter values for the distribution are given in \(A, B\), and \(C\).

If \(A, B\), and \(C\) are arrays, they must be the same size. If any of \(A, B\), or \(C\) are scalars, they are expanded to constant matrices of the same size.
\(Y=\operatorname{random}(\) name \(, A, m, n, \ldots)\) or \(Y=\) random(name, \(A,[m, n, \ldots])\) returns an \(m\)-by-n-by... matrix of random numbers.

Similarly, \(Y=\) random(name, \(A, B, m, n, \ldots\) ) or \(Y=\) random(name, \(A, B,[m, n, \ldots]\) ) returns an m-by-n-by... matrix of random numbers for distributions that require two parameters. \(\mathrm{Y}=\) random(name, \(\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{m}, \mathrm{n}, \ldots\) ) or \(\mathrm{Y}=\)
random(name, \(A, B, C,[m, n, \ldots])\) returns an \(m\)-by-n-by... matrix of random numbers for distributions that require three parameters.
If any of \(A, B\), or \(C\) are arrays, then the specified dimensions must match the common dimensions of A, B, and C after any necessary scalar expansion.

The following table denotes the acceptable strings for name, as well as the parameters for that distribution:
\begin{tabular}{l|l|l|l|l}
\hline name & Distribution & \begin{tabular}{l} 
Input \\

Examples
Generate a 2 -by- 4 array of random values from the normal distribution with mean 0 and standard deviation 1 :
```

x1 = random('Normal', 0, 1, 2,4)
x1 =

```
```

1.1650 0.0751 -0.6965 0.0591
0.6268 0.3516 1.6961 1.7971

```

The order of the parameters is the same as for normrnd.
Generate a single random value from Poisson distributions with rate parameters \(1,2, \ldots, 6\), respectively:
```

x2 = random('Poisson',1:6,1,6)
x2 =
0

```

\section*{GeneralizedLinearModel.random}

\section*{Purpose}

Simulate responses for generalized linear regression model
ysim \(=\) random(mdl,Xnew) ysim \(=\) random(mdl,Xnew, Name, Value)

Description

\section*{Input Arguments}
ysim \(=\) random(mdl, Xnew) simulates responses from the mdl generalized linear model to the data in Xnew.
ysim = random(mdl,Xnew,Name,Value) simulates responses with additional options specified by one or more Name, Value pair arguments.

\section*{mdl}

Generalized linear model, as constructed by GeneralizedLinearModel.fit or GeneralizedLinearModel.stepwise.

\section*{Xnew}

Points at which mdl predicts responses.
- If Xnew is a dataset array, it must contain the predictor names in mdl.
- If Xnew is a numeric matrix, it must have the same number of variables (columns) as was used to create mdl. Furthermore, all variables used in creating mdl must be numeric.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'BinomialSize'}

\section*{GeneralizedLinearModel.random}
alue of the binomial \(n\) parameter for each row in the training data. BinomialSize can be a vector the same length as Xnew, or a scalar that applies to each row. The default value 1 produces ysim values that are predicted proportions. Use BinomialSize only if mdl is fit to a binomial distribution.

Default: 1

\section*{'Offset'}

Value of the offset for each row in Xnew. Offset can be a vector the same length as Xnew, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1 . In other words, if \(b\) is the fitted coefficient vector, and link is the link function,
```

    link(ysim) = Offset + Xnew * b.
    ```

Default: zeros(size(Xnew,1))

\section*{Output ysim}

Arguments
Vector of simulated values at Xnew. random generates ysim using random values with mean given by the fitted model, and with the distribution used in mdl. The values in ysim are independent conditional on the predictors. For binomial and Poisson fits, random generates ysim with the specified distribution with no adjustment for any estimated dispersion.

\section*{Examples Generalized Linear Model Simulation}

Create a generalized linear model, and simulate its response to new data.

Generate artificial data for the model, Poisson random numbers with one underlying predictors X .
```

rng('default') % reproducible

```

\section*{GeneralizedLinearModel.random}
```

X = rand (20,1);
mu = exp(1 + 2*X);
y = poissrnd(mu);

```

Create a generalized linear regression model of Poisson data.
```

mdl = GeneralizedLinearModel.fit(X,y,...
'y ~ x1','distr','poisson');

```

Create points for prediction.
Xnew = (0:.05:1)';
Simulate responses at the new points.
ysim \(=\) random(mdl,Xnew);
Plot the simulated values along with the original values.
```

plot(X,y,'rx',Xnew,ysim,'bo',...
Xnew,feval(mdl,Xnew),'g-')
legend('Data','Simulated','Fitted Mean',...
'Location','best')

```

\section*{GeneralizedLinearModel.random}

Alternatives For predictions without random noise, use predict or feval.
See Also GeneralizedLinearModel I predict I
Related - "random" on page 9-170
Examples
Concepts - "Generalized Linear Models" on page 9-143

\section*{Purpose Random numbers from Gaussian mixture distribution}
Syntax \(\quad\)\begin{tabular}{ll} 
& \(y=\operatorname{random}(o b j)\) \\
& \(Y=\operatorname{random}(o b j, n)\) \\
& {\([Y, i d x]=\operatorname{random}(o b j, n)\)}
\end{tabular}

Description \(\quad y=\) random(obj) generates a 1 -by- \(d\) vector \(y\) drawn at random from the \(d\)-dimensional Gaussian mixture distribution defined by obj. obj is an object created by gmdistribution or fit.
\(\mathrm{Y}=\) random (obj, n ) generates an n -by- \(d\) matrix Y of \(\mathrm{n} d\)-dimensional random samples.
[ \(\mathrm{Y}, \mathrm{idx}\) ] = random(obj, n ) also returns an n -by-1 vector idx, where \(\operatorname{idx}(\mathrm{I})\) is the index of the component used to generate \(Y(I,:)\).

\section*{Examples}

Create a gmdistribution object defining a two-component mixture of bivariate Gaussian distributions:
```

MU = [1 2;-3 -5];
SIGMA = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(MU,SIGMA,P);
ezcontour(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
hold on

```

\section*{gmdistribution.random}

Generate 1000 random values:
```

Y = random(obj,1000);
scatter(Y(:,1),Y(:,2),10,'.')

```

\section*{See Also}
gmdistribution | fit | mvnrnd

\section*{LinearModel.random}

\section*{Purpose Simulate responses for linear regression model}

Syntax \(\quad\) ysim \(=\) random \((m d l\), Xnew \()\)

Description

Input
Arguments

\section*{Output Arguments}

\section*{Examples}

\section*{ysim}

Vector of predicted mean values at Xnew, perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

\section*{Simulate Response Data}

Create a model of car mileage as a function of weight, and simulate the response.

Create a quadratic model of car mileage as a function of weight from the carsmall data.
load carsmall
X = Weight;
```

y = MPG;
mdl = LinearModel.fit(X,y,'quadratic');

```

Create simulated responses to the data.
```

Xnew = X;
ysim = random(mdl,Xnew);

```

Plot the original responses and the simulated responses to see how they differ.
```

plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')

```

\section*{LinearModel.random}
Alternatives For predictions without random noise, use predict or feval.
See Also feval | LinearModel | predict
Tutorials - "random" on page 9-41
How To - "Linear Regression" on page 9-11

\section*{Input Arguments}

\section*{Purpose}

Simulate responses for nonlinear regression model
Syntax
```

ysim $=$ random(mdl,Xnew)
ysim $=$ random(mdl,Xnew,'Weights', W)
ysim = random(mdl,Xnew,'Weights',W)

```
ysim = random(mdl,Xnew) simulates responses from the mdl nonlinear model to the data in Xnew, adding random noise.
ysim = random(mdl,Xnew, 'Weights', W) simulates responses using the observation weights, W .

\section*{mdl}

Nonlinear regression model, constructed by NonLinearModel.fit.

\section*{Xnew}

Points at which mdl predicts responses.
- If Xnew is a dataset array, it must contain the predictor names in mdl.
- If Xnew is a numeric matrix, it must have the same number of variables (columns) as was used to create mdl. Furthermore, all variables used in creating mdl must be numeric.

\section*{W}

Vector of real, positive value weights or a function handle.
- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in Xnew.
- If you specify a function handle, the function must accept a vector of predicted response values as input, and returns a vector of real positive weights as output.

Given weights, W, random estimates the error variance at observation i by MSE* (1/W(i)), where MSE is the mean squared error.

\section*{NonLinearModel.random}

Default: No weights

\section*{Output ysim}

Arguments

\section*{Examples}

\section*{Simulate Responses}

Create a nonlinear model of car mileage as a function of weight, and simulate the response.

Create an exponential model of car mileage as a function of weight from the carsmall data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.
```

load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [$$
\begin{array}{lll}{1}&{1}&{1}\end{array}
$$];
mdl = NonLinearModel.fit(X,y,modelfun,betaO);

```

Create simulated responses to the data.
```

Xnew = X;
ysim = random(mdl,Xnew);

```

Plot the original responses and the simulated responses to see how they differ.
```

plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')

```

Alternatives For predictions without added noise, use predict.
See Also feval | NonLinearModel | predict |
Related - "Predict or Simulate Responses to New Data" on page 9-208 Examples
Concepts - "Nonlinear Regression" on page 9-198

\section*{piecewisedistribution.random}

Purpose Random numbers from piecewise distribution
```

Syntax r = random(obj)
R = random(obj,n)
R = random(obj,m,n)
R = random(obj,[m,n])
R = random(obj,m,n,p,···...
R = random(obj,[m,n,p,···..])

```

Description \(r=\) random \((o b j)\) generates a pseudo-random number \(r\) drawn from the piecewise distribution object obj.
\(\mathrm{R}=\) random(obj, n ) generates an \(n\)-by- \(n\) matrix of pseudo-random numbers R.
\(R=\operatorname{random}(o b j, m, n)\) or \(R=\operatorname{random}(o b j,[m, n])\) generates an \(m\)-by- \(n\) matrix of pseudo-random numbers \(R\).
\(R=\operatorname{random}(o b j, m, n, p, \ldots)\) or \(R=\operatorname{random}(o b j,[m, n, p, \ldots])\) generates an \(m\)-by- \(n\)-by- \(p\)-by-... array of pseudo-random numbers R .

\section*{Examples \(\quad\) Fit Pareto tails to a \(t\) distribution at cumulative probabilities 0.1 and} 0.9:
```

t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
r = random(obj)
r=
0.8285

```

\section*{See Also paretotails | cdf | icdf}

\section*{Purpose}

Generate random number drawn from ProbDist object
Syntax
\(Y=\operatorname{random}(P D)\)
\(Y=\operatorname{random}(P D, N)\)
\(Y=\operatorname{random}(P D, N, M, \ldots)\)
\(Y=\operatorname{random}(P D)\) generates a random number drawn from the distribution specified by \(P D\), a ProbDist object.
\(Y=\operatorname{random}(P D, N)\) generates an \(N\)-by- \(N\) array of random numbers drawn from the distribution specified by \(P D\), a ProbDist object.
\(Y=\operatorname{random}(P D, N, M, \ldots)\) generates an \(N\)-by- \(M\)-by ... array of random numbers drawn from the distribution specified by \(P D\), a ProbDist object.

\section*{Input \\ Arguments}

\section*{Output \\ Arguments}

See Also

An object of the class ProbDistUnivParam or ProbDistUnivKernel.

A positive integer.
A positive integer.

A random number drawn from the distribution specified by \(P D\).

\section*{prob.TruncatableDistribution.random}

Purpose Generate random numbers from probability distribution object
Syntax \(\quad\)\begin{tabular}{rl}
\(r\) & \(=\operatorname{random}(p d)\) \\
\(r\) & \(=\operatorname{random}(p d, s z 1, \ldots, s z N)\) \\
\(r\) & \(=\operatorname{random}(p d,[s z 1, \ldots, s z N])\)
\end{tabular}

Description

Input
Arguments
\(r=\operatorname{random}(p d)\) generates a random number \(r\) from the probability distribution pd.
\(r=r a n d o m(p d, s z 1, \ldots, s z N)\) generates a sz1-by-...-by-szN array of random numbers from the probability distribution pd .
\(r=r a n d o m(p d,[s z 1, \ldots, s z N])\) generates a sz1-by-...-by-szN array of random numbers from the probability distribution pd .

\author{
pd - Probability distribution
}
probability distribution object
Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using fitdist or dfittool.

\section*{sz \(1, \ldots, s z N\) - Size of each dimension}
two or more integer values | vector of integer values
Size of each dimension, specified as two or more integer values, or a vector of such values. For example, specifying 5,3,2 or [ \(5,3,2\) ] generates a 5 -by-3-by- 2 array of random numbers from the probability distribution pd.

\author{
Data Types \\ single | double
}

\title{
prob.TruncatableDistribution.random
}

\section*{Output \\ Arguments}

\section*{r-Random number}
scalar value | array of values
Random number generated from the probability distribution, returned as a scalar value or an array of scalar values with the dimensions specified by sz1, ...,szN.

\section*{Examples Generate One Random Number}

Create a standard normal probability distribution object.
```

pd = makedist('Normal')
pd =

```

NormalDistribution

Normal distribution
mu = 0
sigma = 1
Generate one random number from the distribution.
```

r = random(pd)

```
\(r=\)
0.5377

\section*{Generate Multiple Random Numbers}

Create a Weibull probability distribution object using the default parameter values.
```

pd = makedist('Weibull')
pd =

```

WeibullDistribution
```

Weibull distribution
A = 1
B = 1

```

Generate random numbers from distribution and visualize with a histogram.
```

r = random(pd,10000,1);
hist(r,100)

```

\section*{Generate a Multidimensional Array of Random Numbers}

Create a standard normal probability distribution object.
```

pd = makedist('Normal')
pd =
NormalDistribution
Normal distribution
mu = 0
sigma = 1

```

Generate a 2-by-3-by-2 array of random numbers from the distribution.
```

r = random(pd,[2,3,2])

```
random_make_array(:,:,1) =
\begin{tabular}{rrr}
-1.0689 & -2.9443 & 0.3252 \\
-0.8095 & 1.4384 & -0.7549
\end{tabular}
```

random_make_array(:,:,2) =
1.3703 -0.1022 0.3192
-1.7115 -0.2414 0.3129

```
See Also makedist | fitdist | dfittool

\section*{randsample}

Purpose Random sample
```

Syntax y = randsample(n,k)
y = randsample(population,k)
y = randsample(n,k,replacement)
y = randsample(population, k,replacement)
y = randsample(n,k,true,w)
y = randsample(population,k,true,w)
y = randsample(s,...)

```

\section*{Description}

\section*{Examples}

Draw a single value from the integers 1 through 10:
```

n = 10;
x = randsample(n,1);

```

Draw a single value from the population 1 through \(n\), where \(n>1\) :
y = randsample(1:n,1);

Note If population is a numeric vector containing only nonnegative integer values, and population can have length 1, use
```

y = population(randsample(length(population),k))

```
instead of \(y=\) randsample(population, \(k\) ).

Generate a random sequence of the characters A, C, G, and T, with replacement, according to the specified probabilities.
```

R = randsample('ACGT',48,true,[0.15 0.35 0.35 0.15])

```

See Also rand | randperm | RandStream

\section*{randtool}

Purpose Interactive random number generation

\section*{Syntax randtool}

Description randtool opens the Random Number Generation Tool.
The Random Number Generation Tool is a graphical user interface that generates random samples from specified probability distributions and displays the samples as histograms. Use the tool to explore the effects of changing parameters and sample size on the distributions.

\section*{randtool}

Start by selecting a distribution, then enter the desired sample size.
You can also
- Use the controls at the bottom of the window to set parameter values for the distribution and to change their upper and lower bounds.
- Draw another sample from the same distribution, with the same size and parameters.
- Export the current sample to your workspace. A dialog box enables you to provide a name for the sample.

\section*{See Also}
disttool | dfittool
Purpose Range of values
Syntax range (X) ..... y = range(X, dim)
Description
ExamplesThe range of a large sample of standard normal random numbers isapproximately six. This is the motivation for the process capabilityindices \(C_{\mathrm{p}}\) and \(C_{\mathrm{pk}}\) in statistical quality control applications.
```

rv = normrnd(0,1,1000,5);
near6 = range(rv)
near6 =
6.1451 6.4986 6.2909 5.8894 7.0002

```
See Also std \| iqr \| mad

Purpose Find all neighbors within specified distance
```

Syntax idx = rangesearch(X,Y,r)
[idx,D]= rangesearch(X,Y,r)
[idx,D]= rangesearch(X,Y,r,Name,Value)

```

\section*{Description}

Tips

Input
Arguments
idx \(=\) rangesearch \((X, Y, r)\) finds all the \(X\) points that are within distance \(r\) of the \(Y\) points. Rows of \(X\) and \(Y\) correspond to observations, and columns correspond to variables.
[idx, D]= rangesearch ( \(\mathrm{X}, \mathrm{Y}, \mathrm{r}\) ) returns the distances between each row of \(Y\) and the rows of \(X\) that are \(r\) or less distant.
[idx, D]= rangesearch ( \(X, Y, r\), Name, Value) finds nearby points with additional options specified by one or more Name, Value pair arguments.
- For a fixed positive integer K, knnsearch finds K points in X that are nearest each \(Y\) point. In contrast, for a fixed positive real value \(r\), rangesearch finds all the \(X\) points that are within a distance \(r\) of each \(Y\) point.

\section*{X}
\(m x\)-by- \(n\) numeric matrix, where each row represents one \(n\)-dimensional point. The number of columns \(n\) must equal as the number of columns in Y .

\section*{Y}
\(m y\)-by- \(n\) numeric matrix, where each row represents one \(n\)-dimensional point. The number of columns \(n\) must equal as the number of columns in \(X\).
r
Search radius, a scalar. rangesearch finds all \(X\) points (rows) that are within distance \(r\) of each \(Y\) point. The meaning of distance depends on the Distance name-value pair.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'BucketSize'}

Maximum number of data points in the leaf node of the \(k d\)-tree. This argument is only meaningful when \(k d\)-tree is used for finding nearest neighbors.

Default: 50

\section*{'Cov'}

Positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This argument is only valid when the Distance name-value pair is 'mahalanobis'.

Default: nancov (X)

\section*{'Distance'}

String or function handle specifying the distance metric.
\begin{tabular}{l|l}
\hline Value & Description \\
\hline 'euclidean' & Euclidean distance. \\
\hline 'seuclidean' & \begin{tabular}{l} 
Standardized Euclidean distance. Each \\
coordinate difference between X and a query \\
point is scaled, meaning divided by a scale \\
value S. The default value of S is the standard \\
deviation computed from X, S=nanstd (X). To \\
specify another value for S, use the Scale \\
name-value pair.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Value & Description \\
\hline 'mahalanobis' & \begin{tabular}{l} 
Mahalanobis distance, computed using a \\
positive definite covariance matrix C. The \\
default value of C is the sample covariance \\
matrix of X, as computed by nancov (X). To \\
specify a different value for C, use the 'Cov' \\
name-value pair.
\end{tabular} \\
\hline 'cityblock' & City block distance. \\
\hline 'minkowski' & \begin{tabular}{l} 
Minkowski distance. The default exponent is \\
2. To specify a different exponent, use the 'P' \\
name-value pair.
\end{tabular} \\
\hline 'chebychev' & \begin{tabular}{l} 
Chebychev distance (maximum coordinate \\
difference).
\end{tabular} \\
\hline 'cosine' & \begin{tabular}{l} 
One minus the cosine of the included angle \\
between observations (treated as vectors).
\end{tabular} \\
\hline 'correlation' & \begin{tabular}{l} 
One minus the sample linear correlation \\
between observations (treated as sequences \\
of values).
\end{tabular} \\
\hline 'hamming' & \begin{tabular}{l} 
Hamming distance, percentage of coordinates \\
that differ.
\end{tabular} \\
\hline 'jaccard ' & \begin{tabular}{l} 
One minus the Jaccard coefficient, the \\
percentage of nonzero coordinates that differ.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Value & Description \\
\hline 'spearman' & One minus the sample Spearman's rank correlation between observations (treated as sequences of values). \\
\hline @distfun & \begin{tabular}{l}
Distance function handle. distfun has the form \\
function D2 = DISTFUN(ZI,ZJ) \\
where \\
- ZI is a 1 -by- N vector containing one row of X or Y . \\
- ZJ is an M2-by-N matrix containing multiple rows of X or Y . \\
- D2 is an M2-by-1 vector of distances, D2 (k) is the distance between the observations ZI and \(Z J(J,:)\).
\end{tabular} \\
\hline
\end{tabular}

For definitions, see "Distance Metrics" on page 15-9.
Default: 'euclidean'

\section*{'NSMethod'}

Nearest neighbors search method.
\begin{tabular}{l|l}
\hline Value & Meaning \\
\hline 'kdtree' & \begin{tabular}{l} 
Creates and uses a kd-tree to find nearest \\
neighbors. 'kdtree' is only valid when the \\
distance metric is one of:
\end{tabular} \\
& - 'chebyshev' \\
- 'cityblock' \\
& - 'euclidean' \\
& - 'minkowski'
\end{tabular}

Default: 'kdtree' when the number of columns of X is not greater than \(10, \mathrm{X}\) is not sparse, and the distance metric is one of the valid 'kdtree' metrics. Otherwise, the default is 'exhaustive'.

\section*{'P'}

Positive scalar indicating the exponent of Minkowski distance.
This argument is only valid when the Distance name-value pair is 'minkowski'.

\section*{Default: 2}

\section*{'Scale'}

Vector \(S\) containing nonnegative values, with length equal to the number of columns in \(X\). Each coordinate difference between \(X\) and a query point is scaled by the corresponding element of \(S\). This argument is only valid when the Distance name-value pair is 'seuclidean'.

Default: nanstd(X)

\section*{Output \\ idx}

Arguments

\section*{Definitions}

Examples
\(m y\)-by- 1 cell array, where \(m y\) is the number of rows in Y . idx\{I\} contains the indices of points (rows) in X whose distances to \(\mathrm{Y}(\mathrm{I},:\) ) are not greater than \(r\). The entries in idx \(\{I\}\) are in ascending order of distance.

\section*{D}
\(m y\)-by- 1 cell array, where \(m y\) is the number of rows in Y . D\{I \} contains the distance values between \(Y(I,:)\) and the corresponding points in idx\{I\}.

\section*{Distance Metrics}

For definitions, see "Distance Metrics" on page 15-9.

Find the \(X\) points that are within a Euclidean distance 1.5 of each \(Y\) point. Both \(X\) and \(Y\) are samples of 5-D normally distributed variables.
```

rng('default') % for reproducibility
X = randn(100,5);
Y = randn(10,5);
[idx, dist] = rangesearch(X,Y,1.5)
idx =
[1x7 double]
[1x2 double]
[1\times11 double]
[1x2 double]
[1\times12 double]
[1x9 double]
[ 89]
[1x0 double]
[1x0 double]
[1x0 double]
dist =

```
\begin{tabular}{ll}
{\([1 \times 7\)} & double \(]\) \\
{\([1 \times 2\)} & double \(]\) \\
{\([1 \times 11\)} & double \(]\) \\
{\([1 \times 2\)} & double \(]\) \\
{\([1 \times 12\)} & double \(]\) \\
{\([1 \times 9\)} & double \(]\) \\
{\([\)} & \(1.1739]\) \\
{\([1 \times 0\)} & double \(]\) \\
{\([1 \times 0\)} & double \(]\) \\
{\([1 \times 0\)} & double \(]\)
\end{tabular}

In this case, the last three \(Y\) points are more than 1.5 distant from any \(X\) point. \(X(89,:)\) is 1.1739 distant from \(Y(7,:)\), and there is no other \(X\) point that is within distance 1.5 of \(Y(7,:)\). There are 12 points in \(X\) within distance 1.5 of \(Y(5,:)\).

\footnotetext{
Algorithms
For an overview of the \(k\) d-tree algorithm, see " \(k\)-Nearest Neighbor Search Using a \(k\) d-Tree" on page 15-14.

The exhaustive search algorithm finds the distance of each point in \(X\) to each point in \(Y\).

How To \(\quad\) " \(k\)-Nearest Neighbor Search and Radius Search" on page 15-12
}

\section*{Purpose}

Syntax
idx = rangesearch(NS, \(\mathrm{Y}, \mathrm{r}\) )
[idx, D]= rangesearch(NS,Y,r)
[idx, D] = rangesearch(NS, Y, r, Name, Value)

Find all neighbors within specified distance using ExhaustiveSearcher object

\section*{Tips}

Input
Arguments
idx \(=\) rangesearch(NS, \(Y, r\) ) finds all points in NS. \(X\) that are within distance \(r\) of the \(Y\) points. Rows of NS. \(X\) and \(Y\) correspond to observations, and columns correspond to variables.
[idx, D]= rangesearch(NS, Y, r) returns the distances between each row of \(Y\) and the rows of NS. \(X\) that are \(r\) or less distant.
[idx, D]= rangesearch(NS, Y, r, Name, Value) finds nearby points with additional options specified by one or more Name, Value pair arguments.
- For a fixed positive integer K, knnsearch finds the K points in NS.X that are nearest each \(Y\) point. In contrast, for a fixed positive real value \(r\), rangesearch finds all the points in NS. \(X\) that are within a distance \(r\) of each \(Y\) point.

NS
ExhaustiveSearcher object, constructed using ExhaustiveSearcher or createns.

Y
\(m y\)-by- \(n\) numeric matrix, where each row represents one \(n\)-dimensional point. The number of columns \(n\) must equal the number of columns in NS. X.
r

Search radius, a scalar. rangesearch finds all NS.X points (rows) that are within distance \(r\) of each \(Y\) point. The meaning of distance depends on the Distance name-value pair.

\section*{ExhaustiveSearcher.rangesearch}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'Cov'}

Positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This argument is only valid when the Distance name-value pair is 'mahalanobis'.

Default: nancov (X)

\section*{'Distance'}

String or function handle specifying the distance metric.
\begin{tabular}{l|l}
\hline Value & Description \\
\hline 'euclidean' & Euclidean distance. \\
\hline 'seuclidean' & \begin{tabular}{l} 
Standardized Euclidean distance. Each \\
coordinate difference between X and a \\
query point is scaled, meaning divided by \\
a scale value S. The default value of S is \\
the standard deviation computed from X, \\
S=nanstd (X). To specify another value for \\
S, use the Scale name-value pair.
\end{tabular} \\
\hline 'mahalanobis' & \begin{tabular}{l} 
Mahalanobis distance, computed using a \\
positive definite covariance matrix C. The \\
default value of C is the sample covariance \\
matrix of X, as computed by nancov (X). \\
To specify a different value for C, use the \\
'Cov' name-value pair.
\end{tabular} \\
\hline 'cityblock' & City block distance. \\
\hline
\end{tabular}
\(\left.\left.\begin{array}{l|l}\hline \text { Value } & \text { Description } \\ \hline \text { 'minkowski' } & \begin{array}{l}\text { Minkowski distance. The default exponent } \\ \text { is 2. To specify a different exponent, use } \\ \text { the 'P' name-value pair. }\end{array} \\ \hline \text { 'chebychev' } & \begin{array}{l}\text { Chebychev distance (maximum coordinate } \\ \text { difference). }\end{array} \\ \hline \text { 'cosine' } & \begin{array}{l}\text { One minus the cosine of the included angle } \\ \text { between observations (treated as vectors). }\end{array} \\ \hline \text { 'correlation' } & \begin{array}{l}\text { One minus the sample linear correlation } \\ \text { between observations (treated as } \\ \text { sequences of values). }\end{array} \\ \hline \text { 'hamming' } & \begin{array}{l}\text { Hamming distance, percentage of } \\ \text { coordinates that differ. }\end{array} \\ \hline \text { 'jaccard' } & \begin{array}{l}\text { One minus the Jaccard coefficient, the } \\ \text { percentage of nonzero coordinates that } \\ \text { differ. }\end{array} \\ \hline \text { 'spearman' } & \begin{array}{l}\text { One minus the sample Spearman's rank } \\ \text { correlation between observations (treated } \\ \text { as sequences of values). }\end{array} \\ \hline \text { @distfun } & \begin{array}{l}\text { Distance function handle. distfun has } \\ \text { the form }\end{array} \\ \text { function D2 = DISTFUN(ZI , ZJ) }\end{array}\right\} \begin{array}{l}\text { I. } \\ \text { where } \\ \text { - ZI is a 1-by-N vector containing one row } \\ \text { of X or Y. } \\ \text { - ZJ is an M2-by-N matrix containing } \\ \text { multiple rows of X or Y. }\end{array}\right\}\)

\section*{ExhaustiveSearcher.rangesearch}
\begin{tabular}{l|l} 
Value & Description \\
\hline & - D2 is an M2-by-1 vector of distances, \\
& D2 (k) is the distance between the \\
observations ZI and \(\mathrm{ZJ}(J,:)\). \\
\hline
\end{tabular}

For definitions, see "Distance Metrics" on page 15-9.
Default: 'euclidean'

\section*{'P'}

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the Distance name-value pair is 'minkowski'.

\section*{Default: 2}

\section*{'Scale'}

Vector \(S\) containing nonnegative values, with length equal to the number of columns in \(X\). Each coordinate difference between X and a query point is scaled by the corresponding element of \(S\). This argument is only valid when the Distance name-value pair is 'seuclidean'.

Default: nanstd (X)
```

Output idx
Arguments
my-by-1 cell array, where my is the number of rows in Y. idx{I }
contains the indices of points (rows) in NS.X whose distances
to Y(I,:) are not greater than r. The entries in idx{I} are in
ascending order of distance.

```

\section*{D}

\section*{ExhaustiveSearcher.rangesearch}
\(m y\)-by- 1 cell array, where \(m y\) is the number of rows in Y . \(D\{I\}\) contains the distance values between \(Y(I,:)\) and the corresponding points in idx\{I \(\}\).

\section*{Definitions Distance Metrics}

For definitions, see "Distance Metrics" on page 15-9.
Examples Create \(X\) and \(Y\) as samples of 5-D normally distributed variables. Create an ExhaustiveSearcher object NS from X. Find the points in NS.X that are within a Euclidean distance 1.5 of each point in \(Y\).
```

rng('default') % for reproducibility
X = randn(100,5);
Y = randn(10,5);
NS = ExhaustiveSearcher(X);
[idx, dist] = rangesearch(NS,Y,1.5)
idx =
[1x7 double]
[1x2 double]
[1x11 double]
[1x2 double]

\section*{Description}

\section*{Tips}

Input
Arguments

Find all neighbors within specified distance using KDTreeSearcher object
idx = rangesearch(NS, \(Y, r\) )
[idx, D]= rangesearch(NS, Y, r)
[idx, D] = rangesearch(NS, Y, r,Name, Value)
\(i d x=\) rangesearch(NS, \(Y, r\) ) finds all points in NS. \(X\) that are within distance \(r\) of the \(Y\) points. Rows of NS. \(X\) and \(Y\) correspond to observations, and columns correspond to variables.
[idx, D]= rangesearch(NS,Y,r) returns the distances between each row of \(Y\) and the rows of NS. \(X\) that are \(r\) or less distant.
[idx, D] = rangesearch(NS, Y, r, Name, Value) finds nearby points with additional options specified by one or more Name, Value pair arguments.
- For a fixed positive integer K, knnsearch finds the K points in NS.X that are nearest each \(Y\) point. In contrast, for a fixed positive real value \(r\), rangesearch finds all the points in NS. \(X\) that are within a distance \(r\) of each \(Y\) point.

NS
KDTreeSearcher object, constructed using KDTreeSearcher or createns.

Y
\(m y\)-by- \(n\) numeric matrix, where each row represents one \(n\)-dimensional point. The number of columns \(n\) must equal the number of columns in NS. X.
r

Search radius, a scalar. rangesearch finds all NS.X points (rows) that are within distance \(r\) of each \(Y\) point. The meaning of distance depends on the Distance name-value pair.

\section*{KDTreeSearcher.rangesearch}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'Distance'}

String or function handle specifying the distance metric.
\begin{tabular}{l|l}
\hline Value & Description \\
\hline 'euclidean' & Euclidean distance. \\
\hline 'cityblock' & City block distance. \\
\hline 'minkowski' & \begin{tabular}{l} 
Minkowski distance. The default exponent \\
is 2. To specify a different exponent, use \\
the 'P' name-value pair.
\end{tabular} \\
\hline 'chebychev' & \begin{tabular}{l} 
Chebychev distance (maximum coordinate \\
difference).
\end{tabular} \\
\hline
\end{tabular}

For definitions, see "Distance Metrics" on page 15-9.
Default: NS.Distance

\section*{'P'}

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the Distance name-value pair is 'minkowski'.

Default: 2

\section*{Output idx}

Arguments
\(m y\)-by- 1 cell array, where \(m y\) is the number of rows in Y . idx \(\{\mathrm{I}\}\) contains the indices of points (rows) in NS. X whose distances
to \(Y(I,:)\) are not greater than \(r\). The entries in idx\{I\} are in ascending order of distance.

\section*{D}
\(m y\)-by- 1 cell array, where \(m y\) is the number of rows in Y . \(\mathrm{D}\{\mathrm{I}\}\) contains the distance values between \(\mathrm{Y}(\mathrm{I},:\) ) and the corresponding points in idx\{I\}.

\section*{Definitions \\ Distance Metrics}

For definitions, see "Distance Metrics" on page 15-9.

\section*{Purpose Wilcoxon rank sum test}

\section*{Syntax}
```

p = ranksum(x,y)
[p,h] = ranksum(x,y)
[p,h,stats] = ranksum(x,y)
[ ___] = ranksum(x,y,Name,Value)

```

Description

\section*{Input Arguments}
\(\mathrm{p}=\) ranksum ( \(\mathrm{x}, \mathrm{y}\) ) returns the \(p\)-value of a two-sided Wilcoxon rank sum test. ranksum tests the null hypothesis that data in \(x\) and \(y\) are samples from continuous distributions with equal medians, against the alternative that they are not. The test assumes that the two samples are independent. \(x\) and \(y\) can have different lengths.

This test is equivalent to a Mann-Whitney U-test.
\([p, h]=\operatorname{ranksum}(x, y)\) also returns a logical value indicating the test decision. The result \(\mathrm{h}=1\) indicates a rejection of the null hypothesis, and \(h=0\) indicates a failure to reject the null hypothesis at the \(5 \%\) significance level.
[p,h,stats] = ranksum( \(x, y\) ) also returns the structure stats with information about the test statistic.
[ __ ] = ranksum( \(x, y\), Name, Value) returns any of the output arguments in the previous syntaxes, for a rank sum test with additional options specified by one or more Name,Value pair arguments.

\section*{x-Sample data}
vector
Sample data, specified as a vector.
Data Types
single | double

\section*{\(y\)-Sample data}
vector
Sample data, specified as a vector. The length of \(y\) does not have to be the same as the length of \(x\).

\section*{Data Types \\ single | double}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'alpha', 0.01,'method','approximate','tail','right' specifies a right-tailed rank sum test with \(1 \%\) significance level, which returns the approximate p -value.

\section*{'alpha' - Significance level}
0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1 . The significance level of h is 100 * alpha\%.

Example: 'alpha', 0.01
```

Data Types
double | single

```

\section*{'method' - Computation method of the p-value}
'exact' | 'approximate'
Computation method of the \(p\)-value, p , specified as the comma-separated pair consisting of 'method' and one of the following:
\begin{tabular}{l|l}
\hline 'exact' & Exact computation of the \(p\)-value, p. \\
\hline 'approximate & 'Normal approximation while computing the \(p\)-value, p. \\
\hline
\end{tabular}

When 'method ' is unspecified, the default is:
- 'exact' if \(\min \left(n_{x}, n_{y}\right)<10\) and \(n_{x}+n_{y}<20\)
- 'approximate' otherwise
\(n_{x}\) and \(n_{y}\) are the sizes of the samples in x and y , respectively.
Example: 'method','exact'

\section*{Data Types}
char
```

'tail' - Type of test

```
'both' (default) | 'right' | 'left'
Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:
\begin{tabular}{l|l}
\hline 'both' & \begin{tabular}{l} 
Two-sided hypothesis test, where the alternative \\
hypothesis states that \(x\) and \(y\) have different medians. \\
Default test type if 'tail' is not specified.
\end{tabular} \\
\hline 'right' & \begin{tabular}{l} 
Right-tailed hypothesis test, where the alternative \\
hypothesis states that the median of \(x\) is greater than the \\
median of y.
\end{tabular} \\
\hline 'left' & \begin{tabular}{l} 
Left-tailed hypothesis test, where the alternative \\
hypothesis states that the median of \(x\) is less than the \\
median of y.
\end{tabular} \\
\hline
\end{tabular}

Example: 'tail','left'

\section*{Data Types \\ char}

\section*{Output \\ Arguments}

\section*{\(\mathbf{p}\) - \(\boldsymbol{p}\)-value of the test}
nonnegative scalar
\(p\)-value of the test, returned as a positive scalar from 0 to \(1 . \mathrm{p}\) is the probability of observing a test statistic as or more extreme than
the observed value under the null hypothesis. ranksum computes the two-sided \(p\)-value by doubling the most significant one-sided value.

\section*{h-Result of the hypothesis test}

1 | 0
Result of the hypothesis test, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates rejection of the null hypothesis at the 100 * alpha\% significance level.
- If \(\mathrm{h}=0\), this indicates a failure to reject the null hypothesis at the 100 * alpha\% significance level.

\section*{stats - Test statistics}

\section*{structure}

Test statistics, returned as a structure. The test statistics stored in stats are:
- ranksum : Value of the rank sum test statistic
- zval: Value of the z-statistic (computed when 'method' is 'approximate')

\section*{Examples Test for Equal Median of Two Populations}

Test the hypothesis of equal medians for two independent unequal-sized samples.

Generate sample data.
```

rng('default') % for reproducibility
x = unifrnd(0,1,10,1);
y = unifrnd(0.25,1.25,15,1);

```

These samples come from populations with identical distributions except for a shift of 0.25 in the location.

Test the equality of medians of \(x\) and \(y\).
```

p = ranksum(x,y)
p =
0.0375

```

The \(p\)-value of 0.0375 indicates that ranksum rejects the null hypothesis of equal medians at the default \(5 \%\) significance level.

\section*{Statistics of the Test for Two Population Medians}

Obtain the statistics of the test for the equality of two population medians.

Load the sample data.
```

load mileage

```

Test if the mileage per gallon is the same for the first and second type of cars.
```

[p,h,stats] = ranksum(mileage(:,1),mileage(:,2))
p =
0.0043
h =
1
stats =
ranksum: 21.5000

```

Both the \(p\)-value, 0.043 , and \(\mathrm{h}=1\) indicate the rejection of the null hypothesis of equal medians at the default \(5 \%\) significance level. Because the sample sizes are small (six each), ranksum calculates the \(p\)-value using the exact method. The structure stats includes only the value of the rank sum test statistic.

\section*{Increase in the Median}

Test the hypothesis of an increase in the population median.

Navigate to a folder containing sample data.
```

cd(matlabroot)
cd('help/toolbox/stats/examples')

```

Load the sample data.
load weather

The weather data shows the daily high temperatures taken in the same month in two consecutive years.

Perform a left-sided test to assess the increase in the median at the \(1 \%\) significance level.
```

[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left')
p =
0.1271
h =
0
stats =
zval: -1.1403
ranksum: 837.5000

```

Both the \(p\)-value of 0.1271 and \(\mathrm{h}=0\) indicate that there is not enough evidence to reject the null hypothesis and conclude that there is a positive shift in the median of observed high temperatures in the same month from year 1 to year 2 at the \(1 \%\) significance level. Notice that
ranksum uses the approximate method to calculate the \(p\)-value due to the large sample sizes.

Use the exact method to calculate the \(p\)-value.
```

[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left','method','exact')
p =

```
    0.1273
\(\mathrm{h}=\)
    0
stats =
ranksum: 837.5000
The results of the approximate and exact methods are consistent with each other.

\section*{Definitions Wilcoxon Rank Sum Test}

The Wilcoxon rank sum test is a nonparametric test for two populations when samples are independent. If \(X\) and \(Y\) are independent samples with different sample sizes, the test statistic which ranksum returns is the rank sum of the first sample.

The Wilcoxon rank sum test is equivalent to the Mann-Whitney U-test. The Mann-Whitney U-test is a nonparametric test for equality of population medians of two independent samples \(X\) and \(Y\).
The Mann-Whitney U-test statistic, \(U\), is the number of times a \(y\) precedes an \(x\) in an ordered arrangement of the elements in the two
independent samples \(X\) and \(Y\). It is related to the Wilcoxon rank sum statistic in the following way: If \(\mathbf{X}\) is a sample of size \(n_{X}\), then
\[
U=W-\frac{n_{X}\left(n_{X}+1\right)}{2} .
\]

\section*{z-Statistic}

For large samples, ranksum uses a \(z\)-statistic to compute the approximate \(p\)-value of the test.

If \(X\) and \(Y\) are two independent samples of size \(n_{X}\) and \(n_{Y}\), where \(n_{X}<\) \(n_{Y}\) the \(z\)-statistic is
\[
z=\frac{W-E(W)}{\sqrt{V(W)}}=\frac{W-\left[\frac{n_{X} n_{Y}+n_{X}\left(n_{X}+1\right)}{2}\right]-0.5 * \operatorname{sign}(W-E(W))}{\sqrt{\frac{n_{X} n_{Y}\left(n_{X}+n_{Y}+1\right)-\operatorname{tiescor}}{12}}},
\]
with continuity correction and tie adjustment. Here tiescor is given by
\[
\text { tiescor }=\frac{2 * \text { tieadj }}{\left(n_{X}+n_{Y}\right)\left(n_{X}+n_{Y}-1\right)},
\]
where ranksum uses [ranks, tieadj] = tiedrank \((x, y)\) to obtain tie adjustments. The standard normal distribution gives the \(p\)-value for this \(z\)-statistic.

\section*{Algorithms}
ranksum treats NaNs in x and y as missing values and ignores them. For a two-sided test of medians with unequal sample sizes, the test statistic that ranksum returns is the rank sum of the first sample.

Purpose Rayleigh cumulative distribution function

\section*{Syntax \(\quad P=\operatorname{raylcdf}(X, B)\)}

Description
\(P=\operatorname{raylcdf}(X, B)\) computes the Rayleigh cdf at each of the values in \(X\) using the corresponding scale parameter, \(B . X\) and \(B\) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for \(X\) or \(B\) is expanded to a constant array with the same dimensions as the other input.

The Rayleigh cdf is
\[
y=F(x \mid b)=\int_{0}^{x} \frac{t}{b^{2}} e^{\left(\frac{-t^{2}}{2 b^{2}}\right)} d t
\]

\section*{Examples}
```

x = 0:0.1:3;
p = raylcdf(x,1);
plot(x,p)

```

\section*{Superclasses ToolboxFittableParametricDistribution}

Purpose Rayleigh probability distribution object
Description prob.RayleighDistribution is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd = makedist('Rayleigh') creates a Rayleigh probability distribution object using the default parameter values.
pd = makedist('Rayleigh', 'b', b) creates a Rayleigh probability distribution object using the specified parameter value.

\section*{Input Arguments}

\section*{b-Defining parameter}

1 (default) | positive scalar value
Defining parameter for the Rayleigh distribution, specified as a positive scalar value.

\section*{Data Types}
single | double

\section*{Properties}
b
Defining parameter for the Rayleigh distribution, stored as a positive scalar value.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{prob.RayleighDistribution}

\section*{Data Types \\ char \\ InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

\section*{Data Types}
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types \\ single | double \\ ParameterCovariance}

Covariance matrix of the parameter estimates, stored as a \(p\)-by- \(p\) matrix, where \(p\) is the number of parameters in the distribution. The ( \(\mathrm{i}, \mathrm{j}\) ) element is the covariance between the estimates of the ith parameter and the \(j\) th parameter. The ( \(i, i\) ) element is the
estimated variance of the ith parameter. If parameter \(i\) is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{Data Types}
char

\section*{ParameterlsFixed}

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

\section*{Data Types}
logical

\section*{ParameterNames}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types \\ char \\ ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\author{
Data Types \\ single | double \\ Truncation
}

\section*{prob.RayleighDistribution}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

\section*{Definitions Rayleigh Distribution}

The Rayleigh distribution is a special case of the Weibull distribution. It is often used in communication theory to model scattered signals that reach a receiver by multiple paths.

The Rayleigh distribution uses the following parameter.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline b & Defining parameter & \(b>0\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid b)=\frac{x}{b^{2}} \exp \left\{\frac{-x^{2}}{2 b^{2}}\right\} \quad ; \quad x \geq 0
\]

\section*{Examples Create a Rayleigh Distribution Object Using Default Parameters}

How To - "Rayleigh Distribution" on page B-104

Purpose Rayleigh inverse cumulative distribution function
\[
\text { Syntax } \quad X=\operatorname{raylinv}(P, B)
\]

Description \(\quad X=\operatorname{raylinv}(P, B)\) returns the inverse of the Rayleigh cumulative distribution function using the corresponding scale parameter, B at the corresponding probabilities in P. P and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for P or B is expanded to a constant array with the same dimensions as the other input.
Examples \(\quad\)\begin{tabular}{rl}
\(x\) & \(=\operatorname{raylinv}(0.9,1)\) \\
& \(x=\) \\
& 2.1460
\end{tabular}

See Also raylcdf | raylpdf | raylrnd | raylstat
How To
- icdf
- "Rayleigh Distribution" on page B-104

\section*{Purpose}

Rayleigh probability density function

\section*{Syntax \\ Y = raylpdf(X,B)}
\(Y=\operatorname{raylpdf}(X, B)\) computes the Rayleigh pdf at each of the values in \(X\) using the corresponding scale parameter, \(B . X\) and \(B\) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for X or B is expanded to a constant array with the same dimensions as the other input.

The Rayleigh pdf is
\[
y=f(x \mid b)=\frac{x}{b^{2}} e^{\left(\frac{-x^{2}}{2 b^{2}}\right)}
\]

\section*{Examples}
```

x = 0:0.1:3;
p = raylpdf(x,1);
plot(x,p)

```

\section*{raylrnd}

Purpose Rayleigh random numbers
Syntax
\(R\) = raylrnd(B)
\(R\) = raylrnd( \(B, v\) )
\(R\) = raylrnd( \(B, m, n\) )

\section*{Description}

\section*{Examples}

How To

See Also random | raylpdf | raylcdf | raylinv | raylstat | raylfit
\(R=\) raylrnd( \(B\) ) returns a matrix of random numbers chosen from the Rayleigh distribution with scale parameter, B. B can be a vector, a matrix, or a multidimensional array. The size of \(R\) is the size of \(B\).
\(R=\) raylrnd( \(B, v\) ) returns a matrix of random numbers chosen from the Rayleigh distribution with parameter \(B\), where \(v\) is a row vector. If \(v\) is a 1 -by- 2 vector, \(R\) is a matrix with \(v(1)\) rows and \(v(2)\) columns. If \(v\) is 1-by- \(\mathrm{n}, \mathrm{R}\) is an n -dimensional array.
\(R=\operatorname{raylrnd}(B, m, n)\) returns a matrix of random numbers chosen from the Rayleigh distribution with parameter \(B\), where scalars \(m\) and \(n\) are the row and column dimensions of R .
```

r = raylrnd(1:5)
r =
1.7986

```
random | raylpdf | raylcdf | raylinv | raylstat | raylfit
- "Rayleigh Distribution" on page B-104

\section*{Purpose}

Rayleigh mean and variance

\section*{Syntax}

Description
\([M, V]=\operatorname{raylstat}(B)\)
\([M, V]=\) raylstat \((B)\) returns the mean of and variance for the Rayleigh distribution with scale parameter B.

The mean of the Rayleigh distribution with parameter \(b\) is \(b \sqrt{\pi / 2}\) and the variance is
\[
\frac{4-\pi}{2} b^{2}
\]
```

Examples
[mn, v] = raylstat(1)
mn =
1.2533
v =
0.4292

```

See Also
raylpdf | raylcdf | raylinv | raylfit | raylrnd
How To . "Rayleigh Distribution" on page B-104

Purpose Residual case order plot

\section*{Syntax \\ rcoplot(r,rint)}

Description
rcoplot( \(r\), rint) displays an errorbar plot of the confidence intervals on the residuals from a regression. The residuals appear in the plot in case order. Inputs \(r\) and rint are outputs from the regress function.

Examples The following plots residuals and prediction intervals from a regression of a linearly additive model to the data in moore. mat:
```

load moore
X = [ones(size(moore,1),1) moore(:,1:5)];
y = moore(:,6);
alpha = 0.05;
[betahat,Ibeta,res,Ires,stats] = regress(y,X,alpha);
rcoplot(res,Ires)

```

The interval around the first residual, shown in red, does not contain zero. This indicates that the residual is larger than expected in \(95 \%\) of new observations, and suggests the data point is an outlier.

See Also regress

\section*{Purpose Add reference curve to plot}
```

Syntax refcurve(p)
refcurve
hcurve = refcurve(...)

```

\section*{Description}
refcurve ( \(p\) ) adds a polynomial reference curve with coefficients \(p\) to the current axes. If \(p\) is a vector with \(n+1\) elements, the curve is:
\(y=p(1) * x^{\wedge} n+p(2) * x^{\wedge}(n-1)+\ldots+p(n) * x+p(n+1)\)
refcurve with no input arguments adds a line along the \(x\) axis.
hcurve \(=\) refcurve(...) returns the handle hcurve to the curve.

\section*{Examples}

\section*{Example 1}

Plot data from a population with a polynomial trend and use refcurve to add both the population and fitted mean functions:
```

p = [1 -2 -1 0];
t = 0:0.1:3;
y = polyval(p,t) + 0.5*randn(size(t));
plot(t,y,'ro')
h = refcurve(p);
set(h,'Color','r')
q = polyfit(t,y,3);
refcurve(q)
legend('Data','Population Mean','Fitted Mean',...
'Location','NW')

```

\section*{Example 2}

Plot trajectories of a batted baseball, with and without air resistance.
Relevant physical constants are:
\begin{tabular}{ll}
\(M=0.145 ;\) & \%Mass (kg) \\
\(R=0.0366 ;\) & \%Radius (m) \\
\(A=p i * R^{\wedge} 2 ;\) & \% Area (m^2) \\
rho = 1.2; & \%Density of air (kg/m^3) \\
\(C=0.5 ;\) & \%Drag coefficient
\end{tabular}
```

D = rho*C*A/2;
% Drag proportional to the square of the speed
g = 9.8; %Acceleration due to gravity (m/s^2)

```

First, simulate the trajectory with drag proportional to the square of the speed, assuming constant acceleration in each time interval:
```

dt = 1e-2; % Simulation time interval (s)
rO = [0 1]; % Initial position (m)
sO = 50; % Initial speed (m/s)
alpha0 = 35; % Initial angle (deg)
v0=s0*[cosd(alphaO) sind(alpha0)]; % Initial velocity (m/s)
r = ro;
v = v0;
trajectory = r0;
while r(2) > 0
a = [0 -g]-(D/M)*norm(v)*v;
v = v + a*dt;
r = r + v*dt + (1/2)*a*(dt^2);
trajectory = [trajectory;r];
end

```

Second, use refcurve to add the drag-free parabolic trajectory (found analytically) to a plot of trajectory:
```

plot(trajectory(:,1),trajectory(:,2),'m','LineWidth',2)
xlim([0,250])
h = refcurve([-g/(2*v0(1)^2),...
(g*r0(1)/v0(1)^2)+(v0(2)/v0(1)),...
(-g*r0(1)^2/(2*v0(1)^2))-(v0(2)*r0(1)/v0(1))+r0(2)]);
set(h,'Color','c','LineWidth',2)
axis equal
ylim([0,50])
grid on
xlabel('Distance (m)')
ylabel('Height (m)')
title('{\bf Baseball Trajectories}')

```

\section*{legend('With Drag','Without Drag')}

Baseball Trajectories

See Also refline | lsline | gline | polyfit

\section*{Purpose Add reference line to plot}

\section*{Syntax \\ Description}
refline (m, b)
refline(coeffs)
refline
hline = refline(...)
refline( \(m, b\) ) adds a reference line with slope \(m\) and intercept \(b\) to the current axes.
refline(coeffs), where coeffs is a two-element coefficient vector, adds the line
\[
y=\operatorname{coeffs}(1) * x+\operatorname{coeffs}(2)
\]
to the figure.
refline with no input arguments is equivalent to lsline.
hline \(=\) refline(...) returns the handle hline to the line.

\section*{Examples}

Add a reference line at the mean of a data scatter and its least-squares line:
\(x=1: 10 ;\)
\(y=x+r a n d n(1,10) ;\)
scatter(x,y,25,'b','*')
lsline
mu = mean(y);
hline = refline([0 mu]);
set(hline, 'Color', 'r')

\section*{See Also}
refcurve | lsline | gline

\section*{Purpose \\ Multiple linear regression}

Syntax
```

b = regress(y,X)
[b,bint] = regress(y,X)
[b,bint,r] = regress(y,X)
[b,bint,r,rint] = regress(y,X)
[b,bint,r,rint,stats] = regress(y,X)
[...] = regress(y,x,alpha)

```

\section*{Description}
\(\mathrm{b}=\) regress \((\mathrm{y}, \mathrm{X})\) returns a \(p\)-by- 1 vector b of coefficient estimates for a multilinear regression of the responses in y on the predictors in \(\mathrm{X} . \mathrm{X}\) is an \(n\)-by- \(p\) matrix of \(p\) predictors at each of \(n\) observations. y is an \(n\)-by- 1 vector of observed responses.
regress treats NaNs in X or y as missing values, and ignores them.
If the columns of \(X\) are linearly dependent, regress obtains a basic solution by setting the maximum number of elements of \(b\) to zero.
[b, bint] \(=\) regress \((y, X)\) returns a \(p\)-by- 2 matrix bint of \(95 \%\) confidence intervals for the coefficient estimates. The first column of bint contains lower confidence bounds for each of the \(p\) coefficient estimates; the second column contains upper confidence bounds.

If the columns of \(X\) are linearly dependent, regress returns zeros in elements of bint corresponding to the zero elements of \(b\).
[ \(b\), bint, \(r\) ] \(=\) regress \((y, X)\) returns an \(n\)-by- 1 vector \(r\) of residuals.
[b,bint,r,rint] = regress \((y, X)\) returns an \(n\)-by- 2 matrix rint of intervals that can be used to diagnose outliers. If the interval rint (i, : ) for observation \(i\) does not contain zero, the corresponding residual is larger than expected in \(95 \%\) of new observations, suggesting an outlier.

In a linear model, observed values of y are random variables, and so are their residuals. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, they are "Studentized," that is, they are divided by an estimate of their standard deviation that is independent of their value. Studentized residuals have \(t\) distributions with known
degrees of freedom. The intervals returned in rint are shifts of the \(95 \%\) confidence intervals of these \(t\) distributions, centered at the residuals.
[b,bint, r, rint, stats] = regress \((y, X)\) returns a 1-by-4 vector stats that contains, in order, the \(R^{2}\) statistic, the \(F\) statistic and its \(p\) value, and an estimate of the error variance.

Note When computing statistics, X should include a column of 1 s so that the model contains a constant term. The \(F\) statistic and its \(p\) value are computed under this assumption, and they are not correct for models without a constant.

The \(F\) statistic is the test statistic of the F-test on the regression model, for a significant linear regression relationship between the response variable and the predictor variables.

The \(R^{2}\) statistic can be negative for models without a constant, indicating that the model is not appropriate for the data.
[...] = regress(y, X, alpha) uses a 100*(1-alpha)\% confidence level to compute bint and rint.

\section*{Examples}

Load data on cars; identify weight and horsepower as predictors, mileage as the response:
```

load carsmall
x1 = Weight;
x2 = Horsepower; % Contains NaN data
y = MPG;

```

Compute regression coefficients for a linear model with an interaction term:
```

X = [ones(size(x1)) x1 x2 x1.*x2];
b = regress(y,X) % Removes NaN data
b =

```
\[
\begin{array}{r}
60.7104 \\
-0.0102 \\
-0.1882 \\
0.0000
\end{array}
\]

Plot the data and the model:
```

scatter3(x1,x2,y,'filled')
hold on
x1fit = min(x1):100:max(x1);
x2fit = min(x2):10:max(x2);
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT + b(4)*X1FIT.*X2FIT;
mesh(X1FIT,X2FIT,YFIT)
xlabel('Weight')
ylabel('Horsepower')
zlabel('MPG')
view(50,10)

```

Weight
Horsepower

\section*{RegressionBaggedEnsemble}

Superclasses RegressionEnsemble
Purpose Regression ensemble grown by resampling
Description RegressionBaggedEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

\section*{Construction \\ ens =}
fitensemble(X,Y,'bag', nlearn, learners,'type', 'regression') creates a bagged regression ensemble. For more information on the syntax, see the fitensemble function reference page.

\section*{Properties}

\section*{CategoricalPredictors}

List of categorical predictors. CategoricalPredictors is a numeric vector with indices from 1 to \(p\), where \(p\) is the number of columns of \(X\).

\section*{CombineWeights}

A string describing how the ensemble combines learner predictions.

\section*{FitInfo}

A numeric array of fit information. The FitInfoDescription property describes the content of this array.

\section*{FitInfoDescription}

String describing the meaning of the FitInfo array.

\section*{FResample}

A numeric scalar between 0 and 1. FResample is the fraction of training data fitensemble resampled at random for every weak learner when constructing the ensemble.

\section*{LearnerNames}

Cell array of strings with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, LearnerNames is \{'Tree'\}.

\section*{Method}

A string with the name of the algorithm fitensemble used for training the ensemble.

\section*{ModelParams}

Parameters used in training ens.

\section*{NObservations}

Numeric scalar containing the number of observations in the training data.

\section*{NTrained}

Number of trained learners in the ensemble, a positive scalar.

\section*{PredictorNames}

A cell array of names for the predictor variables, in the order in which they appear in \(X\).

\section*{ReasonForTermination}

A string describing the reason fitensemble stopped adding weak learners to the ensemble.

\section*{Regularization}

A structure containing the result of the regularize method. Use Regularization with shrink to lower resubstitution error and shrink the ensemble.

\section*{Replace}

Boolean flag indicating if training data for weak learners in this ensemble were sampled with replacement. Replace is true for sampling with replacement, false otherwise.

\section*{RegressionBaggedEnsemble}

\section*{ResponseName}

A string with the name of the response variable Y .

\section*{ResponseTransform}

Function handle for transforming scores, or string representing a built-in transformation function. ' none' means no transformation; equivalently, 'none' means @(x)x.

Add or change a ResponseTransform function by dot addressing:
ens.ResponseTransform = @function

\section*{Trained}

The trained learners, a cell array of compact regression models.

\section*{TrainedWeights}

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

\section*{UseObsForLearner}

A logical matrix of size \(N\)-by-NTrained, where \(N\) is the number of rows (observations) in the training data X , and NTrained is the number of trained weak learners. UseObsForLearner (I, J) is true if observation I was used for training learner \(J\), and is false otherwise.

\section*{W}

The scaled weights, a vector with length n , the number of rows in \(X\). The sum of the elements of \(W\) is 1 .

\section*{X}

The matrix of predictor values that trained the ensemble. Each column of \(X\) represents one variable, and each row represents one observation.

\section*{Y}

The numeric column vector with the same number of rows as \(X\) that trained the ensemble. Each entry in \(Y\) is the response to the data in the corresponding row of X .

Create a bagged regression ensemble to predict the mileage of cars in the carsmall data set based on their engine displacement, horsepower, and weight:
```

load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
'type','regression')
ens =
classreg.learning.regr.RegressionBaggedEnsemble:
PredictorNames: {'x1' 'x2' 'x3'}
CategoricalPredictors: []
ResponseName: 'Y'
ResponseTransform: 'none'
NObservations: 94
NTrained: 100
Method: 'Bag'
LearnerNames: {'Tree'}
ReasonForTermination: [1x77 char]
FitInfo: []
FitInfoDescription: 'None'
Regularization: []
FResample: 1
Replace: 1
UseObsForLearner: [94x100 logical]

```

Predict the mileage of a car whose characteristics are the average of those of the first 10 cars:
```

car10 = mean(X(1:10,:));
predict(ens,car10)

```

\section*{Examples}

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Create a boosted regression ensemble to predict the mileage of cars in the carsmall data set based on their weights and numbers of cylinders:
```

load carsmall
learner = RegressionTree.template('MinParent',20);
ens = fitensemble([Weight, Cylinders],MPG,...
'LSBoost',100,learner,'PredictorNames',{'W','C'},...
'categoricalpredictors',2)
ens =
classreg.learning.regr.RegressionEnsemble:
PredictorNames: {'W' 'C'}
CategoricalPredictors: 2

```

\section*{RegressionEnsemble}
```

            ResponseName: 'Response'
            ResponseTransform: 'none'
            NObservations: 94
            NTrained: 100
                Method: 'LSBoost'
            LearnerNames: {'Tree'}
    ReasonForTermination: [1x77 char]
FitInfo: [100x1 double]
FitInfoDescription: [2x83 char]
Regularization: []

```

Predict the mileage of 4,000-pound cars with 4,6 , and 8 cylinders:
```

mileage4K = predict(ens,[4000 4; 4000 6; 4000 8])

```
mileage4K =
    20.0294
    19.4206
    15.5000

\section*{RegressionPartitionedEnsemble}

\section*{Superclasses RegressionPartitionedModel}

Purpose Cross-validated regression ensemble
Description RegressionPartitionedEnsemble is a set of regression ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more "kfold" methods: kfoldfun, kfoldLoss, or kfoldPredict. Every "kfold" method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly \(4 / 5\) of the data and every test fold contains roughly \(1 / 5\) of the data. The first model stored in Trained \(\{1\}\) was trained on \(X\) and \(Y\) with the first \(1 / 5\) excluded, the second model stored in Trained \(\{2\}\) was trained on \(X\) and \(Y\) with the second \(1 / 5\) excluded, and so on. When you call kfoldPredict, it computes predictions for the first \(1 / 5\) of the data using the first model, for the second \(1 / 5\) of data using the second model and so on. In short, response for every observation is computed by kfoldPredict using the model trained without this observation.

\section*{Construction}
cvens = crossval(ens) creates a cross-validated ensemble from ens, a regression ensemble. For syntax details, see the crossval method reference page.
cvens = fitensemble(X,Y,method, nlearn,learners, name, value) creates a cross-validated ensemble when name is one of 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. For syntax details, see the fitensemble function reference page.

\section*{Input Arguments}

\section*{ens}

A regression ensemble constructed with fitensemble.

\section*{RegressionPartitionedEnsemble}

\section*{Properties CategoricalPredictors}

List of categorical predictors. CategoricalPredictors is a numeric vector with indices from 1 to \(p\), where \(p\) is the number of columns of X .

\section*{CrossValidatedModel}

Name of the cross-validated model, a string.

\section*{Kfold}

Number of folds used in a cross-validated tree, a positive integer.

\section*{ModelParams}

Object holding parameters of tree.

\section*{NObservations}

Numeric scalar containing the number of observations in the training data.

\section*{NTrainedPerFold}

Vector of Kfold elements. Each entry contains the number of trained learners in this cross-validation fold.

\section*{Partition}

The partition of class cvpartition used in creating the cross-validated ensemble.

\section*{PredictorNames}

A cell array of names for the predictor variables, in the order in which they appear in X .

\section*{ResponseName}

Name of the response variable Y , a string.

\section*{ResponseTransform}

Function handle for transforming scores, or string representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means @(x)x.

Add or change a ResponseTransform function by dot addressing: ens.ResponseTransform = @function

\section*{Trainable}

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

\section*{Trained}

Cell array of compact ensembles trained on cross-validation folds.

\section*{W}

The scaled weights, a vector with length n , the number of rows in \(X\).

\section*{X}

A matrix of predictor values. Each column of \(X\) represents one variable, and each row represents one observation.

\section*{Y}

A numeric column vector with the same number of rows as \(X\). Each entry in \(Y\) is the response to the data in the corresponding row of \(X\).

\section*{Methods}
\begin{tabular}{ll} 
kfoldLoss & \begin{tabular}{l}

\section*{RegressionPartitionedModel}

\section*{Purpose \\ Cross-validated regression model}

Description

\section*{Construction}
cvmodel \(=\) crossval(tree) creates a cross-validated classification model from a regression tree. For syntax details, see the crossval method reference page.
cvmodel = RegressionTree.fit(X,Y, name, value) creates a cross-validated model when name is one of 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. For syntax details, see the RegressionTree.fit function reference page.

\section*{Input Arguments}

\section*{tree}

A regression tree constructed with RegressionTree.fit.

\section*{Properties}

\section*{CategoricalPredictors}

List of categorical predictors. CategoricalPredictors is a numeric vector with indices from 1 to \(p\), where \(p\) is the number of columns of \(X\).

\section*{RegressionPartitionedModel}

\section*{CrossValidaredModel}

Name of the cross-validated model, a string.

\section*{Kfold}

Number of folds used in a cross-validated tree, a positive integer.

\section*{ModelParams}

Object holding parameters of tree.

\section*{Partition}

The partition of class cvpartition used in the cross-validated model.

\section*{PredictorNames}

A cell array of names for the predictor variables, in the order in which they appear in X .

\section*{ResponseName}

Name of the response variable Y , a string.

\section*{ResponseTransform}

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means @(x)x, or no transformation.

Add or change a ResponseTransform function by dot addressing:
ctree.ResponseTransform = @function

\section*{Trained}

The trained learners, a cell array of compact regression models.

\section*{W}

The scaled weights, a vector with length n , the number of rows in \(X\).

\section*{RegressionPartitionedModel}

\section*{X}

A matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

\section*{Y}

A numeric column vector with the same number of rows as \(X\). Each entry in Y is the response to the data in the corresponding row of X .

\section*{Methods}
\begin{tabular}{ll} 
kfoldfun & Cross validate function \\
kfoldLoss & \begin{tabular}{l} 
Cross-validation loss of \\
partitioned regression model
\end{tabular} \\
kfoldPredict & \begin{tabular}{l} 
Predict response for observations \\
not used for training.
\end{tabular}
\end{tabular}

\section*{Copy Semantics \\ Value. To learn how value classes affect copy operations, see Copying}

\section*{Examples}

Evaluate the cross-validation error of the carsmall data using Horsepower and Weight as predictor variables for mileage (MPG):
load carsmall
X = [Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
cvtree = crossval(tree);
L = kfoldLoss(cvtree)
L =
26.4414

See Also \(\quad \begin{aligned} & \text { RegressionPartitionedEnsemble | } \\ & \text { ClassificationPartitionedModel }\end{aligned}\)

\section*{RegressionTree}

\section*{Superclasses CompactRegressionTree}

\section*{Purpose Regression tree}

Description A decision tree with binary splits for regression. An object of class RegressionTree can predict responses for new data with the predict method. The object contains the data used for training, so can compute resubstitution predictions.

Construction
tree \(=\) RegressionTree.fit \((X, Y)\) returns a regression tree based on the input variables (also known as predictors, features, or attributes) \(X\) and output (response) \(Y\). tree is a binary tree where each branching node is split based on the values of a column of \(X\).
tree \(=\) RegressionTree.fit(X,Y,Name, Value) fits a tree with additional options specified by one or more Name, Value pair arguments.

\section*{Input Arguments}

\section*{X}

A matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

RegressionTree.fit considers NaN values in X as missing values. RegressionTree.fit does not use observations with all missing values for X the fit. RegressionTree.fit uses observations with some missing values for \(X\) to find splits on variables for which these observations have valid values.

\section*{Y}

A numeric column vector with the same number of rows as \(X\). Each entry in \(Y\) is the response to the data in the corresponding row of \(X\).

RegressionTree.fit considers NaN values in \(Y\) to be missing values. RegressionTree.fit does not use observations with missing values for Y in the fit.

\section*{RegressionTree}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{CategoricalPredictors}

List of categorical predictors. Pass CategoricalPredictors as one of:
- A numeric vector with indices from 1 to \(p\), where \(p\) is the number of columns of \(X\).
- A logical vector of length \(p\), where a true entry means that the corresponding column of X is a categorical variable.
- 'all', meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the PredictorNames property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.

\section*{Default: []}

\section*{crossval}

Flag to grow a cross-validated decision tree. Possible value are 'on' or 'off'.

If 'on', RegressionTree.fit grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'kfold', 'holdout', 'leaveout', or 'cvpartition' name-value pair arguments. Note that you can only use one of these four options ('kfold', 'holdout',

\section*{RegressionTree}
'leaveout', or 'cvpartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the crossval method.

Default: 'off'

\section*{cvpartition}

Partition created with cvpartition to use in cross-validated tree.
Note that if you use 'cvpartition', you cannot use any of the 'kfold', 'holdout', or 'leaveout' name-value pair arguments.

\section*{holdout}

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1 .

Note that if you use 'holdout', you cannot use any of the 'cvpartition', 'kfold', or 'leaveout' name-value pair arguments.

\section*{kfold}

Number of folds to use in a cross-validated tree, a positive integer.
Note that if you use 'kfold', you cannot use any of the 'cvpartition', 'holdout', or 'leaveout' name-value pair arguments.

Default: 10

\section*{leaveout}

Use leave-one-out cross validation by setting to 'on'.
Note that if you use 'leaveout', you cannot use any of the 'cvpartition', 'holdout', or 'kfold' name-value pair arguments.

\section*{MergeLeaves}

When 'on', RegressionTree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', RegressionTree does not merge leaves.

Default: 'on'

\section*{MinLeaf}

Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves: MinParent=max (MinParent,2*MinLeaf).

Default: 1

\section*{MinParent}

Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves: MinParent=max (MinParent, 2*MinLeaf).

Default: 10

\section*{NVarToSample}

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

Default: 'all'

\section*{PredictorNames}

A cell array of names for the predictor variables, in the order in which they appear in \(X\).

\section*{RegressionTree}

Default: \{'x1','x2',...\}

\section*{Prune}

When 'on', RegressionTree computes the full tree and the optimal sequence of pruned subtrees. When 'off' RegressionTree computes the full tree without pruning.

Default: 'on'

\section*{PruneCriterion}

String with the pruning criterion, always 'error'.
Default: 'error'

\section*{QEToler}

Defines tolerance on quadratic error per node for regression trees. Splitting nodes stops when quadratic error per node drops below QEToler*QED, where QED is the quadratic error for the entire data computed before the decision tree is grown.

Default: 1e-6

\section*{ResponseName}

Name of the response variable Y , a string.
Default: ' \(Y\) '

\section*{ResponseTransform}

Function handle for transforming the raw response values. The function handle should accept a matrix of response values and return a matrix of the same size. The default string ' none ' means \(@(x) x\), or no transformation.

Add or change a ResponseTransform function by dot addressing:
tree.ResponseTransform = @function
Default: 'none'

\section*{SplitCriterion}

Criterion for choosing a split, always the string 'MSE ', meaning mean squared error.

Default: 'MSE'

\section*{Surrogate}

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.
- When 'on', RegressionTree.fit finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, RegressionTree.fit finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', RegressionTree.fit finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Default: 'off'

\section*{Weights}

Vector of observation weights. The length of weights is the number of rows in \(X\).

Default: ones(size(X,1),1)

\section*{RegressionTree}

\section*{Properties}

\section*{CategoricalPredictors}

List of categorical predictors, a numeric vector with indices from 1 to \(p\), where \(p\) is the number of columns of \(X\).

\section*{CatSplit}

An \(n\)-by- 2 cell array, where n is the number of categorical splits in tree. Each row in CatSplit gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable \(z\), the left child is chosen if \(z\) is in CatSplit \((j, 1)\) and the right child is chosen if \(z\) is in CatSplit ( \(\mathrm{j}, 2\) ). The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running cuttype and selecting 'categorical' cuts from top to bottom.

\section*{Children}

An \(n\)-by- 2 array containing the numbers of the child nodes for each node in tree, where \(n\) is the number of nodes. Leaf nodes have child node 0 .

\section*{CutCategories}

An \(n\)-by- 2 cell array of the categories used at branches in tree, where \(n\) is the number of nodes. For each branch node \(i\) based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in CutCategories \{i, 1\}, and the right child is chosen if \(x\) is among those listed in CutCategories \(\{i, 2\}\). Both columns of CutCategories are empty for branch nodes based on continuous predictors and for leaf nodes.

CutVar contains the cut points for 'continuous ' cuts, and CutCategories contains the set of categories.

\section*{CutPoint}

An \(n\)-element vector of the values used as cut points in tree, where \(n\) is the number of nodes. For each branch node i based on a continuous predictor variable \(x\), the left child is chosen if \(x<\) CutPoint (i) and the right child is chosen if \(x>=\) CutPoint(i).

CutPoint is NaN for branch nodes based on categorical predictors and for leaf nodes.

\section*{CutType}

An \(n\)-element cell array indicating the type of cut at each node in tree, where \(n\) is the number of nodes. For each node i, CutType\{i\} is:
- 'continuous' - If the cut is defined in the form \(\mathrm{x}<\mathrm{v}\) for a variable x and cut point v .
- 'categorical' - If the cut is defined by whether a variable \(x\) takes a value in a set of categories.
- ' ' - If i is a leaf node.

CutVar contains the cut points for 'continuous ' cuts, and CutCategories contains the set of categories.

\section*{CutVar}

An \(n\)-element cell array of the names of the variables used for branching in each node in tree, where \(n\) is the number of nodes. These variables are sometimes known as cut variables. For leaf nodes, CutVar contains an empty string.

CutVar contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

\section*{IsBranch}

An \(n\)-element logical vector ib that is true for each branch node and false for each leaf node of tree.

\section*{ModelParams}

Object holding parameters of tree.

\section*{NObservations}

\section*{RegressionTree}

Number of observations in the training data, a numeric scalar. NObservations can be less than the number of rows of input data \(X\) when there are missing values in \(X\) or response \(Y\).

\section*{NodeErr}

An \(n\)-element vector e of the errors of the nodes in tree, where \(n\) is the number of nodes. \(e(i)\) is the misclassification probability for node i.

\section*{NodeMean}

An \(n\)-element numeric array with mean values in each node of tree, where \(n\) is the number of nodes in the tree. Every element in NodeMean is the average of the true \(Y\) values over all observations in the node.

\section*{NodeProb}

An \(n\)-element vector p of the probabilities of the nodes in tree, where \(n\) is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

\section*{NodeRisk}

An \(n\)-element vector of the risk of the nodes in the tree, where \(n\) is the number of nodes. The risk for each node is the node error weighted by the node probability.

\section*{NodeSize}

An \(n\)-element vector sizes of the sizes of the nodes in tree, where \(n\) is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

\section*{NumNodes}

The number of nodes n in tree.

\section*{Parent}

\section*{RegressionTree}

An \(n\)-element vector \(p\) containing the number of the parent node for each node in tree, where \(n\) is the number of nodes. The parent of the root node is 0 .

\section*{PredictorNames}

A cell array of names for the predictor variables, in the order in which they appear in X.

\section*{PruneAlpha}

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to \(M\), then PruneAlpha has \(M+1\) elements sorted in ascending order. PruneAlpha(1) is for pruning level 0 (no pruning), PruneAlpha(2) is for pruning level 1, and so on.

\section*{PruneList}

An \(n\)-element numeric vector with the pruning levels in each node of tree, where \(n\) is the number of nodes. The pruning levels range from 0 (no pruning) to \(M\), where \(M\) is the distance between the deepest leaf and the root node.

\section*{ResponseName}

Name of the response variable Y , a string.

\section*{ResponseTransform}

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means @(x)x, or no transformation.

Add or change a ResponseTransform function by dot addressing:
tree. ResponseTransform = @function

\section*{SurrCutCategories}

An \(n\)-element cell array of the categories used for surrogate splits in tree, where \(n\) is the number of nodes in tree. For each node k, SurrCutCategories \(\{k\}\) is a cell array. The

\section*{RegressionTree}
length of SurrCutCategories \(\{\mathrm{k}\}\) is equal to the number of surrogate predictors found at this node. Every element of SurrCutCategories \(\{\mathrm{k}\}\) is either an empty string for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in SurrCutVar. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrCutCategories contains an empty cell.

\section*{SurrCutFlip}

An \(n\)-element cell array of the numeric cut assignments used for surrogate splits in tree, where \(n\) is the number of nodes in tree. For each node k, SurrCutFlip \(\{\mathrm{k}\}\) is a numeric vector. The length of SurrCutFlip\{k\} is equal to the number of surrogate predictors found at this node. Every element of SurrCutFlip\{k\} is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or +1 . For every surrogate split with a numeric cut \(C\) based on a continuous predictor variable \(Z\), the left child is chosen if \(Z<C\) and the cut assignment for this surrogate split is +1 , or if \(Z \geq C\) and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if \(Z \geq C\) and the cut assignment for this surrogate split is +1 , or if \(Z<C\) and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in SurrCutVar. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrCutFlip contains an empty array.

\section*{SurrCutPoint}

An \(n\)-element cell array of the numeric values used for surrogate splits in tree, where \(n\) is the number of nodes in tree. For each node \(k\), SurrCutPoint \(\{k\}\) is a numeric vector. The length of

\section*{RegressionTree}

SurrCutPoint \(\{\mathrm{k}\}\) is equal to the number of surrogate predictors found at this node. Every element of SurrCutPoint \(\{k\}\) is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut \(C\) based on a continuous predictor variable \(Z\), the left child is chosen if \(Z<C\) and SurrCutFlip for this surrogate split is -1 . Similarly, the right child is chosen if \(Z \geq C\) and SurrCutFlip for this surrogate split is +1 , or if \(Z<C\) and SurrCutFlip for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by SurrCutVar. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrCutPoint contains an empty cell.

\section*{SurrCutType}

An \(n\)-element cell array indicating types of surrogate splits at each node in tree, where \(n\) is the number of nodes in tree. For each node k, SurrCutType \(\{\mathrm{k}\}\) is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in SurrCutVar. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrCutType contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form \(\mathrm{Z}<\mathrm{V}\) for a variable Z and cut point V or 'categorical' if the cut is defined by whether \(Z\) takes a value in a set of categories.

