## How to Contact MathWorks

[www.mathworks.com](http://www.mathworks.com) Web  
[comp.soft-sys.matlab](mailto:comp.soft-sys.matlab) Newsgroup  
[www.mathworks.com/contact\\_TS.html](http://www.mathworks.com/contact_TS.html) Technical Support

[suggest@mathworks.com](mailto:suggest@mathworks.com) Product enhancement suggestions  
[bugs@mathworks.com](mailto:bugs@mathworks.com) Bug reports  
[doc@mathworks.com](mailto:doc@mathworks.com) Documentation error reports  
[service@mathworks.com](mailto:service@mathworks.com) Order status, license renewals, passcodes  
[info@mathworks.com](mailto:info@mathworks.com) Sales, pricing, and general information

508-647-7000 (Phone)

508-647-7001 (Fax)

The MathWorks, Inc.  
3 Apple Hill Drive  
Natick, MA 01760-2098

For contact information about worldwide offices, see the MathWorks Web site.

### *MATLAB Function Reference*

© COPYRIGHT 1984–2013 by The MathWorks, Inc.

The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

### **Trademarks**

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See [www.mathworks.com/trademarks](http://www.mathworks.com/trademarks) for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

### **Patents**

MathWorks products are protected by one or more U.S. patents. Please see [www.mathworks.com/patents](http://www.mathworks.com/patents) for more information.

## Revision History

December 1996	First printing	For MATLAB 5.0 (Release 8)
June 1997	Online only	Revised for MATLAB 5.1 (Release 9)
October 1997	Online only	Revised for MATLAB 5.2 (Release 10)
January 1999	Online only	Revised for MATLAB 5.3 (Release 11)
June 1999	Second printing	For MATLAB 5.3 (Release 11)
June 2001	Online only	Revised for MATLAB 6.1 (Release 12.1)
July 2002	Online only	Revised for 6.5 (Release 13)
June 2004	Online only	Revised for 7.0 (Release 14)
September 2006	Online only	Revised for 7.3 (Release 2006b)
March 2007	Online only	Revised for 7.4 (Release 2007a)
September 2007	Online only	Revised for Version 7.5 (Release 2007b)
March 2008	Online only	Revised for Version 7.6 (Release 2008a)
October 2008	Online only	Revised for Version 7.7 (Release 2008b)
March 2009	Online only	Revised for Version 7.8 (Release 2009a)
September 2009	Online only	Revised for Version 7.9 (Release 2009b)
March 2010	Online only	Revised for Version 7.10 (Release 2010a)
September 2010	Online only	Revised for Version 7.11 (Release 2010b)
April 2011	Online only	Revised for Version 7.12 (Release 2011a)
September 2011	Online only	Revised for Version 7.13 (Release 2011b)
March 2012	Online only	Revised for Version 7.14 (Release 2012a)
September 2012	Online only	Revised for Version 8.0 (Release 2012b)
March 2013	Online only	Revised for Version 8.1 (Release 2013a)
September 2013	Online only	Revised for Version 8.2 (Release 2013b)

# Relational Operators < > <= >= == ~=

---

**Purpose** Relational operations

**Syntax**

```
A < B
A > B
A <= B
A >= B
A == B
A ~= B
```

**Description** The relational operators are <, >, <=, >=, ==, and ~=. Relational operators perform element-by-element comparisons between two arrays. They return a logical array of the same size, with elements set to logical 1 (true) where the relation is true, and elements set to logical 0 (false) where it is not.

The operators <, >, <=, and >= use only the real part of their operands for the comparison. The operators == and ~= test real and imaginary parts.

To test if two strings are equivalent, use strcmp, which allows vectors of dissimilar length to be compared.

---

**Note** For some toolboxes, the relational operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type help followed by the operator name. For example, type help lt. The toolboxes that overload lt (<) are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

---

**Examples** If one of the operands is a scalar and the other a matrix, the scalar expands to the size of the matrix. For example, the two pairs of statements

```
X = 5; X >= [1 2 3; 4 5 6; 7 8 10]
X = 5*ones(3,3); X >= [1 2 3; 4 5 6; 7 8 10]
```

produce the same result:

ans =

```
1 1 1
1 1 0
0 0 0
```

## See Also

all | any | find | strcmp | Logical Operators: Elementwise & |  
~ | Logical Operators: Short-circuit && ||

# Logical Operators: Elementwise & | ~

---

**Purpose** Elementwise logical operations on arrays

**Syntax**  
expr1 & expr2  
expr1 | expr2  
~expr

**Description** The symbols &, |, and ~ are the logical array operators AND, OR, and NOT. These operators are commonly used in conditional statements, such as `if` and `while`, to determine whether or not to execute a particular block of code. Logical operations return a logical array with elements set to 1 (true) or 0 (false), as appropriate.

`expr1 & expr2` represents a logical AND operation between values, arrays, or expressions `expr1` and `expr2`. In an AND operation, if `expr1` is true *and* `expr2` is true, then the AND of those inputs is true. If either expression is false, the result is false. Here is a pseudocode example of AND:

```
IF (expr1: all required inputs were passed) AND ...  
    (expr2: all inputs are valid)  
THEN (result: execute the function)
```

`expr1 | expr2` represents a logical OR operation between values, arrays, or expressions `expr1` and `expr2`. In an OR operation, if `expr1` is true *or* `expr2` is true, then the OR of those inputs is true. If both expressions are false, the result is false. Here is a pseudocode example of OR:

```
IF (expr1: S is a string) OR ...  
    (expr2: S is a cell array of strings)  
THEN (result: parse string S)
```

`~expr` represents a logical NOT operation applied to expression `expr`. In a NOT operation, if `expr` is false, then the result of the operation is true. If `expr` is true, the result is false. Here is a pseudocode example of NOT:

```
IF (expr: function returned a Success status) is NOT true
```

THEN (*result*: throw an error)

The function `xor(A,B)` implements the exclusive OR operation.