\section*{SurrCutVar}

An \(n\)-element cell array of the names of the variables used for surrogate splits in each node in tree, where \(n\) is the number of nodes in tree. Every element of SurrCutVar is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only

\section*{RegressionTree}
variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrCutVar contains an empty cell.

\section*{SurrVarAssoc}

An \(n\)-element cell array of the predictive measures of association for surrogate splits in tree, where \(n\) is the number of nodes in tree. For each node k, SurrVarAssoc \(\{k\}\) is a numeric vector. The length of SurrVarAssoc \(\{k\}\) is equal to the number of surrogate predictors found at this node. Every element of SurrVarAssoc \{k\} gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in SurrCutVar. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrVarAssoc contains an empty cell.

\section*{W}

The scaled weights, a vector with length n , the number of rows in \(X\).

\section*{X}

A matrix of predictor values. Each column of \(X\) represents one variable, and each row represents one observation.

\section*{Y}

A numeric column vector with the same number of rows as X. Each entry in Y is the response to the data in the corresponding row of X .

Load the data in carsmall.mat, and make a regression tree to predict the mileage of cars based on their weights and numbers of cylinders:

\section*{RegressionTree}
```

load carsmall
tree = RegressionTree.fit([Weight, Cylinders],MPG,...
'categoricalpredictors',2,'MinParent',20,...
'PredictorNames',{'W','C'})
tree =
RegressionTree
PredictorNames: {'W' 'C'}
ResponseName: 'Y'
ResponseTransform: 'none'
CategoricalPredictors: 2
NObservations: 94

```
Properties, MethodsPredict the mileage of 4,000 -pound cars with 4,6 , and 8 cylinders:

                    mileage4K = predict(tree,[4000 4; 4000 6; 4000 8])

                    mileage4K =

            19.2778

            19.2778

Tutorials - "Classification Trees and Regression Trees" on page 15-30
```

Purpose Regression diagnostics
Syntax regstats(y,x,model)
stats = regstats(...)
stats = regstats(y,X,model,whichstats)

```

\section*{Description}
regstats ( \(y, x\), model) performs a multilinear regression of the responses in y on the predictors in X . X is an \(n\)-by- \(p\) matrix of \(p\) predictors at each of \(n\) observations. y is an \(n\)-by- 1 vector of observed responses.

Note By default, regstats adds a first column of 1s to \(X\), corresponding to a constant term in the model. Do not enter a column of 1s directly into X .

The optional input model controls the regression model. By default, regstats uses a linear additive model with a constant term. model can be any one of the following strings:
- 'linear' - Constant and linear terms (the default)
- 'interaction' - Constant, linear, and interaction terms
- 'quadratic' - Constant, linear, interaction, and squared terms
- 'purequadratic' - Constant, linear, and squared terms

Alternatively, model can be a matrix of model terms accepted by the x2fx function. See x2fx for a description of this matrix and for a description of the order in which terms appear. You can use this matrix to specify other models including ones without a constant term.

With this syntax, the function displays a graphical user interface (GUI) with a list of diagnostic statistics, as shown in the following figure.

When you select check boxes corresponding to the statistics you want to compute and click OK, regstats returns the selected statistics to the MATLAB workspace. The names of the workspace variables are displayed on the right-hand side of the interface. You can change the name of the workspace variable to any valid MATLAB variable name.
stats \(=\) regstats(...) creates the structure stats, whose fields contain all of the diagnostic statistics for the regression. This syntax does not open the GUI. The fields of stats are listed in the following table.
\begin{tabular}{l|l}
\hline Field & Description \\
\hline\(Q\) & \(Q\) from the \(Q R\) decomposition of the design matrix \\
\hline R & \(R\) from the \(Q R\) decomposition of the design matrix \\
\hline beta & Regression coefficients \\
\hline covb & Covariance of regression coefficients \\
\hline yhat & Fitted values of the response data \\
\hline\(r\) & Residuals \\
\hline mse & Mean squared error \\
\hline rsquare & \(R^{2}\) statistic \\
\hline adjrsquare & Adjusted \(R^{2}\) statistic \\
\hline leverage & Leverage \\
\hline hatmat & Hat matrix \\
\hline s2_i & Delete-1 variance \\
\hline beta_i & Delete-1 coefficients \\
\hline standres & Standardized residuals \\
\hline studres & Studentized residuals \\
\hline dfbetas & Scaled change in regression coefficients \\
\hline dffit & Change in fitted values \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Field & Description \\
\hline dffits & Scaled change in fitted values \\
\hline covratio & Change in covariance \\
\hline cookd & Cook's distance \\
\hline tstat & \(t\) statistics and \(p\)-values for coefficients \\
\hline fstat & \(F\) statistic and \(p\)-value \\
\hline dwstat & Durbin-Watson statistic and \(p\)-value \\
\hline
\end{tabular}

Note that the fields names of stats correspond to the names of the variables returned to the MATLAB workspace when you use the GUI. For example, stats.beta corresponds to the variable beta that is returned when you select Coefficients in the GUI and click OK.
stats \(=\) regstats \((y, X\), model, whichstats) returns only the statistics that you specify in whichstats. whichstats can be a single string such as 'leverage' or a cell array of strings such as \{'leverage' 'standres' 'studres'\}. Set whichstats to 'all' to return all of the statistics.

Note The \(F\) statistic is computed under the assumption that the model contains a constant term. It is not correct for models without a constant. The \(R^{2}\) statistic can be negative for models without a constant, which indicates that the model is not appropriate for the data.

Examples Open the regstats GUI using data from hald.mat:
```

load hald
regstats(heat,ingredients,'linear');

```

Select Fitted Values and Residuals in the GUI:

Click OK to export the fitted values and residuals to the MATLAB workspace in variables named yhat and \(r\), respectively.

You can create the same variables using the stats output, without opening the GUI:
```

whichstats = {'yhat','r'};
stats = regstats(heat,ingredients,'linear',whichstats);
yhat = stats.yhat;
r = stats.r;

```

\section*{RegressionEnsemble.regularize}

Purpose
Find weights to minimize resubstitution error plus penalty term

\section*{Syntax}

Description

Input
Arguments
ens1 = regularize(ens)
ens1 = regularize(ens,Name, Value)
ens1 = regularize(ens) finds optimal weights for learners in ens by lasso regularization. regularize returns a regression ensemble identical to ens, but with a populated Regularization property.
ens1 = regularize(ens, Name, Value) computes optimal weights with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, , NameN, ValueN.

\section*{ens}

A regression ensemble, created by fitensemble.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'lambda'}

Vector of nonnegative regularization parameter values for lasso. For the default setting of lambda, regularize calculates the smallest value lambda_max for which all optimal weights for learners are 0 . The default value of lambda is a vector including 0 and nine exponentially-spaced numbers from lambda_max/1000 to lambda_max.

Default: [0
logspace(log10(lambda_max/1000), log10(lambda_max),9)]

\section*{'npass'}

\section*{RegressionEnsemble.regularize}

Maximal number of passes for lasso optimization, a positive integer.

Default: 10

\section*{'reltol'}

Relative tolerance on the regularized loss for lasso, a numeric positive scalar.

Default: 1e-3

\section*{'verbose'}

Verbosity level, either 0 or 1 . When set to 1, regularize displays more information as it runs.

Default: 0

\section*{Output Arguments}

\section*{ens 1}

A regression ensemble. Usually you set ens1 to the same name as ens.

\section*{Lasso}

The lasso algorithm finds an optimal set of learner weights \(\alpha_{t}\) that minimize
\[
\sum_{n=1}^{N} w_{n} g\left(\left(\sum_{t=1}^{T} \alpha_{t} h_{t}\left(x_{n}\right)\right), y_{n}\right)+\lambda \sum_{t=1}^{T}\left|\alpha_{t}\right| .
\]

Here
- \(\lambda \geq 0\) is a parameter you provide, called the lasso parameter.
- \(h_{t}\) is a weak learner in the ensemble trained on \(N\) observations with predictors \(x_{n}\), responses \(y_{n}\), and weights \(w_{n}\).

\section*{RegressionEnsemble.regularize}
- \(g(f, y)=(f-y)^{2}\) is the squared error.

\section*{Examples}

Regularize an ensemble of bagged trees:
```

X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
bag = fitensemble(X,Y,'Bag',300,'Tree',...
'type','regression');
bag = regularize(bag,'lambda',[0.001 0.1],'verbose',1);
regularize reports on its progress.

```

To see the resulting regularization structure:
```

bag.Regularization
ans =
Method: 'Lasso'
TrainedWeights: [300x2 double]
Lambda: [1.0000e-003 0.1000]
ResubstitutionMSE: [0.0616 0.0812]
CombineWeights: @classreg.learning.combiner.WeightedSum

```

See how many learners in the regularized ensemble have positive weights (so would be included in a shrunken ensemble):
```

sum(bag.Regularization.TrainedWeights > 0)
ans =
116 91

```

To shrink the ensemble using the weights from Lambda \(=0.1\) :
cmp = shrink(bag,'weightcolumn',2)
cmp \(=\)
classreg.learning.regr.CompactRegressionEnsemble:
    PredictorNames: \{1x20 cell\}

\title{
RegressionEnsemble.regularize
}

\author{
CategoricalPredictors: [] \\ ResponseName: ' \(Y\) ' \\ ResponseTransform: 'none' NTrained: 91
}

There are 91 members in the regularized ensemble, which is less than \(1 / 3\) of the original 300.

\section*{gmdistribution.RegV property}

Purpose Value of 'Regularize' parameter
Description The value of the parameter 'Regularize '.

Note This property applies only to gmdistribution objects constructed with fit.

\section*{Purpose \\ Importance of attributes (predictors) using ReliefF algorithm}

\section*{Syntax}

\section*{Description}

Name-Value
Pair
Arguments
```

[RANKED,WEIGHT] = relieff(X,Y,K)
[RANKED,WEIGHT] = relieff(X,Y,K,'PARAM1',val1,'PARAM2',val2,
...)

```
[RANKED, WEIGHT] = relieff \((X, Y, K)\) computes ranks and weights of attributes (predictors) for input data matrix \(X\) and response vector \(Y\) using the ReliefF algorithm for classification or RReliefF for regression with K nearest neighbors. For classification, relieff uses K nearest neighbors per class. RANKED are indices of columns in X ordered by attribute importance, meaning RANKED (1) is the index of the most important predictor. WEIGHT are attribute weights ranging from -1 to 1 with large positive weights assigned to important attributes.

If \(Y\) is numeric, relieff by default performs RReliefF analysis for regression. If \(Y\) is categorical, logical, a character array, or a cell array of strings, relieff by default performs ReliefF analysis for classification.

Attribute ranks and weights computed by relieff usually depend on K. If you set K to 1 , the estimates computed by relieff can be unreliable for noisy data. If you set K to a value comparable with the number of observations (rows) in X, relieff can fail to find important attributes. You can start with \(K=10\) and investigate the stability and reliability of relieff ranks and weights for various values of \(K\).
[RANKED, WEIGHT] =
relieff(X,Y,K,'PARAM1',val1,'PARAM2',val2,...) specifies optional parameter name/value pairs.

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{method}

Either 'regression' (default if \(Y\) is numeric) or 'classification' (default if \(Y\) is not numeric).

\section*{prior}

Prior probabilities for each class, specified as a string ('empirical' or 'uniform') or as a vector (one value for each distinct group name) or as a structure \(S\) with two fields:
- S.group containing the group names as a categorical variable, character array, or cell array of strings
- S.prob containing a vector of corresponding probabilities

If the input value is 'empirical' (default), class probabilities are determined from class frequencies in Y. If the input value is 'uniform', all class probabilities are set equal.

\section*{updates}

Number of observations to select at random for computing the weight of every attribute. By default all observations are used.

\section*{categoricalx}
'on' or 'off', 'off' by default. If 'on', treat all predictors in X as categorical. If 'off', treat all predictors in \(X\) as numerical. You cannot mix numerical and categorical predictors.

\section*{sigma}

Distance scaling factor. For observation \(i\), influence on the attribute weight from its nearest neighbor \(j\) is multiplied by \(\exp \left((-\operatorname{rank}(i, j) / \text { sigma })^{\wedge} 2\right)\), where \(\operatorname{rank}(i, j)\) is the position of \(j\) in the list of nearest neighbors of \(i\) sorted by distance in the ascending order. Default is Inf (all nearest neighbors have the same influence) for classification and 50 for regression.

\section*{Examples Identify important predictors in the ionosphere dataset: \\ load ionosphere;}
[ranked,weights] = relieff( \(\mathrm{X}, \mathrm{Y}, 10\) ) ; bar(weights(ranked));
xlabel('Predictor rank');
ylabel('Predictor importance weight');

Examine the Fisher iris data to find the important predictors:
```

load fisheriris
[ranked,weight] = relieff(meas,species,10)
ranked =

```
```

    4 3 1 2
    weight =
0.1399 0.1226 0.3590 0.3754

```

The fourth predictor is the most important, and the second predictor is the least important.

\section*{GeneralizedLinearModel.removeTerms}

\section*{Purpose}

Remove terms from generalized linear model

\section*{Syntax}

Description

\section*{Input \\ Arguments}

\section*{Output}

Arguments
mdll
Generalized linear model, the same as mdl but without the terms given in terms. You can set mdl1 equal to mdl to overwrite mdl.

\section*{GeneralizedLinearModel.removeTerms}

\section*{Definitions}

\section*{Examples}

\section*{Wilkinson Notation}

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.
\begin{tabular}{l|l}
\hline Wilkinson Notation & Factors in Standard Notation \\
\hline 1 & Constant (intercept) term \\
\hline\(A^{\wedge} k\), where \(k\) is a positive integer & \(A, A^{2}, \ldots, A^{k}\) \\
\hline\(A+B\) & \(A, B\) \\
\hline\(A * B\) & \(A, B, A * B\) \\
\hline\(A: B\) & \(A * B\) only \\
\hline\(-B\) & Do not include \(B\) \\
\hline\(A * B+C\) & \(A, B, C, A * B\) \\
\hline\(A+B+C+A: B\) & \(A, B, C, A * B\) \\
\hline\(A * B * C-A: B: C\) & \(A, B, C, A * B, A * C, B * C\) \\
\hline\(A *(B+C)\) & \(A, B, C, A * B, A * C\) \\
\hline
\end{tabular}

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using - 1 .
For details, see Wilkinson and Rogers [1].

\section*{Remove a Term from a Generalized Linear Regression Model}

This example makes a model using two predictors, then removes one.
Generate artificial data for the model, Poisson random numbers with two underlying predictors \(\mathrm{X}(1)\) and \(\mathrm{X}(2)\).
rng('default') \% for reproducibility rndvars = randn(100,2);
X = [2+rndvars(:,1), rndvars(: 2)];
mu \(=\exp \left(1+X^{*}[1 ; 2]\right)\);
```

y = poissrnd(mu);
Create a generalized linear regression model of Poisson data.
mdl = GeneralizedLinearModel.fit(X,y,...
'y ~ x1 + x2','distr','poisson')
mdl =
Generalized Linear regression model:
log(y) ~ 1 + x1 + x2
Distribution = Poisson
Estimated Coefficients:

Purpose
Syntax
Description

Input
Arguments

## Output <br> Arguments

Remove terms from linear model
mdl1 $=$ removeTerms(mdl,terms)
mdl1 = removeTerms(mdl, terms) returns a linear model the same as mdl but with terms removed.
mdl
Linear model, as constructed by LinearModel.fit or LinearModel.stepwise.

## terms

Terms to remove from the mdl regression model. Specify as either a:

- Text string representing one or more terms to remove. For details, see "Wilkinson Notation" on page 20-2462.
- Row or rows in the terms matrix (see modelspec in LinearModel.fit). For example, if there are three variables $\mathrm{A}, \mathrm{B}$, and C :
[0 0 0] represents a constant term or intercept
[0 100$]$ represents $B$; equivalently, $A^{\wedge} 0$ * $B^{\wedge 1}$ * $C^{\wedge} 0$
$\left[\begin{array}{lll}1 & 0 & 1\end{array}\right]$ represents $A^{*} C$
[2 0 0] represents A^2
$\left[\begin{array}{lll}0 & 1 & 2\end{array}\right]$ represents $B^{*}\left(C^{\wedge} 2\right)$
mdll
Linear model, the same as mdl but with terms removed. You can set mdl1 equal to mdl to overwrite mdl.

## LinearModel.removeTerms

## Definitions

## Examples

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation | Factors in Standard Notation |
| :--- | :--- |
| 1 | Constant (intercept) term |
| $A^{\wedge} k$, where $k$ is a positive integer | $A, A^{2}, \ldots, A^{k}$ |
| $A+B$ | $A, B$ |
| $A * B$ | $A, B, A * B$ |
| $A: B$ | $A * B$ only |
| $-B$ | Do not include B |
| $A * B+C$ | $A, B, C, A * B$ |
| $A+B+C+A: B$ | $A, B, C, A * B$ |
| $A * B * C-A: B: C$ | $A, B, C, A * B, A * C, B * C$ |
| $A *(B+C)$ | $A, B, C, A * B, A * C$ |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For details, see Wilkinson and Rogers [1].

## Remove Terms from Model

Construct a default linear model of the Hald data. Remove terms with high $p$-values.

Load the data.
load hald
$\mathrm{X}=$ ingredients; \% predictor variables
y = heat; \% response

Fit a default linear model to the data.

```
mdl = LinearModel.fit(X,y)
mdl =
Linear regression model:
    y ~ 1 + x1 + x2 + x3 + x4
Estimated Coefficients:
\begin{tabular}{lrrrr} 
& Estimate & \multicolumn{1}{l}{ SE } & tStat & \multicolumn{1}{l}{ pValue } \\
(Intercept) & 62.405 & 70.071 & 0.8906 & 0.39913 \\
x1 & 1.5511 & 0.74477 & 2.0827 & 0.070822 \\
x2 & 0.51017 & 0.72379 & 0.70486 & 0.5009 \\
x3 & 0.10191 & 0.75471 & 0.13503 & 0.89592 \\
x4 & -0.14406 & 0.70905 & -0.20317 & 0.84407
\end{tabular}
```

Number of observations: 13, Error degrees of freedom: 8 Root Mean Squared Error: 2.45
R-squared: 0.982, Adjusted R-Squared 0.974
F-statistic vs. constant model: 111, p-value $=4.76 e-07$
Remove the x 3 and x 4 terms because their $p$-values are so high.

```
terms = 'x3 + x4'; % terms to remove
mdl1 = removeTerms(mdl, terms)
mdl1 =
Linear regression model:
    y ~ 1 + x1 + x2
Estimated Coefficients:
\begin{tabular}{lcrll} 
& Estimate & \multicolumn{1}{l}{ SE } & tStat & \multicolumn{1}{l}{ pValue } \\
(Intercept) & 52.577 & 2.2862 & 22.998 & \(5.4566 \mathrm{e}-10\) \\
x1 & 1.4683 & 0.1213 & 12.105 & \(2.6922 \mathrm{e}-07\) \\
x2 & 0.66225 & 0.045855 & 14.442 & \(5.029 \mathrm{e}-08\)
\end{tabular}
```

## LinearModel.removeTerms

```
Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979, Adjusted R-Squared 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

The new model has the same adjusted $R$-Squared value (0.974) as the previous model, meaning it is about as good a fit. All the terms in the new model have extremely low $p$-values.

## Purpose Reorder levels

Syntax
$B$ = reorderlevels(A, newlevels)

Description $\quad B=$ reorderlevels(A, newlevels) reorders the levels of the categorical array A. newlevels is a cell array of strings or a $2-\mathrm{D}$ character matrix that specifies the new order. newlevels must be a reordering of getlabels(A).
The order of the levels of an ordinal array has significance for relational operators, minimum and maximum, and for sorting.

Examples Reorder hockey standings:

```
standings = ordinal(1:3,{'Leafs','Canadiens','Bruins'});
getlabels(standings)
ans =
    'Leafs' 'Canadiens' 'Bruins'
standings = reorderlevels(standings,...
    {'Canadiens','Leafs','Bruins'});
getlabels(standings)
ans =
    'Canadiens' 'Leafs' 'Bruins'
```

See Also addlevels | droplevels | getlabels | islevel | mergelevels

## cvpartition.repartition

Purpose Repartition data for cross-validation
Syntax $\quad$ cnew $=$ repartition(c)
Description cnew = repartition(c) constructs an object cnew of the cvpartition class defining a random partition of the same type as $c$, where $c$ is also an object of the cvpartition class.
Repartitioning is useful for Monte-Carlo repetitions of cross-validation analyses. repartition is called by crossval when the 'mcreps' parameter is specified.

## Examples <br> Partition and repartition 100 observations for 3 -fold cross-validation:

c = cvpartition(100,'kfold',3)
c =
K-fold cross validation partition
N: 100
NumTestSets: 3
TrainSize: $67 \quad 66 \quad 67$
TestSize: $33 \quad 3433$
cnew = repartition(c)
cnew $=$
K-fold cross validation partition
N: 100
NumTestSets: 3
TrainSize: $67 \quad 66 \quad 67$
TestSize: 333433
Check for equality of the test data in the first fold:

```
isequal(test(c,1),test(cnew,1))
ans =
    0
```

See Also cvpartition

## dataset.replacedata

| Purpose | Replace dataset variables |
| :--- | :--- |
| Syntax | $B=\operatorname{replacedata}(A, X)$ |
|  | $B=$ replacedata $(A, X$, vars $)$ |
|  | $B=$ replacedata $(A, f u n)$ |
|  | $B=\operatorname{replacedata}(A, f u n$, vars $)$ |

Description

Examples
$B=$ replacedata $(A, X)$ creates a dataset array $B$ with the same variables as the dataset array $A$, but with the data for those variables replaced by the data in the array $X$. replacedata creates each variable in B using one or more columns from $X$, in order. $X$ must have as many columns as the total number of columns in all of the variables in $A$, and as many rows as A has observations.
$B=$ replacedata( $A, X$, vars $)$ creates a dataset array $B$ with the same variables as the dataset array $A$, but with the data for the variables specified in vars replaced by the data in the array $X$. The remaining variables in $B$ are copies of the corresponding variables in $A$. vars is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. Each variable in $B$ has as many columns as the corresponding variable in $A$. $X$ must have as many columns as the total number of columns in all the variables specified in vars.
$B=$ replacedata( $A, f u n$ ) or $B=r e p l a c e d a t a(A, f u n, v a r s)$ creates a dataset array B by applying the function fun to the values in A's variables. replacedata first horizontally concatenates A's variables into a single array, then applies the function fun. The specified variables in A must have types and sizes compatible with the concatenation. fun is a function handle that accepts a single input array and returns an array with the same number of rows and columns as the input.

```
data = dataset({rand(3,3),'Var1','Var2','Var3'})
% Use ZSCORE to normalize each variable in a dataset array
% separately, by explicitly extracting and transforming the
% data, and then replacing it.
```

## dataset.replacedata

```
X = double(data);
X = zscore(X);
data = replacedata(data,X)
% Equivalently, provide a handle to ZSCORE.
data = replacedata(data,@zscore)
% Use ZSCORE to normalize each observation in a dataset
% array separately by creating an anonymous function.
data = replacedata(data,@(x) zscore(x,[],2))
```

## See Also <br> dataset

## dataset.replaceWithMissing

## Purpose

Insert missing data indicators into a dataset array
Syntax ds2 = replaceWithMissing(ds, Name, Value)

Input
Arguments
ds2 = replaceWithMissing(ds,Name, Value) replaces specified values in a dataset array with standard missing data indicators using options specified by one or more Name, Value pair arguments. Use replaceWithMissing to specify:

- Which numeric missing value indicators to replace with NaN.
- Which string missing value indicators to replace with an empty string.
- Which categorical levels to replace with <undefined>.

## ds

dataset array.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'NumericValues'

Vector of numeric values that replaceWithMissing replaces with NaN .

## 'CategoricalLevels'

String or cell array of strings naming the categorical levels that replaceWithMissing replaces with <undefined>.

## 'Strings'

## dataset.replaceWithMissing

or cell array of strings containing the strings that replaceWithMissing replaces with the empty string, ' '.

## 'DataVars'

Specified set of variables in ds for which replaceWithMissing replaces values. You can specify a positive integer or vector of positive integers indicating the variable column numbers, a variable name or a cell array of variables names, or a logical vector indicating which variables to replace missing values in.

Default: All variables in ds.

## Output Arguments

## Examples

## Replace Nonstandard Missing Value Indicators

Replace nonstandard missing value indicators with standard missing value indicators.

Replace numeric missing values coded 99 with NaN, and string missing values coded '.' with the empty string.

```
ds = replaceWithMissing(ds,'NumericValues',99,'Strings','.');
```

Concepts - "Dataset Arrays" on page 2-135

## Purpose Replicate and tile categorical array

Syntax
$B=\operatorname{repmat}(A, m, n)$
B = repmat(A,[m n p ...])

Description $\quad B=\operatorname{repmat}(A, m, n)$ creates a large array $B$ consisting of an $m$-by- $n$ tiling of copies of the categorical array $A$. The size of $B$ is $[\operatorname{size}(A, 1) * M$ $\operatorname{size}(A, 2) * N, \operatorname{size}(A, 3), \ldots]$. repmat $(A, n)$ creates an $n$-by-n tiling.
$B=\operatorname{repmat}(A,[m \mathrm{n} \mathrm{p} . .]$.$) tiles the categorical array A$ to produce a multidimensional array $B$ composed of copies of $A$. The size of $B$ is [size(A,1)*M, size(A,2)*N, size(A,3)*P, ...].

See Also<br>ndims | size

## qrandstream.reset

Purpose Reset state

## Syntax reset(q)

Description reset (q) resets the state of the quasi-random number stream $q$ of the qrandstream class back to its initial state, 1. Subsequent points drawn from the stream will be the same as those drawn from a new stream. The command is equivalent to q.State $=1$.

Examples Use qrandstream to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:
q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
$q=$
Halton quasi-random stream in 3 dimensions
Point set properties:
Skip : 1000
Leap : 100
ScrambleMethod : none
nextIdx = q.State
nextIdx =
1

Use qrand to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928 0.3475 0.0051
    0.6958 0.2035 0.2371
    0.3013 0.8496 0.4307
    0.9087 0.5629 0.6166
nextIdx = q.State
nextIdx =
    5
X2 = qrand(q,4)
```

```
X2 =
    0.2446 0.0238 0.8102
    0.5298 0.7540 0.0438
    0.3843 0.5112 0.2758
    0.8335 0.2245 0.4694
nextIdx = q.State
nextIdx =
    9
```

Use reset to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
    1
```

$X=\operatorname{qrand}(q, 4)$
$X=$
$0.0928 \quad 0.3475 \quad 0.0051$
$0.6958 \quad 0.2035 \quad 0.2371$
$0.3013 \quad 0.8496 \quad 0.4307$
$0.9087 \quad 0.5629 \quad 0.6166$

See Also
qrandstream | qrand

Purpose Resize categorical array

## Description

$B=r e s h a p e(A, M, N)$ returns an m-by-n categorical matrix whose elements are taken columnwise from the categorical array A. An error results if A does not have $m * n$ elements.
$B=\operatorname{reshape}(A, m, n, p, \ldots)$ or reshape (A,[m n p ...]) returns an array with the same elements as $A$ but reshaped to have the size $m$-by-n-by-p-by-... . m*n*p*... must be the same as numel(A).
$B=\operatorname{reshape}(A, \ldots,[], \ldots)$ calculates the length of the dimension represented by [], such that the product of the dimensions equals numel (A). numel (A) must be evenly divisible by the product of the known dimensions. You can use only one occurrence of [].

In general, reshape (A, siz) returns an array with the same elements as A but reshaped to the size siz. prod(siz) must be the same as numel(A).

## ClassificationDiscriminant.resubEdge

Purpose Classification edge by resubstitution

```
Syntax edge = resubEdge(obj)
```

Description edge $=$ resubEdge $(\mathrm{obj})$ returns the classification edge obtained by obj on its training data.

## Input <br> Arguments

## Output <br> Arguments

## Definitions

obi
Discriminant analysis classifier, produced using ClassificationDiscriminant.fit.
edge
Classification edge obtained by resubstituting the training data into the calculation of edge.

## Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in obj. Prior. If you supply weights in the weights name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

## Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix obj. $x$. A high value of margin indicates a more reliable prediction than a low value.

## Score (discriminant analysis)

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 14-7.

## ClassificationDiscriminant.resubEdge

Examples | Estimate the quality of a discriminant analysis classifier for the Fisher |

## ClassificationEnsemble.resubEdge

## Purpose Classification edge by resubstitution

Syntax

Description

Input
Arguments
edge = resubEdge(ens)
edge = resubEdge(ens,Name, Value)
edge $=$ resubEdge(ens) returns the classification edge obtained by ens on its training data.
edge = resubEdge(ens,Name, Value) calculates edge with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

## ens

A classification ensemble created with fitensemble.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'learners'

Indices of weak learners in the ensemble ranging from 1 to NTrained. resubEdge uses only these learners for calculating edge.

Default: 1:NTrained

## 'mode'

String representing the meaning of the output edge:

- 'ensemble' - edge is a scalar value, the loss for the entire ensemble.

## ClassificationEnsemble.resubEdge

- 'individual' - edge is a vector with one element per trained learner.
- 'cumulative' - edge is a vector in which element $J$ is obtained by using learners $1: J$ from the input list of learners.

Default: 'ensemble'

## Output Arguments

## Definitions

## edge

Classification edge obtained by ens by resubstituting the training data into the calculation of edge. Classification edge is classification margin averaged over the entire data. edge can be a scalar or vector, depending on the setting of the mode name-value pair.

## Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in ens. Prior.

## Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix ens. $x$.

## Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to $\infty$.
- Bag scores range from 0 to 1 .

## ClassificationEnsemble.resubEdge

```
Examples Find the resubstitution edge for an ensemble that classifies the Fisher iris data:
```

```
load fisheriris
```

load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
edge = resubEdge(ens)
edge = resubEdge(ens)
edge =
edge =
3.2486

## ClassificationKNN.resubEdge

Purpose Edge of $k$-nearest neighbor classifier by resubstitution
Syntax $\quad E=$ resubEdge $(m d l)$
Description
$E=r e s u b E d g e(m d l)$ returns the classification edge for mdl with the data used to train mdl (see "Edge" on page 20-2480).

Input
Arguments
mdl
$k$-nearest neighbor classifier, created by ClassificationKNN.fit.
Output
Arguments

## Definitions

## Edge

The edge is the mean value of the classification margin.

## Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

Margin is a column vector with the same number of rows as in the training data.

## Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see "Posterior Probability" on page 20-2181.

## Examples Resubstitution Edge Calculation

Construct a $k$-nearest neighbor classifier for the Fisher iris data, where $k=5$.

## ClassificationKNN.resubEdge

Load the data.
load fisheriris
X = meas;
$Y=$ species;
Construct a classifier for 5-nearest neighbors.

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5);
```

Examine the resubstitution edge of the classifier.
$E=r e s u b E d g e(m d l)$
E =
0.9253

## ClassificationTree.resubEdge

Purpose Classification edge by resubstitution
Syntax edge = resubEdge (tree)

Description

Input
Arguments
tree
A classification tree created by ClassificationTree.fit.
Output
Arguments

## Definitions

## edge

Classification edge obtained by resubstituting the training data into the calculation of edge.

## Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in tree. Prior.

## Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix $X$.

## Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.
For example, consider classifying a predictor $X$ as true when $X<0.15$ or $X>0.95$, and $X$ is false otherwise.

## ClassificationTree.resubEdge

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - . 55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

2
Prune the tree:
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')

## ClassificationTree.resubEdge

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than .15 should be about $.05 / .85=.06$ for true, and about $.8 / .85=.94$ for false.

3
Compute the prediction scores for the first 10 rows of X :
[~,score] = predict(tree1, X(1:10));
[score X(1:10,:)]
ans $=$

| 0.9059 | 0.0941 | 0.8147 |
| ---: | ---: | ---: |
| 0.9059 | 0.0941 | 0.9058 |
| 0 | 1.0000 | 0.1270 |
| 0.9059 | 0.0941 | 0.9134 |
| 0.9059 | 0.0941 | 0.6324 |
| 0 | 1.0000 | 0.0975 |
| 0.9059 | 0.0941 | 0.2785 |

## ClassificationTree.resubEdge

| 0.9059 | 0.0941 | 0.5469 |
| :--- | :--- | :--- |
| 0.9059 | 0.0941 | 0.9575 |
| 0.9059 | 0.0941 | 0.9649 |

Indeed, every value of $X$ (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1 , while the other values of $X$ have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range ( $.95,1$ ) instead of the expected 5 observations.

```
Examples Estimate the quality of a classification tree for the Fisher iris data by
resubstitution:
```

```
load fisheriris
```

load fisheriris
tree = ClassificationTree.fit(meas,species);
tree = ClassificationTree.fit(meas,species);
redge = resubEdge(tree)
redge = resubEdge(tree)
redge =
redge =
0.9384

```
    0.9384
```

```
See Also edge | resubMargin | resubLoss | resubPredict
```

## ClassificationDiscriminant.resubLoss

## Purpose Classification error by resubstitution

```
Syntax
L = resubLoss(obj)
L = resubLoss(obj,Name,Value)
```

Description

Input
Arguments
$\mathrm{L}=$ resubLoss $(\mathrm{obj})$ returns the resubstitution loss, meaning the loss computed for the data that ClassificationDiscriminant.fit used to create obj.
L = resubLoss(obj,Name, Value) returns loss statistics with additional options specified by one or more Name, Value pair arguments.
obj
Discriminant analysis classifier, produced using ClassificationDiscriminant.fit.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'lossfun'

Function handle or string representing a loss function. Built-in loss functions are:

- 'binodeviance' - See "Loss Functions" on page 20-2487.
- 'classiferror' - Fraction of misclassified observations. See "Loss Functions" on page 20-2487.
- 'exponential' - See "Loss Functions" on page 20-2487.
- 'mincost' - Smallest misclassification cost as given by the obj.Cost matrix.

## ClassificationDiscriminant.resubLoss

You can write your own loss function using the syntax described in "Loss Functions" on page 20-2487.

Default: 'mincost'

## Output <br> Arguments <br> L

Classification error, a scalar. The meaning of the error depends on the values in weights and lossfun. See "Classification Error" on page 20-2487.

## Classification Error

The default classification error is the fraction of the training data $X$ that obj misclassifies.

Weighted classification error is the sum of weight $i$ times the Boolean value that is 1 when obj misclassifies the $i$ th row of X , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' - For binary classification, assume the classes $y_{n}$ are -1 and 1 . With weight vector $w$ normalized to have sum 1 , and predictions of row $n$ of data $X$ as $f\left(X_{n}\right)$, the binomial deviance is

$$
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right) .
$$

- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is

$$
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
$$

- 'classiferror' - Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.

## ClassificationDiscriminant.resubLoss

- 'mincost' - Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the Cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:
function loss $=$ lossfun(C, S, W, COST)

- $N$ is the number of rows of $X$.
- $K$ is the number of classes in the classifier, represented in the ClassNames property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.
- $S$ is an N -by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.
- $W$ is a numeric vector with $N$ elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use COST = ones (K) - eye (K), which means a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

## Posterior Probability

The posterior probability that a point $z$ belongs to class $j$ is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean $\mu_{j}$ and covariance $\Sigma_{j}$ at a point $z$ is

## ClassificationDiscriminant.resubLoss

$$
P(x \mid k)=\frac{1}{\left(2 \pi\left|\Sigma_{k}\right|\right)^{1 / 2}} \exp \left(-\frac{1}{2}\left(x-\mu_{k}\right)^{T} \Sigma_{k}^{-1}\left(x-\mu_{k}\right)\right)
$$

where $\left|\Sigma_{k}\right|$ is the determinant of $\Sigma_{k}$, and $\Sigma_{k}^{-1}$ is the inverse matrix.
Let $P(k)$ represent the prior probability of class $k$. Then the posterior probability that an observation $x$ is of class $k$ is

$$
\hat{P}(k \mid x)=\frac{P(x \mid k) P(k)}{P(x)}
$$

where $P(x)$ is a normalization constant, the sum over $k$ of $P(x \mid k) P(k)$.

## Prior Probability

The prior probability is one of three choices:

- 'uniform' - The prior probability of class $k$ is one over the total number of classes.
- 'empirical' - The prior probability of class $k$ is the number of training samples of class $k$ divided by the total number of training samples.
- Custom - The prior probability of class k is the kth element of the prior vector. See ClassificationDiscriminant.fit.

After creating a classifier obj, you can set the prior by dot addressing:

```
obj.Prior = v;
```

where $v$ is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

## Cost

The matrix of expected costs per observation is defined in "Cost" on page 14-8.

## ClassificationDiscriminant.resubLoss

$\begin{array}{ll}\text { Examples } & \begin{array}{l}\text { Compute the resubstituted classification error for the Fisher iris data: } \\ \text { load fisheriris } \\ \text { obj }=\text { ClassificationDiscriminant.fit(meas, species); } \\ L=\text { resubLoss }(o b j)\end{array} \\ L= \\ \text { See Also } & \text { ClassificationDiscriminant | loss } \\ \text { How To } & \text { - "Discriminant Analysis" on page 14-3 }\end{array}$

## ClassificationEnsemble.resubLoss

## Purpose

Classification error by resubstitution
Syntax
L = resubLoss(ens)
L = resubLoss(ens,Name, Value)
$\mathrm{L}=$ resubLoss(ens) returns the resubstitution loss, meaning the loss computed for the data that fitensemble used to create ens.
L = resubLoss(ens,Name, Value) calculates loss with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

## Input Arguments

## ens

A classification ensemble created with fitensemble.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'learners'

Indices of weak learners in the ensemble ranging from 1 to NTrained. resubLoss uses only these learners for calculating loss.

Default: 1:NTrained

## 'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' - See "Loss Functions" on page 20-2492
- 'classiferror' - Fraction of misclassified data

## ClassificationEnsemble.resubLoss

- 'exponential' - See "Loss Functions" on page 20-2492

You can write your own loss function in the syntax described in "Loss Functions" on page 20-2492.

Default: 'classiferror'

## 'mode'

String representing the meaning of the output L:

- 'ensemble' - L is a scalar value, the loss for the entire ensemble.
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - $L$ is a vector in which element $J$ is obtained by using learners $1: J$ from the input list of learners.

Default: 'ensemble'

## Output

Arguments

## Definitions

## Classification Error

The default classification error is the fraction of the training data $X$ that ens misclassifies.

Weighted classification error is the sum of weight $i$ times the Boolean value that is 1 when tree misclassifies the $i$ th row of x , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

## ClassificationEnsemble.resubLoss

- 'binodeviance' - For binary classification, assume the classes $y_{n}$ are -1 and 1 . With weight vector $w$ normalized to have sum 1 , and predictions of row $n$ of data $X$ as $f\left(X_{n}\right)$, the binomial deviance is

$$
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
$$

- 'classiferror' - Fraction of misclassified data, weighted by $w$.
- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is

$$
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- $N$ is the number of rows of ens. $X$.
- $K$ is the number of classes in ens, represented in ens.ClassNames.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in tree.ClassNames.
- $S$ is an $N$-by-K numeric matrix. $S$ is a matrix of posterior probabilities for classes with one row per observation, similar to the score output from predict.
- W is a numeric vector with $N$ elements, the observation weights.
- COST is a K-by-K numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

## ClassificationEnsemble.resubLoss

```
Examples Compute the resubstitution loss for a classification ensemble for the Fisher iris data:
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
loss = resubLoss(ens)
loss =
    0.0333
```

See Also resubEdge | resubMargin | resubPredict | resubLoss

## ClassificationKNN.resubLoss

## Purpose

Loss of $k$-nearest neighbor classifier by resubstitution

## Syntax

## Input Arguments

L = resubLoss(mdl)
L = resubLoss(mdl,Name,Value)

## Description

$\mathrm{L}=$ resubLoss $(\mathrm{mdl})$ returns the resubstitution loss, meaning the loss computed for the data that ClassificationKNN. fit used to create mdl.

L = resubLoss(mdl,Name, Value) returns loss statistics with additional options specified by one or more Name, Value pair arguments.

## mdl

$k$-nearest neighbor classifier, created by ClassificationKNN.fit.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'lossfun'

Function handle or string representing a loss function. Built-in loss functions are:

- 'binodeviance' - See "Loss Functions" on page 20-2496.
- 'classiferror' - Fraction of misclassified observations. See "Loss Functions" on page 20-2496.
- 'exponential ' - See "Loss Functions" on page 20-2496.
- 'mincost' - Smallest misclassification cost as given by the mdl. Cost matrix.

## ClassificationKNN.resubLoss

You can write your own loss function using the syntax described in "Loss Functions" on page 20-2496.

Default: 'mincost'

## Output

Arguments

## Definitions

## Classification Error

The default classification error is the fraction of data $X$ that mdl misclassifies, where Y represents the true classifications.

The weighted classification error is the sum of weight $i$ times the Boolean value that is 1 when mdl misclassifies the $i$ th row of $X$, divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' - For binary classification, assume the classes $y_{n}$ are -1 and 1 . With weight vector $w$ normalized to have sum 1, and predictions of row $n$ of data $X$ as $f\left(X_{n}\right)$, the binomial deviance is

$$
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right)
$$

- 'exponential' - With the same definitions as for 'binodeviance ', the exponential loss is

$$
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right) .
$$

- 'classiferror' - Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.

## ClassificationKNN.resubLoss

- 'mincost' - Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- $N$ is the number of rows of $X$.
- K is the number of classes in the classifier, represented in the ClassNames property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.
- $S$ is an N-by-K numeric matrix. $S$ is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.
- $W$ is a numeric vector with $N$ elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use COST = ones (K) - eye (K), which means a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

## ClassificationKNN.resubLoss

You can set the true misclassification cost per class in the Cost name-value pair when you run ClassificationKNN.fit. Cost(i,j) is the cost of classifying an observation into class $j$ if its true class is $i$. By default, $\operatorname{Cost}(i, j)=1$ if $i \sim=j$, and $\operatorname{Cost}(i, j)=0$ if $i=j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of predict is the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier mdl. Suppose you have K classes. You place the observations into a matrix Xnew with one observation per row. The command
[label,score, cost] = predict(mdl,Xnew)
returns, among other outputs, a cost matrix of size Nobs-by-K. Each row of the cost matrix contains the expected (average) cost of classifying the observation into each of the $K$ classes. cost $(n, k)$ is

$$
\sum_{i=1}^{K} \hat{P}(i \mid X n e w(n)) C(k \mid i)
$$

where

- $K$ is the number of classes.
- $\hat{P}(i \mid \operatorname{Xnew}(n))$ is the posterior probability of class $i$ for observation Xnew ( $n$ ).
- $C(k \mid i)$ is the true misclassification cost of classifying an observation as $k$ when its true class is $i$.

## ClassificationKNN.resubLoss

Examples Loss CalculationConstruct a $k$-nearest neighbor classifier for the Fisher iris data, where$k=5$.
Load the data.
load fisheririsConstruct a classifier for 5-nearest neighbors.

```
mdl = ClassificationKNN.fit(meas,species,'NumNeighbors',5);
```

Examine the resubstitution loss of the classifier.

```
L = resubLoss(mdl)
```

$\mathrm{L}=$
0.0333
The classifier predicts incorrect classifications for $1 / 30$ of its training data.

## ClassificationTree.resubLoss

Purpose
Classification error by resubstitution
Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'subtrees',subtreevector)
[L,se] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'subtrees',
    subtreevector)
[L,...] =
resubLoss(tree,'subtrees',subtreevector,Name,Value)
```

Description
$\mathrm{L}=$ resubLoss(tree) returns the resubstitution loss, meaning the loss computed for the data that ClassificationTree.fit used to create tree.
$\mathrm{L}=$ resubLoss(tree, Name, Value) returns the loss with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, , NameN, ValueN.

L = resubLoss(tree,'subtrees', subtreevector) returns a vector of classification errors for the trees in the pruning sequence subtreevector.
[L,se] = resubLoss(tree,'subtrees', subtreevector) returns the vector of standard errors of the classification errors.
[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector) returns the vector of numbers of leaf nodes in the trees of the pruning sequence.
[L,se,NLeaf,bestlevel] = resubLoss(tree, 'subtrees', subtreevector) returns the best pruning level as defined in the treesize name-value pair. By default, bestlevel is the pruning level that gives loss within one standard deviation of minimal loss.

```
[L,...] =
resubLoss(tree,'subtrees',subtreevector,Name,Value) returns
```

## ClassificationTree.resubLoss

## ClassificationTree.resubLoss

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level max(tree. PruneList).

Default: 0

## 'treesize'

One of the following strings:

- 'se' - loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+s e$, where $L$ and se relate to the smallest value in subtrees).
- 'min' - loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Output Arguments <br> L

Classification error, a vector the length of subtrees. The meaning of the error depends on the values in weights and lossfun; see "Classification Error" on page 20-2503.

## se

Standard error of loss, a vector the length of subtrees.

## NLeaf

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

## bestlevel

A scalar whose value depends on treesize:

- treesize = 'se' - loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+s e$, where $L$ and se relate to the smallest value in subtrees).
- treesize $=$ 'min' - loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## ClassificationTree.resubLoss

## Definitions Classification Error

The default classification error is the fraction of the training data $X$ that tree misclassifies.

Weighted classification error is the sum of weight $i$ times the Boolean value that is 1 when tree misclassifies the $i$ th row of X , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' - For binary classification, assume the classes $y_{n}$ are -1 and 1 . With weight vector $w$ normalized to have sum 1 , and predictions of row $n$ of data $X$ as $f\left(X_{n}\right)$, the binomial deviance is

$$
\sum w_{n} \log \left(1+\exp \left(-2 y_{n} f\left(X_{n}\right)\right)\right) .
$$

- 'exponential' - With the same definitions as for 'binodeviance', the exponential loss is

$$
\sum w_{n} \exp \left(-y_{n} f\left(X_{n}\right)\right)
$$

- 'classiferror' - Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' - Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the Cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of X .

## ClassificationTree.resubLoss

- K is the number of classes in the classifier, represented in the ClassNames property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.
- $S$ is an $N$-by-K numeric matrix. $S$ is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.
- $W$ is a numeric vector with $N$ elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use COST $=$ ones $(K)$ - eye (K), which means a cost of 0 for correct classification, and 1 for misclassification.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

## True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.
You can set the true misclassification cost per class in the Cost name-value pair when you create the classifier using the ClassificationTree.fit method. Cost( $i, j$ ) is the cost of classifying an observation into class $j$ if its true class is $i$. By default, $\operatorname{Cost}(i, j)=1$ if $i \sim=j$, and $\operatorname{Cost}(i, j)=0$ if $i=j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

## ClassificationTree.resubLoss

Suppose you have Nobs observations that you want to classify with a trained classifier. Suppose you have K classes. You place the observations into a matrix Xnew with one observation per row.

The expected cost matrix CE has size Nobs-by-K. Each row of CE contains the expected (average) cost of classifying the observation into each of the $K$ classes. $C E(n, k)$ is

$$
\sum_{i=1}^{K} \hat{P}(i \mid X n e w(n)) C(k \mid i)
$$

where

- $K$ is the number of classes.
- $\hat{P}(i \mid \operatorname{Xnew}(n))$ is the posterior probability of class $i$ for observation Xnew(n).
- $C(k \mid i)$ is the true misclassification cost of classifying an observation as $k$ when its true class is $i$.

Examples Compute the resubstituted classification error for the ionosphere data:

```
load ionosphere
tree = ClassificationTree.fit(X,Y);
L = resubLoss(tree)
L =
    0.0114
```

## RegressionEnsemble.resubLoss

Purpose Regression error by resubstitution
Syntax L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
Description$\mathrm{L}=$ resubLoss(ens) returns the resubstitution loss, meaning themean squared error computed for the data that fitensemble used tocreate ens.L = resubLoss(ens,Name, Value) calculates loss with additionaloptions specified by one or more Name, Value pair arguments. Youcan specify several name-value pair arguments in any order asName1, Value1, ,NameN, ValueN.
Input ..... ens
ArgumentsA regression ensemble created with fitensemble.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'learners'

Indices of weak learners in the ensemble ranging from 1 to NTrained. resubLoss uses only these learners for calculating loss.
Default: 1:NTrained

## 'lossfun'

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle fun, resubLoss calls it as
FUN(Y,Yfit,w)
where $\mathrm{Y}, \mathrm{Yfit}$, and W are numeric vectors of the same length. Y is the observed response, Yfit is the predicted response, and $W$ is the observation weights.

Default: 'mse'

## 'mode'

String representing the meaning of the output L:

- 'ensemble' - L is a scalar value, the loss for the entire ensemble.
- 'individual' - L is a vector with one element per trained learner.
- 'cumulative' - $L$ is a vector in which element $J$ is obtained by using learners $1: J$ from the input list of learners.

Default: 'ensemble'

## Output

Arguments

## Examples

L
Loss, by default the mean squared error. L can be a vector, and can mean different things, depending on the name-value pair settings.

Find the resubstitution predictions of mileage from the carsmall data based on horsepower and weight, and look at their mean square difference from the training data.

```
load carsmall
X = [Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
MSE = resubLoss(ens)
MSE =
    6.4336
```

See Also

## RegressionTree.resubLoss

Purpose
Regression error by resubstitution
Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'subtrees',subtreevector)
[L,se] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'subtrees',
    subtreevector)
[L,...] =
resubLoss(tree,'subtrees',subtreevector,Name,Value)
```

Description
$\mathrm{L}=$ resubLoss(tree) returns the resubstitution loss, meaning the loss computed for the data that RegressionTree.fit used to create tree.
$\mathrm{L}=$ resubLoss(tree, Name, Value) returns the loss with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

L = resubLoss(tree,'subtrees', subtreevector) returns a vector of mean squared errors for the trees in the pruning sequence subtreevector.
[L,se] = resubLoss(tree,'subtrees',subtreevector) returns the vector of standard errors of the classification errors.
[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector) returns the vector of numbers of leaf nodes in the trees of the pruning sequence.
[L,se,NLeaf,bestlevel] = resubLoss(tree,'subtrees', subtreevector) returns the best pruning level as defined in the treesize name-value pair. By default, bestlevel is the pruning level that gives loss within one standard deviation of minimal loss.

```
[L,...] =
resubLoss(tree,'subtrees',subtreevector,Name,Value) returns
loss statistics with additional options specified by one or more
```

## RegressionTree.resubLoss

Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, , NameN, ValueN.

## Input <br> tree

Arguments
A regression tree constructed by RegressionTree.fit.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'lossfun'

Function handle, or the string 'mse' meaning mean squared error.

You can write your own loss function in the syntax described in "Loss Functions" on page 20-2510.

Default: 'mse'
Name, Value arguments associated with pruning subtrees:

## 'subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level max(tree. PruneList).

Default: 0

## 'treesize'

One of the following strings:

## RegressionTree.resubLoss

- 'se' - loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+$ se, where $L$ and se relate to the smallest value in subtrees).
- 'min' - loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Output Arguments

## Definitions

L
Mean squared error, a vector the length of subtrees. The meaning of the error depends on the values in weights and lossfun.
se
Standard error of loss, a vector the length of subtrees.

## NLeaf

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

## bestlevel

A scalar whose value depends on treesize:

- treesize = 'se' - loss returns the highest pruning level with loss within one standard deviation of the minimum ( $\mathrm{L}+\mathrm{se}$, where $L$ and se relate to the smallest value in subtrees).
- treesize $=$ 'min' - loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Loss Functions

The built-in loss function is 'mse', meaning mean squared error.
To write your own loss function, create a function file of the form
function loss = lossfun(Y,Yfit, W)

- $N$ is the number of rows of tree. $X$.
- Y is an N -element vector representing the observed response.

## RegressionTree.resubLoss

- Yfit is an N -element vector representing the predicted responses.
- $W$ is an $N$-element vector representing the observation weights.
- The output loss should be a scalar.

Pass the function handle @lossfun as the value of the lossfun name-value pair.

Examples Find the mean square error of a model of the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
resubLoss(tree)
ans =
    4 . 8 9 5 2
```

## ClassificationDiscriminant.resubMargin

| Purpose | Classification margins by resubstitution |
| :---: | :---: |
| Syntax | M = resubMargin(obj) |
| Description | M = resubMargin(obj) returns resubstitution classification margins for obj. |
| Input Arguments | obi <br> Discriminant analysis classifier, produced using ClassificationDiscriminant.fit. |
| Output Arguments | M <br> Numeric column-vector of length size(obj. $\mathrm{X}, 1$ ) containing the classification margins. |
| Definitions | Margin |
|  | The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix obj.x. A high value of margin indicates a more reliable prediction than a low value. |
|  | Score (discriminant analysis) |
|  | For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 14-7. |
| Examples | Find the margins for a classification tree for the Fisher iris data by resubstitution. Examine several entries: |
|  | ```load fisheriris obj = ClassificationDiscriminant.fit(meas,species); M = resubMargin(obj); M(1:25:end)``` |

## ClassificationDiscriminant.resubMargin

$$
\begin{aligned}
& \text { ans }= \\
& 1.0000 \\
& 1.0000 \\
& 0.9998 \\
& 0.9998 \\
& 1.0000 \\
& 0.9946
\end{aligned}
$$

## See Also ClassificationDiscriminant | margin

How To . "Discriminant Analysis" on page 14-3

## ClassificationEnsemble.resubMargin

| Purpose | Classification margins by resubstitution |
| :---: | :---: |
| Syntax | ```margin = resubMargin(ens) margin = resubMargin(ens,Name,Value)``` |
| Description | margin = resubMargin(ens) returns the classification margin obtained by ens on its training data. |
|  | margin $=$ resubMargin(ens, Name, Value) calculates margins with additional options specified by one or more Name, Value pair arguments. |
| Input Arguments | ens A classification ensemble created with fitensemble. |
|  | Name-Value Pair Arguments |
|  | Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN. |
|  | 'learners' |
|  | Indices of weak learners in the ensemble ranging from 1 to NTrained. resubMargin uses only these learners for calculating margin. |
|  | Default: 1:NTrained |
| Output Arguments | margin |
|  | A numeric column-vector of length size(ens.X,1) containing the classification margins. |

## ClassificationEnsemble.resubMargin

## Definitions Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix ens. x .

## Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to $\infty$.
- Bag scores range from 0 to 1 .

Examples Find the resubstitution margins for an ensemble that classifies the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
margin = resubMargin(ens);
[min(margin) mean(margin) max(margin)]
ans =
    -0.5674 3.2486 4.6245
```

See Also
resubEdge | resubLoss | resubPredict | resubMargin

## ClassificationKNN.resubMargin

```
Purpose Margin of \(k\)-nearest neighbor classifier by resubstitution
Syntax \(\quad m=\) resubMargin(mdl)
```

Description $m=$ resubMargin(mdl) returns the classification margins of the data
used to train mdl. For the definition, see "Margin" on page 20-2516.
Input mdl
Arguments
$k$-nearest neighbor classifier, created by ClassificationKNN.fit.

Output
Arguments

## Definitions

## Examples Resubstitution Margin Calculation

Construct a $k$-nearest neighbor classifier for the Fisher iris data, where $k=5$.

Load the data.

## ClassificationKNN.resubMargin

```
load fisheriris
X = meas;
Y = species;
Construct a classifier for 5-nearest neighbors.
```

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5);
```

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5);
```

Examine some statistics of the resubstitution margin of the classifier.
m = resubMargin(mdl);
$[\max (m) \min (m)$ mean(m)]
ans $=$

```
    1.0000 -0.6000 0.9253
```

The mean margin is over 0.9 , indicating fairly high classification accuracy for resubstitution. For more reliable assessment of model accuracy, consider cross validation, such as kfoldLoss.

## ClassificationTree.resubMargin

Purpose Classification margins by resubstitution
Syntax $\quad M=$ resubMargin(tree)
Description

Input
Arguments
Output
Arguments

## Definitions

## Margin

Classification margin is the difference between classification score for the true class and maximal classification score for the false classes. A high value of margin indicates a more reliable prediction than a low value.

## Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.
For example, consider classifying a predictor $X$ as true when $X<0.15$ or $X>0.95$, and $X$ is false otherwise.

## 1

Generate 100 random points and classify them:
rng(0,'twister') \% for reproducibility
$X=\operatorname{rand}(100,1)$;

## ClassificationTree.resubMargin

```
Y = (abs(X - . 55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

| Click to display: Identity | Magnification: $100 \%$ | Pruning level: 0 of 2 |
| :--- | :--- | :--- | :--- | :--- |

2
Prune the tree:

```
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')
```

## ClassificationTree.resubMargin

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than . 94 as false. Therefore, the score for observations that are greater than .15 should be about $.05 / .85=.06$ for true, and about $.8 / .85=.94$ for false.

3
Compute the prediction scores for the first 10 rows of X :
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
ans $=$

| 0.9059 | 0.0941 | 0.8147 |
| ---: | ---: | ---: |
| 0.9059 | 0.0941 | 0.9058 |
| 0 | 1.0000 | 0.1270 |
| 0.9059 | 0.0941 | 0.9134 |
| 0.9059 | 0.0941 | 0.6324 |
| 0 | 1.0000 | 0.0975 |
| 0.9059 | 0.0941 | 0.2785 |

## ClassificationTree.resubMargin

| 0.9059 | 0.0941 | 0.5469 |
| :--- | :--- | :--- |
| 0.9059 | 0.0941 | 0.9575 |
| 0.9059 | 0.0941 | 0.9649 |

Indeed, every value of $X$ (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09 . The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range $(.95,1)$ instead of the expected 5 observations.

## Examples

Find the margins for a classification tree for the Fisher iris data by resubstitution. Examine several entries:

```
load fisheriris
tree = ClassificationTree.fit(meas,species);
M = resubMargin(tree);
M(1:25:end)
ans =
    1.0000
    1.0000
    1.0000
    1.0000
    0.9565
    0.9565
```

See Also margin | resubLoss | resubPredict | resubEdge

## ClassificationDiscriminant.resubPredict

| Purpose | Predict resubstitution response of classifier |
| :---: | :---: |
| Syntax | ```label = resubPredict(obj) [label,posterior] = resubPredict(obj) [label,posterior,cost] = resubPredict(obj)``` |
| Description | label = resubPredict(obj) returns the labels obj predicts for the data obj. X. label is the predictions of obj on the data that ClassificationDiscriminant.fit used to create obj. |
|  | [label, posterior] = resubPredict(obj) returns the posterior class probabilities for the predictions. |
|  | [label, posterior, cost] = resubPredict(obj) returns the predicted misclassification costs per class for the resubstituted data. |
| Input Arguments | obi |
|  | Discriminant analysis classifier, produced using ClassificationDiscriminant.fit. |
| Output Arguments | label |
|  | Response obj predicts for the training data. label is the same data type as the training response data obj. Y. The predicted class labels are those with minimal expected misclassification cost; see "How the predict Method Classifies" on page 14-6. |
|  | posterior |
|  | N-by-K matrix of posterior probabilities for classes obj predicts, where $N$ is the number of observations and $K$ is the number of classes. |
|  | cost |
|  | N-by-K matrix of predicted misclassification costs. Each cost is the average misclassification cost with respect to the posterior probability. |

## ClassificationDiscriminant.resubPredict

Definitions Posterior Probabilityposterior (i,k) is the posterior probability of class $k$ for observationi. For the mathematical definition, see "Posterior Probability" on page14-7.
Examples Find the total number of misclassifications of the Fisher iris data for a discriminant analysis classifier:

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas,species);
Ypredict = resubPredict(obj); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?
ans =
    3
```

## See Also <br> ClassificationDiscriminant | predict

How To - "Discriminant Analysis" on page 14-3

## ClassificationEnsemble.resubPredict

Purpose Predict ensemble response by resubstitution
Syntax label = resubPredict(ens)

[label,score] = resubPredict(ens)

[label,score] = resubPredict(ens,Name,Value)
Description
InputArguments
label = resubPredict(ens) returns the labels ens predicts for the data ens.x. label is the predictions of ens on the data that fitensemble used to create ens.
[label,score] = resubPredict(ens) also returns scores for all classes.
[label,score] = resubPredict(ens,Name,Value) finds resubstitution predictions with additional options specified by one or more Name, Value pair arguments.
ens
A classification ensemble created with fitensemble.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'learners'

Indices of weak learners in the ensemble ranging from 1 to NTrained. oobLoss uses only these learners for calculating loss.

Default: 1:NTrained

## ClassificationEnsemble.resubPredict

## Output Arguments

## Definitions

Examples

## label

The response ens predicts for the training data. label is the same data type as the training response data ens. $Y$, and has the same number of entries as the number of rows in ens.X.

## score

An $N$-by- K matrix, where N is the number of rows in ens. X , and K is the number of classes in ens. High score value indicates that an observation likely comes from this class.

## Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to $\infty$.
- Bag scores range from 0 to 1 .

Find the total number of misclassifications of the Fisher iris data for a classification ensemble:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
Ypredict = resubPredict(ens); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?
ans =
    5
```

See Also resubEdge | resubMargin | resubLoss | resubPredict

## ClassificationKNN.resubPredict

Purpose Predict resubstitution response of $k$-nearest neighbor classifier

Syntax

Description

Input
Arguments

## Output <br> Arguments

label = resubPredict(mdl)
[label,score] = resubPredict(mdl)
[label, score, cost] = resubPredict(mdl)
label = resubPredict(mdl) returns the labels mdl predicts for the data mdl. x . label is the predictions of mdl on the data that ClassificationKNN.fit used to create mdl.
[label,score] = resubPredict(mdl) returns the posterior class probabilities for the predictions.
[label,score,cost] = resubPredict(mdl) returns the misclassification costs.
mdl
$k$-nearest neighbor classifier, created by ClassificationKNN.fit.

## label

Predicted class labels for the points in the training data $X$, a vector with length equal to the number of rows in the training data $X$. The label is the class with minimal expected cost (see "Expected Cost" on page 20-2527).

## score

Numeric matrix of size N -by-K, where N is the number of observations (rows) in the training data $X$, and $K$ is the number of classes (in mdl.ClassNames). score ( $i, j$ ) is the posterior probability that row i of $X$ is of class j. See "Posterior Probability" on page 20-2527.

## cost

Matrix of expected costs of size N -by-K, where N is the number of observations (rows) in the training data $X$, and $K$ is the number of

## ClassificationKNN.resubPredict

classes (in mdl.ClassNames). cost( $i, j$ ) is the cost of classifying row i of $X$ as class j. See "Expected Cost" on page 20-2527.

## Definitions

## Posterior Probability

For a vector (single query point) X and model mdl, let

- $K$ be the number of nearest neighbors used in prediction, mdl.NumNeighbors
- $n b d(m d l, X)$ be the $K$ nearest neighbors to $X$ in $m d l$. $X$
- $Y(n b d)$ be the classifications of the points in $n b d(m d l, X)$, namely mdl.Y(nbd)
- W(nbd) be the weights of the points in nbd(mdl, X)
- prior be the priors of the classes in mdl. Y

If there is a vector of prior probabilities, then the observation weights W are normalized by class to sum to the priors. This might involve a calculation for the point $X$, because weights can depend on the distance from $X$ to the points in mdl. $X$.

The posterior probability $p(j \mid X)$ is

$$
p(j \mid \mathrm{X})=\frac{\sum_{i \in \mathrm{nbd}} W(i) 1_{Y(X(i)=j)}}{\sum_{i \in \mathrm{nbd}} W(i)}
$$

Here $1_{Y(X(i)=j)}$ means 1 when mdl. $Y(i)=j$, and 0 otherwise.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of predict is the expected misclassification cost per observation.

## ClassificationKNN.resubPredict

Suppose you have Nobs observations that you want to classify with a trained classifier mdl. Suppose you have K classes. You place the observations into a matrix X with one observation per row. The command
[label,score, cost] = predict(mdl,X)
returns, among other outputs, a cost matrix of size Nobs-by-K. Each row of the cost matrix contains the expected (average) cost of classifying the observation into each of the $K$ classes. cost $(n, k)$ is

$$
\sum_{i=1}^{K} \hat{P}(i \mid X(n)) C(k \mid i)
$$

where

- $K$ is the number of classes.
- $\hat{P}(i \mid X(n))$ is the posterior probability of class $i$ for observation $X(n)$.
- $C(k \mid i)$ is the true misclassification cost of classifying an observation as $k$ when its true class is $i$.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the Cost name-value pair when you run ClassificationKNN.fit. Cost( $i, j$ ) is the cost of classifying an observation into class $j$ if its true class is $i$. By default, $\operatorname{Cost}(i, j)=1$ if $i \sim=j$, and $\operatorname{Cost}(i, j)=0$ if $i=j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Examples Resubstitution Prediction

Examine the quality of a classifier by its resubstitution predictions.

## ClassificationKNN.resubPredict

Load the data.
load fisheriris
X = meas;
Y = species;

Construct a classifier for 5-nearest neighbors.
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5);
Generate the resubstitution predictions.

```
label = resubPredict(mdl);
```

Calculate the number of differences between the predictions label and the original data Y .

```
mydiff = not(strcmp(Y,label)); % mydiff(i) = 1 means they differ
sum(mydiff) % number of differences
ans =
5
```

## ClassificationTree.resubPredict

| Purpose | Predict resubstitution response of tree |
| :--- | :--- |
| Syntax |  |
|  | label $=$ resubPredict(tree) |
|  | $[$ label, posterior $]=$ resubPredict(tree) |
|  | $[$ label, posterior, node $]=$ resubPredict(tree) |
|  | $[$ label, posterior, node, cnum $]=$ resubPredict(tree) |
|  | $[$ label,...] $=$ resubPredict(tree, Name,Value) |

Description

## Input

Arguments
label $=$ resubPredict(tree) returns the labels tree predicts for the data tree. X . label is the predictions of tree on the data that ClassificationTree.fit used to create tree.
[label,posterior] = resubPredict(tree) returns the posterior class probabilities for the predictions.
[label, posterior, node] = resubPredict(tree) returns the node numbers of tree for the resubstituted data.
[label, posterior, node, cnum] = resubPredict(tree) returns the predicted class numbers for the predictions.
[label,...] = resubPredict(tree,Name,Value) returns resubstitution predictions with additional options specified by one or more Name, Value pair arguments.

## tree

A classification tree constructed by ClassificationTree.fit.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'subtrees'

## ClassificationTree.resubPredict

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level max(tree. PruneList). subtrees must be in ascending order.

Default: 0

## Output <br> label

 ArgumentsThe response tree predicts for the training data. label is the same data type as the training response data tree.Y.

If the subtrees name-value argument contains $m>1$ entries, label has $m$ columns, each of which represents the predictions of the corresponding subtree. Otherwise, label is a vector.

## posterior

Matrix or array of posterior probabilities for classes tree predicts.
If the subtrees name-value argument is a scalar or is missing, posterior is an $n$-by-k matrix, where $n$ is the number of rows in the training data tree. x , and k is the number of classes.
If subtrees contains $m>1$ entries, posterior is an $n$-by- $k$-by- $m$ array, where the matrix for each $m$ gives posterior probabilities for the corresponding subtree.

## node

The node numbers of tree where each data row resolves.
If the subtrees name-value argument is a scalar or is missing, node is a numeric column vector with $n$ rows, the same number of rows as tree. X .

If subtrees contains $m>1$ entries, node is a $n$-by-m matrix. Each column represents the node predictions of the corresponding subtree.

## cnum

The class numbers that tree predicts for the resubstituted data.

## ClassificationTree.resubPredict

If the subtrees name-value argument is a scalar or is missing, cnum is a numeric column vector with $n$ rows, the same number of rows as tree. X.

If subtrees contains $m>1$ entries, cnum is a $n$-by-m matrix. Each column represents the class predictions of the corresponding subtree.

## Definitions Posterior Probability

The posterior probability of the classification at a node is the number of training sequences that lead to that node with this classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X<0.15$ or $X>0.95$, and $X$ is false otherwise.

1
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

## ClassificationTree.resubPredict

2
Prune the tree:

```
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')
```

## ClassificationTree.resubPredict

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations between .15 and .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore the score for observations that are greater than .15 should be about $.05 / .85=.06$ for true, and about $.8 / .85=.94$ for false.

3
Compute the prediction scores for the first 10 rows of X :
[~,score] = predict(tree1, X(1:10));
[score X(1:10,:)]
ans $=$

| 0.9405 | 0.0595 | 0.6555 |
| ---: | ---: | ---: |
| 0.9405 | 0.0595 | 0.1712 |
| 0.9405 | 0.0595 | 0.7060 |
| 0 | 1.0000 | 0.0318 |
| 0.9405 | 0.0595 | 0.2769 |
| 0 | 1.0000 | 0.0462 |

## ClassificationTree.resubPredict

| 0 | 1.0000 | 0.0971 |
| ---: | ---: | ---: |
| 0.9405 | 0.0595 | 0.8235 |
| 0.9405 | 0.0595 | 0.6948 |
| 0.9405 | 0.0595 | 0.3171 |

Indeed, every value of $X$ (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1 , while the other values of $X$ have associated scores of 0.94 and 0.06 .

```
Examples
Find the total number of misclassifications of the Fisher iris data for a classification tree:
load fisheriris
tree = ClassificationTree.fit(meas,species);
Ypredict = resubPredict(tree); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?
ans =
    3
```

See Also resubEdge | resubMargin | resubLoss | predict

## RegressionEnsemble.resubPredict

| Purpose | Predict response of ensemble by resubstitution |
| :---: | :---: |
| Syntax | ```Yfit = resubPredict(ens) Yfit = resubPredict(ens,Name,Value)``` |
| Description | Yfit = resubPredict(ens) returns the response ens predicts for the data ens.X. Yfit is the predictions of ens on the data that fitensemble used to create ens. <br> Yfit = resubPredict(ens,Name, Value) predicts responses with additional options specified by one or more Name, Value pair arguments. |
| Input Arguments | ens ${ }^{\text {A regression ensemble created with fitensemble. }}$ |
|  | Name-Value Pair Arguments |
|  | Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN. |
|  | 'learners' |
|  | Indices of weak learners in the ensemble ranging from 1 to NTrained. oobLoss uses only these learners for calculating loss. |
|  | Default: 1:NTrained |
| Output Arguments | Yfit <br> A vector of predicted responses to the training data, with ens. $x$ elements. |

Examples
Find the resubstitution predictions of mileage from the carsmall data based on horsepower and weight, and look at their mean square difference from the training data.

```
load carsmall
X = [Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Yfit = resubPredict(ens);
MSE = mean((Yfit - ens.Y).^2)
MSE =
    6.4336
```

This is the same as the result of resubLoss:
resubLoss(ens)
ans $=$
6.4336

## See Also

resubLoss | resubPredict | predict

## RegressionTree.resubPredict

Purpose Predict resubstitution response of tree
Syntax
Yfit = resubPredict(tree)
[Yfit, node] = resubPredict(tree)
[Yfit, node] = resubPredict(tree,Name,Value)

## Description

## Input

Arguments

Yfit $=$ resubPredict(tree) returns the responses tree predicts for the data tree.X. Yfit is the predictions of tree on the data that RegressionTree.fit used to create tree.
[Yfit, node] = resubPredict(tree) returns the node numbers of tree for the resubstituted data.
[Yfit, node] = resubPredict(tree,Name, Value) predicts with additional options specified by one or more Name, Value pair arguments.

## tree

A regression tree constructed by RegressionTree.fit.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level max (tree. PruneList). subtrees must be in ascending order.

Default: 0

## Output Yfit

Arguments

The response tree predicts for the training data.

## RegressionTree.resubPredict

If the subtrees name-value argument is a scalar or is missing, label is the same data type as the training response data tree.Y.

If subtrees contains $m>1$ entries, label has $m$ columns, each of which represents the predictions of the corresponding subtree.

## node

The tree node numbers where tree sends each data row.
If the subtrees name-value argument is a scalar or is missing, node is a numeric column vector with n rows, the same number of rows as tree. X .

If subtrees contains $m>1$ entries, node is a $n$-by-m matrix. Each column represents the node predictions of the corresponding subtree.

## Examples Find the mean square error of a model of the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
Yfit = resubPredict(tree);
mean((Yfit - tree.Y).^2)
ans =
    4.8952
```

You can get the same answer using resubLoss:
resubLoss(tree)
ans $=$
4.8952

See Also resubloss | predict

## ClassificationEnsemble.resume

Purpose Resume training ensemble
Syntax
ens1 = resume(ens, nlearn)
ens1 = resume(ens, nlearn, Name, Value)
ens1 = resume(ens, nlearn) trains ens for nlearn more cycles. resume uses the same training options fitensemble used to create ens.

Note You cannot resume training when ens is a Subspace ensemble created with 'AllPredictorCombinations' number of learners.
ens1 = resume(ens, nlearn, Name, Value) trains ens with additional options specified by one or more Name, Value pair arguments.

## Input

Arguments
ens
A classification ensemble, created with fitensemble.

## nlearn

A positive integer, the number of cycles for additional training of ens.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'nprint'

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

## ClassificationEnsemble.resume

Default: 'off

## Output

Arguments

## Examples

## ens 1

The classification ensemble ens, augmented with additional training.

Train a classification ensemble for 10 cycles. Examine the resubstitution error. Then train for 10 more cycles and examine the new resubstitution error.

```
load ionosphere
ens = fitensemble(X,Y,'GentleBoost',10,'Tree');
L = resubLoss(ens)
L =
    0.0484
ens1 = resume(ens,10);
L = resubLoss(ens1)
L =
    0.0256
```

The new ensemble has much less resubstitution error than the original.
See Also

## ClassificationPartitionedEnsemble.resume

## Purpose Resume training learners on cross-validation folds

Syntax

Description

Input
Arguments
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn, Name, Value)
ens1 = resume (ens, nlearn) trains ens in every fold for nlearn more cycles. resume uses the same training options fitensemble used to create ens.
ens1 = resume(ens, nlearn, Name, Value) trains ens with additional options specified by one or more Name, Value pair arguments.

## ens

A cross-validated classification ensemble. ens is the result of either:

- The fitensemble function with a cross-validation name-value pair. The names are 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.
- The crossval method applied to a classification ensemble.

## nlearn

A positive integer, the number of cycles for additional training of ens.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'nprint'

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak

## ClassificationPartitionedEnsemble.resume

learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

## Output <br> ens 1

Arguments

Examples
Train a partitioned classification ensemble for 10 cycles. Examine the error. Then train for 10 more cycles and examine the new error.
load ionosphere
cvens = fitensemble(X,Y,'GentleBoost',10,'Tree',...
'crossval', 'on');
L = kfoldLoss(cvens)
$\mathrm{L}=$
0.0883
cvens = resume(cvens,10);
L = kfoldLoss(cvens)

L =
0.0769

The ensemble has less cross-validation error after training for ten more cycles.

## RegressionPartitionedEnsemble.resume

learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

## Output

Arguments

## Examples Train a regression ensemble for 50 cycles, and cross validate it. Examine the cross-validation error. Then train for 50 more cycles and examine the new cross-validation error.

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',50,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)
L =
    25.6573
cvens = resume(cvens,50);
L = kfoldLoss(cvens)
L =
    26.7563
```

The additional training did not improve the cross-validation error.

[^11]
## prob.RicianDistribution

Superclasses ToolboxFittableParametricDistribution
Purpose Rician probability distribution object
Description prob.RicianDistribution is an object consisting of parameters, a model description, and sample data for a Rician probability distribution.
Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

## Construction

pd = makedist('Rician') creates a Rician probability distribution object using the default parameter values.
pd = makedist('Rician','s',s,'sigma', sigma) creates a Rician probability distribution object using the specified parameter values.

## Input Arguments

## s - Noncentrality parameter

1 (default) | nonnegative scalar value
Noncentrality parameter for the Rician distribution, specified as a nonnegative scalar value.

## Data Types <br> single | double

sigma-scale parameter
1 (default) | positive scalar value
Scale parameter for the Rician distribution, specified as a positive scalar value.

Data Types<br>single | double

## Properties

## s

Noncentrality parameter of the Rician distribution, stored as a nonnegative scalar value.

## Data Types

single | double

## sigma

Scale parameter for the Rician distribution, stored as a positive scalar value.

## Data Types

single | double

## DistributionName

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## InputData

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.
Data Types
single | double

## IsTruncated

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

## Data Types

logical

## prob.RicianDistribution

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types<br>single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a $p$-by- $p$ matrix, where $p$ is the number of parameters in the distribution. The ( $i, j$ ) element is the covariance between the estimates of the $i$ ith parameter and the $j$ th parameter. The ( $i, i$ ) element is the estimated variance of the ith parameter. If parameter $i$ is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types <br> char

## ParameterlsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

Data Types

logical
ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

```
Data Types
single | double
```

## Methods Inherited Methods

| cdf | Cumulative distribution function <br> of probability distribution object |
| :--- | :--- |
| icdf | Inverse cumulative distribution <br> function of probability <br> distribution object |
| iqr | Interquartile range of probability <br> distribution object |
| median | Median of probability distribution <br> object |
| pdf | Probability density function of <br> probability distribution object |

## prob.RicianDistribution

| random | Generate random numbers from <br> probability distribution object <br> Truncate probability distribution <br> object |
| :--- | :--- |
| truncate | Mean of probability distribution <br> object |
| mean | Negative loglikelihood of <br> probability distribution object |
| negloglik | Confidence intervals for <br> probability distribution <br> parameters |
| proflik | Profile likelihood function for <br> probability distribution object |
| std | Standard deviation of probability <br> distribution object |
| var | Variance of probability <br> distribution object |

## Definitions Rician Distribution

The Rician distribution is used in communications theory to model scattered signals that reach a receiver using multiple paths.

The Rician distribution uses the following parameters.

| Name | Description | Support |
| :--- | :--- | :--- |
| s | Noncentrality <br> parameter | $s \geq 0$ |
| sigma | Scale parameter | $\sigma>0$ |

The probability density function (pdf) is

$$
f(x \mid s, \sigma)=I_{0}\left(\frac{x s}{\sigma^{2}}\right)\left(\frac{x}{\sigma^{2}}\right) \exp \left\{-\frac{x^{2}+s^{2}}{2 \sigma^{2}}\right\} \quad ; \quad x \geq 0
$$

where $I_{0}$ is the zero-order modified Bessel function of the first kind.

## Examples

## Create a Rician Distribution Object Using Default Parameters

Create a Rician distribution object using the default parameter values.

```
pd = makedist('Rician')
pd =
```

RicianDistribution

Rician distribution $s=1$
sigma $=1$

## Create a Rician Distribution Object Using Specified Parameters

Create a Rician distribution object by specifying the parameter values.

```
pd = makedist('Rician','s',0,'sigma',2)
pd =
```

RicianDistribution

```
Rician distribution
            s = 0
        sigma = 2
```

Compute the mean of the distribution.
$\mathrm{m}=\mathrm{mean}(\mathrm{pd})$
m =

## Purpose <br> Ridge regression

Syntax

Description
b = ridge( $\mathrm{y}, \mathrm{x}, \mathrm{k}$ )
$\mathrm{b}=$ ridge $(\mathrm{y}, \mathrm{X}, \mathrm{k}$, scaled)
$b=r i d g e(y, x, k)$ returns a vector $b$ of coefficient estimates for $a$ multilinear ridge regression of the responses in $y$ on the predictors in $X$. X is an $n$-by- $p$ matrix of $p$ predictors at each of $n$ observations. y is an $n$-by- 1 vector of observed responses. k is a vector of ridge parameters. If k has $m$ elements, b is $p$-by- $m$. By default, b is computed after centering and scaling the predictors to have mean 0 and standard deviation 1. The model does not include a constant term, and $X$ should not contain a column of 1 s .
$b=r i d g e(y, x, k, s c a l e d)$ uses the $\{0,1\}$-valued flag scaled to determine if the coefficient estimates in $b$ are restored to the scale of the original data. ridge $(y, x, k, 0)$ performs this additional transformation. In this case, b contains $p+1$ coefficients for each value of $k$, with the first row corresponding to a constant term in the model. ridge ( $\mathrm{y}, \mathrm{X}, \mathrm{k}, 1$ ) is the same as ridge $(y, X, k)$. In this case, $b$ contains $p$ coefficients, without a coefficient for a constant term.

The relationship between $b 0=r i d g e(y, x, k, 0)$ and $b 1=$ ridge ( $y, x, k, 1$ ) is given by

```
m = mean(X);
s = std(X,0,1)';
b1_scaled = b1./s;
b0 = [mean(y)-m*b1_scaled; b1_scaled]
```

This can be seen by replacing the $x_{i}(i=1, \ldots, n)$ in the multilinear model $y=b_{0}{ }^{0}+b_{1}{ }^{0} x_{1}+\ldots+b_{n}{ }^{0} x_{n}$ with the $z$-scores $z_{i}=\left(x_{i}-\mu_{i}\right) / \sigma_{i}$, and replacing $y$ with $y-\mu_{y}$.
In general, $b 1$ is more useful for producing plots in which the coefficients are to be displayed on the same scale, such as a ridge trace (a plot of the regression coefficients as a function of the ridge parameter). b0 is more useful for making predictions.

Coefficient estimates for multiple linear regression models rely on the independence of the model terms. When terms are correlated and the columns of the design matrix $X$ have an approximate linear dependence, the matrix $\left(X^{T} X\right)^{-1}$ becomes close to singular. As a result, the least-squares estimate

$$
\hat{\beta}=\left(X^{T} X\right)^{-1} X^{T} y
$$

becomes highly sensitive to random errors in the observed response $y$, producing a large variance. This situation of multicollinearity can arise, for example, when data are collected without an experimental design.

Ridge regression addresses the problem by estimating regression coefficients using

$$
\hat{\beta}=\left(X^{T} X+k I\right)^{-1} X^{T} y
$$

where $k$ is the ridge parameter and $I$ is the identity matrix. Small positive values of $k$ improve the conditioning of the problem and reduce the variance of the estimates. While biased, the reduced variance of ridge estimates often result in a smaller mean square error when compared to least-squares estimates.

## Examples

Load the data in acetylene.mat, with observations of the predictor variables x 1 , x 2 , x 3 , and the response variable y :

```
load acetylene
```

Plot the predictor variables against each other:

```
subplot(1,3,1)
plot(x1,x2,'.')
xlabel('x1'); ylabel('x2'); grid on; axis square
subplot(1,3,2)
plot(x1,x3,'.')
xlabel('x1'); ylabel('x3'); grid on; axis square
```

```
subplot(1,3,3)
plot(x2,x3,'.')
xlabel('x2'); ylabel('x3'); grid on; axis square
```

Note the correlation between $\times 1$ and the other two predictor variables.
Use ridge and x2fx to compute coefficient estimates for a multilinear model with interaction terms, for a range of ridge parameters:

X $=$ [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; \% No constant term
k $=0: 1 \mathrm{e}-5: 5 \mathrm{e}-3$;
b = ridge(y, D,k);
Plot the ridge trace:

```
figure
plot(k,b,'LineWidth',2)
ylim([-100 100])
grid on
xlabel('Ridge Parameter')
ylabel('Standardized Coefficient')
title('{\bf Ridge Trace}')
legend('x1','x2','x3','x1x2','x1x3','x2x3')
```

The estimates stabilize to the right of the plot. Note that the coefficient of the $\times 2 \times 3$ interaction term changes sign at a value of the ridge parameter $\approx 5 \times 10^{-4}$.

## classregtree.risk

Purpose Node risks
Syntax
$r=r i s k(t)$
$r=r i s k(t, n o d e s)$

## Description

$r=r i s k(t)$ returns an $n$-element vector $r$ of the risk of the nodes in the tree $t$, where $n$ is the number of nodes. The risk $r(i)$ for node $i$ is the node error $e(i)$ (computed by nodeerr) weighted by the node probability $\mathrm{p}(\mathrm{i})$ (computed by nodeprob).
$r=r i s k(t$, nodes $)$ takes a vector nodes of node numbers and returns the risk values for the specified nodes.

## Examples <br> Create a classification tree for Fisher's iris data:

```
load fisheriris;
t = classregtree(meas,species,...
    'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica
view(t)
```

| Purpose | Interactive robust regression |
| :--- | :--- |
| Syntax | robustdemo <br> robustdemo $(x, y)$ |
| Description | robustdemo shows the difference between ordinary least squares and <br> robust regression for data with a single predictor. With no input <br> arguments, robustdemo displays a scatter plot of a sample of roughly <br> linear data with one outlier. The bottom of the figure displays equations <br> of lines fitted to the data using ordinary least squares and robust <br> methods, together with estimates of the root mean squared errors. |
| Use the right mouse button to click on a point and view its least-squares <br> leverage and robust weight. |  |
| Use the left mouse button to click-and-drag a point. The displays will <br> update. <br> robustdemo $(x, y)$ uses $x$ and $y$ data vectors you supply, in place of the <br> sample data supplied with the function. |  |
| Examples | The following steps show you how to use robustdemo. |
| 1 Start the example. To begin using robustdemo with the built-in <br> data, simply type the function name: |  |
| robustdemo |  |

## robustdemo

Use left mouse button to select and drag points
Use right mouse button to query point properties

Least squares:
$Y=-0.188327+1.10351^{*} X$
Robust:
$Y=-1.77278+1.50415^{*} X$
RMS error $=2.21375$
RMS error $=1.43663$

The resulting figure shows a scatter plot with two fitted lines. The red line is the fit using ordinary least-squares regression. The green line is the fit using robust regression. At the bottom of the figure are the equations for the fitted lines, together with the estimated root mean squared errors for each fit.

2 View leverages and robust weights. Right-click on any data point to see its least-squares leverage and robust weight:

## Use left mouse button to select and drag points <br> Use right mouse button to query point properties

Least squares:
Robust:

$$
\begin{aligned}
& Y=-0.188327+1.10351^{*} X \\
& Y=-1.77278+1.50415^{*} X
\end{aligned}
$$

$$
\text { RMS error }=2.21375
$$

$$
\text { RMS error }=1.43663
$$

In the built-in data, the right-most point has a relatively high leverage of 0.35 . The point exerts a large influence on the least-squares fit, but its small robust weight shows that it is effectively excluded from the robust fit.

3 See how changes in the data affect the fits. With the left mouse button, click and hold on any data point and drag it to a new location. When you release the mouse button, the displays update:

## robustdemo

Use left mouse button to select and drag points
Use right mouse button to query point properties

Least squares:
Robust:

$$
\begin{aligned}
& Y=-1.0661+1.33785^{*} X \\
& Y=-1.18916+1.36459^{*} X
\end{aligned}
$$

RMS error $=1.21477$
RMS error $=1.27697$

Bringing the right-most data point closer to the least-squares line makes the two fitted lines nearly identical. The adjusted right-most data point has significant weight in the robust fit.

## Purpose

Syntax
b = robustfit (X, y$)$
b = robustfit(X,y,wfun,tune)
b = robustfit(X,y,wfun,tune, const)
[b,stats] = robustfit(...)
Robust regression
[b, stats]
$\mathrm{b}=$ robustfit $(\mathrm{X}, \mathrm{y})$ returns a $p$-by- 1 vector b of coefficient estimates for a robust multilinear regression of the responses in y on the predictors in X . X is an $n$-by- $p$ matrix of $p$ predictors at each of $n$ observations. y is an $n$-by- 1 vector of observed responses. By default, the algorithm uses iteratively reweighted least squares with a bisquare weighting function.

Note By default, robustfit adds a first column of 1 s to X , corresponding to a constant term in the model. Do not enter a column of 1 s directly into $X$. You can change the default behavior of robustfit using the input const, below.
robustfit treats NaNs in X or y as missing values, and removes them. $b=$ robustfit( $X, y, w f u n$, tune) specifies a weighting function wfun. tune is a tuning constant that is divided into the residual vector before computing weights.

The weighting function wfun can be any one of the following strings:

| Weight Function | Equation | Default Tuning Constant |
| :---: | :---: | :---: |
| 'andrews ' | w = (abs(r)<pi) .* sin(r) ./ r | 1.339 |
| 'bisquare' <br> (default) | $\begin{aligned} & w=(\operatorname{abs}(r)<1) \cdot *(1- \\ & \left.r \cdot{ }^{\wedge} 2\right) \cdot \wedge 2 \end{aligned}$ | 4.685 |
| 'cauchy' | $w=1 . /(1+r . \wedge 2)$ | 2.385 |

| Weight <br> Function | Equation | Default <br> Tuning <br> Constant |
| :--- | :--- | :--- |
| 'fair' | $w=1 . /(1+\mathrm{abs}(\mathrm{r}))$ | 1.400 |
| 'huber' | $\mathrm{w}=1 . / \max (1, \mathrm{abs}(\mathrm{r}))$ | 1.345 |
| 'logistic' | $\mathrm{w}=$ tanh (r) ./ r | 1.205 |
| 'ols' | Ordinary least squares (no <br> weighting function) | None |
| 'talwar' | $\mathrm{w}=1 *(\mathrm{abs}(\mathrm{r})<1)$ | 2.795 |
| 'welsch' | $\mathrm{w}=\exp (-(\mathrm{r} . \wedge 2))$ | 2.985 |

If tune is unspecified, the default value in the table is used. Default tuning constants give coefficient estimates that are approximately $95 \%$ as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

The value $r$ in the weight functions is

```
r = resid/(tune*s*sqrt(1-h))
```

where resid is the vector of residuals from the previous iteration, $h$ is the vector of leverage values from a least-squares fit, and $s$ is an estimate of the standard deviation of the error term given by
$s=$ MAD/0.6745
Here MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are $p$ columns in X , the smallest $p$ absolute deviations are excluded when computing the median.
You can write your own weight function. The function must take a vector of scaled residuals as input and produce a vector of weights as
output. In this case, wfun is specified using a function handle @ (as in @myfun), and the input tune is required.
b = robustfit ( $\mathrm{X}, \mathrm{y}$, wfun, tune, const) controls whether or not the model will include a constant term. const is 'on' to include the constant term (the default), or 'off' to omit it. When const is 'on', robustfit adds a first column of 1 s to $X$. When const is 'off', robustfit does not alter X .
[b,stats] = robustfit(...) returns the structure stats, whose fields contain diagnostic statistics from the regression. The fields of stats are:

- ols_s - Sigma estimate (RMSE) from ordinary least squares
- robust_s - Robust estimate of sigma
- mad_s - Estimate of sigma computed using the median absolute deviation of the residuals from their median; used for scaling residuals during iterative fitting
- s - Final estimate of sigma, the larger of robust_s and a weighted average of ols_s and robust_s
- resid - Residual
- rstud - Studentized residual (see regress for more information)
- se - Standard error of coefficient estimates
- covb - Estimated covariance matrix for coefficient estimates
- coeffcorr - Estimated correlation of coefficient estimates
- $t$ - Ratio of $b$ to se
- $\mathrm{p}-p$-values for t
- $w$ - Vector of weights for robust fit
- $\mathrm{R}-R$ factor in $Q R$ decomposition of x
- dfe - Degrees of freedom for error
- $h$ - Vector of leverage values for least-squares fit

The robustfit function estimates the variance-covariance matrix of the coefficient estimates using inv ( $\mathrm{X}^{\prime *} \mathrm{X}$ )*stats. $\mathrm{s}^{\wedge} 2$. Standard errors and correlations are derived from this estimate.

## Examples

Generate data with the trend $y=10-2 * x$, then change one value to simulate an outlier:

```
x = (1:10)';
y = 10 - 2*x + randn(10,1);
y(10) = 0;
```

Use both ordinary least squares and robust regression to estimate a straight-line fit:

```
bls = regress(y,[ones(10,1) x])
bls =
    7.2481
    -1.3208
brob = robustfit(x,y)
brob =
    9.1063
    -1.8231
```

A scatter plot of the data together with the fits shows that the robust fit is less influenced by the outlier than the least-squares fit:

```
scatter(x,y,'filled'); grid on; hold on
plot(x,bls(1)+bls(2)*x,'r','LineWidth',2);
plot(x,brob(1)+brob(2)*x,'g','LineWidth', 2)
legend('Data','Ordinary Least Squares','Robust Regression')
```

## Purpose Rotate categorical matrix 90 degrees

Syntax
$B=\operatorname{rot} 90(A)$
$B=\operatorname{rot} 90(A, k)$

Description $\quad B=\operatorname{rot} 90(A)$ returns the 90 degree counterclockwise rotation of the 2-D categorical matrix $A$.
$B=\operatorname{rot} 90(A, k)$ returns the $k * 90$ degree rotation $\mathrm{of} A, k=$ $+-1,+-2, \ldots$

See Also flipdim | fliplr | flipud

## rotatefactors

Purpose Rotate factor loadings
Syntax
Description
$B=$ rotatefactors(A)
B = rotatefactors(A,'Method','orthomax','Coeff',gamma)
B = rotatefactors(A,'Method','procrustes','Target',target)
B = rotatefactors(A,'Method','pattern','Target',target)
B = rotatefactors(A,'Method','promax')
$[B, T]=\operatorname{rotatefactors}(A, \ldots)$
$\mathrm{B}=$ rotatefactors(A) rotates the $d$-by $-m$ loadings matrix A to maximize the varimax criterion, and returns the result in $B$. Rows of A and B correspond to variables and columns correspond to factors, for example, the $(i, j)$ th element of A is the coefficient for the $i$ th variable on the $j$ th factor. The matrix A usually contains principal component coefficients created with pca or pcacov, or factor loadings estimated with factoran.

B = rotatefactors(A,'Method','orthomax','Coeff',gamma) rotates A to maximize the orthomax criterion with the coefficient gamma, i.e., $B$ is the orthogonal rotation of $A$ that maximizes
sum(D*sum(B.^4,1) - GAMMA*sum(B.^2,1).^2)
The default value of 1 for gamma corresponds to varimax rotation. Other possibilities include gamma $=0, m / 2$, and $d(m-1) /(d+m-2)$, corresponding to quartimax, equamax, and parsimax. You can also supply the strings 'varimax', 'quartimax', 'equamax', or 'parsimax' for the 'method' parameter and omit the 'Coeff' parameter.

If 'Method' is 'orthomax', 'varimax', 'quartimax', 'equamax', or 'parsimax', then additional parameters are

- 'Normalize' - Flag indicating whether the loadings matrix should be row-normalized for rotation. If ' on' (the default), rows of A are normalized prior to rotation to have unit Euclidean norm, and unnormalized after rotation. If 'off ', the raw loadings are rotated and returned.
- 'Reltol' - Relative convergence tolerance in the iterative algorithm used to find $T$. The default is sqrt(eps).
- 'Maxit' - Iteration limit in the iterative algorithm used to find $T$. The default is 250 .

B = rotatefactors(A,'Method','procrustes','Target',target) performs an oblique procrustes rotation of A to the $d$-by- $m$ target loadings matrix target.
$B=$ rotatefactors(A,'Method','pattern','Target',target) performs an oblique rotation of the loadings matrix A to the $d$-by-m target pattern matrix target, and returns the result in $B$. target defines the "restricted" elements of B, i.e., elements of B corresponding to zero elements of target are constrained to have small magnitude, while elements of B corresponding to nonzero elements of target are allowed to take on any magnitude.

If 'Method' is 'procrustes' or 'pattern', an additional parameter is 'Type', the type of rotation. If 'Type' is 'orthogonal', the rotation is orthogonal, and the factors remain uncorrelated. If 'Type' is 'oblique ' (the default), the rotation is oblique, and the rotated factors might be correlated.

When 'Method' is 'pattern', there are restrictions on target. If A has $m$ columns, then for orthogonal rotation, the $j$ th column of target must contain at least $m-j$ zeros. For oblique rotation, each column of target must contain at least $m-1$ zeros.

B = rotatefactors(A,'Method','promax') rotates A to maximize the promax criterion, equivalent to an oblique Procrustes rotation with a target created by an orthomax rotation. Use the four orthomax parameters to control the orthomax rotation used internally by promax.

An additional parameter for 'promax' is 'Power', the exponent for creating promax target matrix. 'Power' must be 1 or greater. The default is 4 .
$[B, T]=$ rotatefactors $(A, \ldots)$ returns the rotation matrix $T$ used to create $B$, that is, $B=A * T$. You can find the correlation matrix of the rotated factors by using inv ( $\mathrm{T}^{\prime *} \mathrm{~T}$ ). For orthogonal rotation, this is the
identity matrix, while for oblique rotation, it has unit diagonal elements but nonzero off-diagonal elements.

## Examples

```
rng('default') % for reproducibility
X = randn(100,10);
% Default (normalized varimax) rotation:
% first three principle components.
LPC = pca(X);
[L1,T] = rotatefactors(LPC(:,1:3));
% Equamax rotation:
% first three principle components.
[L2,T] = rotatefactors(LPC(:,1:3),...
                                    'method','equamax');
% Promax rotation:
% first three factors.
LFA = factoran(X,3,'Rotate','none');
[L3,T] = rotatefactors(LFA(:,1:3),...
                                    'method','promax',...
                                    'power',2);
% Pattern rotation:
% first three factors.

Purpose Row exchange
Syntax

```
dRE = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns,model)
[dRE,X] = rowexch(...,param1,val1,param2,val2,...)
```

## Description

dRE = rowexch(nfactors, nruns) uses a row-exchange algorithm to generate a $D$-optimal design dRE with nruns runs (the rows of dRE) for a linear additive model with nfactors factors (the columns of dRE). The model includes a constant term.
[dRE, X] = rowexch(nfactors, nruns) also returns the associated design matrix $X$, whose columns are the model terms evaluated at each treatment (row) of dRE.
[dRE,X] = rowexch(nfactors, nruns,model) uses the linear regression model specified in model. model is one of the following strings:

- 'linear' - Constant and linear terms. This is the default.
- 'interaction' - Constant, linear, and interaction terms
- 'quadratic' - Constant, linear, interaction, and squared terms
- 'purequadratic' - Constant, linear, and squared terms

The order of the columns of $\mathbf{X}$ for a full quadratic model with $n$ terms is:
1 The constant term
2 The linear terms in order $1,2, \ldots, n$
3 The interaction terms in order $(1,2),(1,3), \ldots,(1, n),(2,3), \ldots,(n-1, n)$
4 The squared terms in order $1,2, \ldots, n$
Other models use a subset of these terms, in the same order.

Alternatively, model can be a matrix specifying polynomial terms of arbitrary order. In this case, model should have one column for each factor and one row for each term in the model. The entries in any row of model are powers for the factors in the columns. For example, if a model has factors $\mathrm{X} 1, \mathrm{X} 2$, and X 3 , then a row [ $\left.\begin{array}{lll}0 & 1 & 2\end{array}\right]$ in model specifies the term (X1.^0).*(X2.^1).*(X3.^2). A row of all zeros in model specifies a constant term, which can be omitted.
[dRE,X] = rowexch(...,param1,val1,param2,val2,...) specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

| Parameter | Value |
| :--- | :--- |
| 'bounds ' | Lower and upper bounds for each factor, specified as <br> a 2-by-nfactors matrix. Alternatively, this value <br> can be a cell array containing nfactors elements, <br> each element specifying the vector of allowable <br> values for the corresponding factor. |
| 'categorical' | Indices of categorical predictors. |
| 'display' | Either ' on ' or 'off ' to control display of the <br> iteration counter. The default is 'on'. |
| 'excludefun' | Handle to a function that excludes undesirable <br> runs. If the function is $f$, it must support the syntax <br> $b=f(S)$, where $S$ is a matrix of treatments with <br> nfactors columns and $b$ is a vector of Boolean <br> values with the same number of rows as $S . b(i)$ is <br> true if the $i$ th row $S$ should be excluded. |
| 'init' | Initial design as an nruns-by-nfactors matrix. The <br> default is a randomly selected set of points. |
| 'levels' | Vector of number of levels for each factor. |
| 'maxiter' | Maximum number of iterations. The default is 10. |

| Parameter | Value |
| :--- | :--- |
| options | A structure that specifies whether to run in parallel, <br> and specifies the random stream or streams. Create <br> the options structure with statset. Option fields: |
|  | - UseParallel — Set to true to compute in <br> parallel. Default is false. <br> - UseSubstreams - Set to true to compute in <br> parallel in a reproducible fashion. Default is <br> false. To compute reproducibly, set Streams to <br> a type allowing substreams: 'mlfg6331_64' or <br> 'mrg32k3a'. |
|  | - Streams - A RandStream object or cell array <br> of such objects. If you do not specify Streams, <br> rowexch uses the default stream or streams. If <br> you choose to specify Streams, use a single object <br> except in the case <br> - You have an open MATLAB pool |
|  | - UseParallel is true <br> - UseSubstreams is false |
| In that case, use a cell array the same size as the |  |
| MATLAB pool. |  |

## Algorithms

Both cordexch and rowexch use iterative search algorithms. They operate by incrementally changing an initial design matrix $X$ to increase $D=\left|X^{T} X\right|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, $D$-optimal designs. Run each algorithm multiple times
and select the best result for your final design. Both functions have a 'tries ' parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of $X$ with a row from a design matrix $C$ evaluated at a candidate set of feasible treatments. The rowexch function automatically generates a $C$ appropriate for a specified model, operating in two steps by calling the candgen and candexch functions in sequence. Provide your own $C$ by calling candexch directly. In either case, if $C$ is large, its static presence in memory can affect computation.

## Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$
y=\beta_{0}+\beta_{1} x_{1}+\beta_{2} x_{2}+\beta_{3} x_{3}+\beta_{12} x_{1} x_{2}+\beta_{13} x_{1} x_{3}+\beta_{23} x_{2} x_{3}+\varepsilon
$$

Use rowexch to generate a $D$-optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
dRE =
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline -1 & -1 & 1 & & & & \\
\hline 1 & -1 & 1 & & & & \\
\hline 1 & -1 & -1 & & & & \\
\hline 1 & 1 & 1 & & & & \\
\hline -1 & -1 & -1 & & & & \\
\hline -1 & 1 & -1 & & & & \\
\hline -1 & 1 & 1 & & & & \\
\hline \multicolumn{7}{|l|}{\(\mathrm{X}=\)} \\
\hline 1 & -1 & -1 & 1 & 1 & -1 & -1 \\
\hline 1 & 1 & -1 & 1 & -1 & 1 & -1 \\
\hline 1 & 1 & -1 & -1 & -1 & -1 & 1 \\
\hline 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\hline 1 & -1 & -1 & -1 & 1 & 1 & 1 \\
\hline 1 & -1 & 1 & -1 & -1 & 1 & -1 \\
\hline 1 & -1 & 1 & 1 & -1 & -1 & 1 \\
\hline
\end{tabular}
```

Columns of the design matrix $X$ are the model terms evaluated at each row of the design dRE. The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use $X$ to fit the model, as described in "Linear Regression" on page 9-11, to response data measured at the design points in dRE.

## Purpose Interactive response surface demonstration

## Syntax rsmdemo

Description
rsmdemo opens a group of three graphical user interfaces for interactively investigating response surface methodology (RSM), nonlinear fitting, and the design of experiments.

The interfaces allow you to collect and model data from a simulated chemical reaction. Experimental predictors are concentrations of three reactants (hydrogen, $n$-Pentane, and isopentane) and the response is the reaction rate. The reaction rate is simulated by a Hougen-Watson model (Bates and Watts, [2], pp. 271-272):

$$
\text { rate }=\frac{\beta_{1} x_{2}-x_{3} / \beta_{5}}{1+\beta_{2} x_{1}+\beta_{3} x_{2}+\beta_{4} x_{3}}
$$

where rate is the reaction rate, $x_{1}, x_{2}$, and $x_{3}$ are the concentrations of hydrogen, $n$-pentane, and isopentane, respectively, and $\beta_{1}, \beta_{2}, \ldots, \beta_{5}$ are fixed parameters. Random errors are used to perturb the reaction rate for each combination of reactants.

Collect data using one of two methods:
1 Manually set reactant concentrations in the Reaction Simulator interface by editing the text boxes or by adjusting the associated sliders.

When you click Run, the concentrations and simulated reaction rate are recorded on the Trial and Error Data interface.

You are allowed up to 13 independent experimental runs for data collection.

2 Use a designed experiment to set reactant concentrations in the Experimental Data interface by clicking the Do Experiment button.

A 13 -run $D$-optimal design for a full quadratic model is generated by the cordexch function, and the concentrations and simulated reaction rates are recorded on the same interface.

Once data is collected, scatter plots of reaction rates vs. individual predictors are generated by selecting one of the following from the Plot pop-up menu below the recorded data:

- Hydrogen vs. Rate
- n-Pentane vs. Rate
- Isopentane vs. Rate

Fit a response surface model to the data by clicking the Analyze button below the trial-and-error data or the Response Surface button below the experimental data. Both buttons load the data into the Response Surface Tool rstool. By default, trial-and-error data is fit with a linear additive model and experimental data is fit with a full quadratic model, but the models can be adjusted in the Response Surface Tool.

For experimental data, you have the additional option of fitting a Hougen-Watson model. Click the Nonlinear Model button to load the data and the model in hougen into the Nonlinear Fitting Tool nlintool.

See Also hougen | cordexch | rstool | nlintool

Purpose Interactive response surface modeling

| Syntax | rstool |
| :---: | :---: |
|  | rstool(X, Y,model) |
|  | rstool(x,y,model, alpha) |
|  | rstool(x,y,model, alpha, xname, yname) |

## Description

rstool opens a graphical user interface for interactively investigating one-dimensional contours of multidimensional response surface models.

By default, the interface opens with the data from hald.mat and a fitted response surface with constant, linear, and interaction terms.

A sequence of plots is displayed, each showing a contour of the response surface against a single predictor, with all other predictors held fixed.
rstool plots a $95 \%$ simultaneous confidence band for the fitted response surface as two red curves. Predictor values are displayed in the text boxes on the horizontal axis and are marked by vertical dashed blue lines in the plots. Predictor values are changed by editing the text boxes or by dragging the dashed blue lines. When you change the value of a predictor, all plots update to show the new point in predictor space.

The pop-up menu at the lower left of the interface allows you to choose among the following models:

- Linear - Constant and linear terms (the default)
- Pure Quadratic - Constant, linear, and squared terms
- Interactions - Constant, linear, and interaction terms
- Full Quadratic - Constant, linear, interaction, and squared terms

Click Export to open the following dialog box:

The dialog allows you to save information about the fit to MATLAB workspace variables with valid names.
rstool ( $X, Y$, model $)$ opens the interface with the predictor data in $X$, the response data in $Y$, and the fitted model model. Distinct predictor variables should appear in different columns of X . Y can be a vector, corresponding to a single response, or a matrix, with columns corresponding to multiple responses. Y must have as many elements (or rows, if it is a matrix) as $X$ has rows.

The optional input model can be any one of the following strings:

- 'linear' - Constant and linear terms (the default)
- 'purequadratic' - Constant, linear, and squared terms
- 'interaction' - Constant, linear, and interaction terms
- 'quadratic' - Constant, linear, interaction, and squared terms

To specify a polynomial model of arbitrary order, or a model without a constant term, use a matrix for model as described in x2fx.
rstool(x,y,model, alpha) uses 100(1-alpha)\% global confidence intervals for new observations in the plots.
rstool( $x, y$, model, alpha, xname, yname) labels the axes using the strings in xname and yname. To label each subplot differently, xname and yname can be cell arrays of strings.

## Examples

The following uses rstool to visualize a quadratic response surface model of the 3-D chemical reaction data in reaction. mat:
load reaction
alpha = 0.01; \% Significance level
rstool(reactants, rate, 'quadratic', alpha, $x n, y n$ )

The rstool interface is used by rsmdemo to visualize the results of simulated experiments with data like that in reaction.mat. As described in "Response Surface Designs" on page 17-9, rsmdemo uses a response surface model to generate simulated data at combinations of predictors specified by either the user or by a designed experiment.

Purpose Run test for randomness

```
Syntax
h = runstest(x)
h = runstest(x, v)
h = runstest(x,'ud')
h = runstest(...,param1,val1,param2,val2,...)
[h, p] = runstest(...)
[h,p,stats] = runstest(...)
```

## Description

$\mathrm{h}=$ runstest(x) performs a runs test on the sequence of observations in the vector $x$. This is a test of the null hypothesis that the values in $x$ come in random order, against the alternative that they do not. The test is based on the number of runs of consecutive values above or below the mean of $x$. Too few runs indicate a tendency for high and low values to cluster. Too many runs indicate a tendency for high and low values to alternate. The test returns the logical value $h=1$ if it rejects the null hypothesis at the $5 \%$ significance level, and $\mathrm{h}=0$ if it cannot. The test treats NaN values in x as missing values, and ignores them.
runstest uses a test statistic which is approximately normally distributed when the null hypothesis is true. It is the difference between the number of runs and its mean, divided by its standard deviation.
$h=$ runstest $(x, v)$ performs the test using runs above or below the value $v$. Values exactly equal to $v$ are discarded. The default value of $v$ is the mean of $x$.
$h=r u n s t e s t\left(x,{ }^{\prime} u d '\right)$ performs a test for the number of runs up or down. This also tests the hypothesis that the values in x come in random order. Too few runs indicate a trend. Too many runs indicate an oscillation. Values exactly equal to the preceding value are discarded.
h = runstest(...,param1,val1,param2,val2,...) specifies additional parameters and their values. Valid parameter/value pairs are the following:

- 'alpha ' - A scalar giving the significance level of the test
- 'method ' - Either 'exact' to compute the $p$ value using an exact algorithm, or 'approximate' to use a normal approximation. The
default is 'exact', except for runs up/down when the length of is 51 or more. The 'exact ' method is not available for runs up/down when the length of x is over 50 .
- 'tail' - Performs the test against one of the following alternative hypotheses:
- 'both' - two-tailed test (sequence is not random)
- 'right' - right-tailed test (like values separate for runs above/below, direction alternates for runs up/down)
- 'left' - left-tailed test (like values cluster for runs above/below, values trend for runs up/down)
$[\mathrm{h}, \mathrm{p}]=$ runstest (...) returns the $p$ value of the test. The output p is computed from either the test statistic or the exact distribution of the number of runs, depending on the value of the 'method' parameter.
[h,p,stats] = runstest(...) returns a structure stats with the following fields:
- nruns - The number of runs
- n 1 - The number of values above $v$
- $n 0$ - The number of values below $v$
- z — The test statistic

## Examples $\quad x=\operatorname{randn}(40,1)$;

[h,p] = runstest(x,median(x))
$\mathrm{h}=$
0
$\mathrm{p}=$
0.6286

See Also signrank | signtest

## TreeBagger.SampleWithReplacement property

Purpose Flag to sample with replacement
$\begin{array}{ll}\text { Description } & \begin{array}{l}\text { The SampleWithReplacement property is a logical flag specifying if } \\ \text { data are sampled for each decision tree with replacement. True if }\end{array} \\ & \begin{array}{l}\text { TreeBagger samples data with replacement and false otherwise. True } \\ \text { by default. }\end{array}\end{array}$

Sample size and power of test

```
n = sampsizepwr(testtype,p0,p1)
n = sampsizepwr(testtype,p0,p1,power)
power = sampsizepwr(testtype,p0,p1,[],n)
p1 = sampsizepwr(testtype,p0,[],power,n)
[...] = sampsizepwr(..., n,param1,val1,param2,val2,...)
```

$\mathrm{n}=$ sampsizepwr(testtype, $\mathrm{p0}$, p1) returns the sample size n required for a two-sided test of the specified type to have a power (probability of rejecting the null hypothesis when the alternative hypothesis is true) of 0.90 when the significance level (probability of rejecting the null hypothesis when the null hypothesis is true) is 0.05 . p 0 specifies parameter values under the null hypothesis. p1 specifies the single parameter value being tested under the alternative hypothesis.

The following values are available for testtype:

- 'z' $-z$-test for normally distributed data with known standard deviation. pO is a two-element vector [mu0 sigma0] of the mean and standard deviation, respectively, under the null hypothesis. p1 is the value of the mean under the alternative hypothesis.
- ' t ' $-t$-test for normally distributed data with unknown standard deviation. po is a two-element vector [muo sigma0] of the mean and standard deviation, respectively, under the null hypothesis. p1 is the value of the mean under the alternative hypothesis.
- 'var ' - Chi-square test of variance for normally distributed data. p 0 is the variance under the null hypothesis. p 1 is the variance under the alternative hypothesis.
- ' p ' - Test of the $p$ parameter (success probability) for a binomial distribution. pO is the value of $p$ under the null hypothesis. p 1 is the value of $p$ under the alternative hypothesis.

The ' $p$ ' test is a discrete test for which increasing the sample size does not always increase the power. For $n$ values larger than 200, there may be values smaller than the returned $n$ value that also produce the desired size and power.
$\mathrm{n}=$ sampsizepwr(testtype, $\mathrm{p} 0, \mathrm{p} 1$, power) returns the sample size n such that the power is power for the parameter value $p 1$.
power = sampsizepwr(testtype, p0, p1, [], n) returns the power achieved for a sample size of $n$ when the true parameter value is $p 1$.
p1 = sampsizepwr(testtype, p0,[], power, n) returns the parameter value detectable with the specified sample size n and power power.

When computing p 1 for the ' p ' test, if no alternative can be rejected for a given null hypothesis and significance level, the function displays a warning message and returns NaN .
[...] = sampsizepwr(...,n,param1,val1,param2,val2,...) specifies one or more of the following name/value pairs:

- 'alpha' - Significance level of the test (default 0.05)
- 'tail' - The type of test is one of the following:
- 'both' - Two-sided test for an alternative not equal to p0
- 'right' - One-sided test for an alternative larger than po
- 'left' - One-sided test for an alternative smaller than po

## Examples

Compute the mean closest to 100 that can be determined to be significantly different from 100 using a $t$-test with a sample size of 60 and a power of 0.8 .

```
mu1 = sampsizepwr('t',[100 10],[],0.8,60)
mu1 =
    103.6770
```

Compute the sample size $n$ required to distinguish $p=0.26$ from $p=0.6$ with a binomial test. The result is approximate, so make a plot to see if any smaller $n$ values also have the required power of 0.5 .

```
napprox = sampsizepwr('p',0.2,0.26,0.6)
Warning: Values N>200 are approximate. Plotting the power as a function
of N may reveal lower N values that have the required power.
napprox =
```

```
nn = 1:250;
pwr = sampsizepwr('p',0.2,0.26,[],nn);
nexact = min(nn(pwr>=0.6))
nexact =
    213
```

plot(nn, pwr,'b-',[napprox nexact], pwr([napprox nexact]), 'ro');
grid on

## See Also

vartest | ttest | ztest | binocdf

Purpose Scatter plot with marginal histograms

```
Syntax scatterhist(x,y)
scatterhist(x,y,Name,Value)
h = scatterhist(__)
```

Description

## Input Arguments

scatterhist ( $x, y$ ) creates a 2-D scatter plot of the data in the vectors $x$ and $y$, and puts a univariate histogram on the horizontal and vertical axes of the plot.
scatterhist ( $\mathrm{x}, \mathrm{y}$, Name, Value) creates the plot using additional options specified by one or more name-value pair arguments. For example, you can specify a grouping variable or change the display options.
$h=$ scatterhist (__ ) returns a vector of three axis handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively, using any of the input arguments in the previous syntaxes.

## x-Sample data

vector
Sample data, specified as a vector. The data vectors $x$ and $y$ must be the same length. If $x$ or $y$ contain $N a N$ values, then scatterhist:

- Removes rows with NaN values in either x or y from both data vectors when generating the scatter plot
- Removes rows with NaN values only from the corresponding x or y data vector when generating the marginal histograms

Data Types
single | double
$y$-Sample data
vector
Sample data, specified as a vector. The data vectors $x$ and $y$ must be the same length.

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Location', 'SouthEast','Direction', 'out' specifies a plot with histograms located below and to the right of the scatter plot, with the bars directed away from the scatter plot.

'NBins' - Number of bins for histograms<br>positive integer value | vector

Number of bins for histograms, specified as the comma-separated pair consisting of 'Nbins' and a positive integer value greater than or equal to 2 , or vector of two such values. If the number of bins is specified as a positive integer value, that value is the number of bins for both the $x$ and $y$ histograms. If the number of bins is specified by a vector, the first value is the number of bins for the $x$ data, and the second value is the number of bins for the $y$ data. By default, the number of bins is computed based on the sample standard deviation using Scott's rule.

## Example: 'NBins', [5,7]

## Data Types

single | double

## 'Location' - Location of marginal histograms

'SouthWest' (default) | 'SouthEast' | 'NorthEast' | 'NorthWest'

Location of the marginal histograms in the figure, specified as the comma-separated pair consisting of 'Location' and one of the following.
'SouthWes Plot the histograms below and to the left of the scatter plot.
'SouthEas $\mathbf{P}$ lot the histograms below and to the right of the scatter plot.
' NorthEas Plot the histograms above and to the right of the scatter plot.
'NorthWes $\mathbf{P l o t}$ the histograms above and to the left of the scatter plot.

## Example: 'Location', 'SouthEast'

## 'Direction' - Direction of marginal histograms

'in' (default) | 'out'
Direction of the marginal histograms, specified as the comma-separated pair consisting of 'Direction' and one of the following.

```
'in' Plot the histograms with the bars directed toward the scatter plot.
'out ' Plot the histograms with the bars directed away from the scatter plot.
```

## Example: 'Direction','out'

## 'Group' - Grouping variable

categorical array | logical or numeric vector | cell array of strings
Grouping variable, specified as the comma-separated pair consisting of 'Group ' and a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group.

For example, if Gender is a cell array of strings with values 'Male' and 'Female', you can use Gender as a grouping variable to plot your data by gender.

Multiple grouping variables can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if Smoker is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array \{Gender, Smoker\} divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: 'Group ' , \{Gender, Smoker\}
Data Types
single | double | logical | cell | char

## 'Kernel' - Grouped kernel density plot indicator

'on' | 'off' | 'overlay
Grouped kernel density plot indicator, specified as the comma-separated pair consisting of 'Kernel' and one of the following.
'on ' Display kernel density plots for each group. This is the default if a Group parameter is specified.
'off' Display the overall marginal distribution as histograms. This is the default if a Group parameter is not specified.
' overlay ' Display the overall marginal distribution as kernel density plots overlaid onto histograms, similar to histfit.

Example: 'Kernel', 'overlay'

## 'Bandwidth' - Bandwidth of kernel smoothing window matrix

Bandwidth of kernel smoothing window, specified as the comma-separated pair consisting of 'Bandwidth' and a matrix of size 2 -by- $K$, where $K$ is the number of unique groups. The first row of the matrix gives the bandwidth of each group in $x$, and the second row gives the bandwidth of each group in $y$. By default, scatterhist finds the optimal bandwidth for estimating normal densities. Specifying a different bandwidth value changes the smoothing characteristics of the
resulting kernel density plot. The value specified is a scaling factor for the normal distribution used to generate the kernel density plot.
Example: 'Bandwidth', [.5,.2, .1; . 15,. 25, . 35 ]

Data Types<br>single | double

## 'Legend' - Legend visibility indicator

 'on' | 'off'Legend visibility indicator, specified as the comma-separated pair consisting of 'Legend' and one of the following.

$$
\begin{array}{ll}
\text { 'on ' } & \begin{array}{l}
\text { Set legend visible. This is the default if a Group parameter } \\
\text { is specified. }
\end{array} \\
\text { 'off' } & \begin{array}{l}
\text { Set legend invisible. This is the default if a Group } \\
\text { parameter is not specified. }
\end{array}
\end{array}
$$

## Example: 'Legend','on'

## 'LineStyle' - Style of kernel density plot line

## valid line style string | cell array of strings

Style of kernel density plot line, specified as the comma-separated pair consisting of 'LineStyle' and a valid line style string or a cell array of valid line style strings. See plot for valid line style strings. The default is a solid line. Use a cell array to specify different line styles for each group. When the total number of groups exceeds the number of specified values, scatterhist cycles through the specified values.

## Example: 'LineStyle', \{'-',':','-.'\}

## 'LineWidth' - Width of kernel density plot line

0.5 (default) | nonnegative scalar value | vector

Width of kernel density plot line, specified as the comma-separated pair consisting of 'LineWidth' and a nonnegative scalar value or vector of nonnegative scalar values. The specified value is the size of the kernel
density plot line measured in points. The default size is 0.5 points. Use a vector to specify different line widths for each group. When the total number of groups is greater than the number of specified values, scatterhist cycles through the specified values.

Example: 'LineWidth', [0.5, 1, 2]

## Data Types

single | double

## 'Color' - Marker color for each scatter plot group

valid color designation char | string of chars | matrix of RGB values
Marker color for each scatter plot group, specified as the comma-separated pair consisting of 'Color' and a valid color designation character, a string of valid color designation characters, or a 3 -column matrix of RGB values in the range [0,1]. See ColorSpec for predefined colors and their RGB equivalents. If colors are specified using a matrix, each row of the matrix represents a group, and the three columns represent the $R$ value, $G$ value, and $B$ value, respectively. When the total number of groups exceeds the number of specified colors, scatterhist cycles through the specified colors.
Example: 'Color', kcm '
Example: 'Color', [.5, 0, 1; 0, .5, .5]

## Data Types

single | double | char

## 'Marker' - Marker symbol for each scatterplot group

' o' (default) | valid marker symbol | string of valid marker symbols
Marker symbol for each scatter plot group, specified as the comma-separated pair consisting of 'Marker' and a valid marker symbol or string of valid marker symbols. See plot for valid symbols. The default is ' o ', a circle. When the total number of groups exceeds the number of specified symbols, scatterhist cycles through the specified symbols.

```
Example: 'Marker','+do'
```

## 'MarkerSize' - Marker size for each scatter plot group

6 (default) | nonnegative scalar value | vector

Marker size for each scatter plot group, specified as the comma-separated pair consisting of 'MarkerSize' and a nonnegative scalar value or a vector of nonnegative scalar values, measured in points. When the total number of groups exceeds the number of specified values, scatterhist cycles through the specified values.

## Example: 'MarkerSize',10

```
Data Types
single | double
```

## Output Arguments

## h - Axes handles <br> vector

Axes handles for the three plots, returned as a vector. The vector contains the handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively.

## Examples Create a Scatterhist Plot

Load the sample data. Create data vector x from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector y from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and two marginal histograms to visualize the relationship between sepal length and sepal width.

```
scatterhist(x,y)
```

## Plot Grouped Data

Load the sample data. Create data vector x from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector y from the second column of the data matrix, which contains sepal width measurements from the same flowers.
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width, grouped by species.

```
scatterhist(x,y,'Group',species)
```

| $-\varrho$ |
| :--- |
| $\cdots \cdots$ setosa |
| $-\ominus \cdots$ virginicalor |

The plot shows that the relationship between sepal length and width varies depending on the flower species.

## Customize the Plot Display

Load the sample data. Create data vector x from the first column of the data matrix, which contains sepal length measurements from three different species of iris flowers. Create data vector y from the second column of the data matrix, which contains sepal width measurements from the same flowers.
load fisheriris.mat;
$x=m e a s(:, 1) ;$
$y=$ meas $(:, 2)$;
Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width as measured on three species of iris flowers, grouped by species. Customize the appearance of the plots.

```
scatterhist(x,y,'Group',species,'Location','SouthEast',...
    'Direction','out', 'Color','kbr','LineStyle',{'-',' -.',':'},...
    'LineWidth',[2, 2, 2],'Marker','+od', 'MarkerSize', [4, 5, 6]) ;
```

## Customize Plots Using Axes Handles

Load the sample data. Create data vector x from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector y from the second column of the data matrix, which contains sepal width measurements from the same flowers.
load fisheriris.mat;
x = meas(:,1);
y = meas(: 2);
Use axis handles to replace the marginal histograms with box plots.

```
h = scatterhist(x,y,'Group',species);
hold on;
boxplot(h(2),x,species,'orientation','horizontal');
boxplot(h(3),y,species,'labelorientation','inline');
hold off;
```

| $-\varrho$ |
| :---: |
| $\cdots \cdots$ setosa |
| $\cdots \cdots$ versicolor |
| $-\ominus \cdots$ virginica |

## scatterhist

$\begin{array}{ll}\text { See Also } & \text { hist | gscatter } \\ \text { Concepts } & \text { - "Grouping Variables" on page 2-51 }\end{array}$

Purpose
Scramble quasi-random point set
Syntax
ps = scramble(p,type)
ps = scramble(p,'clear')
ps = scramble(p)

## Description

## Examples

 returns the result in ps. scrambling algorithms.ps = scramble ( p, type) returns a scrambled copy $p s$ of the point set $p$ of the qrandset class, created using the scramble type specified in the string type. Point sets from different subclasses of qrandset support different scramble types, as indicated in the following table.

| Subclass | Scramble Types |
| :--- | :--- |
| haltonset | 'RR2' - A permutation of the radical inverse <br> coefficients derived by applying a reverse-radix <br> operation to all of the possible coefficient values. <br> The scramble is described in [1]. |
| sobolset | 'MatousekAffineOwen' - A random linear <br> scramble combined with a random digital shift. <br> The scramble is described in [2]. |

ps = scramble( p, 'clear') removes all scramble settings from $p$ and
ps = scramble (p) removes all scramble settings from $p$ and then adds them back in the order they were originally applied. This typically results in a different point set because of the randomness of the

Use haltonset to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
            Skip : 1000
```

## qrandset.scramble

Leap : 100
ScrambleMethod : none

Use scramble to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : }100
        Leap : }10
    ScrambleMethod : RR2
```

Use net to generate the first four points:

```
XO = net(p,4)
XO =
    0.0928 0.6950 0.0029
    0.6958 0.2958 0.8269
    0.3013 0.6497 0.4141
    0.9087 0.7883 0.2166
```

Use parenthesis indexing to generate every third point, up to the 11 th point:

```
x = p(1:3:11,:)
X =
    0.0928 0.6950 0.0029
    0.9087 0.7883 0.2166
    0.3843 0.9840 0.9878
    0.6831 0.7357 0.7923
```

## qrandset.ScrambleMethod property

Purpose
Description

Settings that control scrambling
The ScrambleMethod property contains a structure that defines which scrambles to apply to the sequence. The structure consists of two fields:

- Type: A string containing the name of the scramble.
- Options: A cell array of parameter values for the scramble.

Different point sets support different scramble types as outlined in the help for each point set class. An error occurs if you set an invalid scramble type for a given point set.

The ScrambleMethod property also accepts an empty matrix as a value. This will clear all scrambling and set the property to contain a ( $0 \times 0$ ) structure.

The scramble method provides an alternative, easier way to set scrambles.

\author{
Examples <br> Apply a random linear scramble combined with a random digital shift to a sobolset point set class: <br> ```
P = sobolset(5); <br> P = scramble(P, 'MatousekAffineOwen'); <br> P.ScrambleMethod

```
}

See Also sobolset | scramble
Purpose Segments containing values
Syntax S = segment(obj, X, P)
Description \(S=\) segment (obj, \(X, P\) ) returns an array \(S\) of integers indicating whichsegment of the piecewise distribution object obj contains each valueof \(X\) or, alternatively, \(P\). One of \(X\) and \(P\) must be empty ([ ]). If \(X\) isnonempty, \(S\) is determined by comparing \(X\) with the quantile boundaryvalues defined for obj. If \(P\) is nonempty, \(S\) is determined by comparing\(P\) with the probability boundary values.
Examples Fit Pareto tails to a \(t\) distribution at cumulative probabilities 0.1 and0.9:
```

t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
pvals = 0:0.2:1;
s = segment(obj,[],pvals)
s =

\section*{Description}

Sequential feature selection
```

inmodel = sequentialfs(fun, X,y)

```
inmodel = sequentialfs(fun, X,y)
inmodel = sequentialfs(fun, X,Y,Z,\ldots.)
inmodel = sequentialfs(fun, X,Y,Z,\ldots.)
[inmodel,history] = sequentialfs(fun,X,...)
[inmodel,history] = sequentialfs(fun,X,...)
[] = sequentialfs(...,param1,val1,param2,val2,...)
```

[] = sequentialfs(...,param1,val1,param2,val2,...)

```
inmodel = sequentialfs(fun, \(X, y\) ) selects a subset of features from the data matrix \(X\) that best predict the data in \(y\) by sequentially selecting features until there is no improvement in prediction. Rows of \(X\) correspond to observations; columns correspond to variables or features. \(y\) is a column vector of response values or class labels for each observation in \(X\). \(X\) and \(y\) must have the same number of rows. fun is a function handle to a function that defines the criterion used to select features and to determine when to stop. The output inmodel is a logical vector indicating which features are finally chosen.
Starting from an empty feature set, sequentialfs creates candidate feature subsets by sequentially adding each of the features not yet selected. For each candidate feature subset, sequentialfs performs 10 -fold cross-validation by repeatedly calling fun with different training subsets of \(X\) and \(y\), XTRAIN and ytrain, and test subsets of \(X\) and \(y\), XTEST and ytest, as follows:
criterion = fun(XTRAIN,ytrain,XTEST,ytest)
XTRAIN and ytrain contain the same subset of rows of \(X\) and \(Y\), while XTEST and ytest contain the complementary subset of rows. XTRAIN and XTEST contain the data taken from the columns of \(X\) that correspond to the current candidate feature set.

Each time it is called, fun must return a scalar value criterion. Typically, fun uses XTRAIN and ytrain to train or fit a model, then predicts values for XTEST using that model, and finally returns some measure of distance, or loss, of those predicted values from ytest. In the cross-validation calculation for a given candidate feature set, sequentialfs sums the values returned by fun and divides that sum
by the total number of test observations. It then uses that mean value to evaluate each candidate feature subset.

Typical loss measures include sum of squared errors for regression models (sequentialfs computes the mean-squared error in this case), and the number of misclassified observations for classification models (sequentialfs computes the misclassification rate in this case).

Note sequentialfs divides the sum of the values returned by fun across all test sets by the total number of test observations. Accordingly, fun should not divide its output value by the number of test observations.

After computing the mean criterion values for each candidate feature subset, sequentialfs chooses the candidate feature subset that minimizes the mean criterion value. This process continues until adding more features does not decrease the criterion.
```

inmodel = sequentialfs(fun, X,Y,Z,···.) allows any number of
input variables X, Y, Z, ... . sequentialfs chooses features (columns)
only from X, but otherwise imposes no interpretation on X, Y, Z, ... . All
data inputs, whether column vectors or matrices, must have the same
number of rows. sequentialfs calls fun with training and test subsets
of X, Y, Z, ... as follows:
criterion = fun(XTRAIN,YTRAIN,ZTRAIN,....,
XTEST,YTEST,ZTEST,...)

```
sequentialfs creates XTRAIN, YTRAIN, ZTRAIN, ... , XTEST, YTEST, ZTEST, ... by selecting subsets of the rows of \(X, Y, Z, \ldots\). fun must return a scalar value criterion, but may compute that value in any way. Elements of the logical vector inmodel correspond to columns of \(X\) and indicate which features are finally chosen.
[inmodel,history] = sequentialfs(fun, X, ...) returns information on which feature is chosen at each step. history is a scalar structure with the following fields:
- Crit - A vector containing the criterion values computed at each step.
- In - A logical matrix in which row i indicates the features selected at step i.
[] = sequentialfs(...,param1,val1,param2,val2,...) specifies optional parameter name/value pairs from the following table.
\begin{tabular}{l|l}
\hline Parameter & V \\
\hline ' cv' \(^{\prime}\) & T
\end{tabular}

Value
The validation method used to compute the criterion for each candidate feature subset.
- When the value is a positive integer k , sequentialfs uses k-fold cross-validation without stratification.
- When the value is an object of the cvpartition class, other forms of cross-validation can be specified.
- When the value is 'resubstitution', the original data are passed to fun as both the training and test data to compute the criterion.
- When the value is 'none', sequentialfs calls fun as criterion \(=\) fun ( \(X, Y, Z, \ldots\) ), without separating test and training sets.

The default value is 10 , that is, 10 -fold cross-validation without stratification.

So-called wrapper methods use a function fun that implements a learning algorithm. These methods usually apply cross-validation to select features. So-called filter methods use a function
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline & \begin{tabular}{l} 
fun that measures characteristics of the data \\
(such as correlation) to select features.
\end{tabular} \\
\hline 'moreps' & \begin{tabular}{l} 
A positive integer indicating the number of \\
Monte-Carlo repetitions for cross-validation. The \\
default value is 1. The value must be 1 if the \\
value of 'cv' is 'resubstitution' or 'none '.
\end{tabular} \\
\hline 'direction' & \begin{tabular}{l} 
The direction of the sequential search. The \\
default is 'forward '. A value of 'backward ' \\
specifies an initial candidate set including all \\
features and an algorithm that removes features \\
sequentially until the criterion increases.
\end{tabular} \\
\hline 'keepin' & \begin{tabular}{l} 
A logical vector or a vector of column numbers \\
specifying features that must be included. The \\
default is empty.
\end{tabular} \\
\hline 'keepout' & \begin{tabular}{l} 
A logical vector or a vector of column numbers \\
specifying features that must be excluded. The \\
default is empty.
\end{tabular} \\
\hline 'nfeatures' & \begin{tabular}{l} 
The number of features at which sequentialfs \\
should stop. inmodel includes exactly this \\
many features. The default value is empty, \\
indicating that sequentialfs should stop when \\
a local minimum of the criterion is found. A \\
nonempty value overrides values of 'MaxIter' \\
and 'TolFun' in 'options '.
\end{tabular} \\
\hline 'nullmodel' & \begin{tabular}{l} 
A logical value, indicating whether or not the null \\
model (containing no features from X) should be \\
included in feature selection and in the history \\
output. The default is false.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Parameter & Value \\
\hline 'options' & \begin{tabular}{l}
Options structure for the iterative sequential search algorithm, as created by statset. sequentialfs uses the following statset parameters: \\
- Display - Amount of information displayed by the algorithm. The default is 'off'. \\
- MaxIter - Maximum number of iterations allowed. The default is Inf. \\
- TolFun - Termination tolerance for the objective function value. The default is \(1 \mathrm{e}-6\) if 'direction' is 'forward'; 0 if 'direction' is 'backward'. \\
- TolTypeFun - Use absolute or relative objective function tolerances. The default is 'rel'. \\
- UseParallel - Set to true to compute in parallel. Default is false. \\
- UseSubstreams - Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. \\
- Streams - A RandStream object or cell array consisting of one such object. If you do not specify Streams, sequentialfs uses the default stream.
\end{tabular} \\
\hline
\end{tabular}

Examples
Perform sequential feature selection for classification of noisy features:
```

load fisheriris;
X = randn(150,10);

```
```

X(:,[$$
\begin{array}{lllll}{1}&{3}&{5}&{7}\end{array}
$$])= meas;
y = species;
c = cvpartition(y,'k',10);
opts = statset('display','iter');
fun = @(XT,yT,Xt,yt)...
(sum(~strcmp(yt,classify(Xt,XT,yT,'quadratic'))));
[fs,history] = sequentialfs(fun,X,y,'cv',c,'options',opts)
Start forward sequential feature selection:
Initial columns included: none
Columns that can not be included: none
Step 1, added column 7, criterion value 0.04
Step 2, added column 5, criterion value 0.0266667
Final columns included: 5 7
fs =
0
history =
In: [2\times10 logical]
Crit: [0.0400 0.0267]
history.In
ans =
0

```

How To . "Sequential Feature Selection" on page 12-70

Purpose Set and display properties
```

Syntax
set (A)
set(A,PropertyName)
A = set(A,PropertyName,PropertyValue,...)
B $=\operatorname{set}(A$, PropertyName, value)

```

\section*{Description}
set (A) displays all properties of the dataset array \(A\) and their possible values.
set (A,PropertyName) displays possible values for the property specified by the string PropertyName.

A \(=\operatorname{set}(\mathrm{A}\), PropertyName, PropertyValue,...) sets property name/value pairs.
\(B=\operatorname{set}(A\), PropertyName, value) returns a dataset array \(B\) that is a copy of A, but with the property 'PropertyName' set to the value value.

Note Using set(A, 'PropertyName', value) without assigning to a variable does not modify A's properties. Use A = set (A, 'PropertyName', value) to modify A.

\section*{Examples}

Create a dataset array from Fisher's iris data and add a description:
```

load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
{meas,'SL','SW','PL','PW'},...
'ObsNames',NameObs);
iris = set(iris,'Description','Fisher''s Iris Data');
get(iris)
Description: 'Fisher's Iris Data'
Units: {}
DimNames: {'Observations' 'Variables'}

```
```

UserData: []
ObsNames: \{150x1 cell\}
VarNames: \{'species' 'SL' 'SW' 'PL' 'PW'\}

```

See Also get | summary

\section*{CompactTreeBagger.setDefaultYfit}

Purpose Set default value for predict
Syntax \(\quad B=\operatorname{setDefaultYfit(B,Yfit)~}\)
Description \(\quad B=\) setDefaultYfit( \(B, Y f i t\) ) sets the default prediction for ensemble \(B\) to Yfit. The default prediction must be a character variable for classification or a numeric scalar for regression. This setting controls what predicted value CompactTreeBagger returns when no prediction is possible, for example when the predict method needs to predict for an observation which has only false values in the matrix supplied through 'useifort' argument.

\author{

}

\section*{Purpose Set difference for categorical arrays}

Note In a future release, the behavior of categorical.setdiff will change to be consistent with the MATLAB function setdiff. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for setdiff.

Syntax \(\quad C=\operatorname{setdiff}(A, B)\)
[C,IA] \(=\operatorname{setdiff}(A, B)\)
[...] = setdiff(A,B,'rows')
[...] = setdiff(...,'R2012a')
[...] = setdiff(...,'legacy')
[...] = setdiff(A,B,setOrder)
[...] = setdiff(A,B,'rows',setOrder)

\section*{Description}
\(C=\operatorname{setdiff}(A, B)\) for categorical vectors \(A\) and \(B\), returns a categorical vector \(C\) containing the values in \(A\) that are not in \(B\) with no repetitions. The result C is sorted. The set of categorical levels for C is the sorted union of the sets of levels of the inputs.
\([C, I A]=\operatorname{setdiff}(A, B)\) also returns an index vector IA such that \(C=\) \(A(I A)\). If there are repeated values in \(A\) that are not in \(B\), then the index of the last occurrence of each repeated value is returned.
[...] = setdiff(A, B, 'rows') for categorical matrices \(A\) and \(B\) with the same number of columns, returns the rows from \(A\) that are not in \(B\). The rows of the matrix C are sorted. The set of categorical levels for C is the sorted union of the sets of levels of the inputs. The optional output \(I A\) is an index vector such that \(C=C(I A,:)\).
[...] = setdiff(...,'R2012a') adopts the future behavior of setdiff. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.
[...] = setdiff(...,'legacy') preserves the current behavior of setdiff. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.
\([\ldots]=\operatorname{setdiff}(A, B\), setOrder \()\) and \([\ldots]=\) setdiff(A, B, 'rows', setOrder) returns the observations of \(C\) in a specific order. setOrder='sorted ' returns the values or rows of C in sorted order. setOrder='stable' returns the values or rows of \(C\) in the same order as \(A\). If \(A\) is a row vector, then \(C\) is also a row vector. Otherwise, \(C\) is a column vector. IA is a column vector. If there are repeated values in \(A\) that are not in \(B\), then the index of the first occurrence of each repeated value is returned.

Observations in C are in the same order that \\
they appear in A.
\end{tabular}
\end{tabular}

\section*{Output Arguments}

\section*{Examples}

\section*{Set Difference of Two Dataset Arrays}

Create a scalar structure array, and then convert it into two dataset arrays.
```

S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;

```
```

S(3,1).DiastolicBP = 92;
A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));

```

The intersection of \(A\) and \(B\) is the second observation, with last name BROWN.

Return the set difference of A and B.
```

[C,iA] = setdiff(A,B)

```
C =
\begin{tabular}{llll} 
Name & Gender & SystolicBP & DiastolicBP \\
'CLARK' & 'M' & 124 & 93
\end{tabular}
iA =

1

The first observation in \(A\) is not present in \(B\).

Concepts
- "Dataset Arrays" on page 2-135

Purpose Label levels
Syntax \(\quad A=\operatorname{set} \operatorname{labels}(A\), labels \()\)
A = setlabels(A,labels,levels)
Description \(\quad A=\operatorname{setlabels}(A, l a b e l s)\) labels the levels in the categorical array \(A\) using the cell array of strings or 2-D character matrix labels. Labels are assigned in the order given in labels.
A = setlabels(A, labels,levels) labels only the levels specified in the cell array of strings or 2-D character matrix levels.

\section*{Examples \\ Example 1}

Relabel the species in Fisher's iris data using new categories:
```

load fisheriris
species = nominal(species);
species = mergelevels(...
species,{'setosa','virginica'},'parent');
species = setlabels(species,'hybrid','versicolor');
getlabels(species)
ans =
'hybrid' 'parent'

```

\section*{Example 2}

1 Load patient data from the CSV file hospital. dat and store the information in a dataset array with observation names given by the first column in the data (patient identification):
```

patients = dataset('file','hospital.dat',...
'delimiter',',',...
'ReadObsNames',true);

```

2 Make the \(\{0,1\}\)-valued variable smoke nominal, and change the labels to 'No' and 'Yes':
```

patients.smoke = nominal(patients.smoke,{'No','Yes'});

```

3 Add new levels to smoke as placeholders for more detailed histories of smokers:
```

patients.smoke = addlevels(patients.smoke,...
{'0-5 Years','5-10 Years','LongTerm'});

```

4 Assuming the nonsmokers have never smoked, relabel the 'No ' level:
```

patients.smoke = setlabels(patients.smoke,'Never','No');

```

5 Drop the undifferentiated 'Yes' level from smoke:
```

patients.smoke = droplevels(patients.smoke,'Yes');
Warning: OLDLEVELS contains categorical levels that
were present in A, caused some array elements to have
undefined levels.

```

Note that smokers now have an undefined level.
6 Set each smoker to one of the new levels, by observation name:
```

patients.smoke('YPL-320') = '5-10 Years';

```

See Also
```

getlabels

```

Purpose
Set exclusive-or for categorical arrays

Note In a future release, the behavior of categorical.setxor will change to be consistent with the MATLAB function setxor. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for setxor.

Syntax
\(C=\operatorname{set} x o r(A, B)\)
[C,IA,IB] = setxor(A,B)
[...] \(=\operatorname{setxor}(A, B\), 'rows')
[...] = setxor(...,'R2012a')
[...] = setxor(...,'legacy')
[...] = setxor(A,B,setOrder)
[...] = setxor(A,B,'rows',setOrder)

\section*{Description}
\(C=\operatorname{setxor}(A, B)\) for categorical vectors \(A\) and \(B\), returns a categorical vector \(C\) containing the values not in the intersection of \(A\) and \(B\) with no repetitions. The result C is sorted. The set of categorical levels for C is the sorted union of the sets of levels of the inputs.
\([C, I A, I B]=\operatorname{setxor}(A, B)\) also returns index vectors IA and IB such that \(C\) is a sorted combination of the values \(A(I A)\) and \(B(I B)\) If there are repeated values that are not in the intersection in \(A\) or \(B\) then the index of the last occurrence of each repeated value is returned.
\([\ldots]=\operatorname{setxor}\left(A, B, ' r o w s^{\prime}\right)\) for categorical matrices \(A\) and \(B\) with the same number of columns, returns the rows that are not in the intersection of A and B. The rows of the matrix C are sorted. The set of categorical levels for \(C\) is the sorted union of the sets of levels of the inputs. The optional outputs IA and IB are index vectors such that \(C\) is the sorted combination of rows \(A(I A,:)\) and \(B(I B,:)\).
[...] = setxor(...,'R2012a') adopts the future behavior of setxor. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.
[...] = setxor(...,'legacy') preserves the current behavior of setxor. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.
[...] \(=\operatorname{setxor}(\mathrm{A}, \mathrm{B}\), setOrder) and \([. .]=\). setxor(A, B, 'rows', setOrder) returns the observations of \(C\) in a specific order. setOrder='sorted' returns the values or rows of \(C\) in sorted order. setOrder='stable' returns the values or rows of C in the same order as A. If A and B are row vectors, then \(C\) is also a row vector. Otherwise, \(C\) is a column vector. IA and IB are column vectors. If there are repeated values that are not in the intersection of \(A\) and \(B\), then the index of the first occurrence of each repeated value is returned.

Purpose Set exclusive or for dataset array observations

Syntax
Description

Input
Arguments
\(C=\operatorname{set} x o r(A, B)\)
\(C=\operatorname{set} x o r(A, B\), vars \()\)
C = setxor(A,B,vars,setOrder)
[C,iA,iB] = setxor(__ )
\(C=\operatorname{set} x o r(A, B)\) for dataset arrays \(A\) and \(B\) returns the set of observations that are not in the intersection of the two arrays, with repetitions removed. The observations in the dataset array C are sorted.
\(C=\operatorname{setxor}(A, B, v a r s)\) returns the set of observations that are not in the intersection of the two arrays, considering only the variables specified in vars, with repetitions removed. The observations in the dataset array C are sorted by these variables. The values for variables not specified in vars for each observation in C are taken from the corresponding observation in A or B. If there are multiple observations in A or B that correspond to an observation in C, those values are taken from the first occurrence.
\(C=\operatorname{setxor}(A, B\), vars, setOrder) returns the observations in \(C\) in the order specified by setOrder.
\([C, i A, i B]=\operatorname{set} x o r(\ldots)\) also returns index vectors iA and iB such that \(C\) is a sorted combination of the values \(A(i A,:)\) and \(B(i B,:)\). If there are repeated observations in \(A\) or \(B\), then setxor returns the index of the first occurrence. You can use any of the previous input arguments.

\section*{A,B \\ Input dataset arrays.}

\section*{vars}

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in A and B that setxor considers.

Specify vars as [] to use its default value of all variables.

\section*{setOrder}

Flag indicating the sorting order for the observations in C . The possible values of setOrder are:
```

'sorted' Observations in C are in sorted order (default).
'stable ' Observations in C are in the same order that they appear in A, then B.

```

\section*{Output Arguments}

\section*{C}

Dataset array with the observations not in the intersection of A and \(B\), with repetitions removed. \(C\) is in sorted order (by default), or the order specified by setOrder.
iA
Index vector, indicating the observations from A that are in C. The vector iA contains the index to the first occurrence of any repeated observations in A.

\section*{iB}

Index vector, indicating the observations from \(B\) that are in \(C\). The vector iB contains the index to the first occurrence of any repeated observations in B.

\section*{Examples Symmetric Difference of Two Dataset Arrays}

Create a scalar structure array, and then convert it into two dataset arrays.
```

S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
S(2,1).Name = 'BROWN';

```

\section*{dataset.setxor}
```

S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));

```

The intersection of \(A\) and \(B\) is the second observation, with last name BROWN.

Return the symmetric difference of \(A\) and \(B\).
```

[C,iA,iB] = setxor(A,B);

```
C
C =
\begin{tabular}{llll} 
Name & Gender & SystolicBP & DiastolicBP \\
'CLARK' & 'M' & 124 & 93 \\
'MARTIN' & 'M' & 130 & 92
\end{tabular}
[iA iB]
ans =

12

The symmetric difference contains the first observation from A, and the second observation from B.

\section*{gmdistribution.SharedCov property}

Purpose true if all covariance matrices are restricted to be the same
Description Logical true if all the covariance matrices are restricted to be the same (pooled estimate); logical false otherwise.

\section*{Purpose Shift dimensions of categorical array}

Syntax \(\quad B=\operatorname{shiftdim}(A, n)\)
[B,nshifts] = shiftdim(A)
Description \(\quad B=\operatorname{shiftdim}(A, n)\) shifts the dimensions of the categorical array \(A\) by N . When n is positive, shiftdim shifts the dimensions to the left and wraps the n leading dimensions to the end. When n is negative, shiftdim shifts the dimensions to the right and pads with singletons.
[B,nshifts] = shiftdim(A) returns the array B with the same number of elements as A but with any leading singleton dimensions removed. nshifts returns the number of dimensions that are removed. If A is a scalar, shiftdim has no effect.

\section*{See Also}
circshift | reshape | squeeze

\section*{RegressionEnsemble.shrink}
Purpose Prune ensemble
Syntax cmp = shrink(ens)
cmp = shrink(ens,Name, Value)
Description cmp = shrink(ens) returns a compact shrunken version of ens, aregularized ensemble. cmp retains only learners with weights abovea threshold.cmp = shrink(ens,Name, Value) returns an ensemble with additionaloptions specified by one or more Name, Value pair arguments. Youcan specify several name-value pair arguments in any order asName1, Value1, ,NameN, ValueN.
Input ..... ens
ArgumentsA regression ensemble created with fitensemble.

\section*{Name-Value Pair Arguments}
Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'lambda'}
Vector of nonnegative regularization parameter values for lasso. If ens. Regularization is nonempty (populate it with regularize), shrink regularizes ens using lambda. If ens contains a Regularization structure, you cannot pass lambda.
Default: []

\section*{'threshold'}

Lower cutoff on weights for weak learners, a numeric nonnegative scalar. shrink creates cmp from those learners with weights above threshold.

Default: 0

\section*{'weightcolumn'}

Column index of ens.Regularization.TrainedWeights, a positive integer. shrink creates cmp with learner weights from this column.

Default: 1

\section*{Output Arguments}

\section*{Examples}

\section*{cmp}

A regression ensemble of class CompactRegressionEnsemble. Use cmp for making predictions exactly as you use ens, with the predict method.
shrink orders the members of cmp from largest to smallest.
Shrink a 300 -member bagged regression ensemble using 0.1 for the parameter lambda, and view the number of members of the resulting ensemble:
```

X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
bag = fitensemble(X,Y,'Bag',300,'Tree','type','regression');
cmp = shrink(bag,'lambda',0.1);
cmp.NTrained
ans =
83

```

\section*{gmdistribution.Sigma property}
\begin{tabular}{ll} 
Purpose & Input array of covariances \\
Description & Input array of covariances SIGMA.
\end{tabular}

Purpose Wilcoxon signed rank test
Syntax
```

p = signrank(x)
p = signrank(x,y)
p = signrank(x,y,Name,Value)
[p,h] = signrank(___)
[p,h,stats] = signrank(___)
[___] = signrank(x,m)
[___] = signrank(x,m,Name,Value)

```

\section*{Description}
\(\mathrm{p}=\) signrank (x) returns the \(p\)-value of a two-sided Wilcoxon signed rank test.
signrank tests the null hypothesis that data in the vector x come from a distribution whose median is zero at the \(5 \%\) significance level. The test assumes that the data in x come from a continuous distribution symmetric about its median.
\(\mathrm{p}=\) signrank \((\mathrm{x}, \mathrm{y})\) returns the \(p\)-value of a paired, two-sided test for the null hypothesis that \(\mathrm{x}-\mathrm{y}\) comes from a distribution with zero median.
\(\mathrm{p}=\) signrank ( \(\mathrm{x}, \mathrm{y}\), Name, Value) returns the \(p\)-value for the sign test with additional options specified by one or more Name, Value pair arguments.
[ \(\mathrm{p}, \mathrm{h}]=\operatorname{signrank}(\ldots \quad\) ) also returns a logical value indicating the test decision. \(\mathrm{h}=1\) indicates a rejection of the null hypothesis, and \(\mathrm{h}=0\) indicates a failure to reject the null hypothesis at the \(5 \%\) significance level. You can use any of the input arguments in the previous syntaxes.
[p,h,stats] = signrank( \(\qquad\) ) also returns the structure stats with information about the test statistic.

[] = signrank \((x, m)\) returns any of the output arguments in the previous syntaxes for the null hypothesis that the data in x are observations from a distribution with median m .
[___] = signrank(x,m,Name, Value) returns any of the output arguments in the previous syntaxes for the signed rank test with additional options specified by one or more Name, Value pair arguments.

\section*{Input Arguments}

\section*{x-Sample data}
vector
Sample data, specified as a vector.

\section*{Data Types}
single | double

\section*{y-Sample data}
vector
Sample data, specified as a vector. y must be the same length as x .
Data Types
single | double

\section*{\(\mathbf{m}\) - Hypothesized value of the median}

\section*{scalar}

Hypothesized value of the median, specified as a scalar.
Example: signrank (x, 10)

\section*{Data Types}
single | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'alpha', 0.01,'method','approximate','tail','right' specifies a right-tailed signed rank test with \(1 \%\) significance level, which returns the approximate p -value.

\section*{'alpha' - Significance level}
0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1 . Significance level of \(h\) is 100 * alpha\%.

Example: 'alpha', 0.01

\section*{Data Types}
double | single
'method' - Computation method of \(\mathbf{p}\)
'exact' | 'approximate'
Computation method of \(p\), specified as the comma-separated pair consisting of 'method' and one of the following.
\begin{tabular}{l|l}
\hline ' exact' & \begin{tabular}{l} 
Exact computation of the \(p\)-value, p . Default value for 15 \\
or fewer observations in \(\mathrm{x}, \mathrm{x}-\mathrm{m}\), or \(\mathrm{x}-\mathrm{y}\) when method is \\
unspecified.
\end{tabular} \\
\hline ' approximattedrmal approximation while computing the \(p\)-value, p. \\
\begin{tabular}{l} 
Default value for more than 15 observations in \(\mathrm{x}, \mathrm{x}-\mathrm{m}\), \\
or \(\mathrm{x}-\mathrm{y}\) when 'method' is unspecified because the exact \\
method can be slow on large samples.
\end{tabular} \\
\hline
\end{tabular}

Example: 'method','exact'
```

Data Types
char
'tail' - Type of test
'both' (default) | 'right' | 'left'

```

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:
\begin{tabular}{|c|c|}
\hline 'both' & \begin{tabular}{l}
Two-sided hypothesis test, which is the default test type. \\
- For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median different than 0 or m . \\
- For a two-sample test, the alternate hypothesis states that the data in \(x-y\) come from a distribution with median different than 0 .
\end{tabular} \\
\hline & \begin{tabular}{l}
Right-tailed hypothesis test. \\
- For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median greater than 0 or m . \\
- For a two-sample test, the alternate hypothesis states the data in \(x-y\) come from a distribution with median greater than 0 .
\end{tabular} \\
\hline 'left' & \begin{tabular}{l}
Left-tailed hypothesis test. \\
- For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median less than 0 or \(m\). \\
- For a two-sample test, the alternate hypothesis states the data in \(x-y\) come from a distribution with median less than 0 .
\end{tabular} \\
\hline \multicolumn{2}{|l|}{Example: 'tail','left'} \\
\hline \multicolumn{2}{|l|}{\(\mathbf{p}\) - \(\boldsymbol{p}\)-value of the test nonnegative scalar} \\
\hline \multicolumn{2}{|l|}{\(p\)-value of the test, returned as a nonnegative scalar from 0 to \(1 . \mathrm{p}\) is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. signrank computes the two-sided \(p\)-value by doubling the most significant one-sided value.} \\
\hline
\end{tabular}

\section*{signrank}

\section*{h-Result of the hypothesis test}

1| 0
Result of the hypothesis test, returned as a logical value.
- If \(h=1\), this indicates the rejection of the null hypothesis at the 100 * alpha\% significance level.
- If \(\mathrm{h}=0\), this indicates a failure to reject the null hypothesis at the 100 * alpha\% significance level.

\section*{stats - Test statistics}
structure
Test statistics, returned as a structure. The test statistics stored in stats are:
- signrank: Value of the sign rank test statistic.
- zval: Value of the \(z\) - statistic (computed when 'method' is 'approximate').

\section*{Examples Test for Zero Median of a Single Population}

Test the hypothesis of zero median.
Generate the sample data.
rng('default') \% for reproducibility
\(x=\operatorname{randn}(1,25)+1.30\);
Test the hypothesis that the data in x has zero median.
[ \(\mathrm{p}, \mathrm{h}]=\) signrank( x )
\(p=\)
3.2229e-05
h =

At the default \(5 \%\) significance level, the value \(h=1\) indicates that the test rejects the null hypothesis of zero median.

\section*{Test the Median of Differences of Paired Samples}

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.
```

rng('default') % for reproducibility
x = lognrnd(2,.25,10,1);
y = x + trnd(2,10,1);

```

Test the hypothesis that \(\mathrm{x}-\mathrm{y}\) has zero median.
```

[p,h] = signrank(x,y)
p =
0.3223
h =
0

```

The results indicate that the test fails to reject the null hypothesis of zero median in the difference at the default \(5 \%\) significance level.

\section*{Signed Rank Test for Large Samples}

Conduct a -sided test on a large sample using approximation.
Navigate to a folder containing sample data.
cd(matlabroot)
cd('help/toolbox/stats/examples')
Load the sample data.

\section*{signrank}
load gradespaired
Test the null hypothesis that the median of the grade differences of students before and after participating in a tutoring program is 0 against the alternate that it is less than 0 .
```

[p,h,stats] = signrank(gradespaired(:,1),···
gradespaired(:,2),'tail','left')
p =
0.0047
h =
1
stats =
zval: -2.5982
signedrank: 2.0175e+03

```

Because the sample size is greater than 15 , signrank uses an approximate method to calculate the \(p\)-value and also returns the value of the \(z\)-statistic. The value \(\mathrm{h}=1\) indicates that the test rejects the null hypothesis that there is no difference between the grade medians at the \(5 \%\) significance level. There is enough statistical evidence to conclude that the median grade before the tutoring program is less than the median grade after the tutoring program.

Repeat the test using the exact method.
```

[p,h,stats] = signrank(gradespaired(:,1),gradespaired(:,2),···.
'tail','left','method','exact')
p =

```
```

h =

```

1
stats =
signedrank: 2.0175e+03
The results obtained using the approximate method are consistent with the exact method.

\section*{Two-Sided Test for the Median of a Single Population}

Load the sample data.

\section*{load mileage}

The data contains the mileages per gallon for three different types of cars in columns 1 to 3 .

Test the hypothesis that the median mileage for the type of cars in the second column differs from 33.
```

[p,h,stats] = signrank(mileage(:,2),33)
p =
0.0313
h =
1
stats =
signedrank: 21

```

At the \(5 \%\) significance level, the results indicate that the median mileage for the second type of cars differs from 33. Note that signrank uses an exact method to calculate the \(p\)-value for small samples and does not return the \(z\)-statistic.

\section*{Right-Sided Test for the Median of a Single Population}

Use the name-value pair arguments in signrank.
Load the sample data.

\section*{load mileage}

The data contains the mileage per gallon for three different types of cars in columns 1 to 3 .

Test the hypothesis that the median mileage for the type of cars in the second row are larger than 33.
```

[p,h,stats] = signrank(mileage(:,2),33,'tail','right')
p =
0.0156
h =
1
stats =
signedrank: 21

```

Repeat the same test at the \(1 \%\) significance level using the approximate method.
```

[p,h,stats] = signrank(mileage(:,2),33,'tail','right',...

```
'alpha',0.01,'method','approximate')
\(p=\)
0.0180
\(\mathrm{h}=\)

0
stats \(=\)
zval: 2.0966
signedrank: 21
This result, \(\mathrm{h}=0\), indicates that the null hypothesis cannot be rejected at the \(1 \%\) significance level.

\section*{Definitions Wilcoxon Signed Rank Test}

The Wilcoxon signed rank test is a nonparametric test for two populations when the observations are paired. In this case, the test statistic, W , is the sum of the ranks of positive differences between the observations in the two samples (that is, \(x-y\) ). When you use the test for one sample, then W is the sum of the ranks of positive differences between the observations and the hypothesized median value \(M_{0}\) (which is 0 when you use signrank ( \(x\) ) and \(m\) when you use signrank ( \(x, m\) )).

\section*{z-Statistic}

For large samples, or when method is approximate, the signrank function calculates the \(p\)-value using the \(z\)-statistic, given by
\[
z=\frac{(W-n(n+1) / 4)}{\sqrt{\frac{n(n+1)(2 n+1)-\text { tieadj }}{24}}},
\]
where \(n\) is the sample size of the difference \(\mathrm{x} \quad \mathrm{y}\) or \(\mathrm{x}-\mathrm{m}\). For the two-sample case, signrank uses [tie_rank, tieadj] = tiedrank(abs(diffxy), 0, 0, epsdiff) to obtain the tie adjustment value tieadj.

Algorithms
signrank treats NaNs in x and y as missing values and ignores them.
For the two-sample case, signrank uses a tolerance based on the values epsdiff \(=e p s(x)+e p s(y)\). The signrank function treats any pair of values with difference \(d(i)=x(i)-y(i)\) that differ by no more than the sum of their two eps values (abs(d(i)) < epsdiff(i)) as ties.

\section*{Purpose Sign test}

Syntax \(\quad p=\operatorname{signtest}(x)\)
p = signtest(x,y)
\(p\) = signtest( \(x, y\), Name, Value)
[p,h] = signtest(___)
[p,h,stats] = signtest( __ )
[ ___] = signtest(x,m)
\([\ldots]\) ] \(=\) signtest \((x, m\), Name, Value \()\)

\section*{Description}
\(\mathrm{p}=\) signtest( x ) returns the \(p\)-value for a two-sided sign test.
signtest tests the hypothesis that data in x has a continuous distribution with zero median against the alternative that the distribution does not have zero median at the \(5 \%\) significance level.
\(\mathrm{p}=\) signtest \((\mathrm{x}, \mathrm{y})\) returns the \(p\)-value of a two-sided sign test. Here, signtest tests for the hypothesis that the data in \(x-y\) has a distribution with zero median against the alternative that the distribution does not have zero median. Note that a hypothesis of zero median for \(\mathrm{x}-\mathrm{y}\) is not equivalent to a hypothesis of equal median for \(x\) and \(y\).
\(\mathrm{p}=\) signtest ( \(\mathrm{x}, \mathrm{y}\), Name, Value) returns the \(p\)-value for the sign test with additional options specified by one or more Name, Value pair arguments.
[ \(p, h\) ] = signtest ( __ ) also returns a logical value indicating the test decision. The value \(\mathrm{h}=1\) indicates a rejection of the null hypothesis, and \(\mathrm{h}=0\) indicates a failure to reject the null hypothesis at the \(5 \%\) significance level. You can use any of the input arguments in the previous syntaxes.

\section*{signtest}
[p,h,stats] = signtest( __ ) also returns the structure stats containing information about the test statistic.

[] = signtest ( \(\mathrm{x}, \mathrm{m}\) ) returns any of the output arguments in the previous syntaxes for the test whether the data in \(x\) are observations from a distribution with median \(m\) against the alternative that the median is different from m .
[ ___ ] = signtest(x,m,Name, Value) returns any of the output arguments in the previous syntaxes for the sign test with additional options specified by one or more Name,Value pair arguments.

\section*{Input \\ Arguments \\ x-Sample data \\ vector}

Sample data, specified as a vector.

\section*{Data Types \\ single | double}

```

\section*{\(m\) - Hypothesized value of the median}

\section*{scalar}

Hypothesized value of the median, specified as a scalar.
Example: signtest (x,35)

\author{
Data Types \\ single | double
}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'alpha',0.01,'method','approximate','tail','right' specifies a right-tailed sign test with \(1 \%\) significance level, which returns the approximate p -value.

\section*{'alpha' - Significance level}

\subsection*{0.05 (default) | scalar value in the range 0 to 1}

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1 . The default value of alpha is 0.05 . Significance level of h is 100 * alpha\%.

Example: 'alpha', 0.01
Data Types
double | single

\section*{'method' - p-value computation method}
```

'exact' | 'approximate

```
\(p\)-value computation method, specified as the comma-separated pair consisting of 'method ' and one of the following:
\begin{tabular}{l|l}
\hline 'exact' & Exact computation of the \(p\)-value, p. \\
\hline 'approximate' & Normal approximation for computing the \(p\)-value, p. \\
\hline
\end{tabular}

The default computation method is 'exact', if there are fewer than 100 observations and 'approximate' if there are 100 observations or more.

Example: 'method','exact'

\section*{Data Types}
char

\section*{signtest}

\section*{'tail' - Type of test}
'both' (default) | 'right' | 'left'
Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:
\begin{tabular}{|c|c|}
\hline 'both' & \begin{tabular}{l}
Two-sided hypothesis test, which is the default test type. \\
- For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median different than zero (or m). \\
- For a two-sample test, the alternate hypothesis states that the data in \(\mathrm{x}-\mathrm{y}\) come from a distribution with median different than zero.
\end{tabular} \\
\hline & \begin{tabular}{l}
'Right-tailed hypothesis test. \\
- For a one-sample test, the alternate hypothesis states that the data in \(x\) come from a continuous distribution with median greater than zero (or m ). \\
- For a two-sample test, the alternate hypothesis states the data in \(x-y\) come from a distribution with median greater than zero.
\end{tabular} \\
\hline 'left' & \begin{tabular}{l}
Left-tailed hypothesis test. \\
- For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median less than zero (or m). \\
- For a two-sample test, the alternative hypothesis states the data in \(\mathrm{x}-\mathrm{y}\) come from a distribution with median less than zero.
\end{tabular} \\
\hline
\end{tabular}

Example: 'tail','left'

\section*{Output Arguments}

\section*{\(\mathbf{p}\) - \(\boldsymbol{p}\)-value of the test}
nonnegative scalar
\(p\)-value of the test, returned as a nonnegative scalar from 0 to \(1 . \mathrm{p}\) is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. signtest computes the two-sided \(p\)-value by doubling the most significant one-sided value.

\section*{h-Result of the hypothesis test \\ 1 | 0}

Result of the hypothesis test, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates rejection of the null hypothesis at the 100 * alpha\% significance level.
- If \(\mathrm{h}=0\), this indicates a failure to reject the null hypothesis at the 100 * alpha\% significance level.

\section*{stats - Test statistics}
structure
Test statistics, returned as a structure. The test statistics stored in stats are:
- sign: Value of the sign test statistic.
- zval: Value of the z-statistic (computed only for large samples).

\section*{Examples Test for Zero Median of a Single Population}

Test the hypothesis of zero median.
Generate the sample data.
```

rng('default') % for reproducibility
x = randn(1,25);

```

The sampling distribution of x is symmetric with zero median.
Test the null hypothesis that x comes from a distribution with a median different from zero median.

\section*{signtest}
```

[p,h,stats] = signtest(x,0)
p =
0.1078
h =
0
stats =
zval: NaN
sign: 17

```

At the default \(5 \%\) significance level, the result \(\mathrm{h}=0\) indicates that signtest fails to reject to the null hypothesis of zero median. signtest calculates the \(p\)-value using the exact method, hence it does not calculate zval and returns it as a NaN.

\section*{Test for Zero Median for the Difference of Paired Samples}

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.
```

rng('default') % for reproducibility
before = lognrnd(2,.25,10,1);
after = before + (lognrnd(0,.5,10,1) - 1);

```

The sampling distribution of the difference between before and after is symmetric with zero median.

Test the null hypothesis that the difference of before and after has zero median.
[ \(\mathrm{p}, \mathrm{h}]=\) signtest (before, after)
\(p=\)
0.7539

At the default 5\% significance level, the value \(\mathrm{h}=0\) indicates that signtest fails to reject to the null hypothesis of zero median in the difference.

\section*{Medians of Paired Samples}

Test the hypothesis of zero median for the difference between two paired samples using the exact and approximate methods.

Generate the sample data.
```

rng('default') % for reproducibility
x = lognrnd(2,.25,15,1);
y = x + trnd(2,15,1);
display([x y])
ans =
8.4521 7.8047
11.6869 11.4094
4.2009 5.1133
9.1664 12.1655
8.0020 10.0300
5.3285 6.0153
6.6300 5.1235
8.0499 8.6737
18.0763 19.2164
14.7665 15.3380
5.2726 8.4187
15.7798 16.2093
8.8583 8.5575
7.2735 7.4783

```

\section*{signtest}
```

8.8347 7.8894

```

Test the hypothesis that \(\mathrm{x}-\mathrm{y}\) has zero median.
[ \(\mathrm{p}, \mathrm{h}\), stats] \(=\) signtest \((\mathrm{x}, \mathrm{y})\)
p =
    0.3018
h =
    0
stats =
    zval: NaN
    sign: 5

At the default \(5 \%\) significance level, the value \(\mathrm{h}=0\) indicates that the test fails to reject the null hypothesis of zero median in the difference.

Repeat the test using the approximate method.
[p,h,stats] = signtest(x,y,'method','approximate')
\(p=\)
0.3017
\(\mathrm{h}=\)
0
zval: -1.0328
sign: 5
The approximate \(p\)-value, which signtest obtains using the z-statistic, is really close to the exact \(p\)-value.

\section*{Test for Large Samples}

Perform a left-sided sign test for large samples.
Navigate to a folder containing sample data.
```

cd(matlabroot)
cd('help/toolbox/stats/examples')

```

Load the sample data.
load gradespaired
Test the null hypothesis that the median of the grade differences before and after the tutoring program is 0 against the alternate that it is less than 0 .
```

[p,h,stats] = signtest(gradespaired(:,1),gradespaired(:,2),···.
'tail','left')
p =
0.0013
h =
1
stats =

```

\section*{signtest}
zval: - 3.0110
sign: 37

Because the sample size is large (greater than 100), signtest uses an approximate method to calculate the \(p\)-value and also returns the value of the \(z\)-statistic. The test rejects the null hypothesis that there is no difference between the grade medians at the \(5 \%\) significance level.

\section*{Test for Median of a Single Population}

Test the hypothesis that the population median is different from a specified value.

Load the sample data.
load lawdata
The data set has 15 observations for variables gpa and lsat.
Test the hypothesis that the median lsat score is higher than 570.
```

[p,h,stats] = signtest(lsat,570,'tail','right')
p =
0.0176
h =
1
stats =
zval: NaN
sign: 12

```

Both the \(p\)-value, 0.0176 , and \(\mathrm{h}=1\) indicate that at the \(5 \%\) significance level the test concludes in favor of the alternate hypothesis.

\section*{Definitions}

\section*{Algorithms}

\section*{Sign Test}

The sign test is a nonparametric test for the median of a population or median of the difference of two populations.

For example, for tests on a single population median:
- If the test is two-sided, then the test statistic, \(S\), is the minimum of the number of observations that are smaller or larger than the hypothesized median value, \(M_{0}\).
- If the test is right-sided, then \(S\) is the number of observations that are larger than the hypothesized median value \(M_{0}\).
- If the test is left-sided, then \(S\) is the number of observations that are smaller than the hypothesized median value \(M_{0}\).

\section*{z-Statistic}

For a large sample, signtest uses the \(z\)-statistic to approximate the \(p\)-value.

The signtest test statistic is the number of elements that are greater than 0 (for signtest ( \(x\) ) or signtest ( \(x-y\) )), or \(m\) (for signtest ( \(x, m\) ). . Hence, the \(z\)-statistic of the sign test, with the continuity correction, is:
\[
z=\frac{(S-E(S))}{\sqrt{V(S)}}=\frac{(S-(0.5) n-0.5 \operatorname{sign}(n p o s-n n e g))}{\sqrt{(0.5)(0.5) n}},
\]
where npos and nneg are the number of positive and negative differences from the hypothesized median value, respectively.

For a one-sample test, signtest omits values in x that are zero or NaN .
For a two-sample test, signtest omits values in \(x-y\) that are zero or NaN.

\section*{Purpose}

Silhouette plot
```

silhouette(X,clust)

```
s = silhouette(X,clust)
[s,h] = silhouette(X,clust)
[...] = silhouette(X,clust,metric)
[...] = silhouette(X,clust,distfun, p1, p2,...)

Description

\section*{Syntax}
s = silhouette(X, clust)
[s,h] = silhouette(X, clust)
[...] = silhouette(X,clust,metric)
[...] = silhouette(X,clust,distfun, p1,p2,...)
silhouette(X,clust) plots cluster silhouettes for the \(n\)-by- \(p\) data matrix \(X\), with clusters defined by clust. Rows of \(X\) correspond to points, columns correspond to coordinates. clust can be a categorical variable, numeric vector, character matrix, or cell array of strings containing a cluster name for each point. silhouette treats NaNs or empty strings in clust as missing values, and ignores the corresponding rows of \(X\). By default, silhouette uses the squared Euclidean distance between points in X .
\(\mathrm{s}=\) silhouette(X, clust) returns the silhouette values in the \(n\)-by- 1 vector s, but does not plot the cluster silhouettes.
[s,h] = silhouette(X, clust) plots the silhouettes, and returns the silhouette values in the \(n\)-by- 1 vector s, and the figure handle in \(h\).
[...] = silhouette(X, clust,metric) plots the silhouettes using the inter-point distance function specified in metric. Choices for metric are given in the following table.
\begin{tabular}{l|l}
\hline Metric & Description \\
\hline 'Euclidean' & Euclidean distance \\
\hline 'sqEuclidean' & Squared Euclidean distance (default) \\
\hline 'cityblock' & Sum of absolute differences \\
\hline 'cosine' & \begin{tabular}{l} 
One minus the cosine of the included angle \\
between points (treated as vectors)
\end{tabular} \\
\hline 'correlation' & \begin{tabular}{l} 
One minus the sample correlation between points \\
(treated as sequences of values)
\end{tabular} \\
\hline
\end{tabular}

\section*{Definitions}

\section*{Silhouette Value}

The silhouette value for each point is a measure of how similar that point is to points in its own cluster compared to points in other clusters, and ranges from -1 to +1 .
The silhouette value for the ith point, Si , is defined as
```

Si = (bi-ai)/ max(ai,bi)

```
where ai is the average distance from the ith point to the other points in the same cluster as \(i\), and bi is the minimum average distance from the ith point to points in a different cluster, minimized over clusters.

\section*{Examples}
```

X = [randn(10,2)+ones(10,2);
randn(10,2)-ones(10,2)];
cidx = kmeans(X,2,'distance','sqeuclid');
s = silhouette(X,cidx,'sqeuclid');

```

How To - "Grouping Variables" on page 2-51

\section*{categorical.single}

Purpose Convert categorical array to single array

\section*{Syntax \\ \(B\) = single(A)}

Description \(B=\) single \((A)\) converts the categorical array \(A\) to a single array. Each element of \(B\) contains the internal categorical level code for the corresponding element of \(A\).

See Also double

\section*{dataset.single}

Purpose Convert dataset variables to single array
Syntax
\(B=\) single \((A)\)
\(B=\) single(A,vars)

Description \(B=\) single \((A)\) returns the contents of the dataset \(A\), converted to one single array. The classes of the variables in the dataset must support the conversion.
\(B=\) single(A,vars) returns the contents of the dataset variables specified by vars. vars is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

\author{
See Also \\ dataset | double | replacedata
}
Purpose Size of categorical array
```

Syntax
d $=\operatorname{size}(A)$
[m,n] = size(A)
[m1,m2,m3,...,mn] = size(A)
$\mathrm{m}=\operatorname{size}(\mathrm{A}, \operatorname{dim})$

```

Description \(d=\operatorname{size}(A)\) returns the two-element row vector \(d=[m, n]\) containing the number of rows and columns in the matrix for an m-by-n categorical matrix A. For n-D categorical arrays, size (A) returns a 1-by-n vector of dimension lengths. Trailing singleton dimensions are ignored.
\([m, n]=\operatorname{size}(A)\) for a categorical matrix \(A\), returns the number of rows and columns in \(A\) as separate output variables.
\([m 1, m 2, m 3, \ldots, m n]=\operatorname{size}(A)\), for \(n>1\), returns the sizes of the first \(n\) dimensions of the categorical array \(A\). If the number of output arguments \(n\) does not equal ndims ( \(A\) ), then for:
\[
\begin{array}{ll}
\mathrm{n}>\operatorname{ndims}(\mathrm{A}) & \begin{array}{l}
\text { size returns ones in the "extra" variables, } \\
\text { i.e., outputs ndims }(\mathrm{A})+1 \text { through } \mathrm{n} .
\end{array} \\
\mathrm{n}<\operatorname{ndims}(\mathrm{A}) & \begin{array}{l}
\text { mn contains the product of the sizes of } \\
\text { dimensions } n \text { through ndims }(A) .
\end{array}
\end{array}
\]
\(\mathrm{m}=\operatorname{size}(\mathrm{A}, \mathrm{dim})\) returns the length of the dimension specified by the scalar dim. For example, size \((A, 1)\) returns the number of rows. If dim > ndims(A), \(m\) will be 1 .

See Also length | ndims | numel
Purpose Size of dataset array
Syntax

\[
D=\operatorname{SIZE}(A)
\]

[NOBS,NVARS] = SIZE(A)

\[
[\mathrm{M} 1, \mathrm{M} 2, \mathrm{M} 3, \ldots, \mathrm{MN}]=\operatorname{SIZE}(\mathrm{A})
\]

M = size(A,dim)
\(D=\operatorname{SIZE}(A)\) returns the two-element row vector \(D=[\) NOBS, NVARS] containing the number of observations and number of variables in the dataset A. A dataset array always has two dimensions.
[NOBS,NVARS] = SIZE(A) returns the numbers of observations and variables in the dataset A as separate output variables.
[M1, M2, M3, ..., MN] = SIZE (A), for N > 2, returns M1 = NOBS, M2 = NVARS, and M3,..,MN = 1.
\(M=\) size( \(\mathrm{A}, \mathrm{dim}\) ) returns the length of the dimension specified by the scalar dim:
- M = size(A,1) returns NOBS
- \(M=\operatorname{size}(A, 2)\) returns NVARS
- \(M=\operatorname{size}(A, k)\) returns 1 for \(k>2\)

\section*{See Also \\ length | ndims | numel}

\section*{qrandset.size}

Purpose Number of dimensions in matrix
Syntax \(\quad\)\begin{tabular}{ll}
\(d=\operatorname{size}(p)\) \\
& {\([m, n]=\operatorname{size}(p)\)} \\
& \(m=\operatorname{size}(p, \operatorname{dim})\)
\end{tabular}

\section*{Description}
\(d=\operatorname{size}(p)\) returns the two-element row vector \(d=[m, n]\) containing the number of points in the point set and the number of dimensions the points are in, for the point set \(p\). These correspond to the number of rows and columns in the matrix that would be produced by the expression \(\mathrm{p}(:,:\) ).
\([m, n]=\operatorname{size}(p)\) returns the number of points and dimensions for \(p\) as separate output variables.
\(m=\operatorname{size}(p, d i m)\) returns the length of the dimension specified by the scalar dim. For example, size ( \(p, 1\) ) returns the number of rows (points in the point set). If dim is greater than \(2, \mathrm{~m}\) will be 1 .

Examples The commands
```

P = sobolset(12);
d = size(P)
return
d = [9.0072e+015 12]

```

The command
[m,n] = size(P)
returns
\(\mathrm{m}=9.0072 \mathrm{e}+015\)
n = 12

The command
\(\mathrm{m} 2=\operatorname{size}(\mathrm{P}, 2)\)
returns
\(\mathrm{m} 2=12\)

\section*{slicesample}

Slice sampler
```

rnd = slicesample(initial,nsamples,'pdf',pdf)

```
rnd = slicesample(initial,nsamples,'pdf',pdf)
rnd = slicesample(initial,nsamples,'logpdf',logpdf)
rnd = slicesample(initial,nsamples,'logpdf',logpdf)
[rnd,neval] = slicesample(initial,...)
[rnd,neval] = slicesample(initial,...)
[rnd,neval] = slicesample(initial,...,Name,Value)
```

[rnd,neval] = slicesample(initial,...,Name,Value)

```

\section*{Input Arguments}

Tips

\section*{initial}

Initial point, a scalar or row vector. Set initial so pdf(initial) is a strictly positive scalar. length(initial) is the number of dimensions of each sample.

\section*{nsamples}

Positive integer, the number of samples that slicesample generates.

\section*{pdf}

Handle to a function that generates the probability density function, specified with @. pdf can be unnormalized, meaning it need not integrate to 1 .

\section*{logpdf}

Handle to a function that generates the logarithm of the probability density function, specified with @. logpdf can be the logarithm of an unnormalized pdf.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'burnin'}

Nonnegative integer, the number of samples to generate and discard before generating the samples to return. The slice sampling algorithm is a Markov chain whose stationary distribution is proportional to that of the pdf argument. Set burnin to a high enough value that you believe the Markov chain approximately reaches stationarity after burnin samples.

\section*{Default: 0}

\section*{'thin'}

Positive integer, where slicesample discards every thin - 1 samples and returns the next. The slice sampling algorithm is a Markov chain, so the samples are serially correlated. To reduce the serial correlation, choose a larger value of thin.

Default: 1

\section*{slicesample}

\section*{'width'}

Width of the interval around the current sample, a scalar or vector of positive values. slicesample begins with this interval and searches for an appropriate region containing the points of pdf that evaluate to a large enough value.
- If width is a scalar and the samples have multiple dimensions, slicesample uses width for each dimension.
- If width is a vector, it should have the same length as initial.

\section*{Default: 10}

\section*{Output Arguments}

\section*{rnd}
nsamples-by-length(initial) matrix, where each row is one sample.

\section*{neval}

Scalar, the mean number of function evaluations per sample. neval includes the burnin and thin evaluations, not just the evaluations of samples returned in rnd. Therefore the total number of function evaluations is
```

neval*(nsamples*thin + burnin).

```

Generate random samples from a multimodal density using slicesample.

1 Define a function proportional to a multimodal density:
```

f= @(x) exp(-x.^2/2).*(1 + (sin(3*x)).^2).*...
(1 + (cos(5*x).^2));
area = integral(f,-5,5);

```

2 Generate 2000 samples from the density, using a burn-in period of 1000, and keeping one in five samples:
\[
N=2000 ;
\]
```

x = slicesample(1,N,'pdf',f,'thin',5,'burnin',1000);

```

3 Plot a histogram of the sample:
```

[binheight,bincenter] = hist(x,50);
h = bar(bincenter,binheight,'hist');
set(h,'facecolor',[0.8 . 8 1]);

```

4 Scale the density to have the same area as the histogram, and superimpose it on the histogram:
```

hold on
xd = get(gca,'XLim');
xgrid = linspace(xd(1),xd(2),1000);
binwidth = (bincenter(2)-bincenter(1));
y = (N*binwidth/area) * f(xgrid);
plot(xgrid,y,'r','LineWidth',2)
hold off

```

The samples seem to fit the theoretical distribution well, so the burnin value seems adequate.

\section*{Algorithms}

At each point in the sequence of random samples, slicesample selects the next point by "slicing" the density to form a neighborhood around the previous point where the density is above some value. Consequently, the sample points are not independent. Nearby points in the sequence tend to be closer together than they would be from a sample of independent values. For many purposes, the entire set of points can be used as a sample from the target distribution. However, when this type of serial correlation is a problem, the burnin and thin parameters can help reduce that correlation.
slicesample uses the slice sampling algorithm of Neal [1]. For numerical stability, it converts a pdf function into a logpdf function. The algorithm to resize the support region for each level, called "stepping-out" and "stepping-in," was suggested by Neal.

mhsample | rand | randsample

\section*{Purpose Skewness}
Syntax \(\quad\)\begin{tabular}{rl}
\(y\) & \(=\operatorname{skewness}(X)\) \\
\(y\) & \(=\operatorname{skewness}(X, f l a g)\) \\
\(y\) & \(=\operatorname{skewness}(X, f l a g, \operatorname{dim})\)
\end{tabular}

Description

Algorithms
\(y=\) skewness \((X)\) returns the sample skewness of \(X\). For vectors, skewness \((x)\) is the skewness of the elements of \(x\). For matrices, skewness ( X ) is a row vector containing the sample skewness of each column. For N-dimensional arrays, skewness operates along the first nonsingleton dimension of \(X\).
\(y=s k e w n e s s(X, f l a g)\) specifies whether to correct for bias (flag \(=0)\) or not (flag \(=1\), the default). When \(X\) represents a sample from a population, the skewness of \(X\) is biased; that is, it will tend to differ from the population skewness by a systematic amount that depends on the size of the sample. You can set flag \(=0\) to correct for this systematic bias.
\(\mathrm{y}=\) skewness \((\mathrm{X}, \mathrm{fl}\) ag, dim) takes the skewness along dimension dim of \(X\).
skewness treats NaNs as missing values and removes them.
Skewness is a measure of the asymmetry of the data around the sample mean. If skewness is negative, the data are spread out more to the left of the mean than to the right. If skewness is positive, the data are spread out more to the right. The skewness of the normal distribution (or any perfectly symmetric distribution) is zero.

The skewness of a distribution is defined as
\[
s=\frac{E(x-\mu)^{3}}{\sigma^{3}}
\]
where \(\mu\) is the mean of \(x, \sigma\) is the standard deviation of \(x\), and \(E(t)\) represents the expected value of the quantity \(t\). skewness computes a sample version of this population value.

When you set flag to 1 , the following equation applies:
\[
s_{1}=\frac{\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{3}}{\left(\sqrt{\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}}\right)^{3}}
\]

When you set flag to 0 , the following equation applies:
\[
s_{0}=\frac{\sqrt{n(n-1)}}{n-2} s_{1}
\]

This bias-corrected formula requires that X contain at least three elements.

\section*{Examples}
```

X = randn([5 4])
X =
1.1650 1.6961 -1.4462 -0.3600
0.6268 0.0591-0.7012 -0.1356
0.0751 1.7971 1.2460 -1.3493
0.3516 0.2641 -0.6390-1.2704
-0.6965 0.8717 0.5774 0.9846
y = skewness(X)
y =
-0.2933 0.0482 0.2735 0.4641

```

See Also kurtosis | mean | moment | std | var

\section*{qrandset.Skip property}

\section*{Purpose Number of initial points to omit from sequence}

Description The Skip property of a point set contains a positive integer which specifies the number of initial points in the sequence to omit from the point set. The default Skip value is 0 .

Initial points of a sequence sometimes exhibit undesirable properties, for example the first point is often \((0,0,0, \ldots)\) and this may "unbalance" the sequence since its counterpart, ( \(1,1,1, \ldots\) ), never appears. Another common reason is that initial points often exhibit correlations among different dimensions which disappear later in the sequence.

Examples Examine the difference between skipping and not skipping points:
```

% No skipping produces the standard Sobol sequence.
P = sobolset(5);
P(1:3,:)
% Skip the first point of the sequence. The point set now
% starts at the second point of the basic Sobol sequence.
P.Skip = 1;
P(1:3,:)

```

How To . "Quasi-Random Point Sets" on page 6-16
Purpose Construct Sobol quasi-random point set
Syntax

\(\mathrm{p}=\) sobolset(d)

p = sobolset(d,prop1,val1,prop2,val2,...)

Description

\section*{Examples}
\(p=\) sobolset (d) constructs a d-dimensional point set \(p\) of the sobolset class, with default property settings.
p = sobolset(d,prop1,val1,prop2,val2,...) specifies property name/value pairs used to construct \(p\).
The object \(p\) returned by sobolset encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the Skip and Leap properties and by limits on the size of point set indices (maximum value of \(2^{53}\) ). Values of the point set are not generated and stored in memory until you access \(p\) using net or parenthesis indexing.
Generate a 3-D Sobol point set, skip the first 1000 values, and then retain every 101st point:
```

p = sobolset(3,'Skip',1e3,'Leap',1e2)
p =
Sobol point set in 3 dimensions (8.918019e+013 points)
Properties:
Skip : }100
Leap : 100
ScrambleMethod : none
PointOrder : standard

```
Use scramble to apply a random linear scramble combined with a random digital shift:
```

p = scramble(p,'MatousekAffineOwen')
p =
Sobol point set in 3 dimensions (8.918019e+013 points)
Properties:
Skip : 1000

```
```

Leap : 100
ScrambleMethod : MatousekAffineOwen PointOrder : standard

```

Use net to generate the first four points:
```

XO = net(p,4)
XO =
0.7601 0.5919 0.9529
0.1795 0.0856 0.0491
0.5488 0.0785 0.8483
0.3882 0.8771 0.8755

```

Use parenthesis indexing to generate every third point, up to the 11th point:
```

X = p(1:3:11,:)
X =
0.7601 0.5919 0.9529
0.3882 0.8771 0.8755
0.6905 0.4951 0.8464
0.1955 0.5679 0.3192

```

Purpose Sort elements of ordinal array
Syntax
\(B=\operatorname{sort}(A)\)
\(B=\operatorname{sort}(A, d i m)\)
\(B=\operatorname{sort}(A, d i m, m o d e)\)
\([B, I]=\operatorname{sort}(A, \ldots)\)

\section*{Description}
\(B=\operatorname{sort}(A)\), when \(A\) is an ordinal vector, sorts the elements of \(A\) in ascending order. For ordinal matrices, sort (A) sorts each column of A in ascending order. For \(N\)-D ordinal arrays, sort (A) sorts the along the first nonsingleton dimension of \(A\). \(B\) is an ordinal array with the same levels as A.
\(B=\operatorname{sort}(A, d i m)\) sorts \(A\) along dimension dim.
\(B=\operatorname{sort}(A, d i m\), mode \()\) sorts \(A\) in the order specified by mode. mode is ' ascend ' for ascending order, or 'descend' for descending order.
\([B, I]=\operatorname{sort}(A, \ldots)\) also returns an index matrix I. If \(A\) is a vector, then \(B=A(I)\). If \(A\) is an \(m\)-by- \(n\) matrix and \(\operatorname{dim}\) is 1 , then \(B(:, j)=\) \(A(I(:, j), j)\) for \(j=1: n\).
Elements with undefined levels are sorted to the end.

\section*{Examples \\ Sort the columns of an ordinal array in ascending order:}
```

A = ordinal([6 2 5; 2 4 1; 3 2 4],...
A =
hi med hi
med hi lo
med med hi
B = sort(A)
B =
med med lo
med med hi
hi hi hi

```
            \{'lo','med','hi'\},[],[0 0246\(])\)

Related Examples

\section*{Purpose}

Sort rows

\section*{Syntax}
\(B=\) sortrows \((A)\)
\(B=\operatorname{sortrows}(A, c o l)\)
\([B, I]=\) sortrows \((A)\)
\([B, I]=\) sortrows \((A, c o l)\)
Description
\(B=\) sortrows \((A)\) sorts the rows of the 2-D ordinal matrix \(A\) in ascending order, as a group. \(B\) is an ordinal array with the same levels as A.
\(B=\) sortrows(A, col) sorts A based on the columns specified in the vector col. If an element of col is positive, the corresponding column in A is sorted in ascending order; if an element of col is negative, the corresponding column in \(A\) is sorted in descending order.
\([B, I]=\operatorname{sortrows}(A)\) and \([B, I]=\operatorname{sortrows}(A, C o l)\) also returns an index matrix \(I\) such that \(B=A(I,:)\).
Elements with undefined levels are sorted to the end.

\section*{Examples}

Sort the rows of an ordinal array in ascending order for the first column, and then in descending order for the second column:
```

A = ordinal([6 2 5; 2 4 1; 3 2 4],...
{'lo','med','hi'},[],[0}02466]
A =
hi med hi
med hi lo
med med hi
B = sortrows(A,[1 -2])
B =
med hi lo
med med hi
hi med hi

```

See Also sort | sortrows

\section*{Purpose Format distance matrix}
```

Syntax z = squareform(y)
y = squareform(Z)
Z = squareform(y,'tovector')
Y = squareform(Z,'tomatrix')

```

\section*{Description}

\section*{Examples}
```

y = 1:6
y =
1 2 3 3 4 5 6
X = [0 1 2 3; 1 0 4 5; 2 4 0 6; 3 5 6 0]
x =
0}12
1
2 4 0
3 5 6 0

```

Then squareform(y) = X and squareform(X) = y.

See Also pdist

Purpose Squeeze singleton dimensions from categorical array

\section*{Syntax \\ \(B=\) squeeze ( \(A\) )}

Description \(B=\) squeeze \((A)\) returns an array \(B\) with the same elements as the categorical array \(A\) but with all the singleton dimensions removed. A singleton is a dimension such that size (A, dim) \(=1.2\)-D arrays are unaffected by squeeze so that row vectors remain rows.

See Also shiftdim

\section*{Purpose \\ Syntax \\ Description}

Stack data from multiple variables into single variable
tall = stack(wide,datavars)
[tall,iwide] = stack(wide,datavars)
tall = stack(wide,datavars,Parameter,value)
tall = stack(wide, datavars) converts a wide-format dataset array into a tall-format array, by stacking multiple variables in wide into a single variable in tall. In general, tall contains fewer variables but more observations than wide.
datavars specifies a group of \(m\) data variables in wide. stack creates a single data variable in tall by interleaving their values, and if wide has \(n\) observations, then tall has m-by-n observations. In other words, stack takes the \(m\) data values from each observation in wide and stacks them up to create \(m\) observations in tall. datavars is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. stack also creates a grouping variable in tall to indicate which of the \(m\) data variables in wide each observation in tall corresponds to.
stack assigns values for the "per-variable properties (e.g., Units and VarDescription) for the new data variable in tall from the corresponding property values for the first variable listed in datavars.
stack copies the remaining variables from wide to tall without stacking, by replicating each of their values \(m\) times. These variables are typically grouping variables. Because their values are constant across each group of \(m\) observations in tall, they identify which observation in wide an observation in tall came from.
[tall,iwide] = stack(wide,datavars) returns an index vector iwide indicating the correspondence between observations in tall and those in wide. stack creates tall( \(\mathrm{j},:\) ) using wide(iwide( j ), datavarss).

For more information on grouping variables, see "Grouping Variables" on page 2-51.

\section*{Input Arguments}

\section*{Examples}
tall = stack(wide,datavars, Parameter, value) uses the following parameter name/value pairs to control how stack converts variables in wide to variables in tall:
\begin{tabular}{l|l}
\hline 'ConstVars' & \begin{tabular}{l} 
Variables in wide to copy to tall \\
without stacking. ConstVars \\
is a positive integer, a vector \\
of positive integers, a variable \\
name, a cell array containing \\
one or more variable names, or a \\
logical vector. The default is all \\
variables in wide not specified in \\
datavars.
\end{tabular} \\
\hline 'NewDataVarName' & \begin{tabular}{l} 
A name for the data variable to be \\
created in tall. The default is a \\
concatenation of the names of the \\
m variables that are stacked up.
\end{tabular} \\
\hline 'IndVarName' & \begin{tabular}{l} 
A name for the grouping variable \\
to create in tall to indicate the \\
source of each value in the new \\
data variable. The default is \\
based on the 'NewDataVarName' \\
parameter.
\end{tabular} \\
\hline
\end{tabular}

You can also specify multiple groups of data variables in wide, each of which becomes a variable in tall. All groups must contain the same number of variables. Use a cell array to contain multiple parameter values for datavars, and a cell array of strings to contain multiple 'NewDataVarName'.

Convert a wide format data set to tall format, and then back to a different wide format:
load flu
\% FLU has a 'Date' variable, and 10 variables for estimated \% influenza rates (in 9 different regions, estimated from
\% Google searches, plus a nationwide estimate from the
\% CDC). Combine those 10 variables into a "tall" array that
\% has a single data variable, 'FluRate', and an indicator
\% variable, 'Region', that says which region each estimate
\% is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName', 'Region')
\% The second observation in FLU is for \(10 / 16 / 2005\). Find the
\% observations in FLU2 that correspond to that date.
flu(2,:)
flu2(iflu==2,:)
\% Use the 'Date' variable from that tall array to split
\% 'FluRate' into 52 separate variables, each containing the
\% estimated influenza rates for each unique date. The new
\% "wide" array has one observation for each region. In
\% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
    'NewDataVarNames', dateNames)
\% Since observations in FLU3 represent regions, IFLU2
\% indicates the first occurrence in FLU2 of each region.
flu2(iflu2,:)

\section*{qrandstream.State property}

\section*{Purpose Current state of the stream}

\section*{Description The State property of a quasi-random stream contains the index into the associated point set of the next point to draw in the stream. Getting and resetting the State property allows you to return a stream to a previous state. The initial value of State is 1 .}

\section*{Examples}

Q = qrandstream('sobol', 5);
s = Q.State;
u1 = qrand (Q, 10)
Q.State = s;
\(u 2=\) qrand \((Q, 10) \%\) contains exactly the same values as \(u 1\)
See Also qrand

\section*{Purpose Access values in statistics options structure}

Syntax val = statget (options, param)
val = statget(options,param,default)

Description

\section*{Input \\ Arguments}
val \(=\) statget (options, param) returns the value of the parameter specified by the string param in the statistics options structure options. If the parameter is undefined in options, statget returns []. You need to type only enough leading characters to define the parameter name uniquely. statget ignores case for parameter names. For available options, see Inputs.
val = statget(options, param, default) returns default if the specified parameter is undefined in the optimization options structure options.

\section*{DerivStep}

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.

\section*{Display}

Amount of information displayed by the algorithm.
- 'off' - Displays no information.
- 'final' - Displays the final output.
- 'iter' - Displays iterative output to the command window for some functions; otherwise displays the final output.

\section*{FunValCheck}

Check for invalid values, such as NaN or Inf, from the objective function.
- 'off'
- 'on'

\section*{GradObi}

Flags whether the objective function returns a gradient vector as a second output.
- 'off'
- 'on'

\section*{Jacobian}

Flags whether the objective function returns a Jacobian as a second output.
- 'off'
- 'on'

\section*{MaxFunEvals}

Maximum number of objective function evaluations allowed. Positive integer.

\section*{Maxlter}

Maximum number of iterations allowed. Positive integer.

\section*{OutputFen}

The solver calls all output functions after each iteration.
- Function handle specified using @
- a cell array with function handles
- an empty array (default)

\section*{Robust}

Invoke robust fitting option.
- 'off'
- 'on'

\section*{RobustWgtFun}

A weight function for robust fitting. Valid only when Robust is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.
- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

\section*{Streams}

A single instance of the RandStream class, or a cell array of RandStream instances. The Streams option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If 'UseSubstreams' is true, the Streams value must be a scalar, or must be empty. If 'UseParallel' is true and 'UseSubstreams ' is false, then the Streams argument must either be empty, or its length must match the number of processors used in the computation: equal to the matlabpool size if a matlabpool is open, a scalar otherwise.

\section*{TolBnd}

Parameter bound tolerance. Positive scalar.

\section*{Tolfun}

Termination tolerance for the objective function value. Positive scalar.

\section*{TolTypeFun}

Use TolFun for absolute or relative objective function tolerances.
- 'abs'
- 'rel'

\section*{TolTypeX}

Use TolX for absolute or relative parameter tolerances.
- 'abs'
- 'rel'

\section*{TolX}

Termination tolerance for the parameters. Positive scalar.

\section*{Tune}

The tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar.

\section*{UseParallel}

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT matlabpool is in effect. Valid values are false (the default), for serial computation, and true, for parallel computation.

\section*{UseSubstreams}

Flag indicating whether the random number generator in eligible functions should use Substream property of the RandStream class. false (default) or true. When true, high level iterations within the function will set the Substream property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

\section*{WgtFun}

A weight function for robust fitting. Valid only when Robust is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.
- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

\section*{Examples}

This statement returns the value of the Display statistics options parameter from the structure called my_options.
```

val = statget(my_options,'Display')

```

Return the value of the Display statistics options parameter from the structure called my_options (as in the previous example). If the Display parameter is undefined, statget returns the value 'final'.
```

optnew = statget(my_options,'Display','final');

```

See Also statset

Purpose Create statistics options structure
Syntax
statset
statset(statfun)
options = statset(...)
options = statset(fieldname1,val1,fieldname2,val2,...)
options = statset(oldopts,fieldname1,val1,fieldname2,val2, ...)
options = statset(oldopts, newopts)

\section*{Description}
statset with no input arguments and no output arguments displays all fields of a statistics options structure and their possible values.
statset (statfun) displays fields and default values used by the Statistics Toolbox function statfun. Specify statfun using a string name or a function handle.
options = statset(...) creates a statistics options structure options. With no input arguments, all fields of the options structure are an empty array ([ ]). With a specified statfun, function-specific fields are default values and the remaining fields are [ ]. Function-specific fields set to [ ] indicate that the function is to use its default value for that parameter. For available options, see Inputs.
options = statset(fieldname1,val1,fieldname2,val2,...) creates an options structure in which the named fields have the specified values. Any unspecified values are []. Use strings for field names. For fields that are string-valued, you must input the complete string for the value. If you provide an invalid string for a value, statset uses the default.
options =
statset(oldopts,fieldname1,val1,fieldname2, val2,...)
creates a copy of oldopts with the named parameters changed to the specified values.
options = statset(oldopts, newopts) combines an existing options structure, oldopts, with a new options structure, newopts. Any
parameters in newopts with nonempty values overwrite corresponding parameters in oldopts.

\section*{Input \\ Arguments}

\section*{DerivStep}

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.

\section*{Display}

Amount of information displayed by the algorithm.
- 'off' - Displays no information.
- 'final' - Displays the final output.
- 'iter' - Displays iterative output to the command window for some functions; otherwise displays the final output.

\section*{FunValCheck}

Check for invalid values, such as NaN or Inf, from the objective function.
- 'off'
- 'on'

\section*{GradObi}

Flags whether the objective function returns a gradient vector as a second output.
- 'off'
- 'on'

\section*{Jacobian}

Flags whether the objective function returns a Jacobian as a second output.
- 'off'
- 'on'

\section*{MaxFunEvals}

Maximum number of objective function evaluations allowed. Positive integer.

\section*{Maxlter}

Maximum number of iterations allowed. Positive integer.

\section*{OutputFen}

The solver calls all output functions after each iteration.
- Function handle specified using @
- a cell array with function handles
- an empty array (default)

\section*{Robust}

Invoke robust fitting option.
- 'off'
- 'on'

Robust will be removed in a future software release. Use RobustWgtFun for robust fitting.

\section*{RobustWgtFun}

Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See "Robust Options" on page 20-2713.

\section*{Streams}

A single instance of the RandStream class, or a cell array of RandStream instances. The Streams option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If 'UseSubstreams' is true, the Streams value must be a scalar, or must be empty. If 'UseParallel' is true and 'UseSubstreams' is false, then the Streams argument must either be empty, or its length must match the number of processors used in the computation: equal to the matlabpool size if a matlabpool is open, a scalar otherwise.

\section*{TolBnd}

Parameter bound tolerance. Positive scalar.

\section*{Tolfun}

Termination tolerance for the objective function value. Positive scalar.

\section*{TolTypeFun}

Use TolFun for absolute or relative objective function tolerances.
- 'abs'
- 'rel'

\section*{TolTypeX}

Use TolX for absolute or relative parameter tolerances.
- 'abs'
- 'rel'

\section*{TolX}

Termination tolerance for the parameters. Positive scalar.

\section*{Tune}

Tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the
weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar. See "Robust Options" on page 20-2713.

\section*{UseParallel}

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT matlabpool is in effect. Valid values are true (the default), for serial computation, and false, for parallel computation.

\section*{UseSubstreams}

Flag indicating whether the random number generator in eligible functions should use Substream property of the RandStream class. false (default) or true. When true, high level iterations within the function will set the Substream property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

\section*{Wgrfun}

Weight function for robust fitting. Valid only when Robust is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. See "Robust Options" on page 20-2713.

WgtFun will be removed in a future software release. Use RobustWgtFun instead.

\section*{Definitions Robust Options}
\begin{tabular}{|c|c|c|}
\hline Weight Function & Equation & Default Tuning Constant \\
\hline 'andrews ' & \[
w=(\operatorname{abs}(r)<p i) . * \sin (r) . /
\]
r & 1.339 \\
\hline bisquare (default) & \[
\begin{aligned}
& w=(\operatorname{abs}(r)<1) \cdot *(1- \\
& r \cdot \wedge 2) \cdot \wedge 2
\end{aligned}
\] & 4.685 \\
\hline 'cauchy' & \(w=1 . /(1+r . \wedge 2)\) & 2.385 \\
\hline 'fair' & \(w=1 . /(1+a b s(r))\) & 1.400 \\
\hline 'huber' & \(w=1 . / \max (1, \operatorname{abs}(r))\) & 1.345 \\
\hline 'logistic' & \(w=\tanh (r) . / r\) & 1.205 \\
\hline 'talwar' & \(w=1 *(\operatorname{abs}(r)<1)\) & 2.795 \\
\hline 'welsch' & \(w=\exp (-(r . \wedge 2))\) & 2.985 \\
\hline [] & No robust fitting & - \\
\hline
\end{tabular}

\section*{Examples}

Suppose you want to change the default parameter values for the function evfit, which fits an extreme value distribution to data. The defaults parameter values are:
```

statset('evfit')
ans =
Display: 'off'
MaxFunEvals: []
MaxIter: []
TolBnd: []
TolFun: []
TolTypeFun: []
TolX: 1.0000e-06
TolTypeX: []
GradObj: []
Jacobian: []

```
DerivStep: []
    FunValCheck: []
            Robust: []
    RobustWgtFun: []
            WgtFun: []
            Tune: []
    UseParallel: []
UseSubstreams: []
            Streams: []
        OutputFen: []
The only parameters that evfit uses are Display and TolX. To create an options structure with the value of TolX set to \(1 \mathrm{e}-8\), enter:
```

options = statset('TolX',1e-8)
% Pass options to evfit:
mu = 1;
sigma = 1;
data = evrnd(mu,sigma,1,100);
paramhat = evfit(data,[],[],[],options)

```

TriangularDistribution
\(A=-3, B=1, C=3\)
Compute the standard deviation of the distribution.
\(\mathrm{s}=\mathrm{std}(\mathrm{pd})\)
s =
1.2472

See Also makedist

\section*{prob.ToolboxFittableParametricDistribution.std}

Purpose Standard deviation of probability distribution object
Syntax \(\quad s=s t d(p d)\)
Description \(\quad s=s t d(p d)\) returns the standard deviation \(s\) of the probability distribution pd.

Input
Arguments
pd - Probability distribution
probability distribution object
Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, create a probability distribution object by fitting it to data using fitdist or dfittool.

\section*{Output s-Standard deviation \\ Arguments}

\section*{Examples Standard Deviation of a Fitted Distribution}

Load the sample data. Create a vector containing the first column of students' exam grade data.
```

load examgrades;
x = grades(:,1);

```

Fit a normal distribution object to the data.
```

pd = fitdist(x,'Normal')
pd =

```

NormalDistribution

\title{
prob.ToolboxFittableParametricDistribution.std
}
```

Normal distribution
mu = 75.0083 [73.4321, 76.5846]
sigma = 8.7202 [7.7391, 9.98843]

```

Compute the standard deviation of the fitted distribution.
\(s=s t d(p d)\)

S =
8.7202

For a normal distribution, the standard deviation is equal to the parameter sigma.

\section*{Standard Deviation of a Skewed Distribution}

Create a Weibull probability distribution object
```

pd = makedist('Weibull','a',5,'b',2)
pd =

```
    WeibullDistribution
    Weibull distribution
        \(\mathrm{A}=5\)
        \(B=2\)

Compute the standard deviation of the distribution.
```

s = std(pd)
s =
2.3163

```

See Also makedist | fitdist | dfittool

\section*{GeneralizedLinearModel.step}
\begin{tabular}{|c|c|}
\hline Purpose & Improve generalized linear regression model by adding or removing terms \\
\hline Syntax & ```
mdl1 = step(mdl)
mdl1 = step(mdl,Name,Value)
``` \\
\hline Description & \begin{tabular}{l}
mdl1 = step \((\mathrm{mdl})\) returns an improved generalized linear model based on mdl , with one predictor added or removed. \\
mdl1 = step(mdl, Name, Value) improves a generalized linear model with additional options specified by one or more Name, Value pair arguments.
\end{tabular} \\
\hline Tips & - Use addTerms or removeTerms to control exactly which terms enter or leave the model. \\
\hline Input Arguments & \begin{tabular}{l}
mdl \\
Generalized linear model, as constructed by GeneralizedLinearModel.fit or GeneralizedLinearModel.stepwise.
\end{tabular} \\
\hline & Name-Value Pair Arguments \\
\hline & Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN. \\
\hline & 'Criterion' \\
\hline
\end{tabular}

Criterion that step uses in selecting terms to add or remove.
\begin{tabular}{l|l|l|l}
\hline Criterion & PEnter & PRemove & Compared Against \\
\hline 'Deviance' \(^{\text {' }}\) & 0.05 & \(<0.1\) & \(p\)-value for \(F\) or chi-square test \\
\hline 'SSE' \(^{2}\) & 0.05 & \(<0.1\) & \(p\)-value for \(F\) test \\
\hline
\end{tabular}

\section*{GeneralizedLinearModel.step}
\begin{tabular}{l|l|l|l}
\hline Criterion & PEnter & PRemove & Compared Against \\
\hline 'AIC' & 0 & \(<0.01\) & Change in AIC \\
\hline 'BIC' & 0 & \(<0.01\) & Change in BIC \\
\hline 'Rsquared' & 0.1 & \(>0.05\) & Increase in R-squared \\
\hline 'AdjRsquared' & 0 & \(>-0.05\) & Increase in adjusted R-squared \\
\hline
\end{tabular}

Default: 'deviance'

\section*{'Lower'}

Model specification that describes the terms that must exist in the fit.

Default: 'constant'

\section*{'NSteps'}

Maximum number of steps to take.
Default: 1

\section*{'Penter'}

Improvement measure for adding a term.
- If Criterion = 'sse' or 'deviance', Penter is the value of \(p\) such that, if a term has a \(p\)-value less than \(p\), then add the term to the model.
- For other values of Criterion, if the improvement in the criterion is more than Penter, then add the term to the model.

Default: 0.05 for Criterion = 'sse' or 'deviance'; 0 for other values of Criterion

\section*{'PRemove'}

\section*{GeneralizedLinearModel.step}

Improvement measure for removing a term.
- If Criterion = 'sse' or 'deviance', PRemove is the value of \(p\) such that, if a term has a \(p\)-value greater than \(p\), then remove the term from the model.
- For other values of Criterion, if the improvement in the criterion is less than Penter, then remove the term from the model.

Default: 0.1 for Criterion = 'sse' or 'deviance'; 0 for other values of Criterion

\section*{'Upper'}

Model specification describing largest set of terms in the fit.
Default: 'interactions'

\section*{'Verbose'}

Integer from 0 to 2 controlling the display of information.
- 0 suppresses all display.
- 1 displays the action taken at each step.
- 2 also displays the actions evaluated at each step.

Default: 1

\section*{Output \\ mdl1} Arguments

Linear model, the same as mdl but with additional terms given in terms. You can set mdl1 equal to mdl to overwrite mdl.

\section*{Examples \\ Add Predictors One at a Time}

Fit a Poisson regression model using random data and a single predictor, then step in other predictors.

\section*{GeneralizedLinearModel.step}

Generate artificial data with 20 predictors, using three of the predictors for the responses.
```

rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);

```

Construct a generalized linear model using \(X(:, 1)\) as the only predictor.
```

mdl = GeneralizedLinearModel.fit(X,y,...
'y ~ x1','Distribution','poisson')

```
mdl =
Generalized Linear regression model:
    \(\log (y) \sim 1+x 1\)
    Distribution = Poisson
Estimated Coefficients:

\section*{Algorithms}

Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical

\section*{GeneralizedLinearModel.step}
significance in explaining the response variable. The method begins with an initial model, specified using modelspec, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, LinearModel.stepwise and GeneralizedLinearModel.stepwise use the \(p\)-value of an F-statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':
1 Fit the initial model.
2 If any terms not in the model have \(p\)-values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest \(p\)-value and repeat this step; otherwise, go to step 3 .

3 If any terms in the model have \(p\)-values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest \(p\)-value and go to step 2 ; otherwise, end.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared, or deviance (only for GeneralizedLinearModel.stepwise) as a criterion to add or remove terms.

\section*{GeneralizedLinearModel.step}

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.Alternatives Use GeneralizedLinearModel.stepwise to select a model from astarting model, continuing until no single step is beneficial.
Use addTerms or removeTerms to add or remove particular terms.

\section*{Purpose}

Improve linear regression model by adding or removing terms

\section*{Syntax}
mdl1 = step(mdl)
mdl1 = step(mdl,Name,Value)

\section*{Input Arguments}
mdl1 \(=\) step \((\mathrm{mdl})\) returns an improved linear model based on mdl, with one predictor added or removed.

Note You can use step only if mdl. Robust = []. This holds when you create mdl with LinearModel.fit having the RobustOpts name-value pair set to the default 'off'.
mdl1 \(=\) step(mdl, Name, Value) improves a linear model with additional options specified by one or more Name, Value pair arguments.

\section*{mdl}

Linear model, as constructed by LinearModel.fit or LinearModel.stepwise.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'Criterion'}

Criterion that step uses in selecting terms to add or remove:

\section*{LinearModel.step}
\begin{tabular}{l|l|l|l}
\hline Criterion & PEnter & PRemove & Compared Against \\
\hline 'SSE' & 0.05 & \(<0.1\) & \(p\)-value for \(F\) test \\
\hline 'AIC' & 0 & \(<0.01\) & Change in AIC \\
\hline 'BIC' & 0 & \(<0.01\) & Change in BIC \\
\hline 'Rsquared' & 0.1 & \(>0.05\) & Increase in R-squared \\
\hline 'AdjRsquared' & 0 & \(>-0.05\) & Increase in adjusted R-squared \\
\hline
\end{tabular}

Default: 'sse'

\section*{'Lower'}

Model specification that describes the terms that must exist in the fit.

Default: 'constant'

\section*{'NSteps'}

Maximum number of steps to take.
Default: 1

\section*{'Penter'}

Improvement measure for adding a term.
- If Criterion = 'sse' or 'deviance', Penter is the value of \(p\) such that, if a term has a \(p\)-value less than \(p\), then add the term to the model.
- For other values of Criterion, if the improvement in the criterion is more than Penter, then add the term to the model.

Default: 0.05 for Criterion = 'sse' or 'deviance'; 0 for other values of Criterion

\section*{'PRemove'}

Improvement measure for removing a term.
- If Criterion = 'sse' or 'deviance', PRemove is the value of \(p\) such that, if a term has a \(p\)-value greater than \(p\), then remove the term from the model.
- For other values of Criterion, if the improvement in the criterion is less than Penter, then remove the term from the model.

Default: 0.1 for Criterion = 'sse' or 'deviance'; 0 for other values of Criterion

\section*{'Upper'}

Model specification describing largest set of terms in the fit.
Default: 'interactions'

\section*{'Verbose'}

Integer from 0 to 2 controlling the display of information.
- 0 suppresses all display.
- 1 displays the action taken at each step.
- 2 also displays the actions evaluated at each step.

Default: 1

Output
Arguments

\section*{Examples}
mdll
Linear model. Typically you set mdl1 equal to mdl.

\section*{Modify a Linear Model}

Fit a linear model to car data. Use step to see if a quadratic model would help the fit quality.

\section*{LinearModel.step}

Load carsmall data, and make a dataset from weight and model year predictors with MPG response.
```

load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);

```

Make a linear model of MPG as a function of Year and Weight.
```

mdl = LinearModel.fit(ds,'MPG ~ Year + Weight')
mdl =
Linear regression model:
MPG ~ 1 + Weight + Year
Estimated Coefficients:

|  | Estimate | SE | tStat | pValue |
| :--- | ---: | ---: | ---: | :--- |
| (Intercept) | 40.11 | 1.5418 | 26.016 | $1.2024 \mathrm{e}-43$ |
| Weight | -0.0066475 | 0.00042802 | -15.531 | $3.3639 \mathrm{e}-27$ |
| Year_76 | 1.9291 | 0.74761 | 2.5804 | 0.011488 |
| Year_82 | 7.9093 | 0.84975 | 9.3078 | $7.8681 \mathrm{e}-15$ |

Number of observations: 94, Error degrees of freedom: 90
Root Mean Squared Error: 2.92
R-squared: 0.873, Adjusted R-Squared 0.868
F-statistic vs. constant model: 206, p-value = 3.83e-40

```

Use step to adjust the model to potentially include full quadratic terms.
mdl1 = step(mdl,'upper','quadratic')
1. Adding Weight^2, FStat \(=9.9164\), pValue \(=0.0022303\)
mdl1 \(=\)
Linear regression model:
    MPG ~ 1 + Weight + Year + Weight^2

\section*{LinearModel.step}
\begin{tabular}{|c|c|c|c|c|}
\hline & Estimate & SE & tStat & pValue \\
\hline (Intercept) & 54.206 & 4.7117 & 11.505 & 2.6648e-19 \\
\hline Weight & -0.016404 & 0.0031249 & -5.2493 & 1.0283e-06 \\
\hline Year_76 & 2.0887 & 0.71491 & 2.9215 & 0.0044137 \\
\hline Year_82 & 8.1864 & 0.81531 & 10.041 & 2.6364e-16 \\
\hline Weight^2 & 1.5573e-06 & 4.9454e-07 & 3.149 & 0.0022303 \\
\hline
\end{tabular}
```

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885, Adjusted R-Squared 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41

```

\section*{Algorithms}

Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using modelspec, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, LinearModel.stepwise and GeneralizedLinearModel.stepwise use the \(p\)-value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':
1 Fit the initial model.

\section*{LinearModel.step}

2 If any terms not in the model have \(p\)-values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest \(p\)-value and repeat this step; otherwise, go to step 3.

3 If any terms in the model have \(p\)-values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest \(p\)-value and go to step 2 ; otherwise, end.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared, or deviance (only for GeneralizedLinearModel.stepwise) as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

\section*{Purpose Interactive stepwise regression}
```

Syntax stepwise
stepwise(X,y)
stepwise(X,y,inmodel,penter,premove)

```

\section*{Description}
stepwise uses the sample data in hald.mat to display a graphical user interface for performing stepwise regression of the response values in heat on the predictive terms in ingredients.

\section*{stepwise}

The upper left of the interface displays estimates of the coefficients for all potential terms, with horizontal bars indicating \(90 \%\) (colored) and \(95 \%\) (grey) confidence intervals. The red color indicates that, initially, the terms are not in the model. Values displayed in the table are those that would result if the terms were added to the model.

The middle portion of the interface displays summary statistics for the entire model. These statistics are updated with each step.

The lower portion of the interface, Model History, displays the RMSE for the model. The plot tracks the RMSE from step to step, so you can compare the optimality of different models. Hover over the blue dots in the history to see which terms were in the model at a particular step. Click on a blue dot in the history to open a copy of the interface initialized with the terms in the model at that step.

Initial models, as well as entrance/exit tolerances for the \(p\)-values of \(F\)-statistics, are specified using additional input arguments to stepwise. Defaults are an initial model with no terms, an entrance tolerance of 0.05 , and an exit tolerance of 0.10 .

To center and scale the input data (compute \(z\)-scores) to improve conditioning of the underlying least-squares problem, select Scale Inputs from the Stepwise menu.

You proceed through a stepwise regression in one of two ways:
1 Click Next Step to select the recommended next step. The recommended next step either adds the most significant term or removes the least significant term. When the regression reaches a local minimum of RMSE, the recommended next step is "Move no terms." You can perform all of the recommended steps at once by clicking All Steps.

2 Click a line in the plot or in the table to toggle the state of the corresponding term. Clicking a red line, corresponding to a term not currently in the model, adds the term to the model and changes the line to blue. Clicking a blue line, corresponding to a term currently in the model, removes the term from the model and changes the line to red.

To call addedvarplot and produce an added variable plot from the stepwise interface, select Added Variable Plot from the Stepwise menu. A list of terms is displayed. Select the term you want to add, and then click OK.

Click Export to display a dialog box that allows you to select information from the interface to save to the MATLAB workspace.

Check the information you want to export and, optionally, change the names of the workspace variables to be created. Click OK to export the information.
stepwise ( \(\mathrm{X}, \mathrm{y}\) ) displays the interface using the \(p\) predictive terms in the \(n\)-by- \(p\) matrix X and the response values in the \(n\)-by- 1 vector y . Distinct predictive terms should appear in different columns of \(X\).

Note stepwise automatically includes a constant term in all models. Do not enter a column of 1 s directly into X .
stepwise treats NaN values in either X or y as missing values, and ignores them.
stepwise( \(\mathrm{X}, \mathrm{y}\), inmodel, penter, premove) additionally specifies the initial model (inmodel) and the entrance (penter) and exit (premove) tolerances for the \(p\)-values of \(F\)-statistics. inmodel is either a logical vector with length equal to the number of columns of \(X\), or a vector of indices, with values ranging from 1 to the number of columns in \(X\). The value of penter must be less than or equal to the value of premove.

\section*{Algorithms}

Stepwise regression is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the \(p\) value of an \(F\)-statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

1 Fit the initial model.

2 If any terms not in the model have \(p\)-values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest \(p\) value and repeat this step; otherwise, go to step 3.

3 If any terms in the model have \(p\)-values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest \(p\) value and go to step 2 ; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

\section*{GeneralizedLinearModel.stepwise}
Purpose \(\quad\)\begin{tabular}{rl} 
Create generalized linear regression model by stepwise regression \\
Syntax & \(\quad\)\begin{tabular}{rl}
mdl & \(=\) GeneralizedLinearModel.stepwise \((\mathrm{ds}\), modelspec \()\) \\
mdl & \(=\) GeneralizedLinearModel.stepwise \((\mathrm{X}, \mathrm{y}\), modelspec \()\) \\
mdl & \(=\) GeneralizedLinearModel.stepwise \((\ldots\), modelspec, Name, \\
& Value \()\)
\end{tabular}
\end{tabular}

Description

Tips

Input
Arguments
mdl = GeneralizedLinearModel.stepwise(ds,modelspec) creates a generalized linear model of a dataset array ds, using stepwise regression to add or remove predictors. modelspec is the starting model for the stepwise procedure.
mdl = GeneralizedLinearModel.stepwise(X,y,modelspec) creates a generalized linear model of the responses \(y\) to a data matrix \(X\), using stepwise regression to add or remove predictors.
mdl =
GeneralizedLinearModel.stepwise(..., modelspec, Name, Value) creates a generalized linear model with additional options specified by one or more Name, Value pair arguments.
- The generalized linear model mdl is a standard linear model unless you specify otherwise with the Distribution name-value pair.
- For other methods such as fit or devianceTest, or properties of the GeneralizedLinearModel object, see GeneralizedLinearModel.

\section*{ds}

Dataset array, where by default the last column is the response variable, and all other columns are the predictors. Predictors can be numeric, or can be any grouping variable type, such as logical or categorical (see "Grouping Variables" on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the ResponseVar name-value pair. To use a subset of the columns as predictors, use the PredictorVars name-value pair.

\section*{GeneralizedLinearModel.stepwise}

\section*{X}

Matrix of predictor values. Each column of \(X\) represents one variable, and each row represents one observation.

\section*{\(y\)}

Vector of response values with the same number of rows as X . Each entry in \(y\) is the response to the data in the corresponding row of \(X\).

\section*{modelspec}

Model specification. This is the starting model for the stepwise method. Possibilities:
- String specifying the type of model.
\begin{tabular}{l|l}
\hline String & Model Type \\
\hline 'constant' & \begin{tabular}{l} 
Model contains only a constant \\
(intercept) term.
\end{tabular} \\
\hline 'linear' & \begin{tabular}{l} 
Model contains an intercept and linear \\
terms for each predictor.
\end{tabular} \\
\hline 'interactions' & \begin{tabular}{l} 
Model contains an intercept, linear \\
terms, and all products of pairs of \\
distinct predictors (no squared terms).
\end{tabular} \\
\hline 'purequadratic' & \begin{tabular}{l} 
Model contains an intercept, linear \\
terms, and squared terms.
\end{tabular} \\
\hline
\end{tabular}

\section*{GeneralizedLinearModel.stepwise}
\begin{tabular}{l|l}
\hline String & Model Type \\
\hline 'quadratic' & \begin{tabular}{l} 
Model contains an intercept, linear \\
terms, interactions, and squared terms.
\end{tabular} \\
\hline 'polyijk' & \begin{tabular}{l} 
Model is a polynomial with all terms \\
up to degree \(i\) in the first predictor, \\
degree \(j\) in the second predictor, \\
etc. Use numerals 0 through 9. For \\
example, 'poly2111' has a constant \\
plus all linear and product terms, and \\
also contains terms with predictor 1 \\
squared.
\end{tabular} \\
\hline
\end{tabular}
- T-by-P+1 matrix, namely "Terms Matrix" on page 20-2749, specifying terms to include in model, where \(T\) is the number of terms and \(P\) is the number of predictor variables, and plus one is for the response variable.
- String representing a "Formula" on page 20-2753 in the form
'Y ~ terms ',
where the terms are in "Wilkinson Notation" on page 20-2754.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'BinomialSize'}

Vector or name of a variable of the same length as the response, specifying the size of the sample (number of trials) used in fitting the binomial distribution. This is the n parameter for the fitted binomial distribution. BinomialSize applies only when the Distribution parameter is 'binomial'.

\section*{GeneralizedLinearModel.stepwise}

BinomialSize can be a scalar, meaning all observations have the same number of trials.

As an alternative to BinomialSize, you can specify the response as a two-column vector with counts in column 1 and BinomialSize in column 2.

Default: 1

\section*{'CategoricalVars'}

Identify the categorical variables. Choices:
- Cell array of strings of the variable names in the ds dataset array.
- Logical or numerical index vector indicating which data columns are categorical. For example, if predictors 2 and 3 out of 6 are categorical, pass either
\([2,3]\)
or
logical([0 \(\left.1 \begin{array}{lllll}0 & 1 & 0 & 0 & 0\end{array}\right]\)
Default: For data matrix X, default is [ ] (none). For dataset array ds, default is to treat ds variables as categorical if they are categorical, logical, character arrays, or cell arrays of strings.

\section*{'Criterion'}

Criterion that stepwise uses in selecting terms to add or remove:
- 'sse' - \(p\)-value for an \(F\) test of the change in sse by adding or removing the term.
- 'deviance' - p-value for a chi-square test of the change in deviance.
- 'aic' - Change in the value of AIC.

\section*{GeneralizedLinearModel.stepwise}
- 'bic' - Change in the value of BIC.
- 'rsquared' - Change in the value of \(R^{2}\).
- 'adjrsquared ' - Change in the value of adjusted \(R^{2}\).

Default: 'sse'

\section*{'DispersionFlag'}

Logical value that applies only to 'binomial' and 'poisson' distributions. true causes the fitting function to estimate a dispersion parameter when computing standard errors. false causes the fitting function to use the theoretical value. The fitting function always estimates the dispersion for other distributions.

Default: false for 'binomial' and 'poisson' distributions

\section*{'Distribution'}

Name of the distribution of the response, one of:
'normal' Normal distribution
'binomial' Binomial distribution
'poisson' Poisson distribution
'gamma ' Gamma distribution
'inverse Inverse Gaussian distribution
gaussian'

Default: 'normal'

\section*{'Exclude'}

Logical or numerical index vector indicating which observations to exclude from the fit. For example, to exclude observations 2 and 3 out of 6 , pass either

\section*{GeneralizedLinearModel.stepwise}
\([2,3]\)
or
logical([0 \(\left.\left.1 \begin{array}{lllll}1 & 1 & 0 & 0 & 0\end{array}\right]\right)\)
Default: []

\section*{'Intercept'}

Logical value indicating whether to include a constant term (intercept) in the model. Use Intercept only when you specify the model by a string, not a formula or matrix.

Default: true

\section*{'Link'}

The link function to use in place of the canonical link. The link function defines the relationship \(f(\mu)=X^{*} b\) between the mean response \(\mu\) and the linear combination of predictors \(X^{*} b\). Specify the link as follows.
\begin{tabular}{l|l|l}
\hline Link Function Name & Link Function & Mean (Inverse) Function \\
\hline 'identity' & \(f(\mu)=\mu\) & \(\mu=X b\) \\
\hline 'log' & \(f(\mu)=\log (\mu)\) & \(\mu=\exp (X b)\) \\
\hline 'logit' & \(f(\mu)=\log (\mu /(1-\mu))\) & \(\mu=\exp (X b) /(1+\exp (X b))\) \\
\hline 'probit' & \(f(\mu)=\Phi^{-1}(\mu)\) & \(\mu=\Phi(X b)\) \\
\hline 'comploglog' & \(f(\mu)=\log (-\log (1-\mu))\) & \(\mu=1-\exp (-\exp (X b))\) \\
\hline 'reciprocal' & \(f(\mu)=\log (-\log (\mu))\) & \(\mu=\exp (-\exp (X b))\) \\
\hline
\end{tabular}

\section*{GeneralizedLinearModel.stepwise}
\begin{tabular}{l|l|l}
\hline Link Function Name & Link Function & Mean (Inverse) Function \\
\hline p (a number) & \(f(\mu)=\mu^{p}\) & \(\mu=X b^{1 / p}\) \\
\hline \begin{tabular}{l} 
S (a structure) \\
S has three fields, each \\
a function handle that \\
accepts a vector of inputs \\
and returns a vector the \\
same size:
\end{tabular} & \(f(\mu)=\mathrm{S}\). Link \((\mu)\) & \(\mu=\mathrm{S}\). Inverse \((X b)\) \\
- S.Link - The link \\
function & & \\
- S.Inverse - The \\
inverse link function \\
- S.Derivative-The \\
derivative of the link \\
function
\end{tabular}

Default: The canonical link function (see "Definitions" on page 20-784)

\section*{'Lower'}

Model specification that describes the terms that must exist in the fit.

Default: 'constant'

\section*{'Offset'}

Vector or name of a variable with the same length as the response. GeneralizedLinearModel.fit and GeneralizedLinearModel.stepwise use Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

\section*{GeneralizedLinearModel.stepwise}
```

\mu ~ Offset + (terms involving real predictors)

```
with the Offset predictor having coefficient 1.
For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying \(\log (A)\) as an offset, you can force the model to satisfy this theoretical constraint.

Default: []

\section*{'Penter'}

Improvement measure for adding a term.
- If Criterion = 'sse' or 'deviance', Penter is the value of \(p\) such that, if a term has a \(p\)-value less than \(p\), then add the term to the model.
- For other values of Criterion, if the improvement in the criterion is more than Penter, then add the term to the model.

Default: 0.05 for Criterion = 'sse' or 'deviance'; 0 for other values of Criterion

\section*{'PredictorVars'}

Identify the predictors to use for fitting. Choices:
- Cell array of strings of the variable names. The strings should be names in the ds dataset array, or the VarNames name-value pair.
- Logical or numerical index vector indicating which predictors to use. For example, to use predictors 2 and 3 out of 6 , pass either
[2,3]
or

\section*{GeneralizedLinearModel.stepwise}
```

logical([00 1 1 1 0 0 0}]

```

Default: All variables in \(X\), or all variables in ds except for ResponseVar

\section*{'PRemove'}

Improvement measure for removing a term.
- If Criterion = 'sse' or 'deviance', PRemove is the value of \(p\) such that, if a term has a \(p\)-value greater than \(p\), then remove the term from the model.
- For other values of Criterion, if the improvement in the criterion is less than Penter, then remove the term from the model.

Default: 0.1 for Criterion = 'sse' or 'deviance'; 0 for other values of Criterion

\section*{'ResponseVar'}

Variable that the fitting function uses for response data. Give either the variable name or its column number. Typically, you use ResponseVar when fitting a dataset array ds. Choices are:
- String of the variable name.
- Logical or numerical index vector indicating which predictors to use. For example, to use the fourth variable as the response out of six variables, pass either
'ResponseVar',[4]
or
'ResponseVar',logical([0 0 0 1 0 0])
Default: Last column of ds

\section*{GeneralizedLinearModel.stepwise}

\section*{'Upper'}

Model specification describing largest set of terms in the fit.
Default: 'interactions'

\section*{'VarNames'}

Cell array of strings, first naming the columns of \(X\), and with the response variable y last. Not applicable to variables in a dataset array, because those variables already have names.

Default: \{'x1','x2',...,'xn','y'\}, where \(n\) is the number of columns of \(X\)

\section*{'Weights'}

Vector of nonnegative observation weights.
Default: ones(size(y))

\section*{Output mdl}

Arguments
Generalized linear model representing a least-squares fit of the link of the response to the data.

\section*{Definitions Terms Matrix}

A terms matrix is a T-by- \(\mathrm{P}+1\) matrix specifying terms in a model, where T is the number of terms, P is the number of predictor variables, and plus one is for the response variable. The value of \(T(i, j)\) is the exponent of variable \(j\) in term \(i\). For example, if there are three predictor variables A, B, and C:
```

[0 0 0 0] % constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)

```

\section*{GeneralizedLinearModel.stepwise}

The 0 at the end of each term represents the response variable. In general,
- If you have the variables in a dataset array, then a 0 must represent the response variable depending on the position of the response variable in the dataset array. For example:

Load sample data and define the dataset array.
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1), hospital.Age,... hospital.Smoker,'VarNames',\{'Sex','BloodPressure','Age','Smoker'\});

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the data set array, so there must be a column of zeros for the response variable in the second column of the term matrix.
```

T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
T =

| 0 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- |
| 1 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 |
| 0 | 0 | 0 | 1 |

```

Redefine the dataset array.
```

ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});

```

Now, the response variable is the first term in the data set array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a term matrix.
```

T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
T =

```

\section*{GeneralizedLinearModel.stepwise}
\begin{tabular}{llll}
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{tabular}
- If you have the predictor and response variables in a matrix and column vector, then you must include a 0 for the response variable at the end of each term. For example:
Load sample data and define the matrix of predictors.
load carsmall
X = [Acceleration, Weight];
Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to data. This model includes the main effect and two way interaction terms for the variables, Acceleration and Weight, and a second order term for the variable, Weight.
```

T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]

```
\(T=\)
\begin{tabular}{lll}
0 & 0 & 0 \\
1 & 0 & 0 \\
0 & 1 & 0 \\
1 & 1 & 0 \\
0 & 2 & 0
\end{tabular}

Fit a linear model.
mdl = LinearModel.fit(X,MPG,T)
mdl =

Linear regression model:

\section*{GeneralizedLinearModel.stepwise}
\begin{tabular}{|c|c|c|c|c|}
\hline \multicolumn{5}{|l|}{Estimated Coefficients:} \\
\hline & Estimate & SE & tStat & pValue \\
\hline (Intercept) & 48.906 & 12.589 & 3.8847 & 0.00019665 \\
\hline x 1 & 0.54418 & 0.57125 & 0.95261 & 0.34337 \\
\hline x2 & -0.012781 & 0.0060312 & -2.1192 & 0.036857 \\
\hline x1: x 2 & -0.00010892 & 0.00017925 & -0.6076 & 0.545 \\
\hline x2^2 & 9.7518e-07 & 7.5389e-07 & 1.2935 & 0.19917 \\
\hline \multicolumn{5}{|l|}{Number of observations: 94, Error degrees of freedom: 89} \\
\hline \multicolumn{5}{|l|}{Root Mean Squared Error: 4.1} \\
\hline \multicolumn{5}{|l|}{R-squared: 0.751, Adjusted R-Squared 0.739} \\
\hline \multicolumn{5}{|l|}{F-statistic vs. constant model: 67, p -value \(=4.99 \mathrm{e}-26\)} \\
\hline
\end{tabular}

Only the intercept and x2 term, which corresponds to the Weight variable, are significant at the \(5 \%\) significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.
```

T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = LinearModel.stepwise(X,MPG,[0 O O],'upper',T)

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
mdl =
Linear regression model:
y ~ 1 + x2
Estimated Coefficients:

|  | Estimate | SE | tStat | pValue |
| :--- | ---: | ---: | ---: | :--- |
| (Intercept) | 49.238 | 1.6411 | 30.002 | $2.7015 \mathrm{e}-49$ |
| x2 | -0.0086119 | 0.0005348 | -16.103 | $1.6434 e-28$ |

```

Number of observations: 94, Error degrees of freedom: 92

\section*{GeneralizedLinearModel.stepwise}
```

Root Mean Squared Error: 4.13
R-squared: 0.738, Adjusted R-Squared 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28

```

The results of the stepwise regression are consistent with the results of LinearModel.fit in the previous step.

\section*{Formula}

A formula for model specification is a string of the form
'Y ~ terms',
where
- \(Y\) is the response name.
- terms contains
- Variable names
- + means include the next variable
- - means do not include the next variable
- : defines an interaction, a product of terms
- * defines an interaction and all lower-order terms
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
- () groups terms

Note Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

\section*{GeneralizedLinearModel.stepwise}
'Y ~ A + B + C' means a three-variable linear model with intercept.
' \(Y \sim A+B+C-1\) ' is a three-variable linear model without intercept.
' \(Y\) ~ A + B + C + B^2' is a three-variable model with intercept and a \(B^{\wedge} 2\) term.
\(' Y \sim A+B^{\wedge} 2+C\) ' is the same as the previous example because \(B^{\wedge} 2\) includes a \(B\) term.
\(' Y \sim A+B+C+A: B '\) includes an \(A * B\) term.
\(' Y \sim A * B+C '\) is the same as the previous example because \(A * B=\) \(A+B+A: B\).
\(' Y \sim A * B * C-A: B: C '\) has all interactions among \(A, B\), and \(C\), except the three-way interaction.
' \(Y \sim A^{*}(B+C+D)^{\prime}\) has all linear terms, plus products of \(A\) with each of the other variables.

\section*{Wilkinson Notation}

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.
\begin{tabular}{l|l}
\hline Wilkinson Notation & Factors in Standard Notation \\
\hline 1 & Constant (intercept) term \\
\hline\(A^{\wedge} k\), where \(k\) is a positive integer & \(A, A^{2}, \ldots, A^{k}\) \\
\hline\(A+B\) & \(A, B\) \\
\hline\(A * B\) & \(A, B, A * B\) \\
\hline\(A: B\) & \(A * B\) only \\
\hline\(-B\) & Do not include \(B\) \\
\hline\(A * B+C\) & \(A, B, C, A * B\) \\
\hline\(A+B+C+A: B\) & \(A, B, C, A * B\) \\
\hline\(A * B * C-A: B: C\) & \(A, B, C, A * B, A * C, B * C\) \\
\hline\(A *(B+C)\) & \(A, B, C, A * B, A * C\) \\
\hline
\end{tabular}

\section*{GeneralizedLinearModel.stepwise}

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using - 1 .

\section*{Canonical Link Function}

The default link function for a generalized linear model is the canonical link function.

Canonical Link Functions for Generalized Linear Models
\begin{tabular}{l|l|l|l}
\hline Distribution & \begin{tabular}{l} 
Link Function \\
Name
\end{tabular} & Link Function & \begin{tabular}{l} 
Mean (Inverse) \\
Function
\end{tabular} \\
\hline 'normal' & 'identity' & \(f(\mu)=\mu\) & \(\mu=X b\) \\
\hline 'binomial' & 'logit' & \(f(\mu)=\log (\mu /(1-\mu))\) & \(\mu=\exp (X b) /(1+\exp (X b))\) \\
\hline 'poisson' & 'log' & \(f(\mu)=\log (\mu)\) & \(\mu=\exp (X b)\) \\
\hline 'gamma' & -1 & \(f(\mu)=1 / \mu\) & \(\mu=1 /(X b)\) \\
\hline \begin{tabular}{l} 
'inverse \\
gaussian'
\end{tabular} & -2 & \(f(\mu)=1 / \mu^{2}\) & \(\mu=(X b)^{-1 / 2}\) \\
\hline
\end{tabular}

\section*{Examples Create a Generalized Linear Model Stepwise}

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.
```

rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);

```

Fit a generalized linear model using the Poisson distribution.
mdl \(=\) GeneralizedLinearModel.stepwise(X,y,...

\section*{GeneralizedLinearModel.stepwise}
```

    'constant','upper','linear','Distribution','poisson')
    1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094
mdl =
```
Generalized Linear regression model:
    \(\log (y) \sim 1+x 5+x 10+x 15\)
    Distribution \(=\) Poisson

Estimated Coefficients:
\begin{tabular}{lcrll} 
& Estimate & \multicolumn{1}{l}{ SE } & tStat & \multicolumn{1}{l}{ pValue } \\
(Intercept) & 1.0115 & 0.064275 & 15.737 & \(8.4217 \mathrm{e}-56\) \\
x5 & 0.39508 & 0.066665 & 5.9263 & \(3.0977 \mathrm{e}-09\) \\
x10 & 0.18863 & 0.05534 & 3.4085 & 0.0006532 \\
x15 & 0.29295 & 0.053269 & 5.4995 & \(3.8089 \mathrm{e}-08\)
\end{tabular}

100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20

\section*{Algorithms}

Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using modelspec, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, LinearModel.stepwise and GeneralizedLinearModel.stepwise use the \(p\)-value of an F-statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null

\section*{GeneralizedLinearModel.stepwise}
hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':
1 Fit the initial model.
2 If any terms not in the model have \(p\)-values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest \(p\)-value and repeat this step; otherwise, go to step 3.

3 If any terms in the model have \(p\)-values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest \(p\)-value and go to step 2 ; otherwise, end.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared, or deviance (only for GeneralizedLinearModel.stepwise) as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

\section*{GeneralizedLinearModel.stepwise}
Alternatives Use GeneralizedLinearModel.fit to create a model with a fixedspecification. Use step, addTerms, or removeTerms to adjust a fittedmodel.

\section*{LinearModel.stepwise}

\section*{Purpose}

Create linear regression model by stepwise regression
Syntax

\section*{Description}

Tips

\section*{Input Arguments}
```

mdl = LinearModel.stepwise(ds,modelspec)
mdl = LinearModel.stepwise(X,y,modelspec)
mdl = LinearModel.stepwise(___,modelspec,Name,Value)

```
mdl = LinearModel.stepwise(ds,modelspec) returns a linear model of a dataset array ds, using stepwise regression to add or remove predictors. modelspec is the starting model for the stepwise procedure.
mdl = LinearModel.stepwise(X,y,modelspec) creates a linear model of the responses \(y\) to a data matrix \(X\), using stepwise regression to add or remove predictors. modelspec is the starting model for the stepwise procedure.
mdl = LinearModel.stepwise(__, modelspec, Name, Value) creates a linear model for any of the inputs in the previous syntaxes, with additional options specified by one or more Name, Value pair arguments. modelspec is the starting model for the stepwise procedure.
- You cannot use robust regression with stepwise regression. Check your data for outliers before using LinearModel.stepwise.
- For other methods such as fit or anova, or properties of the LinearModel object, see LinearModel.

\section*{ds}

Dataset array, where by default the last column is the response variable, and all other columns are the predictors. Predictors can be numeric, or can be any grouping variable type, such as logical or categorical (see "Grouping Variables" on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the ResponseVar name-value pair. To use a subset of the columns as predictors, use the PredictorVars name-value pair.

\section*{X}

\section*{LinearModel.stepwise}

Matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

\section*{\(y\)}

Vector of response values with the same number of rows as \(X\). Each entry in \(y\) is the response to the data in the corresponding row of \(X\).

\section*{modelspec}

Model specification. This is the starting model for the stepwise method. Possibilities:
- String specifying the type of model.
\begin{tabular}{l|l}
\hline String & Model Type \\
\hline 'constant' & \begin{tabular}{l} 
Model contains only a constant \\
(intercept) term.
\end{tabular} \\
\hline 'linear' & \begin{tabular}{l} 
Model contains an intercept and linear \\
terms for each predictor.
\end{tabular} \\
\hline 'interactions' & \begin{tabular}{l} 
Model contains an intercept, linear \\
terms, and all products of pairs of \\
distinct predictors (no squared terms).
\end{tabular} \\
\hline 'purequadratic' & \begin{tabular}{l} 
Model contains an intercept, linear \\
terms, and squared terms.
\end{tabular} \\
\hline 'quadratic' & \begin{tabular}{l} 
Model contains an intercept, linear \\
terms, interactions, and squared terms.
\end{tabular} \\
\hline 'polyijk' & \begin{tabular}{l} 
Model is a polynomial with all terms \\
up to degree i in the first predictor, \\
degree j in the second predictor, \\
etc. Use numerals 0 through 9. For \\
example, 'poly2111' has a constant \\
plus all linear and product terms, and \\
also contains terms with predictor 1 \\
squared.
\end{tabular} \\
\hline
\end{tabular}

\section*{LinearModel.stepwise}
- T-by-P+1 matrix, namely "Terms Matrix" on page 20-2765, specifying terms to include in model, where \(T\) is the number of terms and \(P\) is the number of predictor variables, and plus one is for the response variable.
- String representing a "Formula" on page 20-2769 in the form
\[
\text { ' } Y \sim \text { terms ', }
\]
where the terms are in "Wilkinson Notation" on page 20-2770.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

\section*{'CategoricalVars'}

Identify the categorical variables. Choices:
- Cell array of strings of the variable names in the ds dataset array.
- Logical or numerical index vector indicating which data columns are categorical. For example, if predictors 2 and 3 out of 6 are categorical, pass either
\([2,3]\)
or
logical([0 \(1 \times 1000])\)
Default: For data matrix X, default is [ ] (none). For dataset array ds, default is to treat ds variables as categorical if they are categorical, logical, character arrays, or cell arrays of strings.

\section*{LinearModel.stepwise}

\section*{'Criterion'}

Criterion that stepwise uses in selecting terms to add or remove:
- 'sse' - \(p\)-value for an \(F\) test of the change in sse by adding or removing the term.
- 'aic' - Change in the value of AIC.
- 'bic' - Change in the value of BIC.
- 'rsquared' - Change in the value of \(R^{2}\).
- 'adjrsquared' - Change in the value of adjusted \(R^{2}\).

Default: 'sse'

\section*{'Exclude'}

Logical or numerical index vector indicating which observations to exclude from the fit. For example, to exclude observations 2 and 3 out of 6 , pass either
[2,3]
or
logical([0 \(\left.1 \begin{array}{lllll}1 & 0 & 0 & 0\end{array}\right]\)

Default: []

\section*{'Intercept'}

Logical value indicating whether to include a constant term (intercept) in the model. Use Intercept only when you specify the model by a string, not a formula or matrix.

Default: true

\section*{'Lower'}

\section*{LinearModel.stepwise}

Model specification that describes the terms that must exist in the fit.

Default: 'constant'

\section*{'NSteps'}

Maximum number of steps to take.
Default: 1

\section*{'Penter'}

Improvement measure for adding a term.
- If Criterion = 'sse', Penter is the value of \(p\) such that, if a term has a \(p\)-value less than \(p\), then add the term to the model.
- For other values of Criterion, if the improvement in the criterion is more than Penter, then add the term to the model.

Default: 0.05 for Criterion = 'sse'; 0 for other values of Criterion

\section*{'PredictorVars'}

Identify the predictors to use for fitting. Choices:
- Cell array of strings of the variable names. The strings should be names in the ds dataset array, or the VarNames name-value pair.
- Logical or numerical index vector indicating which predictors to use. For example, to use predictors 2 and 3 out of 6 , pass either
[2,3]
or
logical([0 \(\left.1 \times 1 \begin{array}{lll} & 0 & 0\end{array}\right)\)

\section*{LinearModel.stepwise}

Default: All variables in X, or all variables in ds except for ResponseVar

\section*{'PRemove'}

Improvement measure for removing a term.
- If Criterion = 'sse', PRemove is the value of \(p\) such that, if a term has a \(p\)-value greater than \(p\), then remove the term from the model.
- For other values of Criterion, if the improvement in the criterion is less than Penter, then remove the term from the model.

Default: 0.1 for Criterion = 'sse'; 0 for other values of Criterion

\section*{'ResponseVar'}

Variable that the fitting function uses for response data. Give either the variable name or its column number. Typically, you use ResponseVar when fitting a dataset array ds. Choices are:
- String of the variable name.
- Logical or numerical index vector indicating which predictors to use. For example, to use the fourth variable as the response out of six variables, pass either
'ResponseVar',[4]
or
'ResponseVar',logical([0 001000\(])\)

Default: Last column of ds

\section*{'Upper'}

\section*{LinearModel.stepwise}

Model specification describing largest set of terms in the fit.
Default: 'interactions'

\section*{'VarNames'}

Cell array of strings, first naming the columns of \(X\), and with the response variable y last. Not applicable to variables in a dataset array, because those variables already have names.

Default: \{'x1','x2',...,'xn', 'y'\}, where \(n\) is the number of columns of \(X\)

\section*{'Verbose'}

Integer from 0 to 2 controlling the display of information.
- O suppresses all display.
- 1 displays the action taken at each step.
- 2 also displays the actions evaluated at each step.

Default: 1

\section*{'Weights'}

Vector of nonnegative observation weights.
Default: ones(size(y))

\section*{Output mdl}

Arguments

\section*{Definitions}

Linear model representing a least-squares fit of the response to the data.

\section*{Terms Matrix}

A terms matrix is a T-by- \(\mathrm{P}+1\) matrix specifying terms in a model, where T is the number of terms, P is the number of predictor variables,

\section*{LinearModel.stepwise}
and plus one is for the response variable. The value of \(T(i, j)\) is the exponent of variable \(j\) in term i. For example, if there are three predictor variables \(\mathrm{A}, \mathrm{B}\), and C :
[0 0 0 0 0 \% \% constant term or intercept
[0 10000 \% B; equivalently, \(\mathrm{A}^{\wedge} 0\) * \(\mathrm{B}^{\wedge} 1\) * \(\mathrm{C}^{\wedge} 0\)
\(\left[\begin{array}{llll}1 & 0 & 1 & 0\end{array}\right] \% A^{*} C\)
[2 0 0 0] \% A^2
[0 1200 \% \(\mathrm{B}^{*}\left(\mathrm{C}^{\wedge} 2\right)\)
The 0 at the end of each term represents the response variable. In general,
- If you have the variables in a dataset array, then a 0 must represent the response variable depending on the position of the response variable in the dataset array. For example:

Load sample data and define the dataset array.
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,... hospital.Smoker,'VarNames',\{'Sex','BloodPressure', 'Age', 'Smoker'\});

Represent the linear model 'BloodPressure ~ \(1+\) Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the data set array, so there must be a column of zeros for the response variable in the second column of the term matrix.
\(\mathrm{T}=[0000 ; 1000 ; 0010 ; 0001]\)
T =
\begin{tabular}{llll}
0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{tabular}

Redefine the dataset array.

\section*{LinearModel.stepwise}
ds = dataset(hospital.BloodPressure(:,1), hospital.Sex, hospital.Age, hospital. Smoker, 'VarNames', \{'BloodPressure', 'Sex', 'Age', 'Smoker'\});

Now, the response variable is the first term in the data set array. Specify the same linear model, 'BloodPressure \(\sim 1+\) Sex + Age + Smoker ', using a term matrix.
```

T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]

```
\(\mathrm{T}=\)
\begin{tabular}{llll}
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{tabular}
- If you have the predictor and response variables in a matrix and column vector, then you must include a 0 for the response variable at the end of each term. For example:

Load sample data and define the matrix of predictors.
```

load carsmall
X = [Acceleration,Weight];

```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to data. This model includes the main effect and two way interaction terms for the variables, Acceleration and Weight, and a second order term for the variable, Weight.
```

T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
T =

```
\begin{tabular}{lll}
0 & 0 & 0 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{tabular}

\section*{LinearModel.stepwise}
\begin{tabular}{lll}
1 & 1 & 0 \\
0 & 2 & 0
\end{tabular}

Fit a linear model.
```

mdl = LinearModel.fit(X,MPG,T)
mdl =
Linear regression model:
y ~ 1 + x1*x2 + x2^2
Estimated Coefficients:

|  | Estimate | SE | tStat | pValue |
| :--- | ---: | ---: | ---: | ---: |
| (Intercept) | 48.906 | 12.589 | 3.8847 | 0.00019665 |
| x1 | 0.54418 | 0.57125 | 0.95261 | 0.34337 |
| x2 | -0.012781 | 0.0060312 | -2.1192 | 0.036857 |
| x1: x2 | -0.00010892 | 0.00017925 | -0.6076 | 0.545 |
| x2^2 | $9.7518 e-07$ | $7.5389 e-07$ | 1.2935 | 0.19917 |

```

Number of observations: 94, Error degrees of freedom: 89 Root Mean Squared Error: 4.1
R-squared: 0.751, Adjusted R-Squared 0.739
F-statistic vs. constant model: 67, \(p\)-value \(=4.99 \mathrm{e}-26\)
Only the intercept and x2 term, which corresponds to the Weight variable, are significant at the \(5 \%\) significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.
```

T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = LinearModel.stepwise(X,MPG,[0 O 0],'upper',T)

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
mdl =
```

\section*{LinearModel.stepwise}
```

Linear regression model:
y ~ 1 + x2
Estimated Coefficients:

|  | Estimate | SE | tStat | pValue |
| :--- | ---: | ---: | ---: | :--- |
| (Intercept) | 49.238 | 1.6411 | 30.002 | $2.7015 \mathrm{e}-49$ |
| x2 | -0.0086119 | 0.0005348 | -16.103 | $1.6434 \mathrm{e}-28$ |

Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
R-squared: 0.738, Adjusted R-Squared 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28

```

The results of the stepwise regression are consistent with the results of LinearModel.fit in the previous step.

\section*{Formula}

A formula for model specification is a string of the form
' \(Y\) ~ terms ',
where
- \(Y\) is the response name.
- terms contains
- Variable names
- + means include the next variable
- - means do not include the next variable
- : defines an interaction, a product of terms
- * defines an interaction and all lower-order terms
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well

\section*{LinearModel.stepwise}
- () groups terms

Note Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include - 1 in the formula.

For example,
'Y ~ A + B + C' means a three-variable linear model with intercept.
' \(Y \sim A+B+C-1 '\) is a three-variable linear model without intercept.
' \(\mathrm{Y} \sim \mathrm{A}+\mathrm{B}+\mathrm{C}+\mathrm{B}^{\wedge} \mathrm{2}^{\prime}\) is a three-variable model with intercept and a \(B^{\wedge} 2\) term.
' \(Y\) ~ \(A+B^{\wedge} 2+C\) ' is the same as the previous example because \(\mathrm{B}^{\wedge} 2\) includes a \(B\) term.
' \(Y\) ~ \(A+B+C+A: B '\) includes an \(A * B\) term.
' \(Y \sim A * B+C\) ' is the same as the previous example because \(A * B=\) \(A+B+A: B\).
\(' Y \sim A * B * C-A: B: C '\) has all interactions among \(A, B\), and \(C\), except the three-way interaction.
' \(Y \sim A^{*}(B+C+D)^{\prime}\) has all linear terms, plus products of \(A\) with each of the other variables.

\section*{Wilkinson Notation}

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.
\begin{tabular}{l|l}
\hline Wilkinson Notation & Factors in Standard Notation \\
\hline 1 & Constant (intercept) term \\
\hline\(A^{\wedge} k\), where \(k\) is a positive integer & \(A, A^{2}, \ldots, A^{k}\) \\
\hline\(A+B\) & \(A, B\) \\
\hline\(A * B\) & \(A, B, A * B\) \\
\hline
\end{tabular}

\section*{LinearModel.stepwise}
\begin{tabular}{l|l}
\hline Wilkinson Notation & Factors in Standard Notation \\
\hline\(A: B\) & \(A * B\) only \\
\hline\(-B\) & Do not include \(B\) \\
\hline\(A * B+C\) & \(A, B, C, A * B\) \\
\hline\(A+B+C+A: B\) & \(A, B, C, A * B\) \\
\hline\(A * B * C-A: B: C\) & \(A, B, C, A * B, A * C, B * C\) \\
\hline\(A *(B+C)\) & \(A, B, C, A * B, A * C\) \\
\hline
\end{tabular}

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using - 1 .

\section*{Examples Linear Model from Stepwise Regression}

Fit a linear model of the Hald data using stepwise regression.
Load the data.
load hald
Fit a linear model to the data.

Root Mean Squared Error: 8.73
R-squared: 0.893, Adjusted R-Squared 0.892
F-statistic vs. constant model: 819, p-value = 2.25e-49

```

The weight of the patients do not seem to differ significantly according to age or the status of smoking, or interaction of these factors with gender. LinearModel.stepwise only includes Sex in the final linear model.

\begin{abstract}
Algorithms
Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using modelspec, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, LinearModel.stepwise and GeneralizedLinearModel.stepwise use the \(p\)-value of an F-statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.
\end{abstract}

Here is how stepwise proceeds when 'Criterion' is 'sse':
1 Fit the initial model.
2 If any terms not in the model have \(p\)-values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest \(p\)-value and repeat this step; otherwise, go to step 3.

\section*{LinearModel.stepwise}

3 If any terms in the model have \(p\)-values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest \(p\)-value and go to step 2 ; otherwise, end.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared, or deviance (only for GeneralizedLinearModel.stepwise) as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

\section*{Purpose \\ Syntax
Description}

Stepwise regression
b = stepwisefit(X,y)
[b,se, pval,inmodel,stats, nextstep,history] = stepwisefit(...)
[...] = stepwisefit(X,y,param1,val1,param2,val2,...)
b = stepwisefit \((x, y)\) uses a stepwise method to perform a multilinear regression of the response values in the \(n\)-by- 1 vector y on the \(p\) predictive terms in the \(n\)-by- \(p\) matrix X. Distinct predictive terms should appear in different columns of \(X\).
b is a \(p\)-by- 1 vector of estimated coefficients for all of the terms in X . The stepwisefit function calculates the coefficient estimate values in \(b\) as follows:
- If a term is not in the final model, then the corresponding coefficient estimate in b results from adding only that term to the predictors in the final model.
- If a term is in the final model, then the coefficient estimate in \(\mathbf{b}\) for that term is a result of the final model, that is stepwise does not consider the terms it excluded from the model while computing these values.

Note stepwisefit automatically includes a constant term in all models. Do not enter a column of 1 s directly into X .
stepwisefit treats NaN values in either X or y as missing values, and ignores them.
[b,se,pval,inmodel,stats,nextstep,history] = stepwisefit(...) returns the following additional information:
- se - A vector of standard errors for b
- pval - A vector of \(p\)-values for testing whether elements of b are 0
- inmodel - A logical vector, with length equal to the number of columns in \(X\), specifying which terms are in the final model
- stats - A structure of additional statistics with the following fields. All statistics pertain to the final model except where noted.
- source - The string 'stepwisefit'
- dfe - Degrees of freedom for error
- df0 - Degrees of freedom for the regression
- SStotal - Total sum of squares of the response
- SSresid - Sum of squares of the residuals
- fstat \(-F\)-statistic for testing the final model vs. no model (mean only)
- pval - \(p\) value of the \(F\)-statistic
- rmse - Root mean square error
- xr - Residuals for predictors not in the final model, after removing the part of them explained by predictors in the model
- yr - Residuals for the response using predictors in the final model
- B - Coefficients for terms in final model, with values for a term not in the model set to the value that would be obtained by adding that term to the model
- SE - Standard errors for coefficient estimates
- TSTAT - \(t\) statistics for coefficient estimates
- PVAL — \(p\)-values for coefficient estimates
- intercept - Estimated intercept
- wasnan - Indicates which rows in the data contained NaN values
- nextstep - The recommended next step-either the index of the next term to move in or out of the model, or 0 if no further steps are recommended
- history - Structure containing information on steps taken, with the following fields:
- B - Matrix of regression coefficients, where each column is one step, and each row is one coefficient.
- rmse - Root mean square errors for the model at each step.
- df0 - Degrees of freedom for the regression at each step.
- in - Logical array indicating which predictors are in the model at each step, where each row is one step, and each column is one predictor.
[...] = stepwisefit(X,y,param1,val1,param2,val2,...) specifies one or more of the name/value pairs described in the following table.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'inmodel' & \begin{tabular}{l} 
A logical vector specifying terms to include in the \\
initial fit. The default is to specify no terms.
\end{tabular} \\
\hline 'penter' & \begin{tabular}{l} 
The maximum \(p\) value for a term to be added. The \\
default is 0.05.
\end{tabular} \\
\hline 'premove' & \begin{tabular}{l} 
The minimum \(p\) value for a term to be removed. The \\
default is the maximum of the value of 'penter' and \\
0.10.
\end{tabular} \\
\hline 'display' & \begin{tabular}{l} 
'on' displays information about each step in the \\
command window. This is the default. \\
'off' omits the display.
\end{tabular} \\
\hline 'maxiter' & \begin{tabular}{l} 
The maximum number of steps in the regression. The \\
default is Inf.
\end{tabular} \\
\hline
\end{tabular}

\section*{stepwisefit}
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'keep' & \begin{tabular}{l} 
A logical vector specifying terms to keep in their initial \\
state. The default is to specify no terms.
\end{tabular} \\
\hline 'scale' & \begin{tabular}{l} 
'on' centers and scales each column of X (computes \\
\(z\)-scores) before fitting. \\
'off' does not scale the terms. This is the default.
\end{tabular} \\
\hline
\end{tabular}

\section*{Algorithms}

Stepwise regression is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the \(p\) value of an \(F\)-statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

1 Fit the initial model.
2 If any terms not in the model have \(p\)-values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest \(p\) value and repeat this step; otherwise, go to step 3.

3 If any terms in the model have \(p\)-values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest \(p\) value and go to step 2 ; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different

\section*{Examples}
models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

Load the data in hald.mat, which contains observations of the heat of reaction of various cement mixtures:
\begin{tabular}{llrl}
\begin{tabular}{l} 
load hald \\
whos
\end{tabular} & & & \\
\(\quad\) Name & Size & Bytes & Class Attributes \\
& & & \\
Description & \(22 \times 58\) & 2552 & char \\
hald & \(13 \times 5\) & 520 & double \\
heat & \(13 \times 1\) & 104 & double \\
ingredients & \(13 \times 4\) & 416 & double
\end{tabular}

The response (heat) depends on the quantities of the four predictors (the columns of ingredients).
Use stepwisefit to carry out the stepwise regression algorithm, beginning with no terms in the model and using entrance/exit tolerances of \(0.05 / 0.10\) on the \(p\)-values:
```

stepwisefit(ingredients,heat,...
'penter',0.05,'premove',0.10);
Initial columns included: none
Step 1, added column 4, p=0.000576232
Step 2, added column 1, p=1.10528e-006
Final columns included: 1 4
'Coeff' 'Std.Err.' 'Status' 'P'
[ 1.4400] [ 0.1384] 'In' [1.1053e-006]
[ 0.4161] [ 0.1856] 'Out' [ 0.0517]
[-0.4100] [ 0.1992] 'Out' [ 0.0697]
[-0.6140] [ 0.0486] 'In' [1.8149e-007]

```
stepwisefit automatically includes an intercept term in the model, so you do not add it explicitly to ingredients as you would for regress. For terms not in the model, coefficient estimates and their standard errors are those that result by adding the corresponding term to the final model.

The inmodel parameter is used to specify terms in an initial model:
```

initialModel = ...
[false true false false]; % Force in 2nd term
stepwisefit(ingredients,heat,...
'inmodel',initialModel,...
'penter',.05,'premove',0.10);
Initial columns included: 2
Step 1, added column 1, p=2.69221e-007
Final columns included: 1 2
'Coeff' 'Std.Err.' 'Status' 'P'

| 1.4683] | 0.1213] | In' | [2.6922e-007] |
| :---: | :---: | :---: | :---: |
| [ 0.6623] | [ 0.0459] | 'In' | [5.0290e-008] |
| [ 0.2500] | [ 0.1847] | 'Out' | $0.2089]$ |
| [-0.2365] | $0.1733]$ | 'Out' | $0.2054]$ |

```

The preceding two models, built from different initial models, use different subsets of the predictive terms. Terms 2 and 4, swapped in the two models, are highly correlated:
```

term2 = ingredients(:,2);
term4 = ingredients(:,4);
R = corrcoef(term2,term4)
R =
1.0000 -0.9730
-0.9730 1.0000

```

To compare the models, use the stats output of stepwisefit:
```

[betahat1,se1,pval1,inmodel1,stats1] = ...
stepwisefit(ingredients,heat,...
'penter',.05,'premove',0.10,...

```
```

    'display','off');
    [betahat2,se2,pval2,inmodel2,stats2] = ...
stepwisefit(ingredients,heat,...
'inmodel',initialModel,...
'penter',.05,'premove',0.10,...
'display','off');
RMSE1 = stats1.rmse
RMSE1 =
2.7343
RMSE2 = stats2.rmse
RMSE2 =
2.4063

```

The second model has a lower Root Mean Square Error (RMSE).

Purpose Subscripted assignment for categorical array

\section*{Syntax \\ \(A=\operatorname{subsasgn}(A, S, B)\)}

Description
\(A=\operatorname{subsasgn}(A, S, B)\) is called for the \(\operatorname{syntax} A(i)=B . S\) is a structure array with the fields:
\begin{tabular}{ll} 
type & \begin{tabular}{l} 
String containing ' ( ) ' specifying \\
the subscript type. Only \\
parenthesis subscripting is \\
allowed.
\end{tabular} \\
subs & \begin{tabular}{l} 
Cell array or string containing \\
the actual subscripts.
\end{tabular}
\end{tabular}

\section*{See Also \\ categorical | subsref}
\begin{tabular}{ll} 
Purpose & Subscripted reference for classregtree object \\
Syntax & \\
Description & Subscript assignment is not allowed for a classregtree object. \\
See Also & classregtree
\end{tabular}

Purpose
Description

Subscripted assignment to dataset array
\(A=\operatorname{subsasgn}(A, S, B)\) is called for the \(\operatorname{syntax} A(i, j)=B, A\{i, j\}=B\), or \(A\). var \(=B\) when \(A\) is a dataset array. \(S\) is a structure array with the fields:
\begin{tabular}{ll} 
type & String containing ' ( ) ', ' \(\}\) ', or \\
subs & '. specifying the subscript type. \\
& Cell array or string containing \\
& the actual subscripts.
\end{tabular}
\(A(i, j)=B\) assigns the contents of the dataset array \(B\) to a subset of the observations and variables in the dataset array A. i and j are one of the following types:
- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

The assignment does not use observation names, variable names, or any other properties of \(B\) to modify properties of \(A\); however properties of \(A\) are extended with default values if the assignment expands the number of observations or variables in A. Elements of B are assigned into A by position, not by matching names.
\(A\{i, j\}=B\) assigns the value \(B\) into an element of the dataset array \(A\). \(i\) and \(J\) are positive integers, or logical vectors. Cell indexing cannot assign into multiple dataset elements, that is, the subscripts i and \(j\) must each refer to only a single observation or variable. B is cast to the type of the target variable if necessary. If the dataset element already exists, A\{i, j\} may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, assignments such as \(\mathrm{A}\{1\), 'CellVar' \(\}=\mathrm{B}\) assign into the contents of the target dataset element in the same way that \{\}-indexing of an ordinary cell array does.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or array, an assignment such as A\{1,'ArrayVar'\} = B assigns into the second and following dimensions of the target dataset element, i.e., the assignment adds a leading singleton dimension to \(B\) to account for the observation dimension of the dataset variable.
A.var \(=B\) or \(A .(\) varname \()=B\) assigns B to a dataset variable. var is a variable name literal, or varname is a character variable containing a variable name. If the dataset variable already exists, the assignment completely replaces that variable. To assign into an element of the variable, A. var or A. (varname) may be followed by further subscripting as supported by the variable. In particular, A.var(obsnames,...) = \(B\) and A.var\{obsnames, ...\} = B (when supported by var) provide assignment into a dataset variable using observation names.
A.properties.propertyname \(=P\) assigns to a dataset property. propertyname is one of the following:
- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'

To assign into an element of the property, A. properties.propertyname may also be followed by further subscripting as supported by the property.

You cannot assign multiple values into dataset variables or properties using assignments such as [A.CellVar\{1:2\}] = B,

\section*{dataset.subsasgn}
[A.StructVar(1:2).field] = B, or [A.Properties.ObsNames\{1:2\}] \(=\) B. Use multiple assignments of the form A.CellVar \(\{1\}=\) B instead.
Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then the contents of that variable for a single observation consists of multiple cells, and you cannot assign to all of them using the syntax A\{1,'CellVar' \(\}=B\). Use multiple assignments of the form [A.CellVar\{1,1\}] = B instead.

\section*{NaiveBayes.subsasgn}

\section*{Purpose Subscripted reference for NaiveBayes object}

Description Subscript assignment is not allowed for a NaiveBayes object.
\begin{tabular}{|c|c|}
\hline Purpose & Subscript index for categorical array \\
\hline Syntax & \(\mathrm{I}=\) subsindex(A) \\
\hline Description & I = subsindex (A) is called for the syntax \(\mathrm{X}(\mathrm{A})^{\prime}\) ' when A is a categorical array and \(X\) is one of the built-in types (most commonly 'double'). subsindex returns the internal categorical level codes of \(A\) converted to zero-based integer indices. subsindex is invoked separately on all the subscripts in an expression such as \(X(A, B)\). \\
\hline Examples & ```
load fisheriris
a = ordinal(species,[],unique(species));
colmeans = grpstats(meas,a,@mean);
residuals = meas - colmeans(a,:);
``` \\
\hline See Also & categorical | double \\
\hline
\end{tabular}

\section*{classregtree.subsref}

Purpose Subscripted reference for classregtree object

\section*{Syntax \\ \(B=\operatorname{subsref}(T, S)\)}

Description
\(B=\) subsref \((T, S)\) is called for the syntax \(T(X)\) when \(T\) is a classregtree object. \(S\) is a structure array with the fields:
type String containing '()', '\{\}', or '.' specifying the subscript type.
subs Cell array or string containing the actual subscripts.
[...]=T(...) invokes the eval method for the tree T.

\section*{See Also \\ classregtree | eval}

Purpose Subscripted reference for categorical array
Syntax \(\quad A=\operatorname{subsref}(A, S, B)\)
Description
\(A=\operatorname{subsref}(A, S, B)\) is called for the \(\operatorname{syntax} A(I)=B\). S is a structure array with the fields:
\begin{tabular}{ll} 
type & \begin{tabular}{l} 
String containing ' ()' specifying \\
the subscript type. Only \\
parenthesis subscripting is \\
allowed.
\end{tabular} \\
subs & \begin{tabular}{l} 
Cell array or string containing \\
the actual subscripts.
\end{tabular}
\end{tabular}

\footnotetext{
See Also
categorical | subsasgn
}

\section*{dataset.subsref}

\section*{Purpose Subscripted reference for dataset array}

\section*{Syntax \\ \(B=\operatorname{subsref}(A, S)\)}

Description
\(B=\operatorname{subsref}(A, S)\) is called for the syntax \(A(i, j), A\{i, j\}\), or \(A . v a r\) when \(A\) is a dataset array. \(S\) is a structure array with the fields:
```

type String containing '()', '{}', or '.' specifying
the subscript type.
subs Cell array or string containing the actual subscripts.

```
\(B=A(i, j)\) returns a dataset array that contains a subset of the observations and variables in the dataset array A. i and \(j\) are one of the following types:
- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

B contains the same property values as A, subsetted for observations or variables where appropriate.
\(B=A\{i, j\}\) returns an element of a dataset variable. \(i\) and \(j\) are positive integers, or logical vectors. Cell indexing cannot return multiple dataset elements, that is, the subscripts \(i\) and \(j\) must each refer to only a single observation or variable. A\{i,j\} may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, expressions such as A\{1, 'CellVar' \} return the contents of the referenced dataset element in the same way that \{\}-indexing on an ordinary cell array does. If the dataset variable is a single column of cells, the contents of a single cell
is returned. If the dataset variable has multiple columns or is n-D, multiple outputs containing the contents of multiple cells are returned.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or an array, expressions such as A\{1, 'ArrayVar'\} return A. ArrayVar \((1,:, \ldots)\) with the leading singleton dimension squeezed out.

B = A.var or A. (varname) returns a dataset variable. var is a variable name literal, or varname is a character variable containing a variable name. A.var or A. (varname) may also be followed by further subscripting as supported by the variable. In particular, A.var(obsnames,...) and A.var\{obsnames,...\} (when supported by var) provide subscripting into a dataset variable using observation names.
\(P=A . P r o p e r t i e s . p r o p e r t y n a m e ~ r e t u r n s ~ a ~ d a t a s e t ~ p r o p e r t y . ~\) propertyname is one of the following:
- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'
A.properties.propertyname may also be followed by further subscripting as supported by the property.

\section*{Limitations}

Subscripting expressions such as A.CellVar\{1:2\}, A.StructVar(1:2).field, or A.Properties.ObsNames \(\{1: 2\}\) are valid, but result in subsref returning multiple outputs in the form of a comma-separated list. If you explicitly assign to output
arguments on the left-hand side of an assignment, for example, [cellval1,cellval2] = A.CellVar\{1:2\}, those variables will receive the corresponding values. However, if there are no output arguments, only the first output in the comma-separated list is returned.
Similarly, if a dataset variable is a cell array with multiple columns or is an \(n\)-D cell array, then subscripting expressions such as A\{1, 'CellVar'\} result in subsref returning the contents of multiple cells. You should explicitly assign to output arguments on the left-hand side of an assignment, for example, [cellval1, cellval2] = A\{1, 'CellVar'\}.

\section*{See Also}
dataset | set | subsasgn

Purpose
Subscripted reference for Gaussian mixture distribution object

\section*{Syntax}
\(B=\operatorname{subsref}(T, S)\)
Description
\(B=\operatorname{subsref}(T, S)\) is called for the syntax \(T(X)\) when \(T\) is a gmdistribution object. \(S\) is a structure array with the following fields:
\(\begin{array}{ll}\text { type } & \begin{array}{l}\text { String containing ' ( ) ', ' }\} \text { ', or '.' specifying the } \\ \text { subscript type. }\end{array} \\ \text { subs } & \text { Cell array or string containing the actual subscripts. }\end{array}\)

See Also gmdistribution

\section*{NaiveBayes.subsref}

\section*{Purpose Subscripted reference for NaiveBayes object}

\section*{Syntax \\ b = subsref(nb,s)}

Description
\(\mathrm{b}=\operatorname{subsref}(\mathrm{nb}, \mathrm{s})\) is called for the syntax \(\mathrm{nb}(\mathrm{s})\) when nb is a NaiveBayes object. \(S\) is a structure array with the fields:
type
subs
string containing '()', '\}, or '.' specifying the subscript type.

Cell array or string containing the actual subscripts.

\section*{Purpose Subscripted reference for qrandset}

Syntax
\(x=p(i, j)\)
\(x=\operatorname{subsref}(p, s)\)

Description
\(x=p(i, j)\) returns a matrix that contains a subset of the points from the point set \(p\). The indices in i select points from the set and the indices in \(j\) select columns from those points. i and \(j\) are vector of positive integers or logical vectors. A colon used as a subscript, as in \(p(i,:)\), indicates the entire row (or column).
\(x=\operatorname{subsref}(p, s)\) is called for the syntax \(p(i), p\{i\}\), or \(p . i . s\) is a structure array with the fields:
type string containing '()', '\}', or '.' specifying the subscript type.
subs Cell array or string containing the actual subscripts.

\section*{Examples}
\begin{tabular}{l|l}
\hline Command & Returns \\
\hline\(p=\operatorname{sobolset}(5) ;\) & The fifth point \\
\hline\(x=p(1: 10,:)\) & All columns of the first 10 points \\
\hline\(x=p(e n d, 1)\) & The first column of the last point \\
\hline\(x=p([1,4,5],:)\) & Points 1,4, and 5 \\
\hline
\end{tabular}

See Also qrandset

Purpose Summary statistics for categorical array
Syntax summary ( \(A\) )
C = summary (A)
[C,labels] = summary(A)

\section*{Description}
summary (A) displays the number of elements in the categorical array A equal to each of the possible levels in A. If A contains any undefined elements, the output also includes the number of undefined elements.
\(C=\) summary (A) returns counts of the number of elements in the categorical array A equal to each of the possible levels in A. If A is a matrix or \(N\)-dimensional array, C is a matrix or array with rows corresponding to the levels of A. If A contains any undefined elements, C contains one more row than the number of levels of \(A\), with the number of undefined elements in \(c\) (end) or \(c\) (end,: ).
[C,labels] = summary (A) also returns the list of categorical level labels corresponding to the counts in C .

Examples Count the number of patients in each age group in the data in hospital.mat:
load hospital edges = 0:10:100;
labels = strcat(num2str( \(0: 10: 90)\) ', '\%d'), \{'s'\});
AgeGroup \(=\) ordinal(hospital.Age,labels, [],edges);
[c,labels] = summary(AgeGroup);
Table = dataset(\{labels,'AgeGroup'\},\{c,'Count'\});
Table(3:6,:)
ans =
    AgeGroup Count
    '20s' 15
    '30s' 41
    '40s' 42
    '50s' 2

See Also islevel | ismember | levelcounts

\section*{Purpose}

Print summary of dataset array
\begin{tabular}{ll} 
Syntax & summary \((A)\) \\
\(s=\operatorname{summary}(A)\)
\end{tabular}
summary (A) prints a summary of a dataset array and the variables that it contains.
s = summary (A) returns a scalar structure \(s\) that contains a summary of the dataset A and the variables that A contains. For more information on the fields in s, see Outputs.

Summary information depends on the type of the variables in the data set:
- For numerical variables, summary computes a five-number summary of the data, giving the minimum, the first quartile, the median, the third quartile, and the maximum.
- For logical variables, summary counts the number of trues and falses in the data.
- For categorical variables, summary counts the number of data at each level.

\section*{Output \\ Arguments}

The following list describes the fields in the structure s:
- Description - A character array containing the dataset description.
- Variables - A structure array with one element for each dataset variable in A. Each element has the following fields:
- Name - A character string containing the name of the variable.
- Description - A character string containing the variable's description.
- Units - A character string containing the variable's units.
- Size - A numeric vector containing the size of the variable.
- Class - A character string containing the class of the variable.
- Data - A scalar structure containing the following fields.

For numeric variables:
- Probabilities - A numeric vector containing the probabilities [0.0 . 25.50 .75 1.0] and NaN (if any are present in the corresponding dataset variable).
- Quantiles - A numeric vector containing the values that correspond to 'Probabilities' for the corresponding dataset variable, and a count of NaNs (if any are present).
For logical variables:
- Values - The logical vector [true false].
- Counts - A numeric vector of counts for each logical value. For categorical variables:
- Levels - A cell array containing the labels for each level of the corresponding dataset variable.
- Counts - A numeric vector of counts for each level.
'Data' is empty if variable is not numeric, categorical, or logical. If a dataset variable has more than one column, then the corresponding 'Quantiles' or 'Counts' field is a matrix or an array.

\section*{Examples Summarize Fisher's iris data:}
```

load fisheriris
species = nominal(species);
data = dataset(species,meas);
summary(data)
species: [150x1 nominal]
setosa versicolor virginica
50 50 50

```
\begin{tabular}{lrrrr} 
meas: \([150 \times 4\) double] & & & \\
min & 4.3000 & 2 & 1 & 0.1000 \\
1st Q & 5.1000 & 2.8000 & 1.6000 & 0.3000 \\
median & 5.8000 & 3 & 4.3500 & 1.3000 \\
3rd Q & 6.4000 & 3.3000 & 5.1000 & 1.8000 \\
max & 7.9000 & 4.4000 & 6.9000 & 2.5000
\end{tabular}

Summarize the data in hospital.mat:
```

load hospital
summary(hospital)
LastName: [100x1 cell string]
Sex: [100x1 nominal]
Female Male
53 47

```
Dataset array created from the data file hospital.dat.
The first column of the file ("id") is used for observation
names. Other columns ("sex" and "smoke") have been
converted from their original coded values into categorical
and logical variables. Two sets of columns ("sys" and
"dia", "trial1" through "trial4") have been combined into
single variables with multivariate observations. Column
headers have been replaced with more descriptive variable
names. Units have been added where appropriate.
Age: [100x1 double, Units = Yrs]
        min 1st \(Q\) median \(3 r d Q\) max
        \(\begin{array}{lllll}25 & 32 & 39 & 44 & 50\end{array}\)
Weight: [100x1 double, Units = Lbs]
min 1st Q median 3rd Q max
Smoker: [100x1 logical]
true false

            3466
BloodPressure: [100x2 double, Units = mm Hg]
Systolic/Diastolic
min 10968
    1st Q \(117.5000 \quad 77.5000\)
    median \(122 \quad 81.5000\)
    3rd Q 127.5000 89
    \(\max 13899\)
Trials: [100x1 cell, Units = Counts]
From zero to four measurement trials performed
```

```

\section*{ProbDist.Support property}

Purpose Read-only structure containing information about support of ProbDist object

\section*{Description}

Support is a read-only property of the ProbDist class. Support is a structure containing information about the support of a ProbDist object. It includes the following fields:
- range
- closedbound
- iscontinuous

\section*{Values}

The values for the three fields in the structure are:
- range - A two-element vector [L, U], such that all of the probability is contained from \(L\) to \(U\).
- closedbound - A two-element logical vector indicating whether the corresponding range endpoint is included. Possible values for each endpoint are 1 (true) or 0 (false).
- iscontinuous - A logical value indicates if the distribution takes values on the entire interval from \(L\) to \(U\) (true), or if it takes only integer values within this range (false). Possible values are 1 (true) or 0 (false).

Use this information to view and compare information about the support of distributions.

\section*{Purpose Convert structure array to dataset array}

Syntax

Description
ds = struct2dataset(S) converts a structure array to a dataset array.
ds = struct2dataset(S,Name, Value) performs the conversion using additional options specified by one or more Name, Value pair arguments.

\section*{Input Arguments}
ds = struct2dataset(S)
ds = struct2dataset(S,Name,Value)

\section*{S - Input structure array}
structure array

Input structure array to convert to a dataset array, specified as a scalar structure array with \(N\) fields, each with \(M\) rows, or a nonscalar \(M\)-by-1 structure array with \(N\) fields.

Data Types
struct

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'ReadObsNames','myField' specifies that the structure field, myField, contains observation names.

\section*{'ReadObsNames' - Name of structure field containing observation names for dataset array \\ false (default) | string}

Name of structure field containing observation names for the output dataset array, specified as the comma-separated pair consisting of 'ReadObsNames' and a string containing a field name from

\section*{struct2dataset}
the input structure array, S. When you specify a field name, struct2dataset uses that field to create observation names, and sets ds.Properties.DimNames equal to \{ReadObsNames, 'Variables'\}.
For example, to specify that observation names are in the structure field, Names, use

\section*{Example: 'ReadObsNames', 'Names'}

By default, or if ReadObsNames is equal to false, struct2dataset does not create observation names unless you specify names using the name-value pair argument ObsNames.

\section*{'ObsNames' - Observation names for dataset array cell array of strings}

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings containing observation names. The names do not need to be valid MATLAB identifiers, but they must be unique.

\section*{'AsScalar' - Indicator for how to treat scalar structure false | true}

Indicator for how to treat a scalar input structure array, specified as the comma-separated pair consisting of 'AsScalar' and either true or false. The default value is true if \(S\) is a scalar structure array, and false otherwise.

By default, struct2dataset converts a scalar structure array with \(N\) fields, each with \(M\) rows, into an \(M\)-by- \(N\) dataset array.

If instead you set AsScalar equal to false for a scalar input structure array, then struct2dataset converts S to a dataset array with \(N\) observations.

\section*{Output \\ Arguments}

\section*{ds - Output dataset array}
dataset array
Output dataset array, returned by default with \(M\) observations and \(N\) variables.
- If S is a scalar structure array with \(N\) fields, each with \(M\) rows, then ds is an \(M\)-by- \(N\) dataset array.
- If S is a nonscalar \(M\)-by- 1 structure array with \(N\) fields, then ds is an \(M\)-by- \(N\) dataset array.
- If S is a scalar structure array with \(N\) fields, each with \(M\) rows, and AsScalar is set equal to false, then ds is a dataset array with \(N\) observations.

\section*{Examples Convert Scalar Structure Array to Dataset Array}

Convert a scalar structure array to a dataset array using the default options.

Create a structure array to convert.
```

S.Name = {'CLARK';'BROWN';'MARTIN'};
S.Gender = {'M';'F';'M'};
S.SystolicBP = [124;122;130];
S.DiastolicBP = [93;80;92];
S
S =

```
\begin{tabular}{rl} 
Name: & \(\{3 \times 1\) cell\} \\
Gender: & \(\{3 \times 1\) cell\} \\
SystolicBP: & {\([3 \times 1\) double \(]\)} \\
DiastolicBP: \([3 \times 1\) double \(]\)
\end{tabular}

The scalar structure array has four fields, each with three rows.
Convert the structure array to a dataset array.
```

ds = struct2dataset(S)
ds =

```

Name
'CLARK'

Gender
'M'

SystolicBP
DiastolicBP 12493
\begin{tabular}{llll} 
'BROWN ' & ' \({ }^{\prime}\) ' & 122 & 80 \\
'MARTIN ' & 'M ' & 130 & 92
\end{tabular}

The structure field names in \(S\) become the variable names in the output dataset array. The size of ds is 3-by-4.

\section*{Convert Nonscalar Structure Array to Dataset Array}

Convert a nonscalar structure array to a dataset array, using one of the structure fields for observation names.

Create a nonscalar structure array to convert.
```

S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
s
S =
3x1 struct array with fields:
Name
Gender
SystolicBP
DiastolicBP

```

This is a 3 -by- 1 structure array with 4 fields.

Convert the structure array to a dataset array, using the Name field for observation names.
```

ds = struct2dataset(S,'ReadObsNames','Name')

```
ds =
\begin{tabular}{llll} 
& Gender & SystolicBP & DiastolicBP \\
CLARK & 'M' & 124 & 93 \\
BROWN & 'F' & 122 & 80 \\
MARTIN & 'M' & 130 & 92
\end{tabular}

The size of ds is 3-by-3 because the structure field Name is used for observation names, and not as a dataset array variable.
ds.Properties.DimNames
ans =
'Name' 'Variables'
ds.Properties.ObsNames
ans \(=\)
'CLARK'
'BROWN'
'MARTIN'
See Also dataset | dataset2struct | cell2dataset

Examples & - "Create a Dataset Array from a File" on page 2-71 \\
Concepts & - "Dataset Arrays" on page 2-135
\end{tabular}

Purpose Interactive contour plot
Syntax surfht ( \(Z\) )
surfht( \(x, y, z\) )
surfht \((Z)\) is an interactive contour plot of the matrix \(Z\) treating the values in Z as height above the plane. The \(x\)-values are the column indices of \(Z\) while the \(y\)-values are the row indices of \(Z\).
surfht ( \(\mathrm{x}, \mathrm{y}, \mathrm{Z}\) ) where x and y are vectors specify the \(x\) and \(y\)-axes on the contour plot. The length of \(x\) must match the number of columns in \(Z\), and the length of \(y\) must match the number of rows in \(Z\).

There are vertical and horizontal reference lines on the plot whose intersection defines the current \(x\) value and \(y\) value. You can drag these dotted white reference lines and watch the interpolated \(z\) value (at the top of the plot) update simultaneously. Alternatively, you can get a specific interpolated \(z\) value by typing the \(x\) value and \(y\) value into editable text fields on the \(x\)-axis and \(y\)-axis respectively.

\section*{classregtree.surrcutcategories}
\begin{tabular}{ll}

\section*{classregtree.surrcutflip}

\section*{Purpose Numeric cutpoint assignments used for surrogate splits in decision tree}
```

Syntax
V = surrcutflip(T)
V = surrcutflip(T,J)

```
\(\mathrm{V}=\operatorname{surrcutflip}(\mathrm{T})\) returns an \(n\)-element cell array V of the numeric cut assignments used for surrogate splits in the decision tree \(T\), where \(n\) is the number of nodes in the tree. For each node K, V\{K\} is a numeric vector. The length of \(\mathrm{V}\{\mathrm{K}\}\) is equal to the number of surrogate predictors found at this node. Every element of \(V\{K\}\) is either zero for a categorical surrogate predictor or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or +1 . For every surrogate split with a numeric cut \(C\) based on a continuous predictor variable \(Z\), the left child is chosen if \(Z<C\) and the cut assignment for this surrogate split is +1 , or if \(Z>=C\) and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if \(Z>=C\) and the cut assignment for this surrogate split is +1 , or if \(Z<C\) and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by surrcutvar. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, V contains an empty array.
\(V=\operatorname{surrcutflip}(T, J)\) takes an array \(J\) of node numbers and returns the cutpoint assignments for the specified nodes.

\section*{Purpose}

Cutpoints used for surrogate splits in decision tree

Syntax

Description

V = surrcutpoint (T)
V = surrcutpoint( \(\mathrm{T}, \mathrm{J}\) )
\(\mathrm{V}=\operatorname{surrcutpoint}(\mathrm{T})\) returns an \(n\)-element cell array V of the numeric values used for surrogate splits in the decision tree \(T\), where \(n\) is the number of nodes in the tree. For each node \(K, V\{K\}\) is a numeric vector. The length of \(\vee\{K\}\) is equal to the number of surrogate predictors found at this node. Every element of V\{K\} is either either NaN for a categorical surrogate predictor or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut \(C\) based on a continuous predictor variable \(Z\), the left child is chosen if \(Z<C\) and surrcutflip for this surrogate split is -1 . Similarly, the right child is chosen if \(Z>=C\) and surrcutflip for this surrogate split is +1 , or if \(Z<C\) and surrcutflip for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by surrcutvar. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, V contains an empty cell.
\(\mathrm{V}=\) surrcutpoint \((\mathrm{T}, \mathrm{J})\) takes an array J of node numbers and returns the cutpoint assignments for the specified nodes.

\section*{classregtree.surrcutłype}

Purpose Types of surrogate splits used at branches in decision tree
Syntax
C = surrcuttype(T)
C = surrcuttype(T,J)

Description

See Also
\(C=\) surrcuttype \((T)\) returns an \(n\)-element cell array \(C\) indicating types of surrogate splits at each node in the tree \(T\), where \(n\) is the number of nodes in the tree. For each node K, C \(\{K\}\) is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables returned by surrcutvar. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, C contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form \(Z<V\) for a variable \(Z\) and cutpoint \(V\) or 'categorical' if the cut is defined by whether \(Z\) takes a value in a set of categories.
\(C=\) surrcuttype \((T, J)\) takes an array \(J\) of node numbers and returns the cut types for the specified nodes.

\section*{Purpose}

Classify using support vector machine (SVM)

\section*{Syntax}

Group = svmclassify(SVMStruct,Sample)
Group = svmclassify(SVMStruct,Sample,'Showplot',true)
Description

\section*{Input Arguments}

Group = svmclassify(SVMStruct, Sample) classifies each row of the data in Sample, a matrix of data, using the information in a support vector machine classifier structure SVMStruct, created using the svmtrain function. Like the training data used to create SVMStruct, Sample is a matrix where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. Therefore, Sample must have the same number of columns as the training data. This is because the number of columns defines the number of features. Group indicates the group to which each row of Sample has been assigned.
Group = svmclassify(SVMStruct,Sample,'Showplot',true) plots the Sample data in the figure created using the Showplot property with the svmtrain function. This plot appears only when the data is two-dimensional.

\section*{SVMStruct}

Support vector machine classifier structure created using the svmtrain function.

\section*{Sample}

A matrix where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. Therefore, Sample must have the same number of columns as the training data. This is because the number of columns defines the dimensionality of the data space.

\section*{Showplot}

Describes whether to display a plot of the classification. Displays only for 2-D problems. Follow with a Boolean argument: true to display the plot, false to give no display.

\section*{Output \\ Arguments}

\section*{Examples}

\section*{Group}

Column vector with the same number of rows as Sample. Each entry (row) in Group represents the class of the corresponding row of Sample.

Find a line separating the Fisher iris data on versicolor and virginica species, according to the petal length and petal width measurements. These two species are in rows 51 and higher of the data set, and the petal length and width are the third and fourth columns.
```

load fisheriris
xdata = meas(51:end,3:4);
group = species(51:end);
svmStruct = svmtrain(xdata,group,'showplot',true);

```

Classify a new flower with petal length 5 and petal width 2 , and circle the new point:
```

species = svmclassify(svmStruct,[5 2],'showplot',true)
hold on;plot(5,2,'ro','MarkerSize',12);hold off
species =
'virginica'

```

\section*{Algorithms}

The svmclassify function uses results from svmtrain to classify vectors \(x\) according to the following equation:
\[
c=\sum_{i} \alpha_{i} k\left(s_{i}, x\right)+b,
\]
where \(s_{i}\) are the support vectors, \(a_{i}\) are the weights, \(b\) is the bias, and \(k\) is a kernel function. In the case of a linear kernel, \(k\) is the dot product.

If \(c \geq 0\), then \(x\) is classified as a member of the first group, otherwise it is classified as a member of the second group.

svmtrain
How To
- "Support Vector Machines (SVM)" on page 15-161

Purpose Train support vector machine classifier
```

Syntax SvMStruct = svmtrain(Training,Group)
SVMStruct = svmtrain(Training,Group,Name,Value)

```

Description SVMStruct = svmtrain(Training, Group) returns a structure, SVMStruct, containing information about the trained support vector machine (SVM) classifier.

SVMStruct = svmtrain(Training, Group, Name, Value) returns a structure with additional options specified by one or more Name, Value pair arguments.

Tips

Input
Arguments
- To classify new data, use the result of training, sVMStruct, with the svmclassify function.

\section*{Training}

Matrix of training data, where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. svmtrain treats NaNs or empty strings in Training as missing values and ignores the corresponding rows of Group.

\section*{Group}

Grouping variable, which can be a categorical, numeric, or logical vector, a cell vector of strings, or a character matrix with each row representing a class label. Each element of Group specifies the group of the corresponding row of Training. Group should divide Training into two groups. Group has the same number of elements as there are rows in Training. svmtrain treats each NaN, empty string, or 'undefined' in Group as a missing value, and ignores the corresponding row of Training.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can
specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'autoscale'}

Boolean specifying whether svmtrain automatically centers the data points at their mean, and scales them to have unit standard deviation, before training.

Default: true

\section*{'boxconstraint'}

Value of the box constraint C for the soft margin. C can be a scalar, or a vector of the same length as the training data.

If C is a scalar, it is automatically rescaled by \(\mathrm{N} /(2 * \mathrm{~N} 1)\) for the data points of group one and by \(\mathrm{N} /\left(2^{*} \mathrm{~N} 2\right)\) for the data points of group two, where N 1 is the number of elements in group one, N 2 is the number of elements in group two, and \(N=N 1+N 2\). This rescaling is done to take into account unbalanced groups, that is cases where N 1 and N 2 have very different values.

If \(C\) is an array, then each array element is taken as a box constraint for the data point with the same index.

\section*{Default: 1}

\section*{'kernelcachelimit'}

Value that specifies the size of the kernel matrix cache for the SMO training method. The algorithm keeps a matrix with up to kernelcachelimit \(\times\) kernelcachelimit double-precision, floating-point numbers in memory.

Default: 5000

\section*{'kernel_function'}

Kernel function svmtrain uses to map the training data into kernel space. The default kernel function is the dot product. The kernel function can be one of the following strings or a function handle:
- 'linear' - Linear kernel, meaning dot product.
- 'quadratic' - Quadratic kernel.
- 'polynomial' - Polynomial kernel (default order 3). Specify another order with the polyorder name-value pair.
- 'rbf' - Gaussian Radial Basis Function kernel with a default scaling factor, sigma, of 1 . Specify another value for sigma with the rbf_sigma name-value pair.
- 'mlp' - Multilayer Perceptron kernel with default scale [11 1 1]. Specify another scale with the mlp_params name-value pair.
- @kfun - Function handle to a kernel function. A kernel function must be of the form
function \(K=k f u n(U, V)\)
The returned value, \(K\), is a matrix of size \(M\)-by- \(N\), where \(U\) and \(V\) have \(M\) and \(N\) rows respectively.
If kfun has extra parameters, include the extra parameters via an anonymous function. For example, suppose that your kernel function is:
```

function k = kfun(u,v,p1,p2)
k = tanh(p1*(u*v')+p2);

```

Set values for p 1 and p 2 , and then use an anonymous function:
@(u,v) kfun(u,v,p1,p2)
Default: 'linear'

\section*{'kktviolationlevel'}

Value that specifies the fraction of variables allowed to violate the Karush-Kuhn-Tucker (KKT) conditions for the SMO training method. Set any value in \([0,1)\). For example, if you set kktviolationlevel to 0.05 , then \(5 \%\) of the variables are allowed to violate the KKT conditions.

Tip Set this option to a positive value to help the algorithm converge if it is fluctuating near a good solution.

For more information on KKT conditions, see Cristianini and Shawe-Taylor [4].

Default: 0

\section*{'method'}

Method used to find the separating hyperplane. Options are:
- 'QP' - Quadratic programming (requires an Optimization Toolbox license). The classifier is a 2 -norm soft-margin support vector machine. Give quadratic programming options with the options name-value pair, and create options with optimset.
- 'SMO' - Sequential Minimal Optimization. Give SMO options with the options name-value pair, and create options with statset.
- 'LS' — Least squares.

Default: SMO

\section*{'mlp_params'}

Parameters of the Multilayer Perceptron (mlp) kernel. The mlp kernel requires two parameters, [P1 P2]. The kernel \(K=\tanh \left(P 1 * U^{*} V^{\prime}+P 2\right)\), where \(P 1>0\) and \(P 2<0\).

Default: [ \(\left.1 \begin{array}{ll}1 & 1\end{array}\right]\)

\section*{'options'}

Options structure for training.
- When you set 'method' to 'SMO' (default), create the options structure using statset. Options are:
Display
\begin{tabular}{l} 
String that specifies the level of information \\
about the optimization iterations that is \\
displayed as the algorithm runs. Choices are: \\
- off (default) - Reports nothing. \\
- iter - Reports every 500 iterations. \\
- final - Reports only when the algorithm \\
finishes.
\end{tabular}
Maxiter
\begin{tabular}{l} 
Integer that specifies the maximum number \\
of iterations of the main loop. If this limit \\
is exceeded before the algorithm converges, \\
then the algorithm stops and returns an error. \\
Default is 15000.
\end{tabular}

The other name-value pairs that relate specifically to the 'SMO' method are kernelcachelimit, kktviolationlevel, and tolkkt.
- When you set method to 'QP', create the options structure using optimset. For details of applicable option choices, see quadprog options. SVM uses a convex quadratic program, so you can choose the 'interior-point-convex' quadprog algorithm. In limited testing, the 'interior-point-convex' algorithm was the best quadprog option for svmtrain, in both speed and memory utilization.

\section*{'polyorder'}

Order of the polynomial kernel.
Default: 3

\section*{'rbf_sigma'}

Scaling factor (sigma) in the radial basis function kernel.
Default: 1

\section*{'showplot'}

Boolean indicating whether to plot the grouped data and separating line. Creates a plot only when the data has two columns (features).

Default: false

\section*{'tolkkt'}

Value that specifies the tolerance with which the Karush-Kuhn-Tucker (KKT) conditions are checked for the SMO training method. For a definition of KKT conditions, see "Karush-Kuhn-Tucker (KKT) Conditions" on page 20-2828.

Default: 1e-3

\section*{Output \\ Arguments}

\section*{SVMStruct}

Structure containing information about the trained SVM classifier in the following fields:
- SupportVectors - Matrix of data points with each row corresponding to a support vector in the normalized data space. This matrix is a subset of the Training input data matrix, after normalization has been applied according to the 'AutoScale' argument.
- Alpha - Vector of weights for the support vectors. The sign of the weight is positive for support vectors belonging to the first group, and negative for the second group.
- Bias - Intercept of the hyperplane that separates the two groups in the normalized data space (according to the 'AutoScale' argument).
- KernelFunction - Handle to the function that maps the training data into kernel space.
- KernelFunctionArgs - Cell array of any additional arguments required by the kernel function.
- GroupNames - Categorical, numeric, or logical vector, a cell vector of strings, or a character matrix with each row representing a class label. Specifies the group identifiers for the support vectors. It has the same number of elements as there are rows in SupportVectors. Each element specifies the group to which the corresponding row in SupportVectors belongs.
- SupportVectorIndices - Vector of indices that specify the rows in Training, the training data, that were selected as support vectors after the data was normalized, according to the AutoScale argument.
- ScaleData - Field containing normalization factors. When 'AutoScale' is set to false, it is empty. When AutoScale is set to true, it is a structure containing two fields:
- shift - Row vector of values. Each value is the negative of the mean across an observation in Training, the training data.
- scaleFactor - Row vector of values. Each value is 1 divided by the standard deviation of an observation in Training, the training data.

Both svmtrain and svmclassify apply the scaling in ScaleData.
- FigureHandles - Vector of figure handles created by svmtrain when using the 'Showplot' argument.

\section*{Definitions}

\section*{Karush-Kuhn-Tucker (KKT) Conditions}

The Karush-Kuhn-Tucker (KKT) conditions are analogous to the condition that the gradient must be zero at a minimum, modified to take constraints into account. The difference is that the KKT conditions hold for constrained problems. The KKT conditions use the auxiliary Lagrangian function:
\[
L(x, \lambda)=f(x)+\sum \lambda_{g, i} g_{i}(x)+\sum \lambda_{h, i} h_{i}(x) .
\]

Here \(f(x)\) is the objective function, \(g(x)\) is a vector of constraint functions \(g(x) \leq 0\), and \(h(x)\) is a vector of constraint functions \(h(x)=0\). The vector \(\lambda\), which is the concatenation of \(\lambda_{g}\) and \(\lambda_{h}\), is the Lagrange multiplier vector. Its length is the total number of constraints.

The KKT conditions are:
\[
\begin{aligned}
\nabla_{x} L(x, \lambda) & =0 \\
\lambda_{g, i} g_{i}(x) & =0 \forall i \\
g(x) & \leq 0 \\
h(x) & =0 \\
\lambda_{g, i} & \geq 0 .
\end{aligned}
\]

For more information, see Karush-Kuhn-Tucker conditions.

\section*{Examples}

Find a line separating the Fisher iris data on versicolor and virginica species, according to the petal length and petal width measurements. These two species are in rows 51 and higher of the data set, and the petal length and width are the third and fourth columns.
```

load fisheriris
xdata = meas(51:end,3:4);
group = species(51:end);
svmStruct = svmtrain(xdata,group,'showplot',true);

```

Algorithms
The svmtrain function uses an optimization method to identify support vectors \(s_{i}\), weights \(\alpha_{i}\), and bias \(b\) that are used to classify vectors \(x\) according to the following equation:
\[
c=\sum_{i} \alpha_{i} k\left(s_{i}, x\right)+b,
\]
where \(k\) is a kernel function. In the case of a linear kernel, \(k\) is the dot product. If \(c \geq 0\), then \(x\) is classified as a member of the first group, otherwise it is classified as a member of the second group.

\section*{Memory Usage and Out of Memory Error}

When you set 'Method' to 'QP', the svmtrain function operates on a data set containing \(N\) elements, and it creates an ( \(\mathrm{N}+1\) )-by- \((\mathrm{N}+1)\) matrix to find the separating hyperplane. This matrix needs at least \(8^{*}(n+1)^{\wedge} 2\) bytes of contiguous memory. If this size of contiguous memory is not available, the software displays an "out of memory" error message.

When you set 'Method' to 'SMO' (default), memory consumption is controlled by the kernelcachelimit option. The SMO algorithm stores only a submatrix of the kernel matrix, limited by the size specified by the kernelcachelimit option. However, if the number of data points exceeds the size specified by the kernelcachelimit option, the SMO algorithm slows down because it has to recalculate the kernel matrix elements.

When using svmtrain on large data sets, and you run out of memory or the optimization step is very time consuming, try either of the following:
- Use a smaller number of samples and use cross-validation to test the performance of the classifier.
- Set 'Method' to 'SMO', and set the kernelcachelimit option as large as your system permits.

How To - "Grouping Variables" on page 2-51

Purpose Read tabular data from file
```

Syntax
[data,varnames,casenames] = tblread
[data,varnames,casenames] = tblread(filename)
[data,varnames,casenames] = tblread(filename,delimiter)

```

\section*{Description}
[data, varnames, casenames] = tblread displays the File Open dialog box for interactive selection of a tabular data file. The file format has variable names in the first row, case names in the first column and data starting in the \((2,2)\) position. Outputs are:
- data - Numeric matrix with a value for each variable-case pair
- varnames - String matrix containing the variable names in the first row of the file
- casenames - String matrix containing the names of each case in the first column of the file
[data, varnames, casenames] = tblread(filename) allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the string filename.
[data, varnames,casenames] = tblread(filename,delimiter) reads from the file using delimiter as the delimiting character. Accepted values for delimiter are:
```

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

```

The default value of delimiter is 'space'.
```

Examples
[data,varnames,casenames] = tblread('sat.dat')
data =
470 530

```

520480
varnames = Male
Female
casenames =
Verbal
Quantitative

Purpose Write tabular data to file
```

Syntax tblwrite(data,varnames,casenames)
tblwrite(data,varnames,casenames,filename)
tblwrite(data,varnames,casenames,filename,delimiter)

```

\section*{Description}
tblwrite(data, varnames, casenames) displays the File Open dialog box for interactive specification of the tabular data output file. The file format has variable names in the first row, case names in the first column and data starting in the \((2,2)\) position.
varnames is a string matrix containing the variable names. casenames is a string matrix containing the names of each case in the first column. data is a numeric matrix with a value for each variable-case pair.
tblwrite(data, varnames, casenames, filename) specifies a file in the current folder, or the complete path name of any file in the string filename.
tblwrite(data, varnames, casenames,filename,delimiter) writes to the file using delimiter as the delimiting character. The following table lists the accepted character values for delimiter and their equivalent string values.
\begin{tabular}{ll}
\hline Character & String \\
' ' & 'space' \\
'\t' & 'tab' \\
',' & 'comma' \\
';' & 'semi' \\
'|' & 'bar' \\
\hline
\end{tabular}

The default value of delimiter is 'space'.

\section*{Examples}

Continuing the example from tblread:
```

tblwrite(data,varnames,casenames,'sattest.dat')

```
type sattest.dat

\section*{Syntax}

Description
\(P=\operatorname{tcdf}(X, V)\) computes Student's \(t\) cdf at each of the values in \(X\) using the corresponding degrees of freedom in \(V . X\) and \(V\) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The \(t \mathrm{cdf}\) is
\[
p=F(x \mid v)=\int_{-\infty}^{x} \frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)} \frac{1}{\sqrt{v \pi}} \frac{1}{\left(1+\frac{t^{2}}{v}\right)^{\frac{v+1}{2}}} d t
\]

The result, \(p\), is the probability that a single observation from the \(t\) distribution with \(v\) degrees of freedom will fall in the interval \([-\infty, x)\).

\section*{Examples}
```

mu = 1; % Population mean
sigma = 2; % Population standard deviation
n = 100; % Sample size
x = normrnd(mu,sigma,n,1); % Random sample from population
xbar = mean(x); % Sample mean
s = std(x); % Sample standard deviation
t = (xbar-mu)/(s/sqrt(n)) % t-statistic
t =
0.2489
p = 1-tcdf(t,n-1) % Probability of larger t-statistic
p =
0.4020

```

This probability is the same as the \(p\) value returned by a \(t\)-test of the null hypothesis that the sample comes from a normal population with mean \(\mu\) :
```

[h,ptest] = ttest(x,mu,0.05,'right')
h =
0
ptest =
0.4020

```
See Also cdf | tpdf | tinv | tstat | trnd
How To . "Student's t Distribution" on page B-108

Purpose Read tab-delimited file
```

Syntax
tdfread
tdfread(filename)
tdfread(filename,delimiter)
s = tdfread(filename,...)

```

\section*{Description}
tdfread displays the File Open dialog box for interactive selection of a data file, then reads data from the file. The file should have variable names separated by tabs in the first row, and data values separated by tabs in the remaining rows. tdfread creates variables in the workspace, one for each column of the file. The variable names are taken from the first row of the file. If a column of the file contains only numeric data in the second and following rows, tdfread creates a double variable. Otherwise, tdfread creates a char variable. After all values are imported, tdfread displays information about the imported values using the format of the tdfread command.
tdfread(filename) allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the string filename.
tdfread(filename, delimiter) indicates that the character specified by delimiter separates columns in the file. Accepted values for delimiter are:
- ' ' or 'space'
- ' \(\backslash t\) ' or 'tab'
- ', ' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

The default delimiter is 'tab'.
\(s=\) tdfread(filename, ...) returns a scalar structure \(s\) whose fields each contain a variable.

Examples The following displays the contents of the file sat2.dat:
type sat2.dat

Test, Gender, Score
Verbal, Male,470
Verbal, Female,530
Quantitative,Male,520
Quantitative,Female, 480
The following creates the variables Gender, Score, and Test from the file sat2.dat and displays the contents of the MATLAB workspace:
```

tdfread('sat2.dat',',')

```
Name Size Bytes Class Attributes
\begin{tabular}{llll} 
Gender & \(4 \times 6\) & 48 & char \\
Score & \(4 \times 1\) & 32 & double \\
Test & \(4 \times 12\) & 96 & char
\end{tabular}

See Also tblread | caseread

\section*{ClassificationDiscriminant.template}
\begin{tabular}{|c|c|}
\hline Purpose & Discriminant analysis classifier template for ensemble \\
\hline Syntax & \[
\begin{aligned}
& \mathrm{t}=\text { ClassificationDiscriminant.template() } \\
& \mathrm{t}=\text { ClassificationDiscriminant.template(Name, Value) }
\end{aligned}
\] \\
\hline Description & \begin{tabular}{l}
t = ClassificationDiscriminant.template() returns a learner template suitable to use in the fitensemble function. \\
t = ClassificationDiscriminant.template(Name, Value) creates a template with additional options specified by one or more Name, Value pair arguments.
\end{tabular} \\
\hline Input Arguments & \begin{tabular}{l}
Name-Value Pair Arguments \\
Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN. \\
'delta'
\end{tabular} \\
\hline & \begin{tabular}{l}
Threshold on linear coefficients, a nonnegative scalar. If a coefficient of obj has magnitude smaller than delta, obj sets this coefficient to 0 , and so you can eliminate the corresponding predictor from the model. Set delta to a higher value to eliminate more predictors. \\
delta must be 0 for quadratic discriminant models. \\
Default: 0
\end{tabular} \\
\hline & 'discrimType' \\
\hline
\end{tabular}

String specifying the discriminant type. Case-insensitive. One of:
- 'linear'
- 'quadratic'

\section*{ClassificationDiscriminant.template}
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Default: 'linear'

\section*{'fillCoeffs'}

String, either 'on' or 'off', specifying whether to populate the Coeffs property in the classifier object. Setting to 'on' can be computationally intensive, especially when cross validating.

Default: 'on', except 'off' when cross validating

\section*{'gamma'}

Parameter for regularizing the correlation matrix of predictors.
- Linear discriminant - Scalar from 0 to 1.
- If you pass a value strictly between 0 and 1, ClassificationDiscriminant.fit sets the discriminant type to 'Linear'.
- If you pass 0 for gamma and 'Linear' for DiscrimType, and if the correlation matrix is singular, ClassificationDiscriminant.fit sets gamma to the minimal value required for inverting the covariance matrix.
- If you set gamma to 1 , ClassificationDiscriminant.fit sets the discriminant type to 'diagLinear'.
- Quadratic discriminant - Either 0 or 1.
- If you pass 0 for gamma and 'Quadratic' for DiscrimType, and if one of the classes has a singular covariance matrix, ClassificationDiscriminant.fit errors.

\section*{ClassificationDiscriminant.template}
- If you set gamma to 1 , ClassificationDiscriminant.fit sets the discriminant type to 'diagQuadratic'.

\section*{'SaveMemory'}

When 'on', ClassificationDiscriminant.fit does not store the full covariance matrix, but instead stores enough information to compute the matrix. The predict method computes the full covariance matrix for prediction, and does not store the matrix. When 'off', ClassificationDiscriminant.fit computes and stores the full covariance matrix in obj.

Set SaveMemory to 'on ' when X has thousands of predictors.
Default: 'off'

\section*{Output t}

\section*{Examples}

\section*{Discriminant analysis template for nondefault options}

Create a nondefault discriminant analysis template for use in fitensemble.

Create a template for pseudolinear discriminant analysis.
```

t = ClassificationDiscriminant.template('discrimType','pseudoLinear')
t =
Fit template for classification Discriminant.
classreg.learning.modelparams.DiscriminantParams
Package: classreg.learning.modelparams
Properties:
DiscrimType: 'pseudoLinear'

```

\section*{ClassificationDiscriminant.template}

\author{
Gamma: [] \\ Delta: [] \\ FillCoeffs: [] \\ SaveMemory: [] \\ Method: 'Discriminant \\ Type: 'classification \\ \section*{Superclasses} \\ You can use \(t\) for ensemble learning. \\ See Also ClassificationDiscriminant | fitensemble
}

\section*{ClassificationKNN.template}
Purpose \(\quad k\)-nearest neighbor classifier template for ensemble
```

Syntax $\quad t=$ ClassificationKNN.template()
t = ClassificationKNN.template(Name, Value)

```

Description
\(\mathrm{t}=\) ClassificationKNN.template() returns a learner template suitable to use in the fitensemble function.
t = ClassificationKNN.template(Name, Value) creates a template with additional options specified by one or more Name, Value pair arguments.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'BreakTies'}

String specifying the method predict uses to break ties if multiple classes have the same smallest cost. By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.
- 'nearest ' - Use the class with the nearest neighbor among tied groups.
- 'random' - Use a random tiebreaker among tied groups.
- 'smallest' - Use the smallest index among tied groups.

Default: 'smallest'

\section*{'BucketSize'}

\section*{ClassificationKNN.template}

Maximum number of data points in the leaf node of the \(k\) d-tree. This argument is meaningful only when NSMethod is 'kdtree'.

Default: 50

\section*{'Cov'}

Positive definite matrix, the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

Default: nancov (X)

\section*{'Distance'}

String or function handle specifying the distance metric. The allowable strings depend on the NSMethod parameter, which you set in ClassificationKNN.fit, and which exists as a field in ModelParams.
\begin{tabular}{l|l}
\hline NSMethod & Distance Metric Names \\
\hline exhaustive & Any distance metric of ExhaustiveSearcher \\
\hline kdtree & \begin{tabular}{l} 
'cityblock', 'chebychev ', 'euclidean ', or \\
'minkowski'
\end{tabular} \\
\hline
\end{tabular}

For definitions, see "Distance Metrics" on page 15-9.
The distance metrics of ExhaustiveSearcher:
\begin{tabular}{l|l}
\hline Value & Description \\
\hline 'cityblock' & City block distance. \\
\hline 'chebychev' & \begin{tabular}{l} 
Chebychev distance (maximum coordinate \\
difference).
\end{tabular} \\
\hline 'correlation' & \begin{tabular}{l} 
One minus the sample linear correlation \\
between observations (treated as \\
sequences of values).
\end{tabular} \\
\hline
\end{tabular}

\section*{ClassificationKNN.template}
\begin{tabular}{l|l}
\hline Value & Description \\
\hline 'cosine' & \begin{tabular}{l} 
One minus the cosine of the included angle \\
between observations (treated as vectors).
\end{tabular} \\
\hline 'euclidean' & Euclidean distance. \\
\hline 'hamming' & \begin{tabular}{l} 
Hamming distance, percentage of \\
coordinates that differ.
\end{tabular} \\
\hline 'jaccard' & \begin{tabular}{l} 
One minus the Jaccard coefficient, the \\
percentage of nonzero coordinates that \\
differ.
\end{tabular} \\
\hline 'mahalanobis' & \begin{tabular}{l} 
Mahalanobis distance, computed using a \\
positive definite covariance matrix C. The \\
default value of C is the sample covariance \\
matrix of X, as computed by nancov (X). \\
To specify a different value for C, use the \\
'Cov' name-value pair.
\end{tabular} \\
\hline 'minkowski' & \begin{tabular}{l} 
Minkowski distance. The default exponent \\
is 2. To specify a different exponent, use \\
the 'P' name-value pair.
\end{tabular} \\
\hline 'seuclidean' & \begin{tabular}{l} 
Standardized Euclidean distance. Each \\
coordinate difference between X and a \\
query point is scaled, meaning divided by \\
a scale value S. The default value of S is \\
the standard deviation computed from X, \\
S = nanstd (X). To specify another value \\
for S, use the Scale name-value pair.
\end{tabular} \\
\hline
\end{tabular}

\section*{ClassificationKNN.template}
\(\left.\begin{array}{l|l}\hline \text { Value } & \text { Description } \\
\hline \text { 'spearman' } & \begin{array}{l}\text { One minus the sample Spearman's rank } \\
\text { correlation between observations (treated } \\
\text { as sequences of values). }\end{array} \\
\hline \text { @distfun } & \begin{array}{l}\text { Distance function handle. distfun has } \\
\text { the form } \\
\text { function D2 = DISTFUN(ZI , ZJ) } \\
\text { \% calculation of distance } \\
\cdots\end{array} \\
\text { where } \\
\text { - ZI is a 1-by-N vector containing one row } \\
\text { of X or Y. } \\
\text { - ZJ is an M2-by-N matrix containing } \\
\text { multiple rows of X or Y. }\end{array}\right\}\)\begin{tabular}{l} 
- D2 is an M2-by-1 vector of distances, \\
and D2 (k) is the distance between \\
observations ZI and ZJ (J, :).
\end{tabular}

Default: 'euclidean', except the default is 'hamming' when CategoricalPredictors is 'all'

\section*{'DistanceWeight'}

String or function handle specifying the distance weighting function.
\begin{tabular}{l|l}
\hline DistanceWeight & Meaning \\
\hline 'equal' & No weighting \\
\hline 'inverse' & Weight is 1/distance \\
\hline
\end{tabular}

\section*{ClassificationKNN.template}
\begin{tabular}{l|l}
\hline DistanceWeight & Meaning \\
\hline 'squaredinverse ' & Weight is \(1 /\) distance \(^{2}\) \\
\hline @fcn & \begin{tabular}{l} 
fcn is a function that accepts a matrix \\
of nonnegative distances, and returns \\
a matrix the same size containing \\
nonnegative distance weights. For \\
example, 'squaredinverse' is equivalent \\
to @(d)d.^(-2).
\end{tabular} \\
\hline
\end{tabular}

Default: 'equal'

\section*{'Exponent'}

Positive scalar specifying the exponent of Minkowski distance. This argument is only valid when 'Distance' is 'minkowski'.

\section*{Default: 2}

\section*{'IncludeTies'}

Logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Default: false

\section*{'NSMethod'}

String specifying the nearest neighbor search method:
- 'kdtree' - Create and use a \(k\) d-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
- 'euclidean'
- 'cityblock'

\section*{ClassificationKNN.template}
- 'minkowski'
- 'chebyshev'
- 'exhaustive' - Use the exhaustive search algorithm. The distance values from all points in \(X\) to each point in \(Y\) are computed to find nearest neighbors.

Default: 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'

\section*{'NumNeighbors'}

Positive integer specifying the number of nearest neighbors in \(X\) to find for classifying each point when predicting.

\section*{Default: 1}

\section*{'Scale'}

Vector containing nonnegative values, with length equal to the number of columns in \(X\). Each coordinate difference between \(X\) and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

Default: nanstd(X)

\section*{Output Arguments}

\section*{Examples KNN template for nondefault options}

Create a nondefault \(k\)-nearest neighbor template for use in fitensemble.

Create a template for 5 -nearest neighbor search.

\section*{ClassificationKNN.template}
t = ClassificationKNN.template('NumNeighbors',5)
t =
Fit template for classification KNN.
classreg.learning.modelparams.KNNParams
Package: classreg.learning.modelparams

Related - "Random Subspace Classification" on page 15-118

\section*{ClassificationTree.template}
\begin{tabular}{|c|c|}
\hline Purpose & Create classification template \\
\hline Syntax & ```
t = ClassificationTree.template
t = ClassificationTree.template(Name,Value)
``` \\
\hline Description & \begin{tabular}{l}
\(\mathrm{t}=\) ClassificationTree.template returns a learner template suitable to use in the fitensemble function. \\
t = ClassificationTree.template(Name, Value) creates a template with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, , NameN, ValueN.
\end{tabular} \\
\hline Input Arguments & \begin{tabular}{l}
Name-Value Pair Arguments \\
Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.
\end{tabular} \\
\hline
\end{tabular}

\section*{'AlgorithmForCategorical'}

Algorithm to find the best split on a categorical predictor for data with \(K=3\) or more classes. The available algorithms are:
\begin{tabular}{ll} 
'Exact' & \begin{tabular}{l} 
For a categorical predictor \\
with \(C\) categories, consider all \\
\(2^{C-1}-1\) combinations.
\end{tabular} \\
'PullLeft' & \begin{tabular}{l} 
Start with all \(C\) categories on \\
the right branch. Consider \\
moving each category to the
\end{tabular} \\
& left branch as it achieves \\
the minimum impurity for \\
the \(K\) classes among the \\
remaining categories. Out of
\end{tabular}

\section*{ClassificationTree.template}
this sequence, choose the split that has the lowest impurity.
'PCA'
'OVAbyClass'

Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all \(C-1\) splits [1].
Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. Out of this sequence, choose the split that has the minimum impurity.

Default: ClassificationTree selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, ClassificationTree always performs the exact search.

\section*{'MaxCat'}

ClassificationTree splits a categorical predictor using the exact search algorithm if the predictor has at most MaxCat levels in

\section*{ClassificationTree.template}
the split node. Otherwise, ClassificationTree finds the best categorical split using one of the inexact algorithms.

Specify MaxCat as a numeric nonnegative scalar value. Passing a small value can lead to long computation time and memory overload.

Default: 10

\section*{'MergeLeaves'}

String that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', ClassificationTree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', ClassificationTree does not merge leaves.

Default: 'off'

\section*{'MinLeaf'}

Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, ClassificationTree uses the setting that gives larger leaves: MinParent=max (MinParent,2*MinLeaf).

Default: Half the number of training observations for boosting, 1 for bagging

\section*{'MinParent'}

Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, ClassificationTree uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).

\section*{ClassificationTree.template}

Default: Number of training observations for boosting, 2 for bagging

\section*{'NVarToSample'}

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

Default: 'all' for boosting, square root of number of predictors for bagging

\section*{'Prune'}

When 'on', ClassificationTree grows the classification tree and computes the optimal sequence of pruned subtrees. When 'off' ClassificationTree grows the tree without pruning.

Default: 'off'

\section*{'PruneCriterion'}

String with the pruning criterion, either 'error' or 'impurity'.
Default: 'error'

\section*{'SplitCriterion'}

Criterion for choosing a split. One of 'gdi' (Gini's diversity index), 'twoing ' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Default: 'gdi'

\section*{'Surrogate'}

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

\section*{ClassificationTree.template}
- When 'on', ClassificationTree finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, ClassificationTree finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', ClassificationTree finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Default: 'off'

\section*{Output Arguments}

Examples

Classification tree template suitable to use in the fitensemble function. In an ensemble, \(t\) specifies how to grow the classification trees.

Create a classification template with surrogate splits, and train an ensemble for the Fisher iris model with the template:
```

t = ClassificationTree.template('surrogate','on');
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,t);

```

\section*{RegressionTree.template}

Purpose Create regression template
Syntax \(\quad \begin{aligned} \mathrm{t} & =\text { RegressionTree.template } \\ \mathrm{t} & =\text { RegressionTree.template (Name, Value) }\end{aligned}\)
Description \(\quad t=\) RegressionTree.template returns a learner template suitable to use in the fitensemble function.
\(\mathrm{t}=\) RegressionTree.template (Name, Value) creates a template with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ,NameN, ValueN.

\section*{Input Arguments}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

\section*{'MergeLeaves'}

String that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', RegressionTree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', RegressionTree does not merge leaves.

Default: 'off'

\section*{'MinLeaf'}

Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).

Default: Half the number of training observations for boosting, 5 for bagging

\section*{'MinParent'}

Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves: MinParent=max (MinParent, 2*MinLeaf).

Default: Number of training observations for boosting, 10 for bagging

\section*{'NVarToSample'}

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

Default: 'all' for boosting, one third of the number of predictors for bagging

\section*{'Prune'}

When 'on', RegressionTree grows the regression tree and computes the optimal sequence of pruned subtrees. When 'off' RegressionTree grows the tree without pruning.

Default: 'off'

\section*{'Surrogate'}

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.
- When 'on', RegressionTree finds at most 10 surrogate splits at each branch node.

\section*{RegressionTree.template}
- When set to a positive integer value, RegressionTree finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', RegressionTree finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Default: 'off'

\section*{Output Arguments}

\section*{Examples}

Create a regression template with surrogate splits, and train an ensemble for the carsmall data with the template:
```

t = RegressionTree.template('surrogate','on');
load carsmall
X = [Acceleration Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,t);

```

See Also RegressionTree | RegressionTree.fit | fitensemble

\author{
Purpose \\ Syntax \\ Description
}

Error rate
cost = test(t,'resubstitution')
cost = test(t,'test', X,y)
cost = test(t,'crossvalidate',X,y)
[cost,secost,ntnodes,bestlevel] = test(...)
[...] = test(...,param1,val1,param2,val2,...)
cost = test(t,'resubstitution') computes the cost of the tree t using a resubstitution method. t is a decision tree as created by classregtree. The cost of the tree is the sum over all terminal nodes of the estimated probability of a node times the cost of a node. If \(t\) is a classification tree, the cost of a node is the sum of the misclassification costs of the observations in that node. If \(t\) is a regression tree, the cost of a node is the average squared error over the observations in that node. cost is a vector of cost values for each subtree in the optimal pruning sequence for \(t\). The resubstitution cost is based on the same sample that was used to create the original tree, so it under estimates the likely cost of applying the tree to new data.
cost \(=\) test( t, 'test', \(\mathrm{X}, \mathrm{y}\) ) uses the matrix of predictors X and the response vector y as a test sample, applies the decision tree \(t\) to that sample, and returns a vector cost of cost values computed for the test sample. \(X\) and \(y\) should not be the same as the learning sample, that is, the sample that was used to fit the tree \(t\).
cost \(=\) test( \(\mathrm{t}, \mathrm{C}\) crossvalidate', \(\mathrm{X}, \mathrm{y}\) ) uses 10 -fold cross-validation to compute the cost vector. X and y should be the learning sample, that is, the sample that was used to fit the tree \(t\). The function partitions the sample into 10 subsamples, chosen randomly but with roughly equal size. For classification trees, the subsamples also have roughly the same class proportions. For each subsample, test fits a tree to the remaining data and uses it to predict the subsample. It pools the information from all subsamples to compute the cost for the whole sample.
[cost, secost, ntnodes, bestlevel] = test(...) also returns the vector secost containing the standard error of each cost value, the vector ntnodes containing the number of terminal nodes for each

\section*{classregtree.test}
subtree, and the scalar bestlevel containing the estimated best level of pruning. A bestlevel of 0 means no pruning. The best level is the one that produces the smallest tree that is within one standard error of the minimum-cost subtree.
[...] = test(...,param1,val1,param2,val2,...) specifies optional parameter name/value pairs for methods other than 'resubstitution', chosen from the following:
- 'weights' - Observation weights.
- 'nsamples' - The number of cross-validation samples (default is 10).
- 'treesize' - Either 'se' (default) to choose the smallest tree whose cost is within one standard error of the minimum cost, or 'min' to choose the minimal cost tree.

\section*{Examples}

Find the best tree for Fisher's iris data using cross-validation. Start with a large tree:
```

load fisheriris;
t = classregtree(meas,species,...
'names',{'SL' 'SW' 'PL' 'PW'},...
'splitmin',5)
t =
Decision tree for classification
if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
class = setosa
if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
class = virginica
if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
if PW<1.55 then node 10 elseif PW>=1.55 then node 11 else virginica
class = versicolor
class = virginica
class = virginica

```

11 class = versicolor
view(t)
\begin{tabular}{|l|l|l|l|l|l|}
\hline Click to display: & Identity & \(\rightarrow\) Magnification: & \(100 \%\) & \(\rightarrow\) & Pruning level: 0 of \(\mathbf{4}\) \\
\hline
\end{tabular}

Find the minimum-cost tree:
```

[c,s,n,best] = test(t,'cross',meas,species);
tmin = prune(t,'level',best)
tmin =
Decision tree for classification

```

\section*{classregtree.test}
```

1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
class = setosa
if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
class = versicolor
class = virginica
view(tmin)

```
\begin{tabular}{|l|l|l|l|l|l|l|}

\hline 0 of 2 & & \\
\hline
\end{tabular}

Plot the smallest tree within one standard error of the minimum cost tree:
```

[mincost, minloc] = min(c);
plot(n, c, 'b-o',...
n(best+1), c(best+1),'bs',..
$\mathrm{n},(\mathrm{mincost}+\mathrm{s}(\operatorname{minloc}))$ *ones(size(n)),'k--')
xlabel('Tree size (number of terminal nodes)')
ylabel('Cost')

```

The solid line shows the estimated cost for each tree size, the dashed line marks one standard error above the minimum, and the square marks the smallest tree under the dashed line.

\section*{classregtree.test}

}

\section*{Purpose Test indices for cross-validation}
```

Syntax
idx = test(c)
idx = test(c,i)

```
\(i d x=\) test (c) returns the logical vector idx of test indices for an object c of the cvpartition class of type 'holdout' or 'resubstitution'.
If c.Type is 'holdout', idx specifies the observations in the test set.
If c.Type is 'resubstitution', idx specifies all observations.
\(i d x=\operatorname{test}(c, i)\) returns the logical vector idx of test indices for repetition \(i\) of an object \(c\) of the cvpartition class of type 'kfold' or 'leaveout'.

If c.Type is 'kfold', idx specifies the observations in the test set in fold i.

If c. Type is 'leaveout', idx specifies the observation left out at repetition i.

Examples Identify the test indices in the first fold of a partition of 10 observations for 3 -fold cross-validation:
c = cvpartition(10, 'kfold', 3)
c =
K-fold cross validation partition
N: 10
NumTestSets: 3
TrainSize: 767
TestSize: 343
test( \(\mathrm{c}, 1\) )

\section*{Purpose Size of each test set}
\(\begin{array}{ll}\text { Description } \quad & \text { Value is a vector in partitions of type 'kfold' and 'leaveout'. } \\ & \text { Value is a scalar in partitions of type 'holdout' and } \\ \text { 'resubstitution'. }\end{array}\)

Purpose Rank adjusted for ties
Syntax \(\quad \begin{aligned} {[R, T I E A D J] } & =\operatorname{tiedrank}(X) \\ {[R, T I E A D J] } & =\operatorname{tiedrank}(X, 1) \\ {[R, T I E A D J] } & =\operatorname{tiedrank}(X, 0,1)\end{aligned}\)

\section*{Description}

Examples
Counting from smallest to largest, the two 20 values are 2nd and 3rd, so they both get rank 2.5 (average of 2 and 3 ):
```

tiedrank([10 20 30 40 20])
ans =
1.0000 2.5000 4.0000 5.0000 2.5000

```
See Also ansaribradley | corr | partialcorr | ranksum | signrank

Purpose Product of categorical arrays
Syntax \(\quad C=\operatorname{times}(A, B)\)
Description \(\quad C=\operatorname{times}(A, B)\) returns a categorical array each of whose elements has the level formed from the concatenation of the levels of the corresponding elements of \(A\) and \(B\). The set of levels of \(C\) is the cartesian product of the sets of levels of A and of B. The syntax A .* B calls C \(=\) times(A,B).

See Also categorical

Purpose
Student's \(t\) inverse cumulative distribution function

\section*{Syntax \\ \(X=\operatorname{tinv}(P, V)\)}
\(X=\operatorname{tinv}(P, V)\) computes the inverse of Student's \(t\) cdf using the degrees of freedom in \(V\) for the corresponding probabilities in \(P\). \(P\) and \(V\) can be vectors, matrices, or multidimensional arrays that are the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The values in P must lie on the interval [01].

The t inverse function in terms of the \(t\) cdf is
\[
x=F^{-1}(p \mid v)=\{x: F(x \mid v)=p\}
\]
where
\[
p=F(x \mid v)=\int_{-\infty}^{x} \frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)} \frac{1}{\sqrt{v \pi}} \frac{1}{\left(1+\frac{t^{2}}{v}\right)^{\frac{v+1}{2}}} d t
\]

The result, \(x\), is the solution of the cdf integral with parameter \(v\), where you supply the desired probability \(p\).

Examples What is the 99th percentile of the \(t\) distribution for one to six degrees of freedom?
```

percentile = tinv(0.99,1:6)
percentile =

| 31.8205 | 6.9646 | 4.5407 | 3.7469 | 3.3649 | 3.1427 |
| :--- | :--- | :--- | :--- | :--- | :--- |

```

Superclasses ToolboxFittableParametricDistribution
Purpose \(\quad t\) Location-Scale probability distribution object
Description prob.tLocationScaleDistribution is an object consisting of parameters, a model description, and sample data for a \(t\) location-scale probability distribution.
Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd \(=\) makedist('tLocationScale') creates a \(t\) location-scale probability distribution object using the default parameter values.
pd = makedist('tLocationScale','mu', mu,'sigma', sigma, 'nu', nu) creates a \(t\) location-scale probability distribution object using the specified parameter values.

\section*{Input Arguments}

\section*{mu - Location parameter}

0 (default) | scalar value
Location parameter for the \(t\) location-scale distribution, specified as a scalar value.

\section*{Data Types}
single | double
sigma-Scale parameter
1 (default) | positive scalar value
Scale parameter for the \(t\) location-scale distribution, specified as a positive scalar value.
```

Data Types
single | double
nu - Degrees of freedom

```

\section*{prob.tLocationScaleDistribution}

\section*{5 (default) | positive scalar value}

Degrees of freedom for the \(t\) location-scale distribution, specified as a positive scalar value.

\author{
Data Types \\ single | double
}

\section*{Properties}
mu
Location parameter of the \(t\) location-scale distribution, stored as a scalar value.

\section*{Data Types \\ single | double}
sigma
Scale parameter of the \(t\) location-scale distribution, stored as a positive scalar value.
```

Data Types
single | double
nu

```

Degrees of freedom of the \(t\) location-scale distribution, stored as a positive scalar value.
```

Data Types
single | double

```

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types \\ char}

\section*{InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

\section*{Data Types}
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated. If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterCovariance}

Covariance matrix of the parameter estimates, stored as a \(p\)-by- \(p\) matrix, where \(p\) is the number of parameters in the distribution. The ( \(\mathrm{i}, \mathrm{j}\) ) element is the covariance between the estimates of the \(i\) ith parameter and the \(j\) th parameter. The ( \(i, i\) ) element is the estimated variance of the ith parameter. If parameter \(i\) is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.
```

Data Types
single | double

```

\section*{prob.tLocationScaleDistribution}

\section*{ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{Data Types \\ char}

\section*{ParameterIsFixed}

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

\section*{Data Types}
logical

\section*{ParameterNames}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types \\ char}

\section*{ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\section*{Data Types}
single | double

\section*{Truncation}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

\section*{prob.tLocationScaleDistribution}

\section*{Definitions}

\section*{Examples}

\section*{t Location-Scale Distribution}

The \(t\) location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as \(v\) approaches infinity, and smaller values of \(v\) yield heavier tails.

The \(t\) location-scale distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline mu & \begin{tabular}{l} 
Location \\
parameter
\end{tabular} & \(-\infty<\mu<\infty\) \\
\hline sigma & Scale parameter & \(\sigma>0\) \\
\hline nu & Shape parameter & \(v>0\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid \mu, \sigma, v)=\frac{\Gamma\left(\frac{v+1}{2}\right)}{\sigma \sqrt{v \pi} \Gamma\left(\frac{v}{2}\right)}\left[\frac{v+\left(\frac{x-\mu}{\sigma}\right)^{2}}{v}\right]^{\left(-\frac{v+1}{2}\right)} \quad ;-\infty<x<\infty
\]
where \(\Gamma(\cdot)\) is the Gamma function.

\section*{Create a t Location-Scale Distribution Object Using Default Parameters}

Create a \(t\) location scale distribution object using the default parameter values.
```

pd = makedist('tLocationScale')

```
pd \(=\)
        \(\mathrm{mu}=0\)
    sigma = 1
        nu \(=5\)

\section*{Create at Location-Scale Distribution Object Using Specified Parameters}

Create a \(t\) location-scale distribution object by specifying the parameter values.
```

pd = makedist('tLocationScale','mu',-2,'sigma',1,'nu', 20)
pd =
tLocationScaleDistribution
t Location-Scale distribution
mu = -2
sigma = 1
nu = 20

```

Compute the interquartile range of the distribution.

Purpose Student's \(t\) probability density function

\section*{Syntax \\ \(Y=\operatorname{tpdf}(X, V)\)}

Description
\(Y=\operatorname{tpdf}(\mathrm{X}, \mathrm{V})\) computes Student's \(t\) pdf at each of the values in X using the corresponding degrees of freedom in \(V . X\) and \(V\) can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

Student's \(t \mathrm{pdf}\) is
\[
y=f(x \mid v)=\frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)} \frac{1}{\sqrt{v \pi}} \frac{1}{\left(1+\frac{x^{2}}{v}\right)^{\frac{v+1}{2}}}
\]

How To - "Student's t Distribution" on page B-108

\section*{cvpartition.training}

Purpose Training indices for cross-validation
```

Syntax idx = training(c)
idx = training(c,i)

```

Description \(\quad i d x=\) training ( \(c\) ) returns the logical vector idx of training indices for an object \(c\) of the cvpartition class of type 'holdout' or 'resubstitution'.

If c.Type is 'holdout', idx specifies the observations in the training set.

If c.Type is 'resubstitution', idx specifies all observations.
idx \(=\) training( \(c, i)\) returns the logical vector idx of training indices for repetition \(i\) of an object \(c\) of the cvpartition class of type 'kfold' or 'leaveout'.

If c.Type is 'kfold', idx specifies the observations in the training set in fold i.

If c.Type is 'leaveout', idx specifies the observations left in at repetition i.

\section*{Examples}

Identify the training indices in the first fold of a partition of 10 observations for 3 -fold cross-validation:
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
N: 10
NumTestSets: 3 TrainSize: 767 TestSize: 343

out-of-bag observations
\end{tabular} \\
& Predict response
\end{tabular}

\section*{Properties}

\section*{ClassNames}

A cell array containing the class names for the response variable Y. This property is empty for regression trees.

\section*{ComputeOOBPrediction}

A logical flag specifying whether out-of-bag predictions for training observations should be computed. The default is false.

If this flag is true, the following properties are available:
- OOBIndices
- OOBInstanceWeight

If this flag is true, the following methods can be called:
- oobError
- oobMargin
- oobMeanMargin

See also oobError, OOBIndices, OOBInstanceWeight, oobMargin, oobMeanMargin.

\section*{ComputeOOBVarimp}

A logical flag specifying whether out-of-bag estimates of variable importance should be computed. The default is false. If this flag is true, then Compute00BPrediction is true as well.
If this flag is true, the following properties are available:
- OOBPermutedVarDeltaError
- OOBPermutedVarDeltaMeanMargin
- OOBPermutedVarCountRaiseMargin

\section*{Cost}

A matrix with misclassification costs. This property is empty for ensembles of regression trees.
See also classregtree.

\section*{DefaultYfit}

Default value returned by predict and oobPredict. The DefaultYfit property controls what predicted value is returned when no prediction is possible. For example, when oobPredict needs to predict for an observation that is in-bag for all trees in the ensemble.
- For classification, you can set this property to either ' ' or 'MostPopular'. If you choose 'MostPopular' (the default), the property value becomes the name of the most probably class in

\section*{TreeBagger}
the training data. If you choose ' ' , the in-bag observations are excluded from computation of the out-of-bag error and margin.
- For regression, you can set this property to any numeric scalar. The default value is the mean of the response for the training data. If you set this property to NaN , the in-bag observations are excluded from computation of the out-of-bag error and margin.

\section*{DeltaCritDecisionSplit}

A numeric array of size 1-by-Nvars of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

See also classregtree.varimportance.

\section*{FBoot}

Fraction of observations that are randomly selected with replacement for each bootstrap replica. The size of each replica is Nobs \(\times\) FBoot, where Nobs is the number of observations in the training set. The default value is 1 .

\section*{MergeLeaves}

A logical flag specifying whether decision tree leaves with the same parent are merged for splits that do not decrease the total risk. The default value is false.

\section*{Method}

Method used by trees. The possible values are 'classification' for classification ensembles, and 'regression' for regression ensembles.

\section*{MinLeaf}

Minimum number of observations per tree leaf. By default, MinLeaf is 1 for classification and 5 for regression. For classregtree training, the MinParent value is set equal to 2*MinLeaf.

\section*{NTrees}

Scalar value equal to the number of decision trees in the ensemble.

\section*{NVarSplit}

A numeric array of size 1-by-Nvars, where every element gives a number of splits on this predictor summed over all trees.

\section*{NVarToSample}

Number of predictor or feature variables to select at random for each decision split. By default, NVarToSample is equal to the square root of the total number of variables for classification, and one third of the total number of variables for regression.

\section*{OOBIndices}

Logical array of size Nobs-by-NTrees, where Nobs is the number of observations in the training data and NTrees is the number of trees in the ensemble. A true value for the \((i, j)\) element indicates that observation \(i\) is out-of-bag for tree \(j\). In other words, observation \(i\) was not selected for the training data used to grow tree \(j\).

\section*{OOBInstanceWeight}

Numeric array of size Nobs-by-1 containing the number of trees used for computing the out-of-bag response for each observation. Nobs is the number of observations in the training data used to create the ensemble.

\section*{OOBPermutedVarCountRaiseMargin}

A numeric array of size 1-by-Nvars containing a measure of variable importance for each predictor variable (feature). For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

\section*{OOBPermutedVarDeltaError}

\section*{TreeBagger}

A numeric array of size 1-by-Nvars containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

\section*{OOBPermutedVarDeltaMeanMargin}

A numeric array of size 1-by-Nvars containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

\section*{OutlierMeasure}

A numeric array of size Nobs-by-1, where Nobs is the number of observations in the training data, containing outlier measures for each observation.

See also CompactTreeBagger.OutlierMeasure.

\section*{Prior}

A vector with prior probabilities for classes. This property is empty for ensembles of regression trees.

See also classregtree.

\section*{Proximity}

A numeric matrix of size Nobs-by-Nobs, where Nobs is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix
with 1 s on the diagonal and off-diagonal elements ranging from 0 to 1 .

See also CompactTreeBagger.proximity, classregtree.varimportance.

\section*{Prune}

The Prune property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

See also classregtree. prune.

\section*{SampleWithReplacement}

A logical flag specifying if data are sampled for each decision tree with replacement. True if TreeBagger samples data with replacement and false otherwise. True by default.

\section*{TreeArgs}

Cell array of arguments for the classregtree constructor. These arguments are used by TreeBagger when growing new trees for the ensemble.

\section*{Trees}

A cell array of size NTrees-by- 1 containing the trees in the ensemble.

See also NTrees.

\section*{VarAssoc}

A matrix of size Nuars-by-Nvars with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting 'surrogate' to 'on ', this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting 'surrogate' to 'off' (default), VarAssoc is diagonal.

\section*{VarNames}

\section*{TreeBagger}

A cell array containing the names of the predictor variables (features). TreeBagger takes these names from the optional 'names' parameter. The default names are 'x1', 'x2', etc.

\section*{W}

Numeric vector of weights of length Nobs, where Nobs is the number of observations (rows) in the training data. TreeBagger uses these weights for growing every decision tree in the ensemble. The default W is ones (Nobs, 1).

X
A numeric matrix of size Nobs-by-Nvars, where Nobs is the number of observations (rows) and Nvars is the number of variables (columns) in the training data. This matrix contains the predictor (or feature) values.

\section*{Y}

An array of true class labels for classification, or response values for regression. Y can be a numeric column vector, a character matrix, or a cell array of strings.

\section*{Copy Semantics}

\section*{How To}

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.
- "Ensemble Methods" on page 15-58
- "Classification Trees and Regression Trees" on page 15-30
- "Grouping Variables" on page 2-51
\begin{tabular}{|c|c|}

decision split. Default is the square root of the \\
number of variables for classification and one third \\
of the number of variables for regression. Valid \\
values are 'all' or a positive integer. Setting this \\
argument to any valid value but 'all' invokes
\end{tabular} \\
Breiman's 'random forest' algorithm.
\end{tabular}
- 'UseSubstreams' - If true select each bootstrap replicate using a separate Substream of the random number generator (aka Stream). This option is available only with RandStream types that support Substreams: 'mlfg6331_64' or 'mrg32k3a'. Default is false, do not use a different Substream to compute each bootstrap replicate.
- Streams - A RandStream object or cell array of such objects. If you do not specify Streams, TreeBagger uses the default stream or streams. If you choose to specify Streams, use a single object except in the case
- You have an open MATLAB pool
- UseParallel is true
- UseSubstreams is false

In that case, use a cell array the same size as the MATLAB pool.
In addition to the optional arguments above, this method accepts all optional classregtree arguments with the exception of 'minparent'. Refer to the documentation for classregtree for more detail.
```

Examples load fisheriris
b = TreeBagger(50,meas,species,'00BPred','on')
plot(oobError(b))
xlabel('number of grown trees')
ylabel('out-of-bag classification error')
returns
b =
Ensemble with 50 bagged decision trees:
Training X: [150x4]

```

- "Grouping Variables" on page 2-51

\section*{Purpose}

Plot tree

Note treedisp will be removed in a future release. Use classregtree.view instead.
```

Syntax
treedisp(t)
treedisp(t,param1,val1,param2,val2,...)

```

\section*{Description}

Note This function is superseded by the view method of the classregtree class and is maintained only for backwards compatibility. It accepts objects \(t\) created with the classregtree constructor.
treedisp ( \(t\) ) takes as input a decision tree \(t\) as computed by the treefit function, and displays it in a figure window. Each branch in the tree is labeled with its decision rule, and each terminal node is labeled with the predicted value for that node.

For each branch node, the left child node corresponds to the points that satisfy the condition, and the right child node corresponds to the points that do not satisfy the condition.
The Click to display pop-up menu at the top of the figure enables you to display more information about each node, as described in the following table.
\begin{tabular}{l|l}
\hline Menu Choice & Displays \\
\hline Identity & \begin{tabular}{l} 
The node number, whether the node is a branch \\
or a leaf, and the rule that governs the node
\end{tabular} \\
\hline Variable ranges & \begin{tabular}{l} 
The range of each of the predictor variables for \\
that node
\end{tabular} \\
\hline Node statistics & \begin{tabular}{l} 
Descriptive statistics for the observations falling \\
into this node
\end{tabular} \\
\hline
\end{tabular}

\section*{treedisp}

After you select the type of information you want, click any node to display the information for that node.

The Pruning level button displays the number of levels that have been cut from the tree and the number of levels in the unpruned tree. For example, 1 of 6 indicates that the unpruned tree has six levels, and that one level has been cut from the tree. Use the spin button to change the pruning level.
treedisp(t,param1,val1,param2,val2,...) specifies optional parameter name-value pairs, listed in the following table.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'names ' & \begin{tabular}{l} 
A cell array of names for the predictor variables, \\
in the order in which they appear in the \(X\) matrix \\
from which the tree was created (see treefit)
\end{tabular} \\
\hline 'prunelevel' & Initial pruning level to display \\
\hline
\end{tabular}

\section*{Examples}

Create and graph classification tree for Fisher's iris data. The names in this example are abbreviations for the column contents (sepal length, sepal width, petal length, and petal width).
```

load fisheriris;
t = treefit(meas,species);
treedisp(t,'names',{'SL' 'SW' 'PL' 'PW'});

```
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline & & & & & & & & - \\
\hline Click to display: & Identity & \(\checkmark\) & Magnification: & 100\% & \(\checkmark\) & Pruning level: & 0 of 4 & - \\
\hline
\end{tabular}

Purpose Fit tree

Note treefit will be removed in a future release. Use classregtree instead.
```

Syntax $\quad t=\operatorname{treefit}(x, y)$
t = treefit(X,y,param1,val1,param2,val2,...)

```

\section*{Description}

Note This function is superseded by the classregtree constructor of the classregtree class and is maintained only for backwards compatibility. It returns objects \(t\) in the classregtree class.
\(t=\operatorname{treefit}(X, y)\) creates a decision tree \(t\) for predicting response \(y\) as a function of predictors \(X\). \(X\) is an \(n\)-by-m matrix of predictor values. \(y\) is either a vector of \(n\) response values (for regression), or a character array or cell array of strings containing \(n\) class names (for classification). Either way, t is a binary tree where each non-terminal node is split based on the values of a column of \(X\).
\(\mathrm{t}=\) treefit \((\mathrm{X}, \mathrm{y}\), param1, val1, param2, val2, ...) specifies optional parameter name-value pairs. Valid parameter strings are:

The following table lists parameters available for all trees.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'catidx' & \begin{tabular}{l} 
Vector of indices of the columns of X . treefit \\
treats these columns as unordered categorical \\
values.
\end{tabular} \\
\hline 'method' & \begin{tabular}{l} 
Either 'classification' (default if y is text) or \\
'regression' (default if y is numeric).
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'splitmin' & \begin{tabular}{l} 
A number n such that impure nodes must have n \\
or more observations to be split (default 10).
\end{tabular} \\
\hline 'prune' & \begin{tabular}{l} 
'on' (default) to compute the full tree and a \\
sequence of pruned subtrees, or 'off' for the full \\
tree without pruning.
\end{tabular} \\
\hline
\end{tabular}

The following table lists parameters available for classification trees only.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'cost' & \begin{tabular}{l} 
p-by-p matrix \(C\), where \(p\) is the number of distinct \\
response values or class names in the input y. \\
\(C(i, j)\) is the cost of classifying a point into class \\
\(j\) if its true class is i. (The default has \(C(i, j)=1\) \\
if \(i \sim=j\), and \(C(i, j)=0\) if \(i=j)\).\(C can also be a\) \\
structure S with two fields: S.group containing \\
the group names, and S.cost containing a matrix \\
of cost values.
\end{tabular} \\
\hline 'splitcriterion' & \begin{tabular}{l} 
Criterion for choosing a split: either ' gdi' \\
(default) for Gini's diversity index, 'twoing' for \\
the twoing rule, or 'deviance ' for maximum \\
deviance reduction.
\end{tabular} \\
\hline 'priorprob' & \begin{tabular}{l} 
Prior probabilities for each class, specified as a \\
vector (one value for each distinct group name) \\
or as a structure S with two fields: S.group \\
containing the group names, and S. prob \\
containing a vector of corresponding probabilities.
\end{tabular} \\
\hline
\end{tabular}

Examples Create a classification tree for Fisher's iris data:
```

load fisheriris;
t = treefit(meas,species);
treedisp(t,'names',{'SL' 'SW' 'PL' 'PW'});

```

\section*{treefit}
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline Click to display: Identity & \(\checkmark\) & Magnification: & 100\% & \(\checkmark\) & Pruning level: & 0 of 4 & - \\
\hline
\end{tabular}

How To . "Grouping Variables" on page 2-51

\section*{Purpose}

Prune tree

Note treeprune will be removed in a future release. Use classregtree. prune instead.

\section*{Syntax}
```

t2 = treeprune(t1,'level',level)
t2 = treeprune(t1,'nodes',nodes)
t2 = treeprune(t1)

```

\section*{Description}

Note This function is superseded by the prune method of the classregtree class and is maintained only for backwards compatibility. It accepts objects \(t 1\) created with the classregtree constructor and returns objects t 2 in the classregtree class.
t2 = treeprune(t1,'level',level) takes a decision tree t1 as created by the treefit function, and a pruning level, and returns the decision tree t2 pruned to that level. Setting level to 0 means no pruning. Trees are pruned based on an optimal pruning scheme that first prunes branches giving less improvement in error cost.
t2 = treeprune(t1, 'nodes', nodes) prunes the nodes listed in the nodes vector from the tree. Any t1 branch nodes listed in nodes become leaf nodes in t2, unless their parent nodes are also pruned. The treedisp function can display the node numbers for any node you select.
t2 \(=\) treeprune( t 1 ) returns the decision tree t2 that is the same as t 1 , but with the optimal pruning information added. This is useful only if you created t1 by pruning another tree, or by using the treefit function with pruning set 'off'. If you plan to prune a tree multiple times, it is more efficient to create the optimal pruning sequence first.

Pruning is the process of reducing a tree by turning some branch nodes into leaf nodes, and removing the leaf nodes under the original branch.

\section*{TreeBagger.Trees property}
Purpose Decision trees in ensemble
Description The Trees property is a cell array of size NTrees-by- 1 containing the trees in the ensemble.
See Also ..... NTrees

\section*{Purpose}

Error rate
Syntax
```

cost = treetest(t,'resubstitution')
cost = treetest(t,'test',X,y)
cost = treetest(t,'crossvalidate',X,y)
[cost,secost,ntnodes,bestlevel] = treetest(...)
[...] = treetest(...,param1,val1,param2,val2,...)

```

Note treetest will be removed in a future release. Use classregtree.test instead.

\section*{Description}

Note This function is superseded by the test method of the classregtree class class and is maintained only for backwards compatibility. It accepts objects \(t\) created with the classregtree constructor.
cost \(=\) treetest( \(t\), 'resubstitution') computes the cost of the tree \(t\) using a resubstitution method. \(t\) is a decision tree as created by the treefit function. The cost of the tree is the sum over all terminal nodes of the estimated probability of that node times the node's cost. If \(t\) is a classification tree, the cost of a node is the sum of the misclassification costs of the observations in that node. If \(t\) is a regression tree, the cost of a node is the average squared error over the observations in that node. cost is a vector of cost values for each subtree in the optimal pruning sequence for \(t\). The resubstitution cost is based on the same sample that was used to create the original tree, so it underestimates the likely cost of applying the tree to new data.
cost \(=\) treetest( \(t\), 'test', \(\mathrm{X}, \mathrm{y}\) ) uses the predictor matrix X and response \(y\) as a test sample, applies the decision tree \(t\) to that sample, and returns a vector cost of cost values computed for the test sample. X and y should not be the same as the learning sample, which is the sample that was used to fit the tree \(t\).
cost \(=\) treetest(t, 'crossvalidate', \(\mathrm{X}, \mathrm{y}\) ) uses 10 -fold cross-validation to compute the cost vector. \(X\) and \(y\) should be the learning sample, which is the sample that was used to fit the tree \(t\). The function partitions the sample into 10 subsamples, chosen randomly but with roughly equal size. For classification trees, the subsamples also have roughly the same class proportions. For each subsample, treetest fits a tree to the remaining data and uses it to predict the subsample. It pools the information from all subsamples to compute the cost for the whole sample.
[cost, secost, ntnodes,bestlevel] = treetest(...) also returns the vector secost containing the standard error of each cost value, the vector ntnodes containing number of terminal nodes for each subtree, and the scalar bestlevel containing the estimated best level of pruning. bestlevel \(=0\) means no pruning, i.e., the full unpruned tree. The best level is the one that produces the smallest tree that is within one standard error of the minimum-cost subtree.
[...] = treetest(...,param1,val1,param2,val2,...) specifies optional parameter name-value pairs chosen from the following table.
\begin{tabular}{l|l}
\hline Parameter & Value \\
\hline 'nsamples ' & \begin{tabular}{l} 
The number of cross-validations samples (default \\
ic -10)
\end{tabular} \\
\hline 'treesize' & \begin{tabular}{l} 
Either 'se' (default) to choose the smallest tree \\
whose cost is within one standard error of the \\
minimum cost, or 'min' to choose the minimal cost \\
tree.
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

Find the best tree for Fisher's iris data using cross-validation. The solid line shows the estimated cost for each tree size, the dashed line marks one standard error above the minimum, and the square marks the smallest tree under the dashed line.
```

% Start with a large tree.
load fisheriris;
t = treefit(meas,species','splitmin',5);

```
```

% Find the minimum-cost tree.
[c,s,n,best] = treetest(t,'cross',meas,species);
tmin = treeprune(t,'level',best);
% Plot smallest tree within 1 std of minimum cost tree.
[mincost,minloc] = min(c);
plot(n,c,'b-o',...
n(best+1),c(best+1),'bs',...
n,(mincost+s(minloc))*ones(size(n)),'k--');
xlabel('Tree size (number of terminal nodes)')
ylabel('Cost')

```

\author{
References [1] Breiman, L., J. Friedman, R. Olshen, and C. Stone. Classification and Regression Trees. Boca Raton, FL: CRC Press, 1984. \\ See Also treefit | treedisp
}

\section*{Purpose}

Predicted responses

Note treeval will be removed in a future release. Use classregtree.eval instead.

\author{
Syntax \\ \section*{Description}
}
```

yfit = treeval(t,x)
yfit = treeval(t,X,subtrees)
[yfit,node] = treeval(...)
[yfit,node,cname] = treeval(...)

```

Note This function is superseded by the eval method of the classregtree class and is maintained only for backwards compatibility. It accepts objects \(t\) created with the classregtree constructor.
yfit \(=\) treeval \((\mathrm{t}, \mathrm{X})\) takes a classification or regression tree t as produced by the treefit function and a matrix \(X\) of predictor values, and produces a vector yfit of predicted response values. For a regression tree, yfit(i) is the fitted response value for a point having the predictor values \(\mathrm{X}(\mathrm{i},:)\). For a classification tree, yfit(i) is the class number into which the tree would assign the point with data X(i,:). To convert the number into a class name, use the third output argument, cname (described below).
yfit \(=\) treeval( \(\mathrm{t}, \mathrm{X}\), subtrees) takes an additional vector subtrees of pruning levels, with 0 representing the full, unpruned tree. T must include a pruning sequence as created by the treefit or prunetree function. If subtree has \(k\) elements and X has \(n\) rows, the output yfit is an \(n\)-by- \(k\) matrix, with the \(j\) th column containing the fitted values produced by the subtrees (j) subtree. subtrees must be sorted in ascending order.
[yfit, node] = treeval(...) also returns an array node of the same size as yfit containing the node number assigned to each row of \(X\). The treedisp function can display the node numbers for any node you select.
[yfit, node, cname] = treeval(...) is valid only for classification trees. It returns a cell array cname containing the predicted class names.

\author{
Examples Find the predicted classifications for Fisher's iris data: \\ load fisheriris; \\ t = treefit(meas,species); \% Create decision tree \\ sfit = treeval(t,meas); \% Find assigned class numbers \\ sfit \(=\) t.classname(sfit); \% Get class names \\ mean(strcmp(sfit,species)) \% Proportion in correct class \\ ans \(=\) \\ 0.9800

\section*{Superclasses ParametricTruncatableDistribution}

Purpose Triangular probability distribution object
Description prob.TriangularDistribution is an object consisting of parameters and a model description for a triangular probability distribution. Create a probability distribution object with specified parameters using makedist.

\section*{Construction}
pd = makedist('Triangular') creates a triangular probability distribution object using the default parameter values.
pd = makedist('Triangular','a', a, 'b', b, 'c', c) creates a triangular distribution object using the specified parameter values.

\section*{Input Arguments}

\section*{a-Lower limit}

\section*{0 (default) | scalar value}

Lower limit for the triangular distribution, specified as a scalar value.

\section*{Data Types \\ single | double \\ b - Peak location}
0.5 (default) | scalar value

Peak location for the triangular distribution, specified as a scalar value greater than or equal to \(a\).

\section*{Data Types}
single | double

\section*{c - Upper limit}

1 (default) | scalar value
Upper limit for the triangular distribution, specified as a scalar value greater than or equal to \(b\).

\section*{prob.TriangularDistribution}

\author{
Data Types \\ single | double
}

\section*{Properties}
a
Lower limit for the triangular distribution, stored as a scalar value.
```

Data Types

\hline & mean & Mean of probability distribution object \\
\hline & std & Standard deviation of probability distribution object \\
\hline & var & Variance of probability distribution object \\
\hline
\end{tabular}

\section*{Definitions Triangular Distribution}

The triangular distribution is frequently used in simulations when limited sample data is available. The lower and upper limits represent the smallest and largest values, and the location of the peak represents an estimate of the mode.

The triangular distribution uses the following parameters.

\section*{prob.TriangularDistribution}
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline a & Lower limit & \(a \leq b\) \\
\hline b & Peak location & \(a \leq b \leq c\) \\
\hline c & Upper limit & \(a \leq b \leq c\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid a, b, c)=\frac{2(x-a)}{(c-a)(b-a)} \quad ; \quad a \leq x \leq b
\]
and
\[
f(x \mid a, b, c)=\frac{2(c-x)}{(c-a)(c-b)} \quad ; \quad b<x \leq c .
\]

The value of the pdf is 0 when \(x<\alpha\) or \(x>c\).

\section*{Examples}

\section*{Create a Triangular Distribution Object Using Default Parameters}

Create a triangular distribution object using the default parameter values.

Concepts - Class Attributes
- Property Attributes
\begin{tabular}{ll} 
Purpose & Mean excluding outliers \\
Syntax & \(m=\operatorname{trimmean}(X\), percent \()\) \\
& trimmean \((X\), percent, dim \()\) \\
& \(m=\operatorname{trimmean}(X\), percent, flag \()\) \\
& \(m=\operatorname{trimmean}(x\), percent,flag, dim \()\)
\end{tabular}

Description

Tips
'floor' Round \(k\) down to the next smaller integer.
'weight ' If \(k=i+f\) where \(i\) is the integer part and \(f\) is the fraction, compute a weighted mean with weight ( \(1-f\) ) for the \((i+1)\) th and ( \(n-i\) )th values, and full weight for the values between them.
\(m=\) trimmean(x, percent,flag,dim) takes the trimmed mean along dimension dim of \(x\).
\(m=\) trimmean(X, percent) calculates the trimmed mean of the values in \(X\). For a vector input, \(m\) is the mean of \(X\), excluding the highest and lowest k data values, where \(\mathrm{k}=\mathrm{n}\) * (percent/100)/2 and where n is the number of values in \(X\). For a matrix input, \(m\) is a row vector containing the trimmed mean of each column of \(X\). For \(n\)-D arrays, trimmean operates along the first non-singleton dimension. percent is a scalar between 0 and 100 .
trimmean (X, percent, dim) takes the trimmed mean along dimension dim of \(X\).
\(m=\) trimmean(X, percent,flag) controls how to trim when \(k\) is not an integer. flag can be chosen from the following:
\begin{tabular}{ll} 
'round ' & \begin{tabular}{l} 
Round \(k\) to the nearest integer (round to a smaller \\
integer if \(k\) is a half integer). This is the default.
\end{tabular} \\
'floor' & \begin{tabular}{l} 
Round \(k\) down to the next smaller integer.
\end{tabular} \\
'weight ' & \begin{tabular}{l} 
If \(k=i+f\) where \(i\) is the integer part and \(f\) is the \\
fraction, compute a weighted mean with weight \\
\((1-f)\) for the \((i+1)\) th and \((n-i)\) th values, and \\
full weight for the values between them.
\end{tabular}
\end{tabular}
,
The trimmed mean is a robust estimate of the location of a sample. If there are outliers in the data, the trimmed mean is a more representative estimate of the center of the body of the data than the mean. However, if the data is all from the same probability distribution,

\section*{trimmean}
then the trimmed mean is less efficient than the sample mean as an estimator of the location of the data.

\section*{Examples}

\section*{Example 1}

This example shows a Monte Carlo simulation of the efficiency of the \(10 \%\) trimmed mean relative to the sample mean for normal data.
```

x = normrnd(0,1,100,100);
m = mean(x);
trim = trimmean(x,10);
sm = std(m);
strim = std(trim);
efficiency = (sm/strim).^2
efficiency =
0.9702

```

\section*{Example 2}

Generate random data from the \(t\) distribution, which tends to have outliers:
```

rng('default') % to reproduce the plot exactly
x = trnd(1,40,1);
probplot(x)

```

Though the distribution is symmetric around zero, there are several outliers which will affect the mean. The trimmed mean is much closer to zero, which is much more representative of the data:
```

mean(x)
ans =
2.7991
trimmean(x,25)
ans =

```

\section*{trimmean}

\title{
prob.TruncatableDistribution.truncate
}

\section*{Purpose Truncate probability distribution object}

Syntax \(\quad t=\) truncate (pd, lower, upper)
Description \(\quad \mathrm{t}=\) truncate (pd, lower, upper) returns a probability distribution t , which is the probability distribution pd truncated to the specified interval with lower limit, lower, and upper limit, upper.

\section*{Input Arguments}

\section*{Output \\ Arguments}

\section*{pd - Probability distribution \\ probability distribution object}

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using fitdist or dfittool.

\section*{lower - Lower truncation limit}
scalar value
Lower truncation limit, specified as a scalar value.

\section*{Data Types}
single | double

\section*{upper - Upper truncation limit}
scalar value
Upper truncation limit, specified as a scalar value.

\section*{Data Types}
single | double

\section*{t- Truncated distribution}
probability distribution object
Truncated distribution, returned as a probability distribution object. The pdf of \(t\) is 0 outside the truncation interval. Inside the truncation interval, the pdf of \(t\) is equal to the \(p d f\) of \(p d\), but divided by the probability assigned to that interval by pd.

\section*{prob.TruncatableDistribution.truncate}

\section*{Examples Truncate a Probability Distribution}

Create a standard normal probability distribution object.
pd = makedist('Normal')
pd =
NormalDistribution
```

Normal distribution
mu = 0
sigma = 1

```

Truncate the distribution to have a lower limit of -2 and an upper limit of 2 .
```

t = truncate(pd,-2,2)

```
\(\mathrm{t}=\)

NormalDistribution
```

Normal distribution
mu = 0
sigma = 1
Truncated to the interval [-2, 2]

```

Plot the pdf of the original and truncated distributions for a visual comparison.
```

x = -3:.1:3;
figure;
plot(x,pdf(pd,x),'Color','red','LineWidth',2)
hold on;
plot(x,pdf(t,x),'Color','blue','LineWidth',2)
hold off;

```

\section*{prob.TruncatableDistribution.truncate}

\section*{Generate Random Numbers from a Truncated Distribution}

Create a standard normal probability distribution object.
pd = makedist('Normal')
pd =
NormalDistribution

\section*{prob.TruncatableDistribution.truncate}
```

Normal distribution
mu = 0
sigma = 1

```

Truncate the distribution by restricting it to positive values. Set the lower limit to 0 and the upper limit to infinity.
```

t = truncate(pd,0,inf)
t =
NormalDistribution
Normal distribution
mu = 0
sigma = 1
Truncated to the interval [0, Inf]

```

Generate random numbers from the truncated distribution and visualize with a histogram.
```

r = random(t,10000,1);
hist(r,100)

```

Purpose
Student's \(t\) mean and variance

\section*{Syntax \\ [M,V] = tstat(NU)}
\([M, V]=\operatorname{tstat}(N U)\) returns the mean of and variance for Student's \(t\) distribution using the degrees of freedom in NU. M and \(V\) are the same size as NU.

The mean of the Student's \(t\) distribution with parameter \(v\) is zero for values of \(v\) greater than 1 . If \(v\) is one, the mean does not exist. The variance for values of \(v\) greater than 2 is \(v /(v-2)\).

\section*{Examples}

Find the mean of and variance for 1 to 30 degrees of freedom.
\begin{tabular}{|c|c|c|c|c|}
\hline \multicolumn{5}{|l|}{\(\mathrm{m}=\)} \\
\hline NaN 0 & 00 & 0 & & \\
\hline 00 & 00 & 0 & & \\
\hline 00 & 00 & 0 & & \\
\hline 00 & 00 & 0 & & \\
\hline 00 & 00 & 0 & & \\
\hline 00 & 00 & 0 & & \\
\hline \multicolumn{5}{|l|}{\(\mathrm{v}=\)} \\
\hline NaN & 1.4000 & 1.1818 & 1.1176 & 1.0870 \\
\hline NaN & 1.3333 & 1.1667 & 1.1111 & 1.0833 \\
\hline 3.0000 & 1.2857 & 1.1538 & 1.1053 & 1.0800 \\
\hline 2.0000 & 1.2500 & 1.1429 & 1.1000 & 1.0769 \\
\hline 1.6667 & 1.2222 & 1.1333 & 1.0952 & 1.0741 \\
\hline 1.5000 & 1.2000 & 1.1250 & 1.0909 & 1.0714 \\
\hline
\end{tabular}

Note that the variance does not exist for one and two degrees of freedom.

\section*{See Also}
```

```
```

Purpose $\quad$ One-sample and paired-sample $t$-test
Syntax $\quad h=$ ttest $(x)$
h = ttest $(x, y)$
h = ttest( $x, y$, Name, Value)
$h=t t e s t(x, m)$
h = ttest(x,m,Name, Value)
[h, p] = ttest(__)
[h,p,ci,stats] = ttest(___)

```

Description \(\quad h=t\) test ( \(x\) ) returns a test decision for the null hypothesis that the data in \(x\) comes from a normal distribution with mean equal to zero and unknown variance, using the one-sample \(t\)-test. The alternative hypothesis is that the population distribution does not have a mean equal to zero. The result h is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, and 0 otherwise.
\(\mathrm{h}=\mathrm{ttest}(\mathrm{x}, \mathrm{y})\) returns a test decision for the null hypothesis that the data in \(x \quad y\) comes from a normal distribution with mean equal to zero and unknown variance, using the paired-sample \(t\)-test.
\(\mathrm{h}=\mathrm{ttest}(\mathrm{x}, \mathrm{y}\), Name, Value) returns a test decision for the paired-sample \(t\)-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.
\(h=t \operatorname{test}(x, m)\) returns a test decision for the null hypothesis that the data in X comes from a normal distribution with mean m and unknown variance. The alternative hypothesis is that the mean is not m .
\(\mathrm{h}=\mathrm{ttest}(\mathrm{x}, \mathrm{m}\), Name, Value) returns a test decision for the one-sample \(t\)-test with additional options specified by one or more name-value
pair arguments. For example, you can change the significance level or conduct a one-sided test.
[ \(\mathrm{h}, \mathrm{p}\) ] = ttest (__) also returns the \(p\)-value, p , of the test, using any of the input arguments from the previous syntax groups.
[h,p,ci,stats] = ttest( __ ) also returns the confidence interval ci for the mean of x , or of \(\mathrm{x} \quad \mathrm{y}\) for the paired \(t\)-test, and the structure stats containing information about the test statistic.

\section*{Input \\ Arguments}

\section*{x-Sample data}

\section*{vector | matrix | multidimensional array}

Sample data, specified as a vector, matrix, or multidimensional array. ttest performs a separate \(t\)-test along each column and returns a vector of results. If \(y\) sample data is specified, \(x\) and \(y\) must be the same size.
```

Data Types
single | double

```

\section*{\(y\)-Sample data}
vector | matrix | multidimensional array
Sample data, specified as a vector, matrix, or multidimensional array. If \(y\) sample data is specified, \(x\) and \(y\) must be the same size.
```

Data Types
single | double

```

\section*{m-Hypothesized population mean}

\section*{0 (default) | scalar value}

Hypothesized population mean, specified as a scalar value.
Data Types
single | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Tail','right', 'Alpha', 0.01 conducts a right-tailed hypothesis test at the \(1 \%\) significance level.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

Example: 'Alpha', 0.01
Data Types
single | double

\section*{'Dim' - Dimension}
first nonsingleton dimension (default) | positive integer value
Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim', 1 tests the column means, while 'Dim' , 2 tests the row means.

\section*{Example: 'Dim',2}

Data Types
single | double

\section*{'Tail' - Type of alternative hypothesis}
'both' (default) | 'right' | 'left'
Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.
\begin{tabular}{ll} 
'both' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean is not m.
\end{tabular} \\
'right' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean is greater than m.
\end{tabular} \\
'left' \(\quad\)\begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean is less than \(m\).
\end{tabular} \\
Example: 'Tail', 'right'
\end{tabular}

\section*{Output Arguments}
h - Hypothesis test result
1|0
Hypothesis test result, returned as a logical value.
- If \(h=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(h=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{p-p-value}
scalar value in the range \((0,1)\)
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.

\section*{ci - Confidence interval}
vector
Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the \(100 \times(1-A l p h a) \%\) confidence interval.

\section*{stats - Test statistics}
structure
Test statistics, returned as a structure containing the following:
- tstat - Value of the test statistic.
- \(d f\) - Degrees of freedom of the test.
- sd - Estimated population standard deviation. For a paired \(t\)-test, this is the standard deviation of \(x \quad y\).

\section*{Examples Test for a Mean Equal to Zero}

Load the sample data. Create a vector containing the third column of the stock returns data.
load stockreturns;
x = stocks(: 3);
Test the null hypothesis that the sample data comes from a population with mean equal to zero.
```

[h,p,ci,stats] = ttest(x)
h =
1
p =
0.0106
ci =
-0.7357
-0.0997
stats =
tstat: -2.6065
df: 99
sd: 1.6027

```

The returned value \(h=1\) indicates that ttest rejects the null hypothesis at the \(5 \%\) significance level.

\section*{Test Hypothesis at a Different Significance Level}

Load the sample data. Create a vector containing the third column of the stock returns data.
load stockreturns;
x = stocks(: 3 );
Test the null hypothesis that the sample data are from a population with mean equal to zero at the \(1 \%\) significance level.
```

h = ttest(x,0,'Alpha',0.01)

```
h =

0
The returned value \(\mathrm{h}=0\) indicates that ttest does not reject the null hypothesis at the \(1 \%\) significance level.

\section*{Paired-Sample \(\boldsymbol{t}\)-Test}

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.
load examgrades;
\(x=\operatorname{grades}(:, 1)\);
y = grades(:,2);
Test the null hypothesis that the pairwise difference between data vectors \(x\) and \(y\) has a mean equal to zero.
```

[h,p] = ttest(x,y)
h =
0
p =
0.9805

```

The returned value of \(\mathrm{h}=0\) indicates that ttest does not reject the null hypothesis at the default \(5 \%\) significance level.

\section*{Paired-Sample \(\boldsymbol{t}\)-Test at a Different Significance Level}

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.
```

load examgrades;
x = grades(:,1);
y = grades(:,2);

```

Test the null hypothesis that the pairwise difference between data vectors \(x\) and \(y\) has a mean equal to zero at the \(1 \%\) significance level.
```

[h,p] = ttest(x,y,'Alpha',0.01)
h =
0
p =
0.9805

```

The returned value of \(h=0\) indicates that ttest does not reject the null hypothesis at the \(1 \%\) significance level.

\section*{Test for a Hypothesized Mean}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
```

load examgrades;
x = grades(:,1);

```

Test the null hypothesis that sample data comes from a distribution with mean \(\mathrm{m}=75\).
h = ttest \((x, 75)\)
h =

0
The returned value of \(\mathrm{h}=0\) indicates that ttest does not reject the null hypothesis at the \(5 \%\) significance level.

\section*{One-Sided Hypothesis Test}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
```

load examgrades;
x = grades(:,1);

```

Test the null hypothesis that the data comes from a population with mean equal to 65 , against the alternative that the mean is greater than 65 .
```

h = ttest(x,65,'Tail','right')
h =
1

```

The returned value of \(h=1\) indicates that ttest rejects the null hypothesis at the \(5 \%\) significance level, in favor of the alternate hypothesis that the data comes from a population with a mean greater than 65.

\section*{Definitions One-Sample \(\mathbf{t}\)-Test}

The one-sample \(t\)-test is a parametric test of the location parameter when the population standard deviation is unknown. The test statistic is
\[
t=\frac{\bar{x}-\mu}{s / \sqrt{n}},
\]
where \(\bar{x}\) is the sample mean, \(\mu\) is the hypothesized population mean, \(s\) is the sample standard deviation, and \(n\) is the sample size. Under the null hypothesis, the test statistic has Student's \(t\) distribution with \(n-1\) degrees of freedom.

\section*{Multidimensional Array}

A multidimensional array has more than two dimensions. For example, if \(x\) is a 1-by- 3 -by- 4 array, then \(x\) is a three-dimensional array.

\section*{First Nonsingleton Dimension}

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if \(x\) is a 1 -by- 2 -by- 3 -by- 4 array, then the second dimension is the first nonsingleton dimension of \(x\).

ztest | ttest2

Purpose \(\quad\) Two-sample \(t\)-test
\(\begin{array}{cl}\text { Syntax } \quad & h=\operatorname{ttest2}(x, y) \\ & h=\operatorname{ttest2}(x, y, \text { Name }, \text { Value }) \\ & {[h, p]=\operatorname{ttest2}(\ldots)} \\ & {[h, p, c i, \operatorname{stats}]=\text { ttest2 }(\ldots)}\end{array}\)

\section*{Description}

\section*{Input \\ Arguments}
\(\mathrm{h}=\mathrm{ttest2}(\mathrm{x}, \mathrm{y})\) returns a test decision for the null hypothesis that the data in vectors \(x\) and \(y\) comes from independent random samples from normal distributions with equal means and equal but unknown variances, using the two-sample \(t\)-test. The alternative hypothesis is that the data in x and y comes from populations with unequal means. The result h is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, and 0 otherwise.
\(\mathrm{h}=\) ttest2( \(\mathrm{x}, \mathrm{y}\), Name, Value) returns a test decision for the two-sample \(t\)-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct the test without assuming equal variances.
[h, p] = ttest2 (__) also returns the p-value, p , of the test, using any of the input arguments in the previous syntaxes.
[h, p, ci, stats] = ttest2(__) also returns the confidence interval on the difference of the population means, ci, and the structure stats containing information about the test statistic.

\section*{x-Sample data}
vector | matrix | multidimensional array
Sample data, specified as a vector, matrix, or multidimensional array. ttest2 treats NaN values as missing data and ignores them.
- If \(x\) and \(y\) are specified as vectors, they do not need to be the same length.
- If \(x\) and \(y\) are specified as matrices, they must have the same number of columns. ttest2 performs a separate \(t\)-test along each column and returns a vector of results.
- If \(x\) and \(y\) are specified as multidimensional arrays, they must have the same size along all but the first nonsingleton dimension.

\section*{Data Types}
single | double

\section*{\(y\)-Sample data}
vector | matrix | multidimensional array
Sample data, specified as a vector, matrix, or multidimensional array. ttest2 treats NaN values as missing data and ignores them.
- If \(x\) and \(y\) are specified as vectors, they do not need to be the same length.
- If \(x\) and \(y\) are specified as matrices, they must have the same number of columns. ttest2 performs a separate \(t\)-test along each column and returns a vector of results.
- If \(x\) and \(y\) are specified as multidimensional arrays, they must have the same size along all but the first nonsingleton dimension. ttest2 works along the first nonsingleton dimension.

\section*{Data Types}
single | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

Example: 'Tail','right','Alpha', 0.01,'Vartype', 'unequal' specifies a right-tailed test at the \(1 \%\) significance level, and does not assume that x and y have equal population variances.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

\section*{Example: 'Alpha',0.01}

\section*{Data Types}
single | double

\section*{'Dim' - Dimension}
first nonsingleton dimension (default) | positive integer value
Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim', 1 tests the column means, while 'Dim' , 2 tests the row means.

Example: 'Dim',2

\section*{Data Types \\ single | double}

\section*{'Tail' - Type of alternative hypothesis \\ 'both' (default) | 'right' | 'left'}

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.
\begin{tabular}{ll} 
'both ' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
means are not equal.
\end{tabular} \\
'right' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean of \(x\) is greater than the population mean of \(y\).
\end{tabular} \\
'left' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
mean of \(x\) is less than the population mean of \(y\).
\end{tabular}
\end{tabular}

Example: 'Tail','right'

\section*{'Vartype' - Variance type \\ 'equal' (default) | 'unequal'}

Variance type, specified as the comma-separated pair consisting of 'Vartype' and one of the following.
'equal' Conduct test using the assumption that x and y are from normal distributions with unknown but equal variances.
'unequal' Conduct test using the assumption that x and y are from normal distributions with unknown and unequal variances. This is called the Behrens-Fisher problem. ttest2 uses Satterthwaite's approximation for the effective degrees of freedom.

Vartype must be a single string, even when X is a matrix or a multidimensional array.

Example: 'Vartype','unequal

\section*{Output Arguments}

\section*{h - Hypothesis test result}

1|0
Hypothesis test result, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(h=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{p-p-value}
scalar value in the range \((0,1)\)
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.

\section*{ttest2}

\section*{ci - Confidence interval}

\section*{vector}

Confidence interval for the difference in population means of \(x\) and \(y\), returned as a two-element vector containing the lower and upper boundaries of the \(100 \times(1-\) Alpha \() \%\) confidence interval.

\section*{stats - Test statistics}

\section*{structure}

Test statistics for the two-sample \(t\)-test, returned as a structure containing the following:
- tstat - Value of the test statistic.
- \(d f\) - Degrees of freedom of the test.
- sd - Pooled estimate of the population standard deviation (for the equal variance case) or a vector containing the unpooled estimates of the population standard deviations (for the unequal variance case).

\section*{Examples}

\section*{Test for Equal Means}

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.
```

load examgrades;
x = grades(:,1);
y = grades(:,2);

```

Test the null hypothesis that the two data samples are from populations with equal means.
```

[h,p,ci,stats] = ttest2(x,y)
h =
0
p =
0.9867

```
```

ci =
-1.9438
1.9771
stats =
tstat: 0.0167
df: 238
sd: 7.7084

```

The returned value of \(\mathrm{h}=0\) indicates that ttest2 does not reject the null hypothesis at the default \(5 \%\) significance level.

\section*{Test for Equal Means Without Assuming Equal Variances}

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.
```

load examgrades;
x = grades(:,1);
y = grades(:,2);

```

Test the null hypothesis that the two data vectors are from populations with equal means, without assuming that the populations also have equal variances.
```

[h,p] = ttest2(x,y,'Vartype','unequal')
h =
0
p =
0.9867

```

The returned value of \(h=0\) indicates that ttest2 does not reject the null hypothesis at the default \(5 \%\) significance level even if equal variances are not assumed.

\section*{Definitions}

\section*{See Also}

\section*{Two-Sample t-test}

The two-sample \(t\)-test is a parametric test that compares the location parameter of two independent data samples. The test statistic is
\[
t=\frac{\bar{x}-\bar{y}}{\sqrt{\frac{s_{x}^{2}}{n}}+\frac{s_{y}^{2}}{m}},
\]
where \(\bar{x}\) and \(\bar{y}\) are the sample means, \(s_{x}\) and \(s_{y}\) are the sample standard deviations, and \(n\) and \(m\) are the sample sizes.

In the case where it is assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has Student's \(t\) distribution with \(n+m-2\) degrees of freedom, and the sample standard deviations are replaced by the pooled standard deviation
\[
s=\sqrt{\frac{(n-1) s_{x}^{2}+(m-1) s_{y}^{2}}{n+m-2}}
\]

In the case where it is not assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has an approximate Student's \(t\) distribution with a number of degrees of freedom given by Satterthwaite's approximation. This test is sometimes called Welch's \(t\)-test.

\section*{Multidimensional Array}

A multidimensional array has more than two dimensions. For example, if \(x\) is a 1-by-3-by-4 array, then \(x\) is a three-dimensional array.

\section*{First Nonsingleton Dimension}

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if \(x\) is a 1 -by- 2 -by- 3 -by- 4 array, then the second dimension is the first nonsingleton dimension of \(x\).
ttest | ztest

\section*{Purpose Tree type}

\section*{Syntax ttype \(=\) type \((t)\)}

Description ttype \(=\) type( \(t\) ) returns the type of the tree \(t\). ttype is 'regression ' for regression trees and 'classification' for classification trees.

\section*{Examples Create a classification tree for Fisher's iris data:}
```

load fisheriris;
t = classregtree(meas,species,...
'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
class = virginica
if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
class = virginica
class = versicolor
class = virginica

```
view(t)
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline Click to display: Identity & \(\checkmark\) & Magnification: & 100\% & & Pruning level: & 0 of 4 & - \\
\hline
\end{tabular}

```

ttype = type(t)
ttype =
classification

```

\section*{See Also \\ classregtree}
Purpose Type of partition
Description The type of validation partition. It is 'kfold', 'holdout', 'leaveout', or 'resubstitution'.
See Also ..... trainsize

\section*{qrandset.Type property}

Purpose Name of sequence on which point set \(P\) is based
Description P.Type returns a string that contains the name of the sequence on which the point set \(P\) is based, for example 'Sobol'. You cannot change the Type property for a point set.

\section*{Purpose Convert categorical array to unsigned 8-bit integers}
Syntax
B = uint8(A)

Description \(\quad B=\) uint8 \((A)\) converts the categorical array \(A\) to unsigned 8-bit integers. Each element of B contains the internal categorical level code for the corresponding element of A. Undefined elements of A are assigned the value 0 in \(B\). If A contains more than intmax ('uint8') levels, the internal codes will saturate to intmax ('uint8')when cast to int8.

See Also double | int8

\section*{categorical.uint 16}

Purpose Convert categorical array to unsigned 16-bit integers

\section*{Syntax \\ \(B=\) uint16(A)}

Description \(\quad B=\) uint16(A) converts the categorical array A to unsigned 16-bit integers. Each element of \(B\) contains the internal categorical level code for the corresponding element of \(A\).

Undefined elements of A are assigned the value 0 in B.
See Also double | int16

\title{
Purpose Convert categorical array to unsigned 32-bit integers
}
Syntax
\(B=\) uint32(A)

Description \(\quad B=\) uint32 \((A)\) converts the categorical array A to unsigned 32-bit integers. Each element of B contains the internal categorical level code for the corresponding element of \(A\).

Undefined elements of A are assigned the value 0 in B.
See Also double | int32

Purpose Convert categorical array to unsigned 64-bit integers

\section*{Syntax \\ \(B=\) uint64(A)}

Description
\(B=\) uint64 (A) converts the categorical array \(A\) to unsigned 64-bit integers. Each element of B contains the internal categorical level code for the corresponding element of \(A\).

Undefined elements of A are assigned the value 0 in B.
See Also
double | int64

Purpose Text label for undefined levels

\section*{prob.UniformDistribution}

Superclasses ParametricTruncatableDistribution
Purpose Uniform probability distribution object
Description prob.UniformDistribution is an object consisting of parameters and a model description for a uniform probability distribution. Create a probability distribution object with specified parameters using makedist.

Construction
pd = makedist('Uniform') creates a uniform probability distribution object using the default parameter values.
pd = makedist('Uniform','Lower',lower,'Upper', upper) creates a uniform distribution object using the specified parameter values.

\section*{Input Arguments}

\section*{lower - Lower parameter}

0 (default) | scalar value
Lower limit for the uniform distribution, specified as a scalar value.
```

Data Types
single | double
upper - Upper parameter
1 (default) | scalar value

```

Upper parameter for the uniform distribution, specified as a scalar value greater than lower.

\section*{Data Types}
single | double

\section*{Properties lower}

Lower parameter for the uniform distribution, stored as a scalar value.

\section*{Data Types \\ single | double \\ upper}

Upper parameter for the uniform distribution, stored as a scalar value greater than lower.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types}
char

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated.
If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{prob.UniformDistribution}

\section*{Data Types \\ char \\ ParameterNames}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types}
char

\section*{ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\section*{Data Types \\ single | double \\ Truncation}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.
```

Data Types
single | double

```

\section*{Definitions Uniform Distribution}

The uniform distribution has a constant probability density function between its two parameters, lower (the minimum) and upper (the maximum). This distribution is appropriate for representing round-off errors in values tabulated to a particular number of decimal places.

The uniform distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline lower & Lower parameter & \(-\infty<\) lower \(<\) upper \\
\hline upper & \begin{tabular}{l} 
Upper \\
parameter
\end{tabular} & lower \(<\) upper \(<\infty\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid \text { lower }, \text { upper })=\left(\frac{1}{\text { upper }- \text { lower }}\right) ; \quad \text { lower } \leq x \leq \text { upper }
\]

\section*{prob.UniformDistribution}
and 0 otherwise.

\section*{Examples Parameters \\ pd = makedist('Uniform') \\ pd \(=\) \\ UniformDistribution \\ Uniform distribution \\ Lower = 0 \\ Upper \(=1\)}

Create a Uniform Distribution Object Using Default

Create a uniform distribution object using the default parameter values.

\section*{Create a Uniform Distribution Object Using Specified Parameters}

Create a uniform distribution object by specifying parameter values.

- Property Attributes

Purpose
Set union for dataset array observations
Syntax
\(C=u n i o n(A, B)\)
\(C=\) union( \(A, B\), vars)
C = union(A, B, vars, setOrder)
[C,iA,iB] = union(__ )

Input
Arguments
\(C=\) union \((A, B)\) for dataset arrays \(A\) and \(B\) returns the combined set of observations from the two arrays, with repetitions removed. The observations in the dataset array C are sorted.
\(C=\) union( \(A, B\), vars) returns the combined set of observations from the two arrays, with repetitions of unique combinations of the variables specified in vars removed. The observations in the dataset array C are sorted by those variables.

The values for variables not specified in vars for each observation in \(C\) are taken from the corresponding observation in \(A\) or \(B\), or from \(A\) if there are common observations in both \(A\) and \(B\). If there are multiple observations in \(A\) or \(B\) that correspond to an observation in \(C\), those values are taken from the first occurrence.
\(C=\) union(A, B, vars, setOrder) returns the observations in \(C\) in the order specified by setOrder.
[C,iA, iB] = union(__) also returns index vectors iA and iB such that \(C\) is a sorted combination of the values \(A(i A,:)\) and \(B(i B,:)\). If there are common observations in \(A\) and \(B\), then union returns only the index from \(A\), in iA. If there are repeated observations in \(A\) or \(B\), then the index of the first occurrence is returned. You can use any of the previous input arguments.

\section*{A,B}

Input dataset arrays.

\section*{vars}

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating
the variables for which union removes repetitions of unique combinations of the variables.

Specify vars as [] to use its default value of all variables.

\section*{setOrder}

Flag indicating the sorting order for the observations in C. The possible values of setOrder are:
\begin{tabular}{ll} 
'sorted' & \begin{tabular}{l} 
Observations in C are in sorted order \\
(default).
\end{tabular} \\
'stable ' & \begin{tabular}{l} 
Observations in C are in the same order that \\
they appear in A, then B.
\end{tabular}
\end{tabular}

\section*{Output}

Arguments

\section*{Examples Union of Two Dataset Arrays}

Load sample data.
```

A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);

```

\section*{dataset.union}
[length(A) length(B)]
ans =

148

The first dataset array, A, has 14 observations. The second dataset array, \(B\), has 8 observations.

Return the union.
\(C=\) union \((A, B)\);
length(C)
ans =
21

The union of the two dataset arrays has 21 observations, indicating that there was one observation replicated in A and B.

\section*{Purpose}

Unique observations in dataset array

Note In a future release, the behavior of dataset. unique will change to be consistent with the MATLAB function unique. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for unique.

Syntax
\(C=\) unique \((A)\)
[C,ia,ic] = unique( \(A\) )
\(C=\) unique ( \(A\), vars)
[C,ia,ic] = unique(A,vars)
[...] = unique(A,vars,occurrence)
[...] = unique(...,'R2012a')
[...] = unique(...,'legacy')
[...] = unique(A, vars,setOrder)
Description
\(C=\) unique (A) returns a copy of the dataset \(A\) that contains only the sorted unique observations. A must contain only variables whose class has a unique method, including:
- numeric
- character
- logical
- categorical
- cell arrays of strings

For a variable with multiple columns, its class's unique method must support the 'rows ' flag.
[C,ia,ic] = unique (A) also returns index vectors ia and ic such that \(C=A(i a,:)\) and \(A=C(i c,:)\).
\(C=\) unique (A, vars) returns a dataset that contains only one observation for each unique combination of values for the variables in \(A\) specified in vars. vars is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. C includes all variables from A. The values in C for the variables not specified in vars are taken from the last occurrence among observations in A with each unique combination of values for the variables specified in vars.
[C,ia,ic] = unique(A,vars) also returns index vectors ia and ic such that \(C=A(i a,:)\) and \(A(:, v a r s)=C(i c, v a r s)\).
[...] = unique(A, vars, occurrence) specifies which index is returned in ia in the case of repeated observations in \(A\). The default value is occurrence='last', which returns the index of the last occurrence of each repeated observation in A. occurrence='first' returns the index of the first occurrence of each repeated observation in \(A\). The values in \(C\) for variables not specified in vars are taken from the observations A(ia,:). Specify vars as [] to use the default value of all variables.
[...] = unique(...,'R2012a') adopts the future behavior of unique. You can specify the flag as the final argument with any previous syntax that accepts A, vars, or occurrence.
[...] = unique(...,'legacy') preserves the current behavior of unique. You can specify the flag as the final argument with any previous syntax that accepts A, vars, or occurrence.
[...] = unique(A, vars, setOrder) returns the observations of \(C\) in a specific order. setOrder='sorted' returns the values of C in sorted order. setOrder='stable' returns the values of \(C\) in the same order as A. If there are repeated observations in \(A\), then ia returns the index of the first occurrence of each repeated observation. Specify vars as [] to use the default value of all variables.

Purpose Units of variables in data set
Description A cell array of strings giving the units of the variables in the data set. This property may be empty, but if not empty, the number of strings must equal the number of variables. Any individual string may be empty for a variable that does not have units defined. The default is an empty cell array.

Purpose Discrete uniform cumulative distribution function

\section*{Syntax \(\quad P=\operatorname{unidcdf}(X, N)\)}

Description
\(P=u n i d c d f(X, N)\) computes the discrete uniform cdf at each of the values in \(X\) using the corresponding maximum observable value in \(N . X\) and \(N\) can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The maximum observable values in \(N\) must be positive integers.

The discrete uniform cdf is
\[
p=F(x \mid N)=\frac{\text { floor }(x)}{N} I_{(1, \ldots, N)}(x)
\]

The result, \(p\), is the probability that a single observation from the discrete uniform distribution with maximum \(N\) will be a positive integer less than or equal to \(x\). The values \(x\) do not need to be integers.

Examples What is the probability of drawing a number 20 or less from a hat with the numbers from 1 to 50 inside?
```

probability = unidcdf(20,50)
probability =
0.4000

```
See Also cdf \| unidpdf \| unidinv \| unidstat \| unidrnd | mle
How To . "Uniform Distribution (Discrete)" on page B-114
```

Purpose Discrete uniform inverse cumulative distribution function
Syntax $\quad X=\operatorname{unidinv}(P, N)$
Description $\quad X=$ unidinv $(P, N)$ returns the smallest positive integer $X$ such that the
discrete uniform cdf evaluated at $X$ is equal to or exceeds $P$. You can
think of $P$ as the probability of drawing a number as large as $X$ out of a
hat with the numbers 1 through $N$ inside.
P and $N$ can be vectors, matrices, or multidimensional arrays that have
the same size, which is also the size of X . A scalar input for N or P is
expanded to a constant array with the same dimensions as the other
input. The values in $P$ must lie on the interval [01] and the values in $N$
must be positive integers.
Examples $\quad x=\operatorname{unidinv}(0.7,20)$
$\mathrm{x}=$
14
$y=u n i d i n v(0.7+e p s, 20)$
y $=$
15

```

A small change in the first parameter produces a large jump in output. The cdf and its inverse are both step functions. The example shows what happens at a step.

How To - "Uniform Distribution (Discrete)" on page B-114

\section*{unidpdf}

Purpose Discrete uniform probability density function

\section*{Syntax \(\quad Y=\operatorname{unidpdf}(X, N)\)}

Description
\(Y=u n i d p d f(X, N)\) computes the discrete uniform pdf at each of the values in \(X\) using the corresponding maximum observable value in \(N . X\) and \(N\) can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in \(N\) must be positive integers.

The discrete uniform pdf is
\[
y=f(x \mid N)=\frac{1}{N} I_{(1, \ldots, N)}(x)
\]

You can think of \(y\) as the probability of observing any one number between 1 and \(n\).

\section*{Examples For fixed n, the uniform discrete pdf is a constant.}
```

y = unidpdf(1:6,10)
y =
0.1000}00.1000 0.1000 0.1000 0.1000 0.1000

```

Now fix x , and vary n .
```

likelihood = unidpdf(5,4:9)
likelihood =

| 0 | 0.2000 | 0.1667 | 0.1429 | 0.1250 | 0.1111 |
| :--- | :--- | :--- | :--- | :--- | :--- |

\section*{Purpose}

Continuous uniform cumulative distribution function

\section*{Syntax \\ \(P=\operatorname{unifcdf}(X, A, B)\)}
\(P=\) unifcdf \((X, A, B)\) computes the uniform cdf at each of the values in \(X\) using the corresponding lower endpoint (minimum), A and upper endpoint (maximum), B. X, A, and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

The uniform cdf is
\[
p=F(x \mid a, b)=\frac{x-a}{b-a} I_{[a, b]}(x)
\]

The standard uniform distribution has \(\mathrm{A}=0\) and \(\mathrm{B}=1\).

\section*{Examples}

What is the probability that an observation from a standard uniform distribution will be less than 0.75 ?
```

probability = unifcdf(0.75)
probability =
0.7500

```

What is the probability that an observation from a uniform distribution with \(a=-1\) and \(b=1\) will be less than 0.75 ?
```

probability = unifcdf(0.75,-1,1)
probability =
0.8750

```

Purpose Set union for categorical arrays

Note In a future release, the behavior of categorical. union will change to be consistent with the MATLAB function union. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for union.

Syntax
\(C=\) union \((A, B)\)
[C,IA,IB] = union(A,B)
[...] \(=\) union( \(A, B\), 'rows')
[...] = union(...,'R2012a')
[...] = union(...,'legacy')
[...] = union(A,B,setOrder)
[...] = union(A, B,'rows',setOrder)

\section*{Description}
\(C=\) union ( \(A, B\) ) for categorical vectors \(A\) and \(B\), returns a categorical vector \(C\) containing the combined values from \(A\) and \(B\) with no repetitions. The result \(C\) is sorted. The set of categorical levels for \(C\) is the sorted union of the sets of levels of the inputs, as determined by their labels.
\([C, I A, I B]=\) union \((A, B)\) also returns index vectors IA and IB such that \(C\) is a sorted combination of the elements \(A(I A)\) and \(B(I B)\). If there are common values in \(A\) and \(B\), then the index is returned in IB. If there are repeated values in \(A\) or \(B\), then the index of the last occurrence of each repeated value is returned.
\([\ldots]=\) union( \(A, B\), 'rows') for categorical matrices \(A\) and \(B\) with the same number of columns, returns the combined rows from the two matrices with no repetitions. The rows of the matrix C are sorted. The set of categorical levels for \(C\) is the sorted union of the sets of levels of the inputs. The optional outputs IA and IB are index vectors such that \(C\) is the sorted combination of the rows \(C=A(I A,:)\) and \(C=B(I B,:)\).
[...] = union(...,'R2012a') adopts the future behavior of union. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.
[...] = union(...,'legacy') preserves the current behavior of union. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows '.
[...] = union(A,B,setOrder) and [...] =
union( \(\mathrm{A}, \mathrm{B}\), 'rows', setOrder) returns the observations of C in a specific order. setOrder='sorted' returns the values or rows of \(C\) in sorted order. setOrder='stable' returns the values or rows of C in the same order as \(A\), then \(B\). If A and B are row vectors, then \(C\) is also a row vector. Otherwise, \(C\) is a column vector. IA and IB are column vectors. If there are repeated common values in \(A\) or \(B\), then the index of the first occurrence of each repeated value is returned.

intersect | ismember | setdiff | setxor | unique

Purpose Unique values in categorical array

Note In a future release, the behavior of categorical. unique will change to be consistent with the MATLAB function unique. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for unique.

Syntax
\(C=\) unique \((A)\)
[C, IA, IC] = unique( A )
[...] = unique(A,'rows')
[...] = unique(A,occurrence)
[...] = unique(A, 'rows',occurrence)
[...] = unique(...,'R2012a')
[...] = unique(...,'legacy')
[...] = unique(A,setOrder)
[...] = unique(A, 'rows', setOrder)

\section*{Description}
\(C=\) unique (A) returns a categorical array containing the same values as in A but with no repetitions. C is sorted by the order of A's levels.
[C,IA, IC] = unique(A) also returns index vectors IA and IC such that \(C=A(I A)\) and \(A=C(I C)\).
[...] = unique (A, 'rows') for the categorical matrix A returns the unique rows of \(A\). The rows of the matrix \(C\) are sorted by the order of A's levels. The optional outputs IA and IC are index vectors such that \(C=A(I A,:)\) and \(A=C(I C,:)\).
[...] = unique(A,occurrence) and [...] = unique ( \(A\), 'rows' , occurrence) specify which index is returned in IA in the case of repeated values or rows in A. The default value is occurrence='last', which returns the index of the last occurrence of each repeated value or row in \(A\). occurrence='first' returns the index of the first occurrence of each repeated value or row in \(A\).
[...] = unique(...,'R2012a') adopts the future behavior of unique. You can specify the flag as the final argument with any previous syntax that accepts A, 'rows', or occurrence.
[...] = unique(...,'legacy') preserves the current behavior of unique. You can specify the flag as the final argument with any previous syntax that accepts A, 'rows', or occurrence.
[...] = unique(A,setOrder) and [...] = unique ( A, 'rows ', setOrder) returns the values or rows of C in a specific order. setOrder='sorted' returns the values or rows of \(C\) in sorted order. setOrder='stable' returns the values or rows of C in the same order as \(A\). If \(A\) is a row vector, then \(C\) is also a row vector. Otherwise, C is a column vector. IA and IC are column vectors. If there are repeated values in A, then IA returns the index of the first occurrence of each repeated value.

Purpose
Unstack data from single variable into multiple variables
Syntax

\section*{Description}
wide = unstack(tall,datavar,indvar)
[wide,itall] = unstack(tall,datavar,indvar)
wide = unstack(tall,datavar,indvar,'Parameter',value)
wide \(=\) unstack(tall, datavar, indvar) converts a dataset array tall to an equivalent dataset array wide that is in wide format, by unstacking a single variable in tall into multiple variables in wide. In general wide contains more variables, but fewer observations, than tall.
datavar specifies the data variable in tall to unstack. indvar specifies an indicator variable in tall that determines which variable in wide each value in datavar is unstacked into. unstack treats the remaining variables in tall as grouping variables. Each unique combination of their values defines a group of observations in tall that will be unstacked into a single observation in wide.
unstack creates \(m\) data variables in wide, where \(m\) is the number of group levels in indvar. The values in indvar indicate which of those \(m\) variables receive which values from datavar. The \(j\)-th data variable in wide contains the values from datavar that correspond to observations whose indvar value was the \(j\)-th of the \(m\) possible levels. Elements of those m variables for which no corresponding data value in tall exists contain a default value.
datavar is a positive integer, a variable name, or a logical vector containing a single true value. indvar is a positive integer, a variable name, or a logical vector containing a single true value.
[wide,itall] = unstack(tall,datavar,indvar) returns an index vector itall indicating the correspondence between observations in wide and those in tall. For each observation in wide, itall contains the index of the first in the corresponding group of observations in tall.

For more information on grouping variables, see "Grouping Variables" on page 2-51.
wide = unstack(tall,datavar,indvar,'Parameter',value) uses the following parameter name/value pairs to control how unstack converts variables in tall to variables in wide:
\(\left.\begin{array}{l|l}\hline \text { 'GroupVars' } & \begin{array}{l}\text { Grouping variables in tall that define groups } \\ \text { of observations. groupvars is a positive } \\ \text { integer, a vector of positive integers, a variable } \\ \text { name, a cell array containing one or more } \\ \text { variable names, or a logical vector. The default } \\ \text { is all variables in tall not listed in datavar } \\ \text { or indvar. }\end{array} \\ \hline \text { 'NewDataVarNames ' } & \begin{array}{l}\text { A cell array of strings containing names for the } \\ \text { data variables unstack should create in wide. } \\ \text { Default is the group names of the grouping } \\ \text { variable specified in indvar. }\end{array} \\ \hline \text { 'AggregationFun' } & \begin{array}{l}\text { A function handle that accepts a subset of } \\ \text { values from datavar and returns a single value. } \\ \text { stack applies this function to observations from } \\ \text { the same group that have the same value of } \\ \text { indvar. The function must aggregate the data } \\ \text { values into a single value, and in such cases } \\ \text { it is not possible to recover tall from wide } \\ \text { using stack. The default is @sum for numeric } \\ \text { data variables. For non-numeric variables, } \\ \text { there is no default, and you must specify }\end{array} \\ \text { 'AggregationFun' if multiple observations } \\ \text { in the same group have the same values of } \\ \text { indvar. }\end{array}\right\}\)
\begin{tabular}{l|l} 
& \begin{tabular}{l} 
containing one or more variable names, or a \\
logical vector. The default is no variables.
\end{tabular} \\
\hline
\end{tabular}

You can also specify more than one data variable in tall, each of which becomes a set of \(m\) variables in wide. In this case, specify datavar as a vector of positive integers, a cell array containing variable names, or a logical vector. You may specify only one variable with indvar. The names of each set of data variables in wide are the name of the corresponding data variable in tall concatenated with the names specified in 'NewDataVarNames'. The function specified in 'AggregationFun' must return a value with a single row.

\section*{Examples}

Convert a "wide format" data set to "tall format", and then back to a different "wide format":
load flu
\% FLU has a 'Date' variable, and 10 variables for estimated \% influenza rates (in 9 different regions, estimated from \% Google searches, plus a nationwide extimate from the \% CDC). Combine those 10 variables into a "tall" array that
\% has a single data variable, 'FluRate', and an indicator
\% variable, 'Region', that says which region each estimate
\% is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName', 'Region')
\% The second observation in FLU is for \(10 / 16 / 2005\). Find the
\% observations in FLU2 that correspond to that date.
flu(2,:)
flu2(iflu==2,:)
\% Use the 'Date' variable from that tall array to split
\% 'FluRate' into 52 separate variables, each containing the
\% estimated influenza rates for each unique date. The new
\% "wide" array has one observation for each region. In
\% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
```

[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
'NewDataVarNames', dateNames)
% Since observations in FLU3 represent regions, IFLU2
% indicates the first occurrence in FLU2 of each region.
flu2(iflu2,:)

```

```

How To . "Grouping Variables" on page 2-51
Purpose Upper Pareto tails parameters
Syntax params = upperparams(obj)
Description params \(=\) upperparams \((\mathrm{obj})\) returns the 2 -element vector params ofshape and scale parameters, respectively, of the upper tail of the Paretotails object obj. upperparams does not return a location parameter.
Examples Fit Pareto tails to a \(t\) distribution at cumulative probabilities 0.1 and ..... 0.9:
```

t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
lowerparams(obj)
ans =
-0.1901 1.1898
upperparams(obj)
ans =
0.3646 0.5103

```

\(\begin{array}{ll}\text { Purpose } & \text { Variable containing additional information associated with data set } \\ \text { Description } & \begin{array}{l}\text { Any variable containing additional information to be associated with } \\ \text { the data set. The default is an empty array. }\end{array}\end{array}\)

\section*{prob.KernelDistribution.var}

Purpose Variance of probability distribution object
Syntax \(\quad v=\operatorname{var}(p d)\)
Description \(\quad v=\operatorname{var}(\mathrm{pd})\) returns the variance v of the probability distribution pd .
Input
Arguments
pd - Probability distribution
probability distribution object
Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using fitdist or dfittool.

\section*{Output \\ Arguments}

\section*{v-Variance}
nonnegative scalar value
Variance of the probability distribution, returned as a nonnegative scalar value.

\section*{Examples Variance of a Fitted Distribution}

Load the sample data. Create a vector containing the first column of students' exam grade data.
```

load examgrades;
x = grades(:,1);

```

Fit a kernel distribution object to the data.
```

pd = fitdist(x,'Kernel')
pd =

```

KernelDistribution
Kernel = normal
Bandwidth = 3.61677
Support = unbounded

Compute the variance of the fitted distribution.
```

v = var(pd)
v =

```
88.4893

\section*{See Also \\ fitdist | dfittool}

\section*{ProbDistUnivParam.var}
Purpose Return variance of ProbDistUnivParam object
Syntax \(V=\operatorname{var}(P D)\)
Description \(V=\operatorname{var}(P D)\) returns \(V\), the variance of the ProbDistUnivParam object \(P D\).
Input ..... \(P D\)
An object of the class ProbDistUnivParam. Arguments
Output ..... V
Arguments
See Also ..... var

\section*{Purpose Variance of probability distribution object}
Syntax
\(\mathrm{v}=\operatorname{var}(\mathrm{pd})\)

Description \(\quad \mathrm{v}=\operatorname{var}(\mathrm{pd})\) returns the variance v of the probability distribution pd .

\section*{Input pd - Probability distribution \\ Arguments \\ probability distribution object}

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using makedist.

\section*{Output v-Variance \\ Arguments \\ nonnegative scalar value}

Variance of the probability distribution, returned as a nonnegative scalar value.

\section*{Examples Variance of a Triangular Distribution}

Create a triangular distribution object.
```

pd = makedist('Triangular','a',-3,'b',1,'c',3)

```
pd \(=\)

TriangularDistribution
\(A=-3, B=1, C=3\)
Compute the variance of the distribution.
\(v=\operatorname{var}(p d)\)

Purpose
Description

Cell array of strings giving descriptions of variables in data set

A cell array of strings giving the descriptions of the variables in the data set. This property may be empty, but if not empty, the number of strings must equal the number of variables. Any individual string may be empty for a variable that does not have a description defined. The default is an empty cell array.

\section*{classregtree.varimportance}

Purpose Compute embedded estimates of input feature importance
```

Syntax imp = varimportance(t)

```

Description imp = varimportance( \(t\) ) computes estimates of input feature importance for tree \(t\) by summing changes in the risk due to splits on every feature. The returned vector imp has one element for each input variable in the data used to train this tree. At each node, the risk is estimated as node impurity if impurity was used to split nodes and node error otherwise. This risk is weighted by the node probability. Variable importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

\section*{See Also \\ risk}

Purpose Cell array giving names of variables in data set
Description A cell array of nonempty, distinct strings giving the names of the variables in the data set. The number of strings must equal the number of variables. The default is the cell array of string names for the variables used to create the data set.

\section*{TreeBagger.VarNames property}

Purpose Variable names
Description The VarNames property is a cell array containing the names of the predictor variables (features). TreeBagger takes these names from the optional 'names' parameter. The default names are 'x1', 'x2', etc.

\section*{Purpose}

Chi-square variance test
Syntax
\(h=\operatorname{vartest}(x, v)\)
h = vartest(x, v,Name, Value)
[h, p] = vartest(__)
[h,p,ci,stats] = vartest( __ )

Description

\section*{Input Arguments}
\(h=\) vartest \((x, v)\) returns a test decision for the null hypothesis that the data in vector \(x\) comes from a normal distribution with variance \(v\), using the chi-square variance test. The alternative hypothesis is that \(x\) comes from a normal distribution with a different variance. The result h is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, and 0 otherwise.
\(h\) = vartest(x,v,Name, Value) performs the chi-square variance test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.
[h, p] = vartest( __ ) also returns the \(p\)-value of the test, p , using any of the input arguments in the previous syntaxes.
[h,p,ci, stats] = vartest(__) also returns the confidence interval for the true variance, ci , and the structure stats containing information about the test statistic.

\section*{x-Sample data}
vector | matrix | multidimensional array
Sample data, specified as a vector, matrix, or multidimensional array. For matrices, vartest performs separate tests along each column of x, and returns a row vector of results. For multidimensional arrays, vartest works along the first nonsingleton dimension of \(x\).
```

Data Types
single | double

```

\section*{v-Hypothesized variance \\ nonnegative scalar value}

Hypothesized variance, specified as a nonnegative scalar value.

\section*{Data Types \\ single | double}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Tail', 'right', 'Alpha', 0.01 specifies a right-tailed hypothesis test at the \(1 \%\) significance level.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

Example: 'Alpha',0.01

\section*{Data Types}
single | double

\section*{'Dim' - Dimension}
first nonsingleton dimension (default) | positive integer value
Dimension of the input matrix to test along, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim', 1 tests the data in each column for equality to the hypothesized variance, while 'Dim' , 2 tests the data in each row.

Example: 'Dim',2

\section*{Data Types \\ single | double \\ 'Tail' - Type of alternative hypothesis \\ 'both' (default) | 'right' | 'left'}

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.
\begin{tabular}{ll} 
'both' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
variance is not \(v\).
\end{tabular} \\
'right ' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
variance is greater than \(v\).
\end{tabular} \\
'left' & \begin{tabular}{l} 
Test the alternative hypothesis that the population \\
variance is less than \(v\).
\end{tabular}
\end{tabular}

Example: 'Tail','right'

\section*{Output \\ h - Hypothesis test result \\ Arguments \\ 1| 0 .}

Hypothesis test result, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(\mathrm{h}=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{p-p-value}
scalar value in the range \((0,1)\)
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.

\section*{ci - Confidence interval}

\section*{vector}

Confidence interval for the true variance, returned as a two-element vector containing the lower and upper boundaries of the \(100 \times(1-\) Alpha)\% confidence interval.

\section*{stats - Test statistics}

\section*{structure}

Test statistics for the chi-square variance test, returned as a structure containing:
- chisqstat - Value of the test statistic.
- df - Degrees of freedom of the test.

\section*{Examples \\ Test for a Specified Variance}

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.
```

load examgrades;
x = grades(:,1);

```

Test the null hypothesis that the data comes from a distribution with a variance of 25 .
```

[h,p,ci,stats] = vartest(x,25)
h =
1
p =
0
ci =
59.8936
99.7688
stats =

```

The returned value \(\mathrm{h}=1\) indicates that vartest rejects the null hypothesis at the default \(5 \%\) significance level. ci shows the lower and upper boundaries of the \(95 \%\) confidence interval for the true variance, and suggests that the true variance is greater than 25.

\section*{One-Sided Hypothesis Test}

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.
```

load examgrades;
x = grades(:,1);

```

Test the null hypothesis that the data comes from a distribution with a variance of 25 , against the alternative hypothesis that the variance is greater than 25.
```

[h,p] = vartest(x,25,'Tail','right')
h =
1
p =
2.4269e-26

```

The returned value of \(h=1\) indicates that vartest rejects the null hypothesis at the default \(5 \%\) significance level, in favor of the alternative hypothesis that the variance is greater than 25 .

\section*{Definitions Chi-Square Variance Test}

The chi-square variance test is used to test if the variance of a population is equal to a hypothesized value.

The test statistic is
\[
T=\frac{(N-1)}{\left(\frac{s}{\sigma_{0}}\right)^{2}}
\]
where \(N\) is the sample size, \(s\) is the sample standard deviation, and \(\sigma_{0}\) is the hypothesized standard deviation. The denominator is the ratio of the sample standard deviation to the hypothesized standard deviation. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. The test statistic \(T\) has a chi-square distribution with \(N-1\) degrees of freedom under the null hypothesis.

\section*{Multidimensional Array}

A multidimensional array has more than two dimensions. For example, if \(x\) is a 1-by-3-by-4 array, then \(x\) is a three-dimensional array.

\section*{First Nonsingleton Dimension}

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of \(x\).

\section*{Purpose}

Two-sample \(F\)-test for equal variances
Syntax
h = vartest2(x,y)
h = vartest2(x,y,Name, Value)
[h, p] = vartest2(___)
[h,p,ci,stats] = vartest2( __ )

Description

\section*{Input Arguments}
\(\mathrm{h}=\) vartest2 \((\mathrm{x}, \mathrm{y})\) returns a test decision for the null hypothesis that the data in vectors x and y comes from normal distributions with the same variance, using the two-sample \(F\)-test. The alternative hypothesis is that they come from normal distributions with different variances. The result \(h\) is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, and 0 otherwise.
\(\mathrm{h}=\) vartest2( \(\mathrm{x}, \mathrm{y}\), Name, Value) returns a test decision for the two-sample \(F\)-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.
[h, p] = vartest2 ( __ ) also returns the \(p\)-value of the test, p , using any of the input arguments in the previous syntaxes.
[h,p,ci,stats] = vartest2( __ ) also returns the confidence interval for the true variance ratio, ci , and the structure stats containing information about the test statistic.

\section*{x-Sample data}
vector | matrix | multidimensional array
Sample data, specified as a vector, matrix, or multidimensional array.
- If \(x\) and \(y\) are vectors, they do not need to be the same length.
- If \(x\) and \(y\) are matrices, they must have the same number of columns, but do not need to have the same number of rows. vartest2 performs separate tests along each column and returns a vector of the results.
- If \(x\) and \(y\) are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension.

\section*{Data Types \\ single | double}

\section*{\(y\)-Sample data}
vector | matrix | multidimensional array
Sample data, specified as a vector, matrix, or multidimensional array.
- If \(x\) and \(y\) are vectors, they do not need to be the same length.
- If \(x\) and \(y\) are matrices, they must have the same number of columns, but do not need to have the same number of rows. vartest2 performs separate tests along each column and returns a vector of the results.
- If \(x\) and \(y\) are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension.

\section*{Data Types \\ single | double}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Tail', 'right','Alpha', 0.01 specifies a right-tailed hypothesis test at the \(1 \%\) significance level.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

Example: 'Alpha', 0.01

\section*{Data Types}
single | double

\section*{'Dim' - Dimension}
first nonsingleton dimension (default) | positive integer value
Dimension of the input matrix to test along, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim', 1 tests the data in each column for variance equality, while 'Dim' , 2 tests the data in each row.

Example: 'Dim',2

\section*{Data Types}
single | double

\section*{'Tail' - Type of alternative hypothesis \\ 'both' (default) | 'right' | 'left'}

Type of alternative hypothesis to evaluate using the \(F\)-test, specified as the comma-separated pair consisting of 'Tail' and one of the following.
\[
\begin{array}{ll}
\text { 'both' } & \begin{array}{l}
\text { Test the alternative hypothesis that the population } \\
\text { variances are not equal. }
\end{array} \\
\text { 'right' } & \begin{array}{l}
\text { Test the alternative hypothesis that the population } \\
\text { variance of } x \text { is greater than that of } y .
\end{array} \\
\text { 'left' } & \begin{array}{l}
\text { Test the alternative hypothesis that the population } \\
\text { variance of } x \text { is less than that of } y .
\end{array}
\end{array}
\]

\section*{Example: 'Tail','right'}

\section*{Output h-Hypothesis test result Arguments \\ 1|0}

Hypothesis test result, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(h=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{p-p-value}
scalar value in the range \((0,1)\)
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.

\section*{ci - Confidence interval}
vector
Confidence interval for the true ratio of the population variances, returned as a two-element vector containing the lower and upper boundaries of the \(100 \times(1-\) Alpha \() \%\) confidence interval.

\section*{stats - Test statistics}
structure
Test statistics for the hypothesis test, returned as a structure containing:
- fstat - Value of the test statistic.
- df1 - Numerator degrees of freedom of the test.
- df2 - Denominator degrees of freedom of the test.

\section*{Examples Test for Equal Variances}

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.
```

load examgrades;
x = grades(:,1);
y = grades(:,2);

```

Test the null hypothesis that the data in x and y comes from distributions with the same variance.
```

[h,p,ci,stats] = vartest2(x,y)
h =
1
p =
0.0019
ci =
1.2383
2.5494
stats =
fstat: 1.7768
df1: 119
df2: }11

```

The returned result \(\mathrm{h}=1\) indicates that vartest2 rejects the null hypothesis at the default \(5 \%\) significance level. ci contains the lower and upper boundaries of the \(95 \%\) confidence interval for the true variance ratio. stats contains the value of the test statistic for the \(F\)-test and the numerator and denominator degrees of freedom.

\section*{One-Sided Hypothesis Test}

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.
```

load examgrades;
x = grades(:,1);
y = grades(:,2);

```

Test the null hypothesis that the data in x and y comes from distributions with the same variance, against the alternative that the population variance of \(x\) is greater than that of \(y\).
```

vartest2(x,y,'Tail','right')
h =
1
p =
9.4364e-04

```

The returned result \(\mathrm{h}=1\) indicates that vartest2 rejects the null hypothesis at the default \(5 \%\) significance level, in favor of the alternative hypothesis that the population variance of \(x\) is greater than that of \(y\).

\section*{Definitions}

\section*{Two-Sample F-Test}

The two-sample \(F\)-test is used to test if the variances of two populations are equal. The test statistic is
\[
F=\frac{s_{1}^{2}}{s_{2}{ }^{2}},
\]
where \(s_{1}\) and \(s_{2}\) are the sample variances. The test statistic is a ratio of the two sample variances. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. Under the null hypothesis, the test statistic \(F\) has a \(F\)-distribution with numerator degrees of freedom equal to \(N_{1}-1\) and denominator degrees of freedom equal to \(N_{2}-1\), where \(N_{1}\) and \(N_{2}\) are the sample sizes of the two data sets.

\section*{Multidimensional Array}

A multidimensional array has more than two dimensions. For example, if \(x\) is a 1-by-3-by-4 array, then \(x\) is a three-dimensional array.

\section*{First Nonsingleton Dimension}

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if x is a 1 -by- 2 -by- 3 -by- 4 array, then the second dimension is the first nonsingleton dimension of \(x\).

\section*{See Also \\ vartest | vartestn}

Purpose Multiple-sample tests for equal variances

\author{
Syntax \\ \section*{Description}
}
vartestn(x)
vartestn(x,Name, Value)
vartestn(x,group)
vartestn(x, group, Name, Value)
\(\mathrm{p}=\) vartestn (__)
[p,stats] = vartestn( __ )
vartestn( x ) returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the columns of data vector \(x\) come from normal distributions with the same variance. The alternative hypothesis is that not all columns of data have the same variance.
vartestn ( \(x\), Name, Value) returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.
vartestn ( \(x\), group) returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the data in each categorical group comes from normal distributions with the same variance. The alternative hypothesis is that not all groups have the same variance.
vartestn(x, group, Name, Value) returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.
\(\mathrm{p}=\) vartestn ( __ ) also returns the \(p\)-value of the test, p , using any of the input arguments in the previous syntaxes.
[p,stats] = vartestn( __ ) also returns the structure stats containing information about the test statistic.

\section*{Input Arguments}

\section*{x-Sample data}
matrix | vector
Sample data, specified as a matrix or vector. If a grouping variable group is specified, \(x\) must be a vector. If a grouping variable is not specified, \(x\) must be a matrix. In either case, vartestn treats NaN values as missing values and ignores them.

\section*{Data Types}
single | double

\section*{group-Grouping variable}
categorical array | logical or numeric vector | cell array of strings
Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings with one row for each element of x. Each unique value in a grouping variable defines a group.
For example, if Gender is a cell array of strings with values 'Male' and 'Female', you can use Gender as a grouping variable to test your data by gender.

Example: Gender
Data Types
single | double | logical | cell | char

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example:
'TestType','BrownForsythe', 'Alpha',0.01,'Display', 'off'
specifies a Brown-Forsythe test at the \(1 \%\) significance level, and omits the plot of the results.

\section*{'Alpha' - Significance level}

\subsection*{0.05 (default) | scalar value in the range ( 0,1 )}

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

Example: 'Alpha',0.01

\section*{Data Types}
single | double

\section*{'Dim' - Dimension}
first nonsingleton dimension (default) | positive integer value
Dimension of the input matrix along which to test the variances, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim', 1 tests the column variances, while 'Dim', 2 tests the row variances.

Example: 'Dim',2

\section*{Data Types \\ single | double}

\section*{'Display' - Display settings for test results}
'on' (default) | 'off'
Display settings for test results, specified as the comma-separated pair consisting of 'Display' and one of the following.
\[
\begin{array}{ll}
\text { 'on ' } & \text { Display a box plot and table of summary statistics. } \\
\text { ' off' } & \begin{array}{l}
\text { Do not display a box plot and table of summary } \\
\text { statistics. }
\end{array}
\end{array}
\]

Example: 'display','off'
```

'TestType' - Type of hypothesis test
'Bartlett' (default)| 'LeveneQuadratic' | 'LeveneAbsolute' |
'BrownForsythe' | 'OBrien'

```

Type of hypothesis test to perform, specified as the comma-separated pair consisting of 'TestType' and one of the following.
'Bartlett' Bartlett's test.
'LeveneQuadratic ' Levene’s test computed by performing ANOVA on the squared deviations of the data values from their group means.
'LeveneAbsolute' Levene's test computed by performing ANOVA on the absolute deviations of the data values from their group means.
'BrownForsythe' Brown-Forsythe test computed by performing ANOVA on the absolute deviations of the data values from the group medians.
'OBrien' O'Brien's modification of Levene's test with \(W=\) 0.5.
```

Example: 'TestType','OBrien'

```

\section*{Output Arguments}

\section*{\(p\) - p-value}
scalar value in the range \((0,1)\)
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.

\section*{stats - Test statistics}
structure
Test statistics for the hypothesis test, returned as a structure containing:
- chistat: Value of the test statistic.
- df: Degrees of freedom of the test.

\section*{Examples Test Data for Equal Variances}

Load the sample data.
load examgrades;

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, grades.
vartestn(grades)
\begin{tabular}{lccc|c|}
\multicolumn{4}{c}{ Group Summary Table } \\
\hline Group & Count & Mean & Std Dev & \\
\hline 1 & 120 & 75.0083 & 8.7202 & \\
2 & 120 & 74.9917 & 6.54204 \\
3 & 120 & 74.9917 & 7.43091 \\
4 & 120 & 75.0333 & 8.60128 \\
5 & 120 & 74.9917 & 5.25884 \\
Pooled & 600 & 75.0033 & 7.42558 \\
& & & \\
Bartlett's statistic & 38.7332 & & \\
Degrees of freedom & 4 & & \\
p-value & 0 & & \\
& & &
\end{tabular}

The low \(p\)-value, \(\mathrm{p}=0\), indicates that vartestn rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

\section*{Test Grouped Data for Equal Variances}

Load the sample data.
```

load carsmall;

```

Test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.
vartestn(MPG,Model_Year)
\begin{tabular}{llll} 
& \multicolumn{3}{c}{ Group Summary Table } \\
\hline Group & Count & Mean & Std Dev \\
\hdashline 70 & 29 & 17.6897 & 5.33923 \\
76 & 34 & 21.5735 & 5.8893 \\
82 & 31 & 31.7097 & 5.39255 \\
Pooled & 94 & 23.7181 & 5.562 \\
& & & \\
Bartlett's statistic & 0.36619 & & \\
Degrees of freedom & 2 & \\
p-value & 0.83269 & &
\end{tabular}

The high \(p\)-value, \(\mathrm{p}=0.83269\), indicates that vartestn does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

\section*{Test for Equal Variances Using Levene's Test}

Load the sample data.
load carsmall;

Use Levene's test to test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.
p = vartestn(MPG,Model_Year,'TestType','LeveneAbsolute')
\(p=\)
0.6320

\section*{Group Summary Table}
\begin{tabular}{|c|c|c|c|}
\hline Group & Count & Mean & Std Dev \\
\hline 70 & 29 & 17.6897 & 5.33923 \\
\hline 76 & 34 & 21.5735 & 5.8893 \\
\hline 82 & 31 & 31.7097 & 5.39255 \\
\hline Pooled & 94 & 23.7181 & 5. 562 \\
\hline Levene's statistic (absolute) & 0.46126 & & \\
\hline Degrees of freedom & 2, 91 & & \\
\hline & 0.63195 & & \\
\hline
\end{tabular}

The high \(p\)-value, \(\mathrm{p}=0.63195\), indicates that vartestn does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

\section*{Test for Equal Variances Using the Brown-Forsythe Test}

Load the sample data.
load examgrades;

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, grades, using the Brown-Forsythe test. Suppress the display of the summary table of statistics and the box plot.
```

[p,stats] = vartestn(grades,'TestType','BrownForsythe','Display','off')
p =
1.3121e-06

```
stats =
    fstat: 8.4160
        df: [4 595]

The low \(p\)-value, \(\mathrm{p}=1.3121 \mathrm{e}-06\), indicates that vartestn rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

\section*{Definitions Bartlett's Test}

Bartlett's test is used to test whether multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances. The test statistic is
\[
T=\frac{(N-k) \ln s_{p}{ }^{2}-\sum_{i=1}^{k}\left(N_{i}-1\right) \ln s_{i}{ }^{2}}{1+(1 /(3(k-1)))\left(\left(\sum_{i=1}^{k} 1 /\left(N_{i}-1\right)\right)-1(N-k)\right)},
\]
where \(s_{i}{ }^{2}\) is the variance of the \(i\) th group, \(N\) is the total sample size, \(N_{i}\) is the sample size of the \(i\) th group, \(k\) is the number of groups, and \(s_{p}{ }^{2}\) is the pooled variance. The pooled variance is defined as
\[
s_{p}{ }^{2}=\sum_{i=1}^{k}\left(N_{i}-1\right) s_{i}^{2} /(N-k) .
\]

The test statistic has a chi-square distribution with \(k-1\) degrees of freedom under the null hypothesis.
Bartlett's test is sensitive to departures from normality. If your data comes from a nonnormal distribution, Levene's test could provide a more accurate result.

\section*{Levene, Brown-Forsythe, and O'Brien Tests}

The Levene, Brown-Forsythe, and O'Brien tests are used to test if multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances. The test statistic is
\[
W=\frac{(N-k) \sum_{i=1}^{k} N_{i}\left(\bar{Z}_{i .}-\bar{Z}_{. .}\right)^{2}}{(k-1) \sum_{i=1}^{k} \sum_{j=1}^{N_{i}}\left(Z_{i j}-\bar{Z}_{i .}\right)^{2}},
\]
where \(N_{i}\) is the sample size of the \(i\) th group, and \(k\) is the number of groups. Depending on the type of test specified with the TestType name-value pair arguments, \(Z_{i j}\) can have one of four definitions:
- If you specify LeveneAbsolute, vartestn uses \(Z_{i j}=\left|Y_{i j}-\bar{Y}_{i .}\right|\), where \(\bar{Y}_{i .}\) is the mean of the \(i\) th subgroup.
- If you specify LeveneQuadratic, vartestn uses \(Z_{i j}{ }^{2}=\left(Y_{i j}-\bar{Y}_{i .}\right)^{2}\), where \(\bar{Y}_{i}\). is the mean of the \(i\) th subgroup.
- If you specify BrownForsythe, vartestn uses \(Z_{i j}=\left|Y_{i j}-\tilde{Y}_{i .}\right|\), where \(\tilde{Y}_{i}\). is the median of the \(i\) th subgroup.
- If you specify OBrien, vartestn uses
\[
Z_{i j}=\frac{\left(0.5+n_{i}-2\right) n_{i}\left(y_{i j}-\bar{y}_{i}\right)^{2}-0.5\left(n_{i}-1\right) \sigma_{i}{ }^{2}}{\left(n_{i}-1\right)\left(n_{i}-2\right)},
\]
where \(n_{i}\) is the size of the \(i\) th group, \(\sigma_{i}^{2}\) is its sample variance.
In all cases, the test statistic has an \(F\)-distribution with \(k-1\) numerator degrees of freedom, and \(N-k\) denominator degrees of freedom.

The Levene, Brown-Forsythe, and O'Brien tests are less sensitive to departures from normality than Bartlett's test, so they are useful alternatives if you suspect the samples come from nonnormal distributions.

\section*{Purpose Vertical concatenation for categorical arrays}
Syntax
\(C=\operatorname{vertcat}(\operatorname{dim}, A, B, \ldots)\)
C = vertcat (A,B)

Description \(\quad C=\) vertcat (dim, \(A, B, \ldots\) ) vertically concatenates the categorical arrays \(A, B, \ldots\). For matrices, all inputs must have the same number of rows. For n-D arrays, all inputs must have the same sizes except in the second dimension. The set of categorical levels for C is the sorted union of the sets of levels of the inputs, as determined by their labels. \(C=\operatorname{vertcat}(A, B)\) is called for the syntax \([A B]\).

\author{
See Also \\ cat | horzcat
}

\section*{dataset.vertcat}

Purpose Vertical concatenation for dataset arrays
```

Syntax
ds = vertcat(ds1, ds2, ...)

```

Description ds = vertcat(ds1, ds2, ...) vertically concatenates the dataset arrays ds1, ds2, ... . Observation names, when present, must be unique across datasets. vertcat fills in default observation names for the output when some of the inputs have names and some do not.

Variable names for all dataset arrays must be identical except for order. vertcat concatenates by matching variable names. vertcat assigns values for the "per-variable" properties (e.g., Units and VarDescription) in ds from the corresponding property values in ds1.

\section*{See Also \\ cat | horzcat}

\section*{Purpose \\ Plot tree}

\section*{Syntax}
view(t)
view(t,param1,val1,param2,val2,...)
view( \(t\) ) displays the decision tree \(t\) as computed by classregtree in a figure window. Each branch in the tree is labeled with its decision rule, and each terminal node is labeled with the predicted value for that node. Click any node to get more information about it. The information displayed is specified by the Click to display pop-up menu at the top of the figure.
view(t,param1,val1,param2,val2,...) specifies optional parameter name/value pairs:
- 'names ' - A cell array of names for the predictor variables, in the order in which they appear in the matrix \(X\) from which the tree was created. (See classregtree.)
- 'prunelevel' - Initial pruning level to display.

For each branch node, the left child node corresponds to the points that satisfy the condition, and the right child node corresponds to the points that do not satisfy the condition.

\section*{Examples \\ Create a classification tree for Fisher's iris data:}
```

load fisheriris;
t = classregtree(meas,species,...
'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica

```

\section*{classregtree.view}
```

6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor

\section*{Purpose Weibull cumulative distribution function}
```

Syntax P = wblcdf(X,A,B)
[P,PLO,PUP] = wblcdf(X,A,B,PCOV,alpha)

```

\section*{Description \(\quad P=\operatorname{wblcdf}(X, A, B)\) computes the \(c d f\) of the Weibull distribution with} scale parameter \(A\) and shape parameter \(B\), at each of the values in \(X\). \(X\), \(A\), and \(B\) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for A and B are both 1. The parameters A and B must be positive.
[P,PLO, PUP] = wblcdf(X,A,B,PCOV,alpha) returns confidence bounds for \(P\) when the input parameters \(A\) and \(B\) are estimates. PCOV is the 2 -by- 2 covariance matrix of the estimated parameters. alpha has a default value of 0.05 , and specifies \(100(1-\mathrm{alpha}) \%\) confidence bounds. PLO and PUP are arrays of the same size as P containing the lower and upper confidence bounds.

The function wblcdf computes confidence bounds for P using a normal approximation to the distribution of the estimate
\[
\hat{b}(\log x-\log \hat{a})
\]
and then transforms those bounds to the scale of the output P. The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and PCOV from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The Weibull cdf is
\[
p=F(x \mid a, b)=\int_{0}^{x} b a^{-b} t^{b-1} e^{-\left(\frac{t}{a}\right)^{b}} d t=1-e^{-\left(\frac{x}{a}\right)^{b}} I_{(0, \infty)}(x)
\]

\section*{Examples}

What is the probability that a value from a Weibull distribution with parameters \(\mathrm{a}=0.15\) and \(\mathrm{b}=0.8\) is less than 0.5 ?
```

probability = wblcdf(0.5, 0.15, 0.8)
probability =
0.9272

```

How sensitive is this result to small changes in the parameters?
```

[A, B] = meshgrid(0.1:0.05:0.2,0.2:0.05:0.3);
probability = wblcdf(0.5, A, B)
probability =
0.7484}00.7198 0.6991
0.7758}00.7411 0.715
0.8022 0.7619 0.7319

```

How To . "Weibull Distribution" on page B-116

Purpose Weibull parameter estimates
```

Syntax parmhat = wblfit(data)
[parmhat,parmci] = wblfit(data)
[parmhat,parmci] = wblfit(data,alpha)
[...] = wblfit(data,alpha,censoring)
[...] = wblfit(data,alpha,censoring,freq)
[...] = wblfit(...,options)

```

\section*{Description}
parmhat = wblfit(data) returns the maximum likelihood estimates, parmhat, of the parameters of the Weibull distribution given the values in the vector data, which must be positive. parmhat is a two-element row vector: parmhat(1) estimates the Weibull parameter \(a\), and parmhat (2) estimates the Weibull parameter \(b\), in the pdf
\[
y=f(x \mid a, b)=b a^{-b} x^{b-1} e^{-\left(\frac{x}{a}\right)^{b}} I_{(0, \infty)}(x)
\]
[parmhat, parmci] = wblfit(data) returns \(95 \%\) confidence intervals for the estimates of \(a\) and \(b\) in the 2 -by- 2 matrix parmci. The first row contains the lower bounds of the confidence intervals for the parameters, and the second row contains the upper bounds of the confidence intervals.
[[parmhat,parmci] = wblfit(data,alpha) returns 100(1-alpha)\% confidence intervals for the parameter estimates.
[...] = wblfit(data, alpha, censoring) accepts a Boolean vector, censoring, of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.
[...] = wblfit(data, alpha, censoring,freq) accepts a frequency vector, freq, of the same size as data. The vector freq typically contains integer frequencies for the corresponding elements in data, but can contain any non-negative values. Pass in [] for alpha, censoring, or freq to use their default values.
[...] = wblfit(...,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The Weibull fit function accepts an options structure that can be created using the function statset. Enter statset ('wblfit') to see the names and default values of the parameters that lognfit accepts in the options structure. See the reference page for statset for more information about these options.
```

How To
- "Weibull Distribution" on page B-116

Purpose Weibull inverse cumulative distribution function
\(\begin{array}{ll}\text { Syntax } & X=\operatorname{wblinv}(P, A, B) \\ & {[X, X L O, X U P]=\operatorname{wblinv}(P, A, B, P C O V, \text { alpha })}\end{array}\)
Description
\(X=\) wblinv \((P, A, B)\) returns the inverse cumulative distribution function (cdf) for a Weibull distribution with scale parameter \(A\) and shape parameter B, evaluated at the values in P. P, A, and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for \(A\) and \(B\) are both 1 .
[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha) returns confidence bounds for \(X\) when the input parameters \(A\) and \(B\) are estimates. PCOV is a 2 -by- 2 matrix containing the covariance matrix of the estimated parameters. alpha has a default value of 0.05 , and specifies 100(1-alpha) \(\%\) confidence bounds. XLO and XUP are arrays of the same size as X containing the lower and upper confidence bounds.

The function wblinv computes confidence bounds for X using a normal approximation to the distribution of the estimate
\[
\log a+\frac{\log q}{b}
\]
where \(q\) is the Pth quantile from a Weibull distribution with scale and shape parameters both equal to 1 . The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and PCOV from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The inverse of the Weibull cdf is
\[
x=F^{-1}(p \mid a, b)=-a[\ln (1-p)]^{1 / b} I_{[0,1]}(p)
\]

\section*{Examples}

The lifetimes (in hours) of a batch of light bulbs has a Weibull distribution with parameters \(\mathrm{a}=200\) and \(\mathrm{b}=6\).

Find the median lifetime of the bulbs:
```

life = wblinv(0.5, 200, 6)
life =
188.1486

```

Generate 100 random values from this distribution, and estimate the 90th percentile (with confidence bounds) from the random sample
```

x = wblrnd(200,6,100,1);

```
p = wblfit(x)
[nlogl,pcov] = wbllike(p,x)
[q90,q9010,q90up] = wblinv(0.9,p(1),p(2),pcov)
\(\mathrm{p}=\)
    \(204.8918 \quad 6.3920\)
nlogl =
    496.8915
pcov \(=\)
    11.33920 .5233
        \(0.5233 \quad 0.2573\)
q90 =
    233.4489
q9010 =
```

226.0092
q90up =
241.1335

```

Weibull probability density function

Y = wblpdf(X,A,B)
\(Y=\operatorname{wblpdf}(X, A, B)\) computes the Weibull pdf at each of the values in \(X\) using the corresponding scale parameter, \(A\) and shape parameter, \(B\). \(X\), \(A\), and \(B\) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The parameters in A and B must be positive.

The Weibull pdf is
\[
f(x \mid a, b)=\frac{b}{a}\left(\frac{x}{a}\right)^{b-1} e^{-(x / a)^{b}} .
\]

Some references refer to the Weibull distribution with a single parameter. This corresponds to wblpdf with \(A=1\).

The exponential distribution is a special case of the Weibull distribution.
```

lambda = 1:6;

\section*{Purpose Weibull mean and variance}

\section*{Syntax \\ \([M, V]=\) wblstat \((A, B)\)}

Description
\([M, V]=\operatorname{wblstat}(A, B)\) returns the mean of and variance for the Weibull distribution with scale parameter, A and shape parameter, B. Vector or matrix inputs for \(A\) and \(B\) must have the same size, which is also the size of \(M\) and \(V\). A scalar input for \(A\) or \(B\) is expanded to a constant matrix with the same dimensions as the other input.
The mean of the Weibull distribution with parameters \(a\) and \(b\) is
\[
a\left[\Gamma\left(1+b^{-1}\right)\right]
\]
and the variance is
\[
a^{2}\left[\Gamma\left(1+2 b^{-1}\right)-\Gamma\left(1+b^{-1}\right)^{2}\right]
\]

\section*{prob.WeibullDistribution}

Superclasses ToolboxFittableParametricDistribution
Purpose Weibull probability distribution object
Description prob.WeibullDistribution is an object consisting of parameters, a model description, and sample data for a Weibull probability distribution.

Create a probability distribution object with specified parameter values using makedist. Alternatively, fit a distribution to data using fitdist or dfittool.

\section*{Construction}
pd = makedist('Weibull') creates a Weibull probability distribution object using the default parameter values.
pd = makedist('Weibull','a', a, 'b', b) creates a Weibull probability distribution object using the specified parameter values.

\section*{Input Arguments}

\section*{a-Scale parameter}

1 (default) | positive scalar value
Scale parameter of the Weibull distribution, specified as a positive scalar value.

\section*{Data Types}
single | double

\section*{b-Shape parameter}

\section*{1 (default) | positive scalar value \\ Shape parameter of the Weibull distribution, specified as a positive scalar value.}

\author{
Data Types \\ single | double
}

\section*{Properties}

Scale parameter of the Weibull distribution, stored as a positive scalar value.

\section*{Data Types}
single | double
b
Shape parameter of the Weibull distribution, stored as a positive scalar value.

\section*{Data Types}
single | double

\section*{DistributionName}

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

\section*{Data Types}
char

\section*{InputData}

Data used for distribution fitting, stored as a structure containing the following:
- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.
Data Types
single | double

\section*{IsTruncated}

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0 , the distribution is not truncated.

\section*{prob.WeibullDistribution}

If IsTruncated equals 1 , the distribution is truncated. This property is read-only.

\section*{Data Types}
logical

\section*{NumParameters}

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

\section*{Data Types \\ single | double}

\section*{ParameterCovariance}

Covariance matrix of the parameter estimates, stored as a \(p\)-by- \(p\) matrix, where \(p\) is the number of parameters in the distribution. The ( \(\mathrm{i}, \mathrm{j}\) ) element is the covariance between the estimates of the \(i\) th parameter and the \(j\) th parameter. The ( \(i, i\) ) element is the estimated variance of the ith parameter. If parameter \(i\) is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0 . This property is read-only.

\section*{Data Types}
single | double

\section*{ParameterDescription}

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

\section*{Data Types \\ char}

\section*{Parameterlsfixed}

Logical flag for fixed parameters, stored as an array of logical values. If 0 , the corresponding parameter in the ParameterNames array is not fixed. If 1 , the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

\section*{Data Types}
logical

\section*{ParameterNames}

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

\section*{Data Types}
char

\section*{ParameterValues}

Values of distribution parameters, stored as a vector. This property is read-only.

\section*{Data Types}
single | double

\section*{Truncation}

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

\section*{Data Types}
single | double

\section*{Definitions Weibull Distribution}

The Weibull distribution is used in reliability and lifetime modeling, and to model the breaking strength of materials.

The Weibull distribution uses the following parameters.
\begin{tabular}{l|l|l}
\hline Parameter & Description & Support \\
\hline a & Scale parameter & \(a>0\) \\
\hline b & Shape parameter & \(b>0\) \\
\hline
\end{tabular}

The probability density function (pdf) is
\[
f(x \mid a, b)=\frac{b}{a}\left(\frac{x}{a}\right)^{b-1} \exp \left\{-\left(\frac{x}{a}\right)^{b}\right\} ; \quad x \geq 0 .
\]

Concepts
- "Weibull Distribution" on page B-116
- Class Attributes
- Property Attributes
Purpose Wishart random numbers
Syntax W = wishrnd(Sigma,df)
W = wishrnd(Sigma,df, D)
[W,D] = wishrnd(Sigma,df)
Description\(\mathrm{W}=\) wishrnd(Sigma, df ) generates a random matrix W having theWishart distribution with covariance matrix Sigma and with df degreesof freedom. The inverse of \(W\) has the Inverse Wishart distribution withparameters Tau \(=\) inv(Sigma) and df degrees of freedom.
W = wishrnd(Sigma, df, D) expects D to be the Cholesky factor of Sigma.
If you call wishrnd multiple times using the same value of Sigma, it'smore efficient to supply D instead of computing it each time.
[W,D] = wishrnd(Sigma,df) returns D so you can provide it as input in future calls to wishrnd.
This function defines the parameter Sigma so that the mean of the output matrix is Sigma*df
See Also iwishrnd
How To . "Wishart Distribution" on page B-119

\section*{TreeBagger.X property}

Purpose \(\quad \mathrm{X}\) data used to create ensemble
Description The \(X\) property is a numeric matrix of size Nobs-by-Nvars, where Nobs is the number of observations (rows) and Nvars is the number of variables (columns) in the training data. This matrix contains the predictor (or feature) values.

\section*{Purpose}

Create dataset array from data stored in SAS XPORT format file

\author{
Syntax \\ Description
}
data \(=\) xptread
data \(=\) xptread(filename)
[data,missing] = xptread(filename)
xptread(...,'ReadObsNames', true)

Examples Read in a SAS XPORT format dataset:

See Also dataset | dataset.export XPORT format. specifying a second output. missing values. file as observation names. The default value is false. support compressed files.
```

data = xptread('sample.xpt')

```
```

data = xptread('sample.xpt')

```
```

dataset | dataset.export

```
data = xptread displays a dialog box for selecting a file, then reads data from the file into a dataset array. The file must be in the SAS
data \(=\) xptread(filename) retrieves data from a SAS XPORT format file filename. The XPORT format allows for 28 missing data types, represented in the file by an upper case letter, '. ' or '_'. xptread converts All missing data to NaN values in data. However, if you need the specific missing types then you can recover this information by
[data,missing] = xptread(filename) returns a nominal array, missing, of the same size as data containing the missing data type information from the xport format file. The entries are undefined for values that are not present and are one of '.', '_', 'A',...,'Z' for
xptread (..., 'ReadObsNames', true) treats the first variable in the
xptread only supports single data sets per file. xptread does not

\section*{Purpose Convert predictor matrix to design matrix}
Syntax \(\quad\)\begin{tabular}{rl} 
D & \(=x 2 f x(X\), model \()\) \\
\(D\) & \(=x 2 f x(X\), model, categ \()\) \\
\(D\) & \(=x 2 f x(X\), model, categ, catlevels \()\)
\end{tabular}

Description
\(D=x 2 f x(X\), model \()\) converts a matrix of predictors \(X\) to a design matrix D for regression analysis. Distinct predictor variables should appear in different columns of X .

The optional input model controls the regression model. By default, x2fx returns the design matrix for a linear additive model with a constant term. model is one of the following strings:
- 'linear' - Constant and linear terms. This is the default.
- 'interaction' - Constant, linear, and interaction terms
- 'quadratic' - Constant, linear, interaction, and squared terms
- 'purequadratic' - Constant, linear, and squared terms

If \(X\) has \(n\) columns, the order of the columns of \(D\) for a full quadratic model is:

1 The constant term
2 The linear terms (the columns of X , in order \(1,2, \ldots, n\) )
3 The interaction terms (pairwise products of the columns of X, in order \((1,2),(1,3), \ldots,(1, n),(2,3), \ldots,(n-1, n))\)

4 The squared terms (in order \(1,2, \ldots, n\) )
Other models use a subset of these terms, in the same order.
Alternatively, model can be a matrix specifying polynomial terms of arbitrary order. In this case, model should have one column for each column in \(X\) and one row for each term in the model. The entries in any row of model are powers for the corresponding columns of \(X\). For example, if X has columns \(\mathrm{X} 1, \mathrm{X} 2\), and X 3 , then a row [ \(\left.\begin{array}{lll}0 & 1 & 2\end{array}\right]\) in model
specifies the term (X1.^0).*(X2.^1).*(X3.^2). A row of all zeros in model specifies a constant term, which can be omitted.

D = x2fx(X,model, categ) treats columns with numbers listed in the vector categ as categorical variables. Terms involving categorical variables produce dummy variable columns in D. Dummy variables are computed under the assumption that possible categorical levels are completely enumerated by the unique values that appear in the corresponding column of \(X\).

D = x2fx(X,model, categ, catlevels) accepts a vector catlevels the same length as categ, specifying the number of levels in each categorical variable. In this case, values in the corresponding column of \(X\) must be integers in the range from 1 to the specified number of levels. Not all of the levels need to appear in X .

\section*{Examples \\ Example 1}

The following converts 2 predictors X1 and X2 (the columns of X ) into a design matrix for a full quadratic model with terms constant, \(\mathrm{X} 1, \mathrm{X} 2\), X1.*X2, X1.^2, and X2.^2.

regstats | rstool | candexch | candgen | cordexch | rowexch

Purpose Y data used to create ensemble
Description The \(Y\) property is an array of true class labels for classification, or response values for regression. \(Y\) can be a numeric column vector, a character matrix, or a cell array of strings.

\section*{Purpose \(\quad\) Standardized \(z\)-scores}

\section*{Syntax}
\(Z=z s c o r e(X)\)
Z = zscore(X,flag)
\(Z=z s c o r e(X, f l a g, d i m)\)
[Z,mu,sigma] = zscore( __ )

\section*{Description}
\(Z=z s c o r e(X)\) returns the \(z\)-score for each element of \(X\) such that columns of \(X\) are centered to have mean 0 and scaled to have standard deviation \(1 . Z\) is the same size as \(X\).
- If \(X\) is a vector, then \(Z\) is a vector of \(z\)-scores.
- If \(X\) is a matrix, then \(Z\) is a matrix of the same size as \(X\), and each column of \(Z\) has mean 0 and standard deviation 1 .
- For multidimensional arrays, \(z\)-scores in \(Z\) are computed along the first nonsingleton dimension of \(X\).

Z = zscore (X,flag) scales X using the standard deviation indicated by flag.
- If flag is 0 (default), then zscore scales X using the sample standard deviation, with \(n-1\) in the denominator of the standard deviation formula. zscore \((X, 0)\) is the same as \(z \operatorname{ccore}(X)\).
- If flag is 1 , then zscore scales \(X\) using the population standard deviation, with \(n\) in the denominator of standard deviation formula.

Z = zscore(X,flag,dim) standardizes X along dimension dim. For example, for a matrix \(X\), if \(\operatorname{dim}=1\), then zscore uses the means and standard deviations along the columns of \(X\), if dim \(=2\), then zscore uses the means and standard deviations along the rows of \(X\).
[Z,mu,sigma] = zscore( __ ) also returns the means and standard deviations used for centering and scaling, mu and sigma, respectively. You can use any of the input arguments in the previous syntaxes.

\section*{Input Arguments}

\section*{Output Arguments}

\section*{X - Input data}
vector | matrix | multidimensional array
Input data, specified as a vector, matrix, or multidimensional array.

\section*{Data Types}
double | single

\section*{flag - Indicator for the standard deviation}

0 (default) | 1
Indicator for the standard deviation used to compute the \(z\)-scores, specified as 0 or 1 .
- If flag is 0 (default), then zscore scales \(X\) using the sample standard deviation. zscore ( \(X, 0\) ) is the same as \(z \operatorname{score}(X)\).
- If flag is 1 , then zscore scales \(X\) using the population standard deviation.

\section*{dim - Dimension}

1 (default) | positive integer
Dimension along which to calculate the \(z\)-scores of X , specified as a positive integer. For example, for a matrix \(X\), if \(\operatorname{dim}=1\), then zscore uses the means and standard deviations along the columns of \(X\), if dim \(=2\), then zscore uses the means and standard deviations along the rows of \(X\).

\section*{Z-z-scores}
vector | matrix | multidimensional array
\(z\)-scores, returned as a vector, matrix, or multidimensional array. A vector of \(z\)-scores has mean 0 and variance 1 .
- If \(X\) is a vector, then \(Z\) is a vector of \(z\)-scores.
- If \(X\) is an array, then zscore is an array, with each column or row standardized to have mean 0 and variance 1 (depending on dim). If dim is not specified, zscore standardizes along the first nonsingleton dimension of \(X\).

\section*{mu - Mean}
scalar | vector
Mean of X used to compute the \(z\)-scores, returned as a scalar or vector.
- If \(X\) is a vector, then mu is a scalar.
- If \(X\) is a matrix, then mu is a row vector if zscore calculates the means along the columns of \(X(\operatorname{dim}=1)\), and a column vector if zscore calculates the means along the rows of \(X(\operatorname{dim}=2)\).

\section*{sigma-Standard deviation}

\section*{scalar | vector}

Standard deviation of X used to compute the \(z\)-scores, returned as a scalar or vector.
- If \(X\) is a vector, then sigma is a scalar.
- If \(X\) is a matrix, then sigma is a row vector if zscore calculates the standard deviations along the columns of \(\mathrm{X}(\operatorname{dim}=1)\), and a column vector if zscore calculates the standard deviations along the rows of \(X(\operatorname{dim}=2)\).

\section*{Examples}

\section*{Z-Scores of Two Data Vectors}

Compute and plot the \(z\)-scores of two data vectors, and then compare the results.

Load the sample data.
load('lawdata.mat')
Two variables load into the workspace: gpa and lsat.
Plot both variables on the same axes.
```

plot([gpa,lsat])
legend('gpa','lsat','Location','East')

```

It is difficult to compare these two measures because they are on a very different scale.

Plot the \(z\)-scores of gpa and lsat on the same axes.
```

Zgpa = zscore(gpa);
Zlsat = zscore(lsat);
plot([Zgpa, Zlsat])
legend('gpa z-scores','lsat z-scores','Location','Northeast')

```

Now, you can see the relative performance of individuals with respect to both their gpa and lsat results. For example, the third individual's gpa and lsat results are both one standard deviation below the sample mean. The eleventh individual's gpa is around the sample mean but has an lsat score almost 1.25 standard deviations above the sample average.

Check the mean and standard deviation of the \(z\)-scores you created.
```

mean([Zgpa,Zlsat])

```
```

ans =
1.0e-14*
-0.1088 0.0357
std([Zgpa,Zlsat])
ans =
1

```

By definition, \(z\)-scores of gpa and lsat have mean 0 and standard deviation 1.

\section*{Z-Scores for a Population vs. Sample}

Load the sample data.
load('lawdata.mat')
Two variables load into the workspace: gpa and lsat.
Compute the \(z\)-scores of gpa using the population formula for standard deviation.
```

Z1 = zscore(gpa,1); % population formula
ZO = zscore(gpa,0); % sample formula
disp([Z1 Z0])

| 1.2554 | 1.2128 |
| ---: | ---: |
| 0.8728 | 0.8432 |
| -1.2100 | -1.1690 |
| -0.2749 | -0.2656 |
| 1.4679 | 1.4181 |
| -0.1049 | -0.1013 |
| -0.4024 | -0.3888 |
| 1.4254 | 1.3771 |
| 1.1279 | 1.0896 |

```
\begin{tabular}{rr}
0.1502 & 0.1451 \\
0.1077 & 0.1040 \\
-1.5076 & -1.4565 \\
-1.4226 & -1.3743 \\
-0.9125 & -0.8815 \\
-0.5724 & -0.5530
\end{tabular}

For a sample from a population, the population standard deviation formula with \(n\) in the denominator corresponds to the maximum likelihood estimate of the population standard deviation, and might be biased. The sample standard deviation formula, on the other hand, is the unbiased estimator of the population standard deviation for a sample.

\section*{Z-Scores of a Data Matrix}

Compute \(z\)-scores using the mean and standard deviation computed along the columns or rows of a data matrix.

Load the sample data.
load('flu.mat')
The dataset array flu is loaded in the workplace. flu has 52 observations on 11 variables. The first variable contains dates (in weeks). The other variables contain the flu estimates for different regions in the U.S.

Convert the dataset array to a data matrix.
flu2 = double(flu(:,2:end));
The new data matrix, flu2, is a 52 -by- 10 double data matrix. The rows correspond to the weeks and the columns correspond to the U.S. regions in the data set array flu.

Standardize the flu estimate for each region (the columns of flu2).
Z1 = zscore(flu2,[ ],1);

You can see the \(z\)-scores in the variable editor by double-clicking on the matrix Z1 created in the workspace.

Standardize the flu estimate for each week (the rows of flu2).
Z2 = zscore(flu2,[ ],2);

\section*{Z-Scores, Mean, and Standard Deviation}

Return the mean and standard deviation used to compute the \(z\)-scores.
Load the sample data.
load('lawdata.mat')
Two variables load into the workspace: gpa and lsat.
Return the \(z\)-scores, mean, and standard deviation of gpa.
```

[Z,gpamean,gpastdev] = zscore(gpa)

```

Z =
1.2128
0.8432
-1.1690
\(-0.2656\)

0.1040
\(-1.4565\)
-1.3743
-0.8815
-0.5530

\section*{Definitions}

\section*{Z-Score}

For a random variable \(X\) with mean \(\mu\) and standard deviation \(\sigma\), the \(z\)-score of a value \(x\) is
\[
z=\frac{(x-\mu)}{\sigma} .
\]

For sample data with mean \(\bar{X}\) and standard deviation \(S\), the \(z\)-score of a data point \(x\) is
\[
z=\frac{(x-\bar{X})}{S}
\]
\(z\)-scores measure the distance of a data point from the mean in terms of the standard deviation. This is also called standardization of data. The standardized data set has mean 0 and standard deviation 1, and retains the shape properties of the original data set (same skewness and kurtosis).

You can use \(z\)-scores to put data on the same scale before further analysis. This lets you to compare two or more data sets with different units.

\section*{Multidimensional Array}

A multidimensional array is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a three-dimensional array.

\section*{First Nonsingleton Dimension}

A first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if X is a 1 -by- 2 -by- 3 -by- 4 array, then the second dimension is the first nonsingleton dimension of \(X\).

\section*{Sample Standard Deviation}

The sample standard deviation, \(S\), is given by
\[
S=\sqrt{\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{X}\right)^{2}}{n-1}} .
\]
\(S\) is the square root of an unbiased estimator of the variance of the population from which X is drawn, as long as X consists of independent, identically distributed samples.

Notice that the denominator in this variance formula is \(n-1\).

\section*{Population Standard Deviation}

If the data is the entire population of values, then you can use the population standard deviation,
\[
\sigma=\sqrt{\frac{\sum_{i=1}^{n}\left(x_{i}-\mu\right)^{2}}{n}}
\]

If \(X\) is a random sample from a population, then \(\mu\) is estimated by the sample mean, and \(\sigma\) is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is \(n\).

\section*{Algorithms}
zscore returns NaNs for any sample containing NaNs.
zscore returns 0s for any sample that is constant (all values are the same). For example, if \(X\) is a vector of the same numeric value, then \(Z\) is a vector of 0 s . If \(X\) is a matrix with a column of consisting of the same value, then that column of \(Z\) consists of 0 s .
See Also ..... mean | std

\section*{Purpose \(\quad z\)-test}

Syntax
```

h = ztest(x,m,sigma)
h= ztest(x,m,sigma,Name,Value)
[h,p] = ztest(___)
[h,p,ci,zval] = ztest(___)

```

\section*{Input Arguments}
\(h=z t e s t(x, m\), sigma) returns a test decision for the null hypothesis that the data in the vector \(x\) comes from a normal distribution with mean m and a standard deviation sigma, using the \(z\)-test. The alternative hypothesis is that the mean is not m . The result h is 1 if the test rejects the null hypothesis at the \(5 \%\) significance level, and 0 otherwise.
\(h=\) ztest( \(x, m\), sigma, Name, Value) returns a test decision for the \(z\)-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.
[h, p] = ztest (__ ) also returns the p-value of the test, using any of the input arguments from previous syntaxes.
[h, p,ci, zval] = ztest( __ ) also returns the confidence interval of the population mean, ci, and the value of the test statistic, zval.

\section*{x-Sample data}
vector | matrix | multidimensional array
Sample data, specified as a vector, matrix, or multidimensional array.
- If \(x\) is specified as a vector, ztest returns a single value for each output argument.
- If x is specified as a matrix, ztest performs a separate \(z\)-test along each column of \(x\) and returns a vector of results.
- If \(x\) is specified as a multidimensional array, ztest works along the first nonsingleton dimension of \(x\).

In all cases, ztest treats \(N a N\) values as missing data and ignores them.

\section*{Data Types \\ single | double}

\section*{m-Hypothesized mean}
scalar value
Hypothesized mean, specified as a scalar value.

\section*{Data Types}
single | double

\section*{sigma - Population standard deviation}

\section*{scalar value}

Population standard deviation, specified as a scalar value.
```

Data Types
single | double

```

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Tail', 'right', 'Alpha', 0.01 specifies a right-tailed hypothesis test at the \(1 \%\) significance level.

\section*{'Alpha' - Significance level}
0.05 (default) | scalar value in the range \((0,1)\)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range \((0,1)\).

\section*{Example: 'Alpha',0.01}

\section*{Data Types}
single | double

\section*{'Dim' - Dimension}
first nonsingleton dimension (default) | positive integer value
Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim', 1 tests the column means, while 'Dim', 2 tests the row means.

Example: 'Dim',2
Data Types
single | double

\section*{'Tail' - Type of alternative hypothesis \\ 'both' (default) | 'right' | 'left'}

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.
\[
\begin{array}{ll}
\text { 'both' } & \begin{array}{l}
\text { Test the alternative hypothesis that the population } \\
\text { mean is not equal to m. }
\end{array} \\
\text { 'right' } & \begin{array}{l}
\text { Test the alternative hypothesis that the population } \\
\text { mean is greater than } m .
\end{array} \\
\text { 'left' } & \begin{array}{l}
\text { Test the alternative hypothesis that the population } \\
\text { mean is less than } m .
\end{array}
\end{array}
\]

\section*{Example: 'Tail','right'}

\section*{Output Arguments}
```

h - Hypothesis test result
1|0

```

Hypothesis test result, returned as a logical value.
- If \(\mathrm{h}=1\), this indicates the rejection of the null hypothesis at the Alpha significance level.
- If \(h=0\), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\section*{p-p-value}
scalar value in the range \((0,1)\)
\(p\)-value of the test, returned as a scalar value in the range \((0,1) . \mathrm{p}\) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \(p\) cast doubt on the validity of the null hypothesis.

\section*{ci - Confidence interval}
vector
Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the \(100 \times(1-A l p h a) \%\) confidence interval.

\section*{zval - Test statistic}
nonnegative scalar value
Test statistic, returned as a nonnegative scalar value.

\section*{Examples Test for a Hypothesized Mean}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
load examgrades;
x = grades(:,1);
Test the null hypothesis that the data comes from a normal distribution with mean \(m=75\) and standard deviation sigma \(=10\).
[h,p,ci,zval] = ztest(x,75,10)
\(\mathrm{h}=\)
```

    0
    p =
0.9927
Ci =
73.2191
76.7975
zval =
0.0091

```

The returned value of \(h=0\) indicates that ztest does not reject the null hypothesis at the default \(5 \%\) significance level.

\section*{One-Sided Hypothesis Test}

Load the sample data. Create a vector containing the first column of the students' exam grades data.
```

load examgrades;
x = grades(:,1);

```

Test the null hypothesis that the data comes from a normal distribution with mean \(m=65\) and standard deviation sigma \(=10\), against the alternative that the mean is greater than 65.
```

[h,p] = ztest(x,65,10,'Tail','right')
h =
1
p =
2.8596e-28

```

The returned value of \(h=1\) indicates that ztest rejects the null hypothesis at the default \(5 \%\) significance level, in favor of the alternative hypothesis that the population mean is greater than 65 .

\section*{Definitions}
z-Test
The \(z\)-test is a parametric hypothesis test used to determine whether a sample data set comes from a population with a particular mean. The test assumes the sample data comes from a population with a normal distribution and a known standard deviation.

The test statistic is
\[
z=\frac{\bar{x}-\mu}{\sigma / \sqrt{n}},
\]
where \(\bar{x}\) is the sample mean, is the population mean, \(\sigma\) is the population standard deviation, and \(n\) is the sample size. Under the null hypothesis, the test statistic has a standard normal distribution.

\section*{Multidimensional Array}

A multidimensional array has more than two dimensions. For example, if \(x\) is a 1-by-3-by-4 array, then \(x\) is a three-dimensional array.

\section*{First Nonsingleton Dimension}

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1 . For example, if \(x\) is a 1 -by- 2 -by- 3 -by- 4 array, then the second dimension is the first nonsingleton dimension of \(x\).

See Also ttest | ttest2

\section*{Sample Data Sets}

Statistics Toolbox software includes the sample data sets in the following table.

To load a data set into the MATLAB workspace, type:
load filename
where filename is one of the files listed in the table.
Data sets contain individual data variables, description variables with references, and dataset arrays encapsulating the data set and its description, as appropriate.
\begin{tabular}{l|l}

\section*{Bernoulli Distribution}

\section*{Definition of the Bernoulli Distribution}

The Bernoulli distribution is a special case of the binomial distribution, with \(n=1\).

\section*{See Also}
"Discrete Distributions" on page 5-8

\section*{Beta Distribution}

\author{
In this section... \\ "Definition" on page B-4 \\ "Background" on page B-4 \\ "Parameters" on page B-5 \\ "Example" on page B-6 \\ "See Also" on page B-6
}

\section*{Definition}

The beta pdf is
\[
y=f(x \mid a, b)=\frac{1}{B(a, b)} x^{a-1}(1-x)^{b-1} I_{(0,1)}(x)
\]
where \(B(\cdot)\) is the Beta function. The indicator function \(I_{(0,1)}(x)\) ensures that only values of \(x\) in the range ( 01 ) have nonzero probability.

\section*{Background}

The beta distribution describes a family of curves that are unique in that they are nonzero only on the interval (01). A more general version of the function assigns parameters to the endpoints of the interval.

The beta cdf is the same as the incomplete beta function.
The beta distribution has a functional relationship with the \(t\) distribution. If \(Y\) is an observation from Student's \(t\) distribution with \(v\) degrees of freedom, then the following transformation generates \(X\), which is beta distributed.
\[
X=\frac{1}{2}+\frac{1}{2} \frac{Y}{\sqrt{v+Y^{2}}}
\]

If \(Y \sim t(v)\), then \(X \square \beta\left(\frac{v}{2}, \frac{v}{2}\right)\)
This relationship is used to compute values of the \(t \mathrm{cdf}\) and inverse function as well as generating \(t\) distributed random numbers.

\section*{Parameters}

Suppose you are collecting data that has hard lower and upper bounds of zero and one respectively. Parameter estimation is the process of determining the parameters of the beta distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the beta pdf. But for the pdf, the parameters are known constants and the variable is \(x\). The likelihood function reverses the roles of the variables. Here, the sample values (the \(x\) 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. Maximum likelihood estimation (MLE) involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function betafit returns the MLEs and confidence intervals for the parameters of the beta distribution. Here is an example using random numbers from the beta distribution with \(a=5\) and \(b=0.2\).
```

r = betarnd(5,0.2,100,1);
[phat, pci] = betafit(r)
phat =
4.5330 0.2301
pci =
2.8051 0.1771
6.2610 0.2832

```

The MLE for parameter \(a\) is 4.5330, compared to the true value of 5 . The \(95 \%\) confidence interval for \(a\) goes from 2.8051 to 6.2610 , which includes the true value.

Similarly the MLE for parameter \(b\) is 0.2301 , compared to the true value of 0.2 . The \(95 \%\) confidence interval for \(b\) goes from 0.1771 to 0.2832 , which
also includes the true value. In this made-up example you know the "true value." In experimentation you do not.

\section*{Example}

The shape of the beta distribution is quite variable depending on the values of the parameters, as illustrated by the plot below.

The constant pdf (the flat line) shows that the standard uniform distribution is a special case of the beta distribution.

\section*{See Also}
"Continuous Distributions (Data)" on page 5-4

\section*{Binomial Distribution}

\section*{In this section...}
"Definition" on page B-7
"Background" on page B-7
"Parameters" on page B-8
"Example" on page B-9
"See Also" on page B-9

\section*{Definition}

The binomial pdf is
\[
f(k \mid n, p)=\binom{n}{k} p^{k}(1-p)^{n-k}
\]
where \(k\) is the number of successes in \(n\) trials of a Bernoulli process with probability of success \(p\).

The binomial distribution is discrete, defined for integers \(k=0,1,2, \ldots n\), where it is nonzero.

\section*{Background}

The binomial distribution models the total number of successes in repeated trials from an infinite population under the following conditions:
- Only two outcomes are possible on each of \(n\) trials.
- The probability of success for each trial is constant.
- All trials are independent of each other.

The binomial distribution is a generalization of the Bernoulli distribution; it generalizes to the multinomial distribution.

\section*{Parameters}

Suppose you are collecting data from a widget manufacturing process, and you record the number of widgets within specification in each batch of 100 . You might be interested in the probability that an individual widget is within specification. Parameter estimation is the process of determining the parameter, \(p\), of the binomial distribution that fits this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the binomial pdf above. But for the pdf, the parameters ( \(n\) and \(p\) ) are known constants and the variable is \(x\). The likelihood function reverses the roles of the variables. Here, the sample values (the \(x\) 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the value of \(p\) that give the highest likelihood given the particular set of data.

The function binofit returns the MLEs and confidence intervals for the parameters of the binomial distribution. Here is an example using random numbers from the binomial distribution with \(n=100\) and \(p=0.9\).
```

r = binornd(100,0.9)
r =
88
[phat, pci] = binofit(r,100)
phat =
0.8800
pci =
0.7998
0.9364

```

The MLE for parameter \(p\) is 0.8800 , compared to the true value of 0.9 . The \(95 \%\) confidence interval for \(p\) goes from 0.7998 to 0.9364 , which includes the true value. In this made-up example you know the "true value" of \(p\). In experimentation you do not.

\section*{Example}

The following commands generate a plot of the binomial pdf for \(n=10\) and \(p=1 / 2\).
x = 0:10;
\(y=\) binopdf(x,10,0.5);
plot(x,y,'+')

\section*{See Also}
"Discrete Distributions" on page 5-8

\section*{Birnbaum-Saunders Distribution}

\section*{In this section...}
"Definition" on page B-10
"Background" on page B-10
"Parameters" on page B-11
"See Also" on page B-11

\section*{Definition}

The Birnbaum-Saunders distribution has the density function
\[
\frac{1}{\sqrt{2 \pi}} \exp \left\{-\frac{(\sqrt{x / \beta}-\sqrt{\beta / x})^{2}}{2 \gamma^{2}}\right\}\left(\frac{(\sqrt{x / \beta}+\sqrt{\beta / x})}{2 \gamma x}\right)
\]
with scale parameter \(B>0\) and shape parameter \(\gamma>0\), for \(x>0\).
If \(x\) has a Birnbaum-Saunders distribution with parameters \(B\) and \(\gamma\), then
\[
\frac{(\sqrt{x / \beta}-\sqrt{\beta / x})}{\gamma}
\]
has a standard normal distribution.

\section*{Background}

The Birnbaum-Saunders distribution was originally proposed as a lifetime model for materials subject to cyclic patterns of stress and strain, where the ultimate failure of the material comes from the growth of a prominent flaw. In materials science, Miner's Rule suggests that the damage occurring after \(n\) cycles, at a stress level with an expected lifetime of \(N\) cycles, is proportional
to \(n / N\). Whenever Miner's Rule applies, the Birnbaum-Saunders model is a reasonable choice for a lifetime distribution model.

\section*{Parameters}

See mle, dfittool.

\section*{See Also}
"Continuous Distributions (Data)" on page 5-4

\section*{Burr Type XII Distribution}

\section*{In this section...}
"Definition" on page B-12
"Background" on page B-13
"Parameters" on page B-14
"Fit a Burr Distribution and Draw the cdf" on page B-15

"Burr pdf for Various Parameters" on page B-19
"Survival and Hazard Functions of Burr Distribution" on page B-20
"Divergence of Parameter Estimates" on page B-22
"See Also" on page B-24

\section*{Definition}

The Burr type XII distribution is a three-parameter family of distributions on the positive real line. The cumulative distribution function (cdf) of the Burr distribution is
\[
F(x \mid \alpha, c, k)=1-\frac{1}{\left(1+\left(\frac{x}{\alpha}\right)^{c}\right)^{k}}, \quad x>0, \alpha>0, c>0, k>0,
\]
where \(c\) and \(k\) are the shape parameters and \(\alpha\) is the scale parameter. The probability density function (pdf) is
\[
f(x \mid \alpha, c, k)=\frac{\frac{k c}{\alpha}\left(\frac{x}{\alpha}\right)^{c-1}}{\left(1+\left(\frac{x}{\alpha}\right)^{c}\right)^{k+1}}, \quad x>0, \alpha>0, c>0, k>0 .
\]

The density of the Burr type XII distribution is L-shaped if \(c \leq 1\) and unimodal, otherwise.

\section*{Background}

Burr distribution was first discussed by Burr (1942) as a two-parameter family. An additional scale parameter was introduced by Tadikamalla (1980). It is a very flexible distribution family that can express a wide range of distribution shapes. The Burr distribution includes, overlaps, or has as a limiting case, many commonly used distributions such as gamma, lognormal, loglogistic, bell-shaped, and J-shaped beta distributions (but not U-shaped). Some compound distributions also correspond to the Burr distribution. For example, compounding a Weibull distribution with a gamma distribution for its scale parameter results in a Burr distribution. Similarly, compounding an exponential distribution with a gamma distribution for its rate parameter, \(1 / \mu\), also yields a Burr distribution. The Burr distribution also has two asymptotic limiting cases: Weibull and Pareto Type I.

The Burr distribution can fit a wide range of empirical data. Different values of its parameters cover a broad set of skewness and kurtosis. Hence, it is used in various fields such as finance, hydrology, and reliability to model a variety of data types. Examples of data modeled by the Burr distribution are household income, crop prices, insurance risk, travel time, flood levels, and failure data.

The survival and hazard functions of Burr type XII distribution are, respectively,
\[
S(x \mid \alpha, c, k)=\frac{1}{\left[1+\left(\frac{x}{\alpha}\right)^{c}\right]^{k}}
\]
and
\[
h(x \mid \alpha, c, k)=\frac{\frac{k c}{\alpha}\left(\frac{x}{\alpha}\right)^{c-1}}{1+\left(\frac{x}{\alpha}\right)^{c}}
\]

If \(c>1\), the hazard function \(\mathrm{h}(x)\) is non-monotonic with a mode at \(x=\alpha(c-1)^{1 / c}\).

\section*{Parameters}

The three-parameter Burr distribution is defined by its scale parameter a and shape parameters \(c\) and \(k\). You can estimate the parameters using mle or fitdist. Both functions support censored data for Burr distribution.

Generate sample data from a Burr distribution with scale parameter 0.5 and shape parameters 2 and 5 .
rng('default')
\(R=\) random('burr', \(0.5,2,5,1000,1\) );
Estimate the parameters and the confidence intervals.
```

[phat,pci] = mle(R,'distribution','burr')
phat =
0.4154 2.1217 4.0550
pci =
0.2985 1.9560 2.4079
0.5782 2.3014 6.8288

```

The default \(95 \%\) confidence intervals for the parameters include the true parameter values.

The three-parameter Burr distribution converges asymptotically to one of the two limiting forms as its parameters diverge:
- If \(k \rightarrow 0, c \rightarrow \infty, c k=\lambda\), then the Burr distribution reduces to a two-parameter Pareto distribution with the cdf
\[
F_{P}=1-\left(\frac{x}{\alpha}\right)^{-\lambda}, x \geq \alpha
\]
- If \(k \rightarrow \infty, \alpha \rightarrow \infty, \alpha / k^{1 / c}=\theta\), then the Burr distribution reduces to a two-parameter Weibull distribution with the cdf
\[
F_{W}(x \mid c, \theta)=1-\exp \left[\left(\frac{x}{\alpha}\right)^{-c}\right]
\]

If mle or fitdist detects such divergence, it returns an error message, but informs you of the limiting distribution and corresponding parameter estimates for that distribution.

\section*{Fit a Burr Distribution and Draw the cdf}

This example shows how to fit a Burr distribution to data, draw the cdf, and construct a histogram with a Burr distribution fit.
1. Load the sample data.
load('arrhythmia.mat')
The fifth column in \(X\) contains a measurement obtained from electrocardiograms, called QRS duration.
2. Fit a Burr distribution to the QRS duration data, and get the parameter estimates.

PD = fitdist(X(:,5),'burr');
PD has the maximum likelihood estimates of the Burr distribution parameters in the property Param. The estimates are \(\alpha=80.4515, c=18.9251, k=0.4492\).
3. Plot the cdf of the QRS duration data.
```

QRScdf=cdf('burr',sortrows(X(:,5)), 80.4515,18.9251,0.4492);
plot(sortrows(X(:,5)),QRScdf)
xlabel('QRS Duration')

```

cdf of QRS duration data
4. Draw the histogram of QRS duration data with 15 bins and the pdf of the Burr distribution fit.
histfit(X(:,5),15,'burr')
xlabel('QRS Duration')

Histogram of QRS data with a Burr distribution fit

\section*{Compare Lognormal and Burr pdfs}

This example compares the lognormal pdf to the Burr pdf using income data generated from a lognormal distribution.
1. Generate the income data.
```

rng('default') % for reproducibility
y = random('logn',log(25000),0.65,500,1);

```
2. Fit a Burr distribution.
```

pd = fitdist(y,'burr');

```
3. Plot both the Burr and lognormal pdfs of income data on the same axis.
p = pdf('burr', sortrows(y),26007,2.6374,1.0966);
p2 = pdf('logn',sortrows(y),log(25000), 0.65);
plot(sortrows(y), p,'g',sortrows(y), p2,'r','LineWidth', 2)
legend('burr','lognormal')

\section*{Burr and Lognormal pdfs fitted to income data}

\section*{Burr pdf for Various Parameters}

This example shows how to create a variety of shapes for probability density functions of the Burr distribution.
```

X = 0:0.01:5;
c = [0.5 0.95 2 5];
k = [0.5 0.75 2 5];
alpha = [0.5 1 2 5];
colors = ['b';'g';'r';'k']'
figure
for i = 1:1:4
pdf1(i,:) = pdf('burr',X,1,c(i),0.5);
pdf2(i,:) = pdf('burr',X,1,2,k(i));
pdf3(i,:) = pdf('burr',X,alpha(i),2,0.5);
axC = subplot(3,1,1);
pC(i) = plot(X,pdf1(i,:),colors(i),'LineWidth',2);
title('Effect of c, \alpha = 1, k = 0.5'),xlabel('x')
hold on
axK = subplot(3,1,2);
pK(i) = plot(X,pdf2(i,:),colors(i),'LineWidth',2);
title('Effect of k, \alpha = 1, c = 2'),xlabel('x')
hold on
axAlpha = subplot(3,1,3);
pAlpha(i) = plot(X,pdf3(i,:),colors(i),'LineWidth',2);
title('Effect of \alpha, c = 2, k = 0.5'),xlabel('x')
hold on
end
set(axC,'XLim',[0 3],'YLim',[0 1.2]);
set(axK,'XLim',[0 3],'YLim',[0 2.1]);
set(axAlpha,'XLim',[0 5],'YLim',[0 1]);
legend(axc,'c=0.5','c=0.95','c=2','c=5');
legend(axK,'k=0.5','k=0.75','k=2','k=5');
legend(axAlpha,'\alpha=0.5','\alpha=1','\alpha=2','\alpha=5');

```

This figure illustrates how the shape and scale of the Burr distribution changes for different values of its parameters.

\section*{Survival and Hazard Functions of Burr Distribution}

This example shows how to find and plot the survival and hazard functions for a sample coming from a Burr distribution.
1. Generate the data.
\[
x=0: 0.015: 2.5
\]
2. Evaluate the pdf and cdf of data in \(X\).
```

Xpdf = pdf('burr',X,0.2,5,0.5);
Xcdf = cdf('burr',X,0.2,5,0.5);

```
3. Evaluate and plot the survival function of data in \(X\).
\(S=1 .-X c d f ; ~ \% ~ s u r v i v a l ~ f u n c t i o n ~\) plot(X,S,'LineWidth', 2)
xlabel('x')

\section*{Survival function}
4. Evaluate and plot the hazard function of data in X.
```

H = Xpdf./S; % hazard function
plot(X,H,'r','LineWidth',2)
xlabel('x')

```

\section*{Hazard function}

\section*{Divergence of Parameter Estimates}

This example shows how to interpret the display when the parameter estimates diverge when fitting a Burr distribution to input data.
1. Generate sample data from the Weibull distribution with parameters 0.5 and 2.
```

rng('default') % for reproducibility
X = wblrnd(0.5,2,100,1);

```
2. Fit a Burr distribution.
```

PD = fitdist(X,'burr');
Error using addburr>burrfit (line 566)
The data are not fit by a Burr distribution with finite
parameters. The maximum likelihood fit is provided by the
k->Inf, alpha->Inf limiting form of the Burr distribution: a
Weibull distribution with the parameters below.
a (scale): 0.476817
b (shape): 1.96219
Error in fitdata (line 24)
p = F(x,fixedparams{:},0.05,opts{:});
Error in ProbDistUnivParam.fit (line 94)
pd = fitdata(pd,spec,x,cens,freq,fixedparams,options);
Error in fitdist (line 124)
pd =
ProbDistUnivParam.fit(x,distname,'cens',cens,'freq',freq,args{:});

```

The error message tells you that the Weibull family seems to fit the data better and gives you the parameter estimates from a Weibull fit. You can use those estimates directly. If you need covariance estimates for the parameters or other information about the fit, you can refit a Weibull distribution to the data.
3. Fit a Weibull distribution to the data and find the confidence intervals for the parameter estimates.
```

PD = fitdist(X,'weibull');
paramci(PD)
ans =

```
```

0.4291 1.6821
0.5298 2.2890

```

These are the \(95 \%\) confidence intervals of the parameter estimates for the Weibull distribution fit.

\section*{Chi-Square Distribution}

\section*{In this section...}
"Definition" on page B-25
"Background" on page B-25
"Example" on page B-26
"See Also" on page B-26

\section*{Definition}

The \(X^{2}\) pdf is
\[
y=f(x \mid v)=\frac{x^{(v-2) / 2} e^{-x / 2}}{2^{\frac{v}{2}} \Gamma(v / 2)}
\]
where \(\Gamma(\cdot)\) is the Gamma function, and \(v\) is the degrees of freedom.

\section*{Background}

The \(x^{2}\) distribution is a special case of the gamma distribution where \(b=2\) in the equation for gamma distribution below.
\[
y=f(x \mid a, b)=\frac{1}{b^{a} \Gamma(a)} x^{a-1} e^{\frac{x}{b}}
\]

The \(x^{2}\) distribution gets special attention because of its importance in normal sampling theory. If a set of \(n\) observations is normally distributed with variance \(\sigma^{2}\), and \(s^{2}\) is the sample standard deviation, then
\[
\frac{(n-1) s^{2}}{\sigma^{2}} \square \chi^{2}(n-1)
\]

This relationship is used to calculate confidence intervals for the estimate of the normal parameter \(\sigma^{2}\) in the function normfit.

\section*{Example}

The \(x^{2}\) distribution is skewed to the right especially for few degrees of freedom \((v)\). The plot shows the \(X^{2}\) distribution with four degrees of freedom.
```

x = 0:0.2:15;
y = chi2pdf(x,4);
plot(x,y)

```

User-defined custom distributions, created using files and function handles, are supported by the Statistics Toolbox functions pdf, cdf, icdf, and mle, and the Statistics Toolbox GUI dfittool.

\section*{Exponential Distribution}

\section*{In this section...}
"Definition" on page B-29
"Background" on page B-29
"Parameters" on page B-29
"Example" on page B-30
"See Also" on page B-31

\section*{Definition}

The exponential pdf is
\[
y=f(x \mid \mu)=\frac{1}{\mu} e^{\frac{-x}{\mu}}
\]

\section*{Background}

Like the chi-square distribution, the exponential distribution is a special case of the gamma distribution (obtained by setting \(a=1\) )
\[
y=f(x \mid a, b)=\frac{1}{b^{a} \Gamma(a)} x^{a-1} e^{\frac{x}{b}}
\]
where \(\Gamma(\cdot)\) is the Gamma function.
The exponential distribution is special because of its utility in modeling events that occur randomly over time. The main application area is in studies of lifetimes.

\section*{Parameters}

Suppose you are stress testing light bulbs and collecting data on their lifetimes. You assume that these lifetimes follow an exponential distribution.

You want to know how long you can expect the average light bulb to last. Parameter estimation is the process of determining the parameters of the exponential distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the exponential pdf above. But for the pdf, the parameters are known constants and the variable is \(x\). The likelihood function reverses the roles of the variables. Here, the sample values (the \(x\) 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function expfit returns the MLEs and confidence intervals for the parameters of the exponential distribution. Here is an example using random numbers from the exponential distribution with \(\mu=700\).
```

lifetimes = exprnd(700,100,1);
[muhat, muci] = expfit(lifetimes)
muhat =
672.8207
muci =

```
    547.4338
    810.9437

The MLE for parameter \(\mu\) is 672 , compared to the true value of 700 . The \(95 \%\) confidence interval for \(\mu\) goes from 547 to 811, which includes the true value.

In the life tests you do not know the true value of \(\mu\) so it is nice to have a confidence interval on the parameter to give a range of likely values.

\section*{Example}

For exponentially distributed lifetimes, the probability that an item will survive an extra unit of time is independent of the current age of the item. The example shows a specific case of this special property.
```

l = 10:10:60;

```
```

lpd = l+0.1;
deltap = (expcdf(lpd,50)-\operatorname{expcdf(1,50))./(1-\operatorname{expcdf}(1,50))}
deltap =
0.0020 0.0020 0.0020 0.0020 0.0020 0.0020

```

The following commands generate a plot of the exponential pdf with its parameter (and mean), \(\mu\), set to 2 .
\(x=0: 0.1: 10 ;\)
\(y=\operatorname{exppdf}(x, 2)\);
plot(x,y)

\section*{Extreme Value Distribution}

\section*{In this section...}
"Definition" on page B-32
"Background" on page B-32
"Parameters" on page B-34
"Example" on page B-35
"See Also" on page B-37

\section*{Definition}

The probability density function for the extreme value distribution with location parameter \(\mu\) and scale parameter \(\sigma\) is
\[
y=f(x \mid \mu, \sigma)=\sigma^{-1} \exp \left(\frac{x-\mu}{\sigma}\right) \exp \left(-\exp \left(\frac{x-\mu}{\sigma}\right)\right)
\]

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

If \(T\) has a Weibull distribution with parameters \(a\) and \(b\), then \(\log T\) has an extreme value distribution with parameters \(\mu=\log a\) and \(\sigma=1 / b\).

\section*{Background}

Extreme value distributions are often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

For example, the following fits an extreme value distribution to minimum values taken over 1000 sets of 500 observations from a normal distribution:
```

xMinima = min(randn(1000,500), [], 2);
paramEstsMinima = evfit(xMinima);
y = linspace(-5,-1.5,1001);
hist(xMinima,-4.75:.25:-1.75);
p = evpdf(y,paramEstsMinima(1),paramEstsMinima(2));
line(y,.25*length(xMinima)*p,'color','r')

```

The following fits an extreme value distribution to the maximum values in each set of observations:
```

xMaxima = max(randn(1000,500), [], 2);
paramEstsMaxima = evfit(-xMaxima);
y = linspace(1.5,5,1001);
hist(xMaxima,1.75:.25:4.75);
p = evpdf(-y,paramEstsMaxima(1),paramEstsMaxima(2));
line(y,.25*length(xMaxima)*p,'color','r')

```

Although the extreme value distribution is most often used as a model for extreme values, you can also use it as a model for other types of continuous data. For example, extreme value distributions are closely related to the Weibull distribution. If T has a Weibull distribution, then \(\log (T)\) has a type 1 extreme value distribution.

\section*{Parameters}

The function evfit returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the extreme value distribution. The following example shows how to fit some sample data using evfit, including estimates of the mean and variance from the fitted distribution.

Suppose you want to model the size of the smallest washer in each batch of 1000 from a manufacturing process. If you believe that the sizes are
independent within and between each batch, you can fit an extreme value distribution to measurements of the minimum diameter from a series of eight experimental batches. The following code returns the MLEs of the distribution parameters as parmhat and the confidence intervals as the columns of parmci.
```

x = [ll9.774 20.141 19.44 20.511 21.377 19.003 19.66 18.83];
[parmhat, parmci] = evfit(x)
parmhat =
20.2506 0.8223
parmci =
19.644 0.49861
20.857 1.3562

```

You can find mean and variance of the extreme value distribution with these parameters using the function evstat.
```

[meanfit, varfit] = evstat(parmhat(1),parmhat(2))
meanfit =
19.776
varfit =
1.1123

```

\section*{Example}

The following code generates a plot of the pdf for the extreme value distribution.
```

t = [-5:.01:2];
y = evpdf(t);
plot(t,y)

```

The extreme value distribution is skewed to the left, and its general shape remains the same for all parameter values. The location parameter, mu, shifts the distribution along the real line, and the scale parameter, sigma, expands or contracts the distribution. This example plots the probability function for different combinations of mu and sigma.
```

x = -15:.01:5;
plot(x,evpdf(x,2,1),'-', ...
x,evpdf(x,0,2),':', ...
x,evpdf(x,-2,4),'-.');
legend({'mu = 2, sigma = 1', ...
'mu = 0, sigma = 2', ...
'mu = -2, sigma = 4'}, ...
'Location','NW')
xlabel('x')
ylabel('f(x|mu,sigma)')

```

\section*{See Also}

\section*{F Distribution}

\section*{In this section...}
"Definition" on page B-38
"Background" on page B-38
"Example" on page B-39
"See Also" on page B-39

\section*{Definition}

The pdf for the \(F\) distribution is
\[
y=f\left(x \mid v_{1}, v_{2}\right)=\frac{\Gamma\left[\frac{\left(v_{1}+v_{2}\right)}{2}\right]}{\Gamma\left(\frac{v_{1}}{2}\right) \Gamma\left(\frac{v_{2}}{2}\right)}\left(\frac{v_{1}}{v_{2}}\right)^{\frac{v_{1}}{2}} \frac{x^{\frac{v_{1}-2}{2}}}{\left[1+\left(\frac{v_{1}}{v_{2}}\right) x\right]^{\frac{v_{1}+v_{2}}{2}}}
\]
where \(\Gamma(\cdot)\) is the Gamma function.

\section*{Background}

The \(F\) distribution has a natural relationship with the chi-square distribution. If \(X_{1}\) and \(x_{2}\) are both chi-square with \(v_{1}\) and \(v_{2}\) degrees of freedom respectively, then the statistic \(F\) below is \(F\)-distributed.
\[
F\left(v_{1}, v_{2}\right)=\frac{\chi_{1} / v_{1}}{\chi_{2} / v_{2}}
\]

The two parameters, \(v_{1}\) and \(v_{2}\), are the numerator and denominator degrees of freedom. That is, \(v_{1}\) and \(v_{2}\) are the number of independent pieces of information used to calculate \(x_{1}\) and \(x_{2}\), respectively.

\section*{Example}

The most common application of the \(F\) distribution is in standard tests of hypotheses in analysis of variance and regression.

The plot shows that the \(F\) distribution exists on the positive real numbers and is skewed to the right.
\[
\begin{aligned}
& x=0: 0.01: 10 ; \\
& y=f p d f(x, 5,3) ; \\
& \operatorname{plot}(x, y)
\end{aligned}
\]

\section*{Gamma Distribution}

\author{
In this section... \\ "Definition" on page B-40 \\ "Background" on page B-40 \\ "Parameters" on page B-41 \\ "Example" on page B-42 \\ "See Also" on page B-42
}

\section*{Definition}

The gamma pdf is
\[
y=f(x \mid a, b)=\frac{1}{b^{a} \Gamma(a)} x^{a-1} e^{\frac{-x}{b}}
\]
where \(\Gamma(\cdot)\) is the Gamma function.

\section*{Background}

The gamma distribution models sums of exponentially distributed random variables.

The gamma distribution family is based on two parameters. The chi-square and exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution has the following relationship with the incomplete Gamma function.
\[
f(x \mid a, b)=\text { gammainc }\left(\frac{x}{b}, a\right)
\]

When \(a\) is large, the gamma distribution closely approximates a normal distribution with the advantage that the gamma distribution has density only for positive real numbers.

\section*{Parameters}

Suppose you are stress testing computer memory chips and collecting data on their lifetimes. You assume that these lifetimes follow a gamma distribution. You want to know how long you can expect the average computer memory chip to last. Parameter estimation is the process of determining the parameters of the gamma distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the gamma pdf above. But for the pdf, the parameters are known constants and the variable is \(x\). The likelihood function reverses the roles of the variables. Here, the sample values (the \(x\) 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function gamfit returns the MLEs and confidence intervals for the parameters of the gamma distribution. Here is an example using random numbers from the gamma distribution with \(a=10\) and \(b=5\).
```

lifetimes = gamrnd(10,5,100,1);

```
[phat, pci] = gamfit(lifetimes)
phat =
    10.98214 .7258
pci \(=\)
    \(7.4001 \quad 3.1543\)
    \(14.5640 \quad 6.2974\)

Note phat (1) \(=\hat{a}\) and phat (2) \(=\hat{b}\). The MLE for parameter \(a\) is 10.98 , compared to the true value of 10 . The \(95 \%\) confidence interval for \(a\) goes from 7.4 to 14.6 , which includes the true value.

Similarly the MLE for parameter \(b\) is 4.7, compared to the true value of 5 . The \(95 \%\) confidence interval for \(b\) goes from 3.2 to 6.3 , which also includes the true value.

In the life tests you do not know the true value of \(a\) and \(b\) so it is nice to have a confidence interval on the parameters to give a range of likely values.

\section*{Example}

In the example the gamma pdf is plotted with the solid line. The normal pdf has a dashed line type.
```

x = gaminv((0.005:0.01:0.995),100,10);
y = gampdf(x,100,10);
y1 = normpdf(x,1000,100);
plot(x,y,'-',x,y1,'-.')

```

\section*{Generalized Extreme Value Distribution}

\section*{In this section...}
"Definition" on page B-45
"Background" on page B-45
"Parameters" on page B-46
"Example" on page B-47
"See Also" on page B-49

\section*{Definition}

The probability density function for the generalized extreme value distribution with location parameter \(\mu\), scale parameter \(\sigma\), and shape parameter \(k \neq 0\) is
\[
y=f(x \mid \mathrm{k}, \mu, \sigma)=\left(\frac{1}{\sigma}\right) \exp \left(-\left(1+\mathrm{k} \frac{(x-\mu)}{\sigma}\right)^{-\frac{1}{k}}\right)\left(1+\mathrm{k} \frac{(x-\mu)}{\sigma}\right)^{-1-\frac{1}{\mathrm{k}}}
\]
for
\[
1+k \frac{(x-\mu)}{\sigma}>0
\]
k > 0 corresponds to the Type II case, while k < 0 corresponds to the Type III case. For k = 0, corresponding to the Type I case, the density is
\[
y=f(x \mid 0, \mu, \sigma)=\left(\frac{1}{\sigma}\right) \exp \left(-\exp \left(-\frac{(x-\mu)}{\sigma}\right)-\frac{(x-\mu)}{\sigma}\right)
\]

\section*{Background}

Like the extreme value distribution, the generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. For example, you might have batches of 1000
washers from a manufacturing process. If you record the size of the largest washer in each batch, the data are known as block maxima (or minima if you record the smallest). You can use the generalized extreme value distribution as a model for those block maxima.

The generalized extreme value combines three simpler distributions into a single form, allowing a continuous range of possible shapes that includes all three of the simpler distributions. You can use any one of those distributions to model a particular dataset of block maxima. The generalized extreme value distribution allows you to "let the data decide" which distribution is appropriate.

The three cases covered by the generalized extreme value distribution are often referred to as the Types I, II, and III. Each type corresponds to the limiting distribution of block maxima from a different class of underlying distributions. Distributions whose tails decrease exponentially, such as the normal, lead to the Type I. Distributions whose tails decrease as a polynomial, such as Student's \(t\), lead to the Type II. Distributions whose tails are finite, such as the beta, lead to the Type III.

Types I, II, and III are sometimes also referred to as the Gumbel, Frechet, and Weibull types, though this terminology can be slightly confusing. The Type I (Gumbel) and Type III (Weibull) cases actually correspond to the mirror images of the usual Gumbel and Weibull distributions, for example, as computed by the functions evcdf and evfit, or wblcdf and wblfit, respectively. Finally, the Type II (Frechet) case is equivalent to taking the reciprocal of values from a standard Weibull distribution.

\section*{Parameters}

If you generate 250 blocks of 1000 random values drawn from Student's \(t\) distribution with 5 degrees of freedom, and take their maxima, you can fit a generalized extreme value distribution to those maxima.
```

blocksize = 1000;
nblocks = 250;
t = trnd(5,blocksize,nblocks);
x = max(t); % 250 column maxima
paramEsts = gevfit(x)
paramEsts =

```
```

0.2438 1.1760
5.8045

```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on block maxima from a Student's \(t\) distribution.
```

hist(x,2:20);
set(get(gca,'child'),'FaceColor',[.8 . 8 1])
xgrid = linspace(2,20,1000);
line(xgrid,nblocks*...
gevpdf(xgrid,paramEsts(1),paramEsts(2),paramEsts(3)));

```

\section*{Example}

The following code generates examples of probability density functions for the three basic forms of the generalized extreme value distribution.
```

x = linspace(-3,6,1000);
y1 = gevpdf(x,-.5,1,0);
y2 = gevpdf(x,0,1,0);
y3 = gevpdf(x,.5,1,0)
plot(x,y1,'-', x,y2,'-', x,y3,'-')
legend({'K<0, Type III' 'K=0, Type I' 'K>0, Type II'});

```

Notice that for \(\mathrm{k}>0\), the distribution has zero probability density for x such that
\[
x<-\frac{\sigma}{\mathrm{k}}+\mu
\]

For k < 0, the distribution has zero probability density for
\[
x>-\frac{\sigma}{\mathrm{k}}+\mu
\]

For \(\mathrm{k}=0\), there is no upper or lower bound.

\section*{Generalized Pareto Distribution}

\section*{In this section...}
"Definition" on page B-50
"Background" on page B-50
"Parameters" on page B-51
"Example" on page B-52
"See Also" on page B-53

\section*{Definition}

The probability density function for the generalized Pareto distribution with shape parameter \(k \neq 0\), scale parameter \(\sigma\), and threshold parameter \(\theta\), is
\[
y=f(x \mid k, \sigma, \theta)=\left(\frac{1}{\sigma}\right)\left(1+k \frac{(x-\theta)}{\sigma}\right)^{-1-\frac{1}{k}}
\]
for \(\theta<x\), when \(k>0\), or for \(\theta<x<-\sigma / k\) when \(k<0\).
For \(k=0\), the density is
\[
y=f(x \mid 0, \sigma, \theta)=\left(\frac{1}{\sigma}\right) \mathrm{e}^{-\frac{(x-\theta)}{\sigma}}
\]
for \(\theta<x\).
If \(k=0\) and \(\theta=0\), the generalized Pareto distribution is equivalent to the exponential distribution. If \(k>0\) and \(\theta=\sigma / k\), the generalized Pareto distribution is equivalent to the Pareto distribution.

\section*{Background}

Like the exponential distribution, the generalized Pareto distribution is often used to model the tails of another distribution. For example, you might have washers from a manufacturing process. If random influences in the process lead to differences in the sizes of the washers, a standard probability
distribution, such as the normal, could be used to model those sizes. However, while the normal distribution might be a good model near its mode, it might not be a good fit to real data in the tails and a more complex model might be needed to describe the full range of the data. On the other hand, only recording the sizes of washers larger (or smaller) than a certain threshold means you can fit a separate model to those tail data, which are known as exceedences. You can use the generalized Pareto distribution in this way, to provide a good fit to extremes of complicated data.

The generalized Pareto distribution allows a continuous range of possible shapes that includes both the exponential and Pareto distributions as special cases. You can use either of those distributions to model a particular dataset of exceedences. The generalized Pareto distribution allows you to "let the data decide" which distribution is appropriate.

The generalized Pareto distribution has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.
- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease as a polynomial, such as Student's \(t\), lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution is used in the tails of distribution fit objects of the paretotails class.

\section*{Parameters}

If you generate a large number of random values from a Student's \(t\) distribution with 5 degrees of freedom, and then discard everything less than 2 , you can fit a generalized Pareto distribution to those exceedences.
```

t = trnd(5,5000,1);
y = t(t > 2) - 2;
paramEsts = gpfit(y)
paramEsts =

```
\[
0.1267 \quad 0.8134
\]

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on exceedences from a Student's \(t\) distribution.
```

hist(y+2,2.25:.5:11.75);
set(get(gca,'child'),'FaceColor',[.8 . 8 1])
xgrid = linspace(2,12,1000);
line(xgrid,.5*length(y)*...
gppdf(xgrid,paramEsts(1),paramEsts(2),2));

```

\section*{Example}

The following code generates examples of the probability density functions for the three basic forms of the generalized Pareto distribution.
x = linspace(0,10,1000);
```

y1 = gppdf(x,-.25,1,0);
y2 = gppdf(x,0,1,0);
y3 = gppdf(x,1,1,0)
plot(x,y1,'-', x,y2,'-', x,y3,'-')
legend({'K<0' 'K=O' 'K>0'});

```

Notice that for \(\mathrm{k}<0\), the distribution has zero probability density for \(x>-\frac{\sigma}{\mathrm{k}}\), while for \(k \geq 0\), there is no upper bound.

\section*{Geometric Distribution}

\author{
In this section... \\ "Definition" on page B-54 \\ "Background" on page B-54 \\ "Example" on page B-54 \\ "See Also" on page B-55
}

\section*{Definition}

The geometric pdf is
\[
y=f(x \mid p)=p q^{x} I_{(0,1, \ldots)}(x)
\]
where \(q=1-p\). The geometric distribution is a special case of the negative binomial distribution, with \(r=1\).

\section*{Background}

The geometric distribution is discrete, existing only on the nonnegative integers. It is useful for modeling the runs of consecutive successes (or failures) in repeated independent trials of a system.

The geometric distribution models the number of successes before one failure in an independent succession of tests where each test results in success or failure.

\section*{Example}

Suppose the probability of a five-year-old battery failing in cold weather is 0.03. What is the probability of starting 25 consecutive days during a long cold snap?

1 - geocdf(25,0.03)
ans =
\[
0.4530
\]

The plot shows the cdf for this scenario.
\(x=0: 25 ;\)
\(y=\operatorname{geocdf}(x, 0.03)\);
stairs(x,y)

\section*{Hypergeometric Distribution}

\section*{In this section...}
"Definition" on page B-56
"Background" on page B-56
"Example" on page B-57
"See Also" on page B-57

\section*{Definition}

The hypergeometric pdf is
\[
y=f(x \mid M, K, n)=\frac{\binom{K}{x}\binom{M-K}{n-x}}{\binom{M}{n}}
\]

\section*{Background}

The hypergeometric distribution models the total number of successes in a fixed-size sample drawn without replacement from a finite population.

The distribution is discrete, existing only for nonnegative integers less than the number of samples or the number of possible successes, whichever is greater. The hypergeometric distribution differs from the binomial only in that the population is finite and the sampling from the population is without replacement.

The hypergeometric distribution has three parameters that have direct physical interpretations.
- \(M\) is the size of the population.
- \(K\) is the number of items with the desired characteristic in the population.
- \(n\) is the number of samples drawn.

Sampling "without replacement" means that once a particular sample is chosen, it is removed from the relevant population for all subsequent selections.

\section*{Example}

The plot shows the cdf of an experiment taking 20 samples from a group of 1000 where there are 50 items of the desired type.
```

x = 0:10;
y = hygecdf(x,1000,50,20);
stairs(x,y)

```

\section*{Inverse Gaussian Distribution}

\section*{In this section...}
"Definition" on page B-58
"Background" on page B-58
"Parameters" on page B-58
"See Also" on page B-58

\section*{Definition}

The inverse Gaussian distribution has the density function
\[
\sqrt{\frac{\lambda}{2 \pi x^{3}}} \exp \left\{-\frac{\lambda}{2 \mu^{2} x}(x-\mu)^{2}\right\}
\]

\section*{Background}

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. The distribution originated in the theory of Brownian motion, but has been used to model diverse phenomena. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

\section*{Parameters}

See mle, dfittool.

\section*{See Also}
"Continuous Distributions (Data)" on page 5-4

\section*{Inverse Wishart Distribution}

\section*{Definition}

The probability density function of the \(d\)-dimensional Inverse Wishart distribution is given by
\[
y=f(\mathrm{X}, \Sigma, v)=\frac{|T|^{(v / 2)} e^{\left(-\frac{1}{2} \operatorname{trace}\left(T X^{-1}\right)\right)}}{2^{(v d) / 2} \pi^{(d(d-1)) / 4}|X|^{(v+d+1) / 2} \Gamma(v / 2) \ldots \Gamma(v-(d-1)) / 2}
\]
where \(X\) and \(T\) are \(d\)-by- \(d\) symmetric positive definite matrices, and \(v\) is a scalar greater than or equal to \(d\). While it is possible to define the Inverse Wishart for singular \(T\), the density cannot be written as above.

If a random matrix has a Wishart distribution with parameters \(T^{-1}\) and \(v\), then the inverse of that random matrix has an inverse Wishart distribution with parameters \(T\) and \(v\). The mean of the distribution is given by
\[
\frac{1}{v-d-1} T
\]
where \(d\) is the number of rows and columns in \(T\).
Only random matrix generation is supported for the inverse Wishart, including both singular and nonsingular \(T\).

\section*{Background}

The inverse Wishart distribution is based on the Wishart distribution. In Bayesian statistics it is used as the conjugate prior for the covariance matrix of a multivariate normal distribution.

\section*{Example}

Notice that the sampling variability is quite large when the degrees of freedom is small.
```

Tau = [1 .5; .5 2];
df = 10; S1 = iwishrnd(Tau,df)*(df-2-1)

```
```

S1 =
1.7959 0.64107
0.64107 1.5496
df = 1000; S2 = iwishrnd(Tau,df)*(df-2-1)
S2 =

| 0.9842 | 0.50158 |
| ---: | ---: |
| 0.50158 | 2.1682 |

```

\section*{Johnson System}

See "Pearson and Johnson Systems" on page 6-25.

\section*{Logistic Distribution}

\author{
In this section... \\ "Definition" on page B-62 \\ "Background" on page B-62 \\ "Parameters" on page B-62 \\ "See Also" on page B-62
}

\section*{Definition}

The logistic distribution has the density function
\[
\frac{e^{\frac{x-\mu}{\sigma}}}{\sigma\left(1+e^{\frac{x-\mu}{\sigma}}\right)^{2}}
\]
with location parameter \(\mu\) and scale parameter \(\sigma>0\), for all real \(x\).

\section*{Background}

The logistic distribution originated with Verhulst's work on demography in the early 1800s. The distribution has been used for various growth models, and is used in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

\section*{Parameters}

See mle, dfittool.

\section*{See Also}
"Continuous Distributions (Data)" on page 5-4

\section*{Loglogistic Distribution}

\author{
In this section... \\ "Definition" on page B-63 \\ "Parameters" on page B-63 \\ "See Also" on page B-63
}

\section*{Definition}

The variable \(x\) has a loglogistic distribution with location parameter \(\mu\) and scale parameter \(\sigma>0\) if \(\ln x\) has a logistic distribution with parameters \(\mu\) and \(\sigma\). The relationship is similar to that between the lognormal and normal distribution.

\section*{Parameters}

See mle, dfittool.

\section*{See Also}
"Continuous Distributions (Data)" on page 5-4

\section*{Lognormal Distribution}

\section*{In this section...}
"Definition" on page B-64
"Background" on page B-64
"Example" on page B-65
"See Also" on page B-66

\section*{Definition}

The lognormal pdf is
\[
y=f(x \mid \mu, \sigma)=\frac{1}{x \sigma \sqrt{2 \pi}} e^{\frac{-(\ln x-\mu)^{2}}{2 \sigma^{2}}}
\]

\section*{Background}

The normal and lognormal distributions are closely related. If \(X\) is distributed \(\operatorname{lognormally}\) with parameters \(\mu\) and \(\sigma\), then \(\log (X)\) is distributed normally with mean \(\mu\) and standard deviation \(\sigma\).

The mean \(m\) and variance \(v\) of a lognormal random variable are functions of \(\mu\) and \(\sigma\) that can be calculated with the lognstat function. They are:
\[
\begin{aligned}
& m=\exp \left(\mu+\sigma^{2} / 2\right) \\
& v=\exp \left(2 \mu+\sigma^{2}\right)\left(\exp \left(\sigma^{2}\right)-1\right)
\end{aligned}
\]

A lognormal distribution with mean \(m\) and variance \(v\) has parameters
\[
\begin{aligned}
& \mu=\log \left(m^{2} / \sqrt{v+m^{2}}\right) \\
& \sigma=\sqrt{\log \left(v / m^{2}+1\right)}
\end{aligned}
\]

The lognormal distribution is applicable when the quantity of interest must be positive, since \(\log (X)\) exists only when \(X\) is positive.

\section*{Example}

Suppose the income of a family of four in the United States follows a lognormal distribution with \(\mu=\log (20,000)\) and \(\sigma^{2}=1.0\). Plot the income density.
```

x = (10:1000:125010)';
y = lognpdf(x,log(20000),1.0);
plot(x,y)
set(gca,'xtick',[0 30000 60000 90000 120000])
set(gca,'xticklabel',{'0','\$30,000','\$60,000',...
'\$90,000','\$120,000'})

```

\section*{See Also}
"Continuous Distributions (Data)" on page 5-4

\section*{Multinomial Distribution}

\section*{In this section...}
"Definition" on page B-67
"Background" on page B-67
"Example" on page B-67
"See Also" on page B-69

\section*{Definition}

The multinomial pdf is
\[
f(x \mid n, p)=\frac{n!}{x_{1}!\cdots x_{k}!} p_{1}^{x_{1}} \cdots p_{k}^{x_{k}}
\]
where \(x=\left(x_{1}, \ldots, x_{k}\right)\) gives the number of each of \(k\) outcomes in \(n\) trials of a process with fixed probabilities \(p=\left(p_{1}, \ldots, p_{k}\right)\) of individual outcomes in any one trial. The vector \(x\) has non-negative integer components that sum to \(n\). The vector \(p\) has non-negative integer components that sum to 1 .

\section*{Background}

The multinomial distribution is a generalization of the binomial distribution. The binomial distribution gives the probability of the number of "successes" and "failures" in \(n\) independent trials of a two-outcome process. The probability of "success" and "failure" in any one trial is given by the fixed probabilities \(p\) and \(q=1-p\). The multinomial distribution gives the probability of each combination of outcomes in \(n\) independent trials of a \(k\)-outcome process. The probability of each outcome in any one trial is given by the fixed probabilities \(p_{1}, \ldots, p_{\mathrm{k}}\).

The expected value of outcome \(i\) is \(n p_{i}\). The variance of outcome \(i\) is \(n p_{i}\left(1-p_{i}\right)\). The covariance of outcomes \(i\) and \(j\) is \(-n p_{i} p_{j}\) for distinct \(i\) and \(j\).

\section*{Example}

The following uses mnpdf to produce a visualization of a trinomial distribution:
```

% Compute the distribution
p = [1/2 1/3 1/6]; % Outcome probabilities
n = 10; % Sample size
x1 = 0:n;
x2 = 0:n;
[X1,X2] = meshgrid(x1,x2);
X3 = n-(X1+X2);
Y = mnpdf([X1(:),X2(:),X3(:)],repmat(p,(n+1)^2,1));
% Plot the distribution
Y = reshape(Y, n+1,n+1);
bar3(Y)
set(gca,'XTickLabel',0:n)
set(gca,'YTickLabel',0:n)
xlabel('x_1')
ylabel('x_2')
zlabel('Probability Mass')

```

Trinomial Distribution

Note that the visualization does not show \(x_{3}\), which is determined by the constraint \(x_{1}+x_{2}+x_{3}=n\).

\title{
Multivariate Gaussian Distribution
}

\author{
See "Multivariate Normal Distribution" on page B-71.
}

\section*{Multivariate Normal Distribution}

\section*{In this section...}
"Definition" on page B-71
"Background" on page B-71
"Example" on page B-72
"See Also" on page B-76

\section*{Definition}

The probability density function of the \(d\)-dimensional multivariate normal distribution is given by
\[
y=f(x, \mu, \Sigma)=\frac{1}{\sqrt{|\Sigma|(2 \pi)^{d}}} e^{-\frac{1}{2}(x-\mu) \Sigma^{-1}(x-\mu)^{\prime}}
\]
where \(x\) and \(\mu\) are 1-by- \(d\) vectors and \(\Sigma\) is a \(d\)-by- \(d\) symmetric positive definite matrix. While it is possible to define the multivariate normal for singular \(\Sigma\), the density cannot be written as above. Only random vector generation is supported for the singular case. Note that while most textbooks define the multivariate normal with \(x\) and \(\mu\) oriented as column vectors, for the purposes of data analysis software, it is more convenient to orient them as row vectors, and Statistics Toolbox software uses that orientation.

\section*{Background}

The multivariate normal distribution is a generalization of the univariate normal to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate normal distribution. In the simplest case, there is no correlation among variables, and elements of the vectors are independent univariate normal random variables.

The multivariate normal distribution is parameterized with a mean vector, \(\mu\), and a covariance matrix, \(\Sigma\). These are analogous to the mean \(\mu\) and variance \(\sigma^{2}\) parameters of a univariate normal distribution. The diagonal elements of \(\Sigma\)
contain the variances for each variable, while the off-diagonal elements of \(\Sigma\) contain the covariances between variables.

The multivariate normal distribution is often used as a model for multivariate data, primarily because it is one of the few multivariate distributions that is tractable to work with.

\section*{Example}

This example shows the probability density function (pdf) and cumulative distribution function (cdf) for a bivariate normal distribution with unequal standard deviations. You can use the multivariate normal distribution in a higher number of dimensions as well, although visualization is not easy.
```

mu = [0 0];
Sigma = [.25 .3; . 3 1];
x1 = -3:.2:3; x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
F = mvnpdf([X1(:) X2(:)],mu,Sigma);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 .4])
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');

```

```

F = mvncdf([X1(:) X2(:)],mu,Sigma);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 1])
xlabel('x1'); ylabel('x2'); zlabel('Cumulative Probability');

```

Since the bivariate normal distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions. For example, this contour plot illustrates the computation that follows, of the probability contained within the unit square.
```

contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);
xlabel('x'); ylabel('y');
line([0 0 1 1 0],[1 0 0 1 1],'linestyle','--','color','k');

```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the mvncdf function computes values to less than full machine precision, and returns an estimate of the error as an optional second output:
```

[F,err] = mvncdf([0 0],[1 1],mu,Sigma)
F =
0.20974
err =
1e-008

```

\section*{See Also}

\section*{Multivariate \(\dagger\) Distribution}

\section*{In this section...}
"Definition" on page B-77
"Background" on page B-77
"Example" on page B-78
"See Also" on page B-82

\section*{Definition}

The probability density function of the \(d\)-dimensional multivariate Student's \(t\) distribution is given by
\[
f(x, \Sigma, v)=\frac{1}{|\Sigma|^{1 / 2}} \frac{1}{\sqrt{(v \pi)^{d}}} \frac{\Gamma((v+d) / 2)}{\Gamma(v / 2)}\left(1+\frac{x^{\prime} \Sigma^{-1} x}{v}\right)^{-(v+d) / 2}
\]
where \(x\) is a 1 -by- \(d\) vector, \(\Sigma\) is a \(d\)-by- \(d\) symmetric, positive definite matrix, and \(v\) is a positive scalar. While it is possible to define the multivariate Student's \(t\) for singular \(\Sigma\), the density cannot be written as above. For the singular case, only random number generation is supported. Note that while most textbooks define the multivariate Student's \(t\) with \(x\) oriented as a column vector, for the purposes of data analysis software, it is more convenient to orient \(x\) as a row vector, and Statistics Toolbox software uses that orientation.

\section*{Background}

The multivariate Student's \(t\) distribution is a generalization of the univariate Student's \(t\) to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate Student's \(t\) distribution. In the same way as the univariate Student's \(t\) distribution can be constructed by dividing a standard univariate normal random variable by the square root of a univariate chi-square random variable, the multivariate Student's \(t\) distribution can be constructed by dividing a multivariate normal random vector having zero mean and unit variances by a univariate chi-square random variable.

The multivariate Student's \(t\) distribution is parameterized with a correlation matrix, \(\Sigma\), and a positive scalar degrees of freedom parameter, \(v . v\) is analogous to the degrees of freedom parameter of a univariate Student's \(t\) distribution. The off-diagonal elements of \(\Sigma\) contain the correlations between variables. Note that when \(\Sigma\) is the identity matrix, variables are uncorrelated; however, they are not independent.

The multivariate Student's \(t\) distribution is often used as a substitute for the multivariate normal distribution in situations where it is known that the marginal distributions of the individual variables have fatter tails than the normal.

\section*{Example}

This example shows the probability density function (pdf) and cumulative distribution function (cdf) for a bivariate Student's \(t\) distribution. You can use the multivariate Student's \(t\) distribution in a higher number of dimensions as well, although visualization is not easy.
```

Rho = [1 .6; .6 1];
nu = 5;
x1 = -3:.2:3; x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
F = mvtpdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 .2])
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');

```

```

F = mvtcdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([[-3 3 -3 3 0 1])
xlabel('x1'); ylabel('x2'); zlabel('Cumulative Probability');

```

Since the bivariate Student's \(t\) distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions. For example, this contour plot illustrates the computation that follows, of the probability contained within the unit square.
```

contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);
xlabel('x'); ylabel('y');
line([0 0 1 1 0],[1 0 0 1 1],'linestyle','--','color','k');

```

```

mvtcdf([00 0],[$$
\begin{array}{ll}{1}&{1}\end{array}
$$],Rho,nu)

```
ans =
0.14013

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the mvtcdf function computes values to less than full machine precision, and returns an estimate of the error as an optional second output:
```

[F,err] = mvtcdf([0 0],[1 1],Rho,nu)
F =
0.14013
err =
1e-008

```

The Nakagami distribution has the density function
\[
2\left(\frac{\mu}{\omega}\right)^{\mu} \frac{1}{\Gamma(\mu)} x^{(2 \mu-1)} e^{\frac{-\mu}{\omega} x^{2}}
\]
with shape parameter \(\mu\) and scale parameter \(\omega>0\), for \(x>0\). If \(x\) has a Nakagami distribution with parameters \(\mu\) and \(\omega\), then \(x^{2}\) has a gamma distribution with shape parameter \(\mu\) and scale parameter \(\omega / \mu\).

\section*{Background}

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

\section*{Negative Binomial Distribution}

\section*{In this section...}
"Definition" on page B-85
"Background" on page B-85
"Parameters" on page B-86
"Example" on page B-87
"See Also" on page B-88

\section*{Definition}

When the \(r\) parameter is an integer, the negative binomial pdf is
\[
y=f(x \mid r, p)=\binom{r+x-1}{x} p^{r} q^{x} I_{(0,1, \ldots)}(x)
\]
where \(q=1-p\). When \(r\) is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression
\[
\frac{\Gamma(r+x)}{\Gamma(r) \Gamma(x+1)}
\]

\section*{Background}

In its simplest form (when \(r\) is an integer), the negative binomial distribution models the number of failures \(x\) before a specified number of successes is reached in a series of independent, identical trials. Its parameters are the probability of success in a single trial, \(p\), and the number of successes, \(r\). A special case of the negative binomial distribution, when \(r=1\), is the geometric distribution, which models the number of failures before the first success.

More generally, \(r\) can take on non-integer values. This form of the negative binomial distribution has no interpretation in terms of repeated trials, but, like the Poisson distribution, it is useful in modeling count data. The negative binomial distribution is more general than the Poisson distribution because it has a variance that is greater than its mean, making it suitable for count data
that do not meet the assumptions of the Poisson distribution. In the limit, as \(r\) increases to infinity, the negative binomial distribution approaches the Poisson distribution.

\section*{Parameters}

Suppose you are collecting data on the number of auto accidents on a busy highway, and would like to be able to model the number of accidents per day. Because these are count data, and because there are a very large number of cars and a small probability of an accident for any specific car, you might think to use the Poisson distribution. However, the probability of having an accident is likely to vary from day to day as the weather and amount of traffic change, and so the assumptions needed for the Poisson distribution are not met. In particular, the variance of this type of count data sometimes exceeds the mean by a large amount. The data below exhibit this effect: most days have few or no accidents, and a few days have a large number.
```

accident = [2 [14 4
mean(accident)
ans =
8.0667
var(accident)
ans =
79.352

```

The negative binomial distribution is more general than the Poisson, and is often suitable for count data when the Poisson is not. The function nbinfit returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the negative binomial distribution. Here are the results from fitting the accident data:
```

[phat,pci] = nbinfit(accident)
phat =
1.0060 0.1109
pci =
0.2152 0.0171
1.7968 0.2046

```

It is difficult to give a physical interpretation in this case to the individual parameters. However, the estimated parameters can be used in a model
for the number of daily accidents. For example, a plot of the estimated cumulative probability function shows that while there is an estimated \(10 \%\) chance of no accidents on a given day, there is also about a \(10 \%\) chance that there will be 20 or more accidents.
```

plot(0:50,nbincdf(0:50,phat(1), phat(2)),'.-');
xlabel('Accidents per Day')
ylabel('Cumulative Probability')

```

\section*{Example}

The negative binomial distribution can take on a variety of shapes ranging from very skewed to nearly symmetric. This example plots the probability function for different values of \(r\), the desired number of successes: . 1, 1, 3, 6 . \(x=0: 10 ;\)
```

plot(x,nbinpdf(x,.1,.5),'s-', ...
x,nbinpdf(x,1,.5),'o-', ...
x,nbinpdf(x,3,.5),'d-', ...
x,nbinpdf(x,6,.5),'^-');
legend({'r = .1' 'r = 1' 'r = 3' 'r = 6'})
xlabel('x')
ylabel('f(x|r,p)')

```

\section*{Noncentral Chi-Square Distribution}

\section*{In this section...}
"Definition" on page B-89
"Background" on page B-89
"Example" on page B-90
"See Also" on page B-90

\section*{Definition}

There are many equivalent formulas for the noncentral chi-square distribution function. One formulation uses a modified Bessel function of the first kind. Another uses the generalized Laguerre polynomials. The cumulative distribution function is computed using a weighted sum of \(x^{2}\) probabilities with the weights equal to the probabilities of a Poisson distribution. The Poisson parameter is one-half of the noncentrality parameter of the noncentral chi-square
\[
F(x \mid v, \delta)=\sum_{j=0}^{\infty}\left(\frac{\left(\frac{1}{2} \delta\right)^{j}}{j!} e^{\frac{-\delta}{2}}\right) \operatorname{Pr}\left[\chi_{v+2 j}^{2} \leq x\right]
\]
where \(\delta\) is the noncentrality parameter.

\section*{Background}

The \(x^{2}\) distribution is actually a simple special case of the noncentral chi-square distribution. One way to generate random numbers with a \(x^{2}\) distribution (with \(v\) degrees of freedom) is to sum the squares of \(v\) standard normal random numbers (mean equal to zero.)

What if the normally distributed quantities have a mean other than zero? The sum of squares of these numbers yields the noncentral chi-square distribution. The noncentral chi-square distribution requires two parameters: the degrees
of freedom and the noncentrality parameter. The noncentrality parameter is the sum of the squared means of the normally distributed quantities.

The noncentral chi-square has scientific application in thermodynamics and signal processing. The literature in these areas may refer to it as the "Rician Distribution" on page B-106 or generalized "Rayleigh Distribution" on page B-104.

\section*{Example}

The following commands generate a plot of the noncentral chi-square pdf.
```

x = (0:0.1:10)';
p1 = ncx2pdf(x,4,2);
p = chi2pdf(x,4);
plot(x,p,'-',x,p1,'-')

```

\section*{Noncentral F Distribution}

\section*{In this section...}
"Definition" on page B-91
"Background" on page B-91
"Example" on page B-92
"See Also" on page B-92

\section*{Definition}

Similar to the noncentral \(x^{2}\) distribution, the toolbox calculates noncentral \(F\) distribution probabilities as a weighted sum of incomplete beta functions using Poisson probabilities as the weights.
\[
F\left(x \mid v_{1}, v_{2}, \delta\right)=\sum_{j=0}^{\infty}\left(\frac{\left(\frac{1}{2} \delta\right)^{j}}{j!} e^{\frac{-\delta}{2}}\right)\left\{\left(\left.\frac{v_{1} \cdot x}{v_{2}+v_{1} \cdot x} \right\rvert\, \frac{v_{1}}{2}+j, \frac{v_{2}}{2}\right)\right.
\]
\(I(x \mid a, b)\) is the incomplete beta function with parameters \(a\) and \(b\), and \(\delta\) is the noncentrality parameter.

\section*{Background}

As with the \(X^{2}\) distribution, the \(F\) distribution is a special case of the noncentral \(F\) distribution. The \(F\) distribution is the result of taking the ratio of \(x^{2}\) random variables each divided by its degrees of freedom.

If the numerator of the ratio is a noncentral chi-square random variable divided by its degrees of freedom, the resulting distribution is the noncentral \(F\) distribution.

The main application of the noncentral \(F\) distribution is to calculate the power of a hypothesis test relative to a particular alternative.

\section*{Example}

The following commands generate a plot of the noncentral \(F \mathrm{pdf}\).
```

x = (0.01:0.1:10.01)';
p1 = ncfpdf(x,5,20,10);
p = fpdf(x,5,20);
plot(x,p,'-',x,p1,'-')

```

\section*{See Also}

\section*{Noncentral † Distribution}

\section*{In this section...}
"Definition" on page B-93
"Background" on page B-93
"Example" on page B-94
"See Also" on page B-94

\section*{Definition}

The most general representation of the noncentral \(t\) distribution is quite complicated. Johnson and Kotz [60] give a formula for the probability that a noncentral \(t\) variate falls in the range \([-u, u]\).
\[
P(-u<x<u \mid v, \delta)=\sum_{j=0}^{\infty}\left(\frac{\left(\frac{1}{2} \delta^{2}\right)^{j}}{j!} e^{\frac{-\delta^{2}}{2}}\right) I\left(\left.\frac{u^{2}}{v+u^{2}} \right\rvert\, \frac{1}{2}+j, \frac{v}{2}\right)
\]
\(I(x \mid v, \delta)\) is the incomplete beta function with parameters \(v\) and \(\delta . \delta\) is the noncentrality parameter, and \(v\) is the number of degrees of freedom.

\section*{Background}

The noncentral \(t\) distribution is a generalization of Student's \(t\) distribution.
Student's \(t\) distribution with \(n-1\) degrees of freedom models the \(t\)-statistic
\[
t=\frac{\bar{x}-\mu}{s / \sqrt{n}}
\]
where \(\bar{x}\) is the sample mean and \(s\) is the sample standard deviation of a random sample of size \(n\) from a normal population with mean \(\mu\). If the population mean is actually \(\mu_{0}\), then the \(t\)-statistic has a noncentral \(t\) distribution with noncentrality parameter
\[
\delta=\frac{\mu_{0}-\mu}{\sigma / \sqrt{n}}
\]

The noncentrality parameter is the normalized difference between \(\mu_{0}\) and \(\mu\).
The noncentral \(t\) distribution gives the probability that a \(t\) test will correctly reject a false null hypothesis of mean \(\mu\) when the population mean is actually \(\mu_{0}\); that is, it gives the power of the \(t\) test. The power increases as the difference \(\mu_{0}-\mu\) increases, and also as the sample size \(n\) increases.

\section*{Example}

The following commands generate a plot of the noncentral \(t \mathrm{pdf}\).
```

x = (-5:0.1:5)';
p1 = nctcdf(x,10,1);
p = tcdf(x,10);
plot(x,p,'-',x,p1,'-')

```

\section*{Nonparametric Distributions}

See the discussion of ksdensity in "Estimating PDFs without Parameters" on page 5-56.

\section*{Normal Distribution}

\section*{In this section...}
"Definition" on page B-96
"Background" on page B-96
"Parameters" on page B-97
"Example" on page B-98
"See Also" on page B-98

\section*{Definition}

The normal pdf is
\[
y=f(x \mid \mu, \sigma)=\frac{1}{\sigma \sqrt{2 \pi}} e^{\frac{-(x-\mu)^{2}}{2 \sigma^{2}}}
\]

\section*{Background}

The normal distribution is a two-parameter family of curves. The first parameter, \(\mu\), is the mean. The second, \(\sigma\), is the standard deviation. The standard normal distribution (written \(\Phi(x)\) ) sets \(\mu\) to 0 and \(\sigma\) to 1 .
\(\Phi(x)\) is functionally related to the error function, erf.
\[
\operatorname{erf}(x)=2 \Phi(x \sqrt{2})-1
\]

The first use of the normal distribution was as a continuous approximation to the binomial.

The usual justification for using the normal distribution for modeling is the Central Limit Theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

\section*{Parameters}

To use statistical parameters such as mean and standard deviation reliably, you need to have a good estimator for them. The maximum likelihood estimates (MLEs) provide one such estimator. However, an MLE might be biased, which means that its expected value of the parameter might not equal the parameter being estimated. For example, an MLE is biased for estimating the variance of a normal distribution. An unbiased estimator that is commonly used to estimate the parameters of the normal distribution is the minimum variance unbiased estimator (MVUE). The MVUE has the minimum variance of all unbiased estimators of a parameter.

The MVUEs of parameters \(\mu\) and \(\sigma^{2}\) for the normal distribution are the sample mean and variance. The sample mean is also the MLE for \(\mu\). The following are two common formulas for the variance.
\[
\begin{align*}
& s^{2}=\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}  \tag{B-1}\\
& s^{2}=\frac{1}{n-1} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2} \tag{B-2}
\end{align*}
\]
where
\[
\bar{x}=\sum_{i=1}^{n} \frac{x_{i}}{n}
\]

Equation 1 is the maximum likelihood estimator for \(\sigma^{2}\), and equation 2 is the MVUE.

As an example, suppose you want to estimate the mean, \(\mu\), and the variance, \(\sigma^{2}\), of the heights of all fourth grade children in the United States. The function normfit returns the MVUE for \(\mu\), the square root of the MVUE for \(\sigma^{2}\), and confidence intervals for \(\mu\) and \(\sigma^{2}\). Here is a playful example modeling the heights in inches of a randomly chosen fourth grade class.
```

height = normrnd(50,2,30,1); % Simulate heights.
[mu,s,muci,sci] = normfit(height)

```
```

mu =
50.2025
S =
1.7946
muci =
49.5210
50.8841
sci =
1.4292
2.4125

```

Note that \(s^{\wedge} 2\) is the MVUE of the variance.
s^2
ans =
3.2206

\section*{Example}

The plot shows the bell curve of the standard normal pdf, with \(\mu=0\) and \(\sigma=1\).

\section*{Poisson Distribution}

\section*{In this section...}
"Definition" on page B-102
"Background" on page B-102
"Parameters" on page B-103
"Example" on page B-103
"See Also" on page B-103

\section*{Definition}

The Poisson pdf is
\[
y=f(x \mid \lambda)=\frac{\lambda^{x}}{x!} e^{-\lambda} I_{(0,1, \ldots)}(x)
\]

\section*{Background}

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. Sample applications that involve Poisson distributions include the number of Geiger counter clicks per second, the number of people walking into a store in an hour, and the number of flaws per 1000 feet of video tape.

The Poisson distribution is a one-parameter discrete distribution that takes nonnegative integer values. The parameter, \(\lambda\), is both the mean and the variance of the distribution. Thus, as the size of the numbers in a particular sample of Poisson random numbers gets larger, so does the variability of the numbers.

The Poisson distribution is the limiting case of a binomial distribution where \(N\) approaches infinity and \(p\) goes to zero while \(N p=\lambda\).

The Poisson and exponential distributions are related. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

\section*{Parameters}

The MLE and the MVUE of the Poisson parameter, \(\lambda\), is the sample mean. The sum of independent Poisson random variables is also Poisson distributed with the parameter equal to the sum of the individual parameters. This is used to calculate confidence intervals \(\lambda\). As \(\lambda\) gets large the Poisson distribution can be approximated by a normal distribution with \(\mu=\lambda\) and \(\sigma^{2}\) \(=\lambda\). This approximation is used to calculate confidence intervals for values of \(\lambda\) greater than 100 .

\section*{Example}

The plot shows the probability for each nonnegative integer when \(\lambda=5\).

\section*{Rayleigh Distribution}

\section*{In this section...}
"Definition" on page B-104
"Background" on page B-104
"Parameters" on page B-105
"Example" on page B-105
"See Also" on page B-105

\section*{Definition}

The Rayleigh pdf is
\[
y=f(x \mid b)=\frac{x}{b^{2}} e^{\left(\frac{-x^{2}}{2 b^{2}}\right)}
\]

\section*{Background}

The Rayleigh distribution is a special case of the Weibull distribution. If \(A\) and \(B\) are the parameters of the Weibull distribution, then the Rayleigh distribution with parameter \(b\) is equivalent to the Weibull distribution with parameters \(A=\sqrt{2} b\) and \(B=2\).

If the component velocities of a particle in the \(x\) and \(y\) directions are two independent normal random variables with zero means and equal variances, then the distance the particle travels per unit time is distributed Rayleigh.

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

\section*{Parameters}

The raylfit function returns the MLE of the Rayleigh parameter. This estimate is
\[
b=\sqrt{\frac{1}{2 n} \sum_{i=1}^{n} x_{i}^{2}}
\]

\section*{Example}

The following commands generate a plot of the Rayleigh pdf.
```

x = [0:0.01:2];
p = raylpdf(x,0.5);
plot(x,p)

```

\section*{See Also}

\section*{In this section...}
"Definition" on page B-106
"Background" on page B-106
"Parameters" on page B-106
"See Also" on page B-107

\section*{Definition}

The Rician distribution has the density function
\[
I_{0}\left(\frac{x s}{\sigma^{2}}\right) \frac{x}{\sigma^{2}} e^{-\left(\frac{x^{2}+s^{2}}{2 \sigma^{2}}\right)}
\]
with noncentrality parameter \(s \geq 0\) and scale parameter \(\sigma>0\), for \(x>0 . I_{0}\) is the zero-order modified Bessel function of the first kind. If \(x\) has a Rician distribution with parameters \(s\) and \(\sigma\), then \((x / \sigma)^{2}\) has a noncentral chi-square distribution with two degrees of freedom and noncentrality parameter \((s / \sigma)^{2}\).

\section*{Background}

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

\section*{Student's † Distribution}

\section*{In this section...}
"Definition" on page B-108
"Background" on page B-108
"Example" on page B-109
"See Also" on page B-109

\section*{Definition}

Student's \(t\) pdf is
\[
y=f(x \mid v)=\frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)} \frac{1}{\sqrt{v \pi}} \frac{1}{\left(1+\frac{x^{2}}{v}\right)^{\frac{v+1}{2}}}
\]
where \(\Gamma(\cdot)\) is the Gamma function.

\section*{Background}

The \(t\) distribution is a family of curves depending on a single parameter \(v\) (the degrees of freedom). As \(v\) goes to infinity, the \(t\) distribution approaches the standard normal distribution.
W. S. Gossett discovered the distribution through his work at the Guinness brewery. At the time, Guinness did not allow its staff to publish, so Gossett used the pseudonym "Student."

If \(x\) is a random sample of size \(n\) from a normal distribution with mean \(\mu\), then the statistic
\[
t=\frac{\bar{x}-\mu}{s / \sqrt{n}}
\]
where \(\bar{x}\) is the sample mean and \(s\) is the sample standard deviation, has Student's \(t\) distribution with \(n-1\) degrees of freedom.

\section*{Example}

The plot compares the \(t\) distribution with \(v=5\) (solid line) to the shorter tailed, standard normal distribution (dashed line).
```

x = -5:0.1:5;
y = tpdf(x,5);
z = normpdf(x,0,1);
plot(x,y,'-',x,z,'-.')

```

\section*{See Also}
"Continuous Distributions (Statistics)" on page 5-7

\section*{t Location-Scale Distribution}

\section*{In this section...}
"Definition" on page B-110
"Background" on page B-110
"Parameters" on page B-110
"See Also" on page B-111

\section*{Definition}

The \(t\) location-scale distribution has the density function
\[
\frac{\Gamma\left(\frac{v+1}{2}\right)}{\sigma \sqrt{v \pi} \Gamma\left(\frac{v}{2}\right)}\left[\frac{v+\left(\frac{x-\mu}{\sigma}\right)^{2}}{v}\right]^{-\left(\frac{v+1}{2}\right)}
\]
with location parameter \(\mu\), scale parameter \(\sigma>0\), and shape parameter \(v>0\). If \(x\) has a \(t\) location-scale distribution, with parameters \(\mu, \sigma\), and \(v\), then
\[
\frac{x-\mu}{\sigma}
\]
has a Student's \(t\) distribution with \(v\) degrees of freedom.

\section*{Background}

The \(t\) location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as \(v\) approaches infinity, and smaller values of \(v\) yield heavier tails.

\section*{Parameters}

See mle, dfittool.

\section*{Uniform Distribution (Continuous)}

\section*{In this section...}
"Definition" on page B-112
"Background" on page B-112
"Parameters" on page B-112
"Example" on page B-112
"See Also" on page B-113

\section*{Definition}

The uniform cdf is
\[
p=F(x \mid a, b)=\frac{x-a}{b-a} I_{[a, b]}(x)
\]

\section*{Background}

The uniform distribution (also called rectangular) has a constant pdf between its two parameters \(a\) (the minimum) and \(b\) (the maximum). The standard uniform distribution ( \(a=0\) and \(b=1\) ) is a special case of the beta distribution, obtained by setting both of its parameters to 1 .

The uniform distribution is appropriate for representing the distribution of round-off errors in values tabulated to a particular number of decimal places.

\section*{Parameters}

The sample minimum and maximum are the MLEs of \(a\) and \(b\) respectively.

\section*{Example}

The example illustrates the inversion method for generating normal random numbers using rand and norminv. Note that the MATLAB function, randn, does not use inversion since it is not efficient for this case.
```

u = rand(1000,1);

```

\section*{See Also}

\section*{Uniform Distribution (Discrete)}

\author{
In this section... \\ "Definition" on page B-114 \\ "Background" on page B-114 \\ "Example" on page B-114 \\ "See Also" on page B-115
}

\section*{Definition}

The discrete uniform pdf is
\[
y=f(x \mid N)=\frac{1}{N} I_{(1, \ldots, N)}(x)
\]

\section*{Background}

The discrete uniform distribution is a simple distribution that puts equal weight on the integers from one to \(N\).

\section*{Example}

As for all discrete distributions, the cdf is a step function. The plot shows the discrete uniform cdf for \(N=10\).
```

x = 0:10;
y = unidcdf(x,10);
stairs(x,y)
set(gca,'Xlim',[0 11])

```

Pick a random sample of 10 from a list of 553 items:
```

numbers = unidrnd(553,1,10)
numbers =
293

```

\section*{Weibull Distribution}

\section*{In this section...}
"Definition" on page B-116
"Background" on page B-116
"Parameters" on page B-117
"Example" on page B-117
"See Also" on page B-118

\section*{Definition}

The Weibull pdf is positive only for positive values of \(x\), and is zero otherwise. For strictly positive values of the shape parameter \(b\) and scale parameter \(a\), the density is
\[
f(x \mid a, b)=\frac{b}{a}\left(\frac{x}{a}\right)^{b-1} e^{-(x / a)^{b}} .
\]

\section*{Background}

Waloddi Weibull offered the distribution that bears his name as an appropriate analytical tool for modeling the breaking strength of materials. Current usage also includes reliability and lifetime modeling. The Weibull distribution is more flexible than the exponential for these purposes.

To see why, consider the hazard rate function (instantaneous failure rate). If \(f(t)\) and \(F(t)\) are the pdf and cdf of a distribution, then the hazard rate is
\[
h(t)=\frac{f(t)}{1-F(t)}
\]

Substituting the pdf and cdf of the exponential distribution for \(f(t)\) and \(F(t)\) above yields a constant. The example below shows that the hazard rate for the Weibull distribution can vary.

\section*{Parameters}

Suppose you want to model the tensile strength of a thin filament using the Weibull distribution. The function wblfit gives maximum likelihood estimates and confidence intervals for the Weibull parameters.
```

strength = wblrnd(0.5,2,100,1); % Simulated strengths.
[p,ci] = wblfit(strength)
p =
0.4715 1.9811
Ci =
0.4248 1.7067
0.5233 2.2996

```

The default \(95 \%\) confidence interval for each parameter contains the true value.

\section*{Example}

The exponential distribution has a constant hazard function, which is not generally the case for the Weibull distribution.

The plot shows the hazard functions for exponential (dashed line) and Weibull (solid line) distributions having the same mean life. The Weibull hazard rate here increases with age (a reasonable assumption).
```

t = 0:0.1:4.5;
h1 = exppdf(t,0.6267) ./ (1-expcdf(t,0.6267));
h2 = wblpdf(t,2,2) ./ (1-wblcdf(t,2,2));
plot(t,h1,'--',t,h2,'-')

```

\section*{In this section...}
"Definition" on page B-119
"Background" on page B-119
"Example" on page B-120
"See Also" on page B-120

\section*{Definition}

The probability density function of the \(d\)-dimensional Wishart distribution is given by
\[
\mathrm{y}=\mathrm{f}(\mathrm{X}, \Sigma, \mathrm{v})=\frac{|\mathrm{X}|^{((\mathrm{v}-\mathrm{d}-1) / 2)} e^{\left(-\frac{1}{2} \operatorname{trace}\left(\Sigma^{-1} \mathrm{X}\right)\right)}}{2^{(\mathrm{vd}) / 2} \pi^{(\mathrm{d}(\mathrm{~d}-1)) / 4}|\Sigma|^{\mathrm{v} / 2} \Gamma(\mathrm{v} / 2) \ldots \Gamma(\mathrm{v}-(\mathrm{d}-1)) / 2}
\]
where \(X\) and \(\Sigma\) are \(d\)-by- \(d\) symmetric positive definite matrices, and \(v\) is a scalar greater than \(d-1\). While it is possible to define the Wishart for singular \(\Sigma\), the density cannot be written as above.

Only random matrix generation is supported for the Wishart distribution, including both singular and nonsingular \(\Sigma\).

\section*{Background}

The Wishart distribution is a generalization of the univariate chi-square distribution to two or more variables. It is a distribution for symmetric positive semidefinite matrices, typically covariance matrices, the diagonal elements of which are each chi-square random variables. In the same way as the chi-square distribution can be constructed by summing the squares of independent, identically distributed, zero-mean univariate normal random variables, the Wishart distribution can be constructed by summing the inner products of independent, identically distributed, zero-mean multivariate normal random vectors.

The Wishart distribution is parameterized with a symmetric, positive semidefinite matrix, \(\Sigma\), and a positive scalar degrees of freedom parameter, \(v\). \(v\) is analogous to the degrees of freedom parameter of a univariate chi-square distribution, and \(\Sigma \mathrm{v}\) is the mean of the distribution.

The Wishart distribution is often used as a model for the distribution of the sample covariance matrix for multivariate normal random data, after scaling by the sample size.

\section*{Example}

If \(x\) is a bivariate normal random vector with mean zero and covariance matrix
\[
\Sigma=\left(\begin{array}{ll}
1 & .5 \\
.5 & 2
\end{array}\right)
\]
then you can use the Wishart distribution to generate a sample covariance matrix without explicitly generating \(x\) itself. Notice how the sampling variability is quite large when the degrees of freedom is small.
```

Sigma = [1 .5; .5 2];
df = 10; S1 = wishrnd(Sigma,df)/df
S1 =
1.7959 0.64107
0.64107 1.5496
df = 1000; S2 = wishrnd(Sigma,df)/df
S2 =
0.9842 0.50158
0.50158 2.1682

```