## Logical Operations on Arrays

The expression operands for AND, OR, and NOT are often arrays of nonsingleton dimensions. When this is the case, The MATLAB<sup>®</sup> software performs the logical operation on each element of the arrays. The output is an array that is the same size as the input array or arrays.

If just one operand is an array and the other a scalar, then the scalar is matched against each element of the array. When the operands include two or more nonscalar arrays, the sizes of those arrays must be equal.

This table shows the output of AND, OR, and NOT statements that use scalar and/or array inputs. In the table, S is a scalar array, A is a nonscalar array, and R is the resulting array:

Operation	Result
S1 & S2	R = S1 & S2
S & A	R(1) = S & A(1); ... R(2) = S & A(2); ...
A1 & A2	R(1) = A1(1) & A2(1); R(2) = A1(2) & A2(2); ...
S1   S2	R = S1   S2
S   A	R(1) = S   A(1); R(2) = S   A(2); ...
A1   A2	R(1) = A1(1)   A2(1); R(2) = A1(2)   A2(2); ...
~S	R = ~S
~A	R(1) = ~A(1); R(2) = ~A(2), ...

# Logical Operators: Elementwise & | ~

---

## Compound Logical Statements

The number of expressions that you can evaluate with AND or OR is not limited to two (e.g., A & B). Statements such as the following are also valid:

```
expr1 & expr2 & expr3 | expr4 & expr5
```

Use parentheses to establish the order in which MATLAB evaluates a compound operation. Note the difference in the following two statements:

```
(expr1 & expr2) | (expr3 & expr4)    % 2-component OR  
expr1 & (expr2 | expr3) & expr4    % 3-component AND
```

## Operator Precedence

The precedence for the logical operators with respect to each other is shown in the table below. MATLAB always gives the & operator precedence over the | operator. Although MATLAB typically evaluates expressions from left to right, the expression a|b&c is evaluated as a|(b&c). It is a good idea to use parentheses to explicitly specify the intended precedence of statements containing combinations of & and |.

Operator	Operation	Priority
~	NOT	Highest
&	Elementwise AND	
	Elementwise OR	
&&	Short-circuit AND	
	Short-circuit OR	Lowest

## Short-Circuiting in Elementwise Operators

The &, and | operators do not short-circuit. See the documentation on the && and || operators if you need short-circuiting capability.

When used in the context of an if or while expression, and only in this context, the elementwise **&** and **|** operators use short-circuiting in

evaluating their expressions. That is, `A&B` and `A|B` ignore the second operand, `B`, if the first operand, `A`, is sufficient to determine the result.

So, although the statement `1|[]` evaluates to `false`, the same statement evaluates to `true` when used in either an `if` or `while` expression:

```
A = 1;   B = [];  
if(A|B) disp 'The statement is true', end;  
    The statement is true
```

while the reverse logical expression, which does not short-circuit, evaluates to `false`:

```
if(B|A) disp 'The statement is true', end;
```

Another example of short-circuiting with elementwise operators shows that a logical expression such as the one shown below, which under most circumstances is invalid due to a size mismatch between `A` and `B`, works within the context of an `if` or `while` expression:

The `A|B` statement generates an error:

```
A = [1 1];   B = [2 0 1];  
A|B
```

```
Error using |  
Inputs must have the same size.
```

But the same statement used to test an `if` condition does not error:

```
if (A|B) disp 'The statement is true', end;  
    The statement is true
```

## Operator Truth Table

The following is a truth table for the operators and functions in the previous example.

# Logical Operators: Elementwise & | ~

Inputs		and	or	not	xor
A	B	A & B	A   B	~A	xor(A,B)
0	0	0	0	1	0
0	1	0	1	1	1
1	0	0	1	0	1
1	1	1	1	0	0

## Equivalent Functions

These logical operators have function equivalents, as shown here.

Logical Operation	Equivalent Function
A & B	and(A,B)
A   B	or(A,B)
~A	not(A)

## Examples

### Example 1 – Conditional Statement with OR

Using OR in a conditional statement, call function `parseString` on `S`, but only if `S` is a character array or a cell array of strings:

```
if ischar(S) | iscellstr(S)
    parseString(S)
end
```

### Example 2 – Array AND Array

Find those elements of array `R` that are both greater than 0.3 AND less than 0.9:

```
rng(0,'twister');
R=rand(5,7)
R =
    0.8147    0.0975    0.1576    0.1419    0.6557    0.7577    0.7060
```

# Logical Operators: Elementwise & | ~

```
0.9058 0.2785 0.9706 0.4218 0.0357 0.7431 0.0318
0.1270 0.5469 0.9572 0.9157 0.8491 0.3922 0.2769
0.9134 0.9575 0.4854 0.7922 0.9340 0.6555 0.0462
0.6324 0.9649 0.8003 0.9595 0.6787 0.1712 0.0971
(R > 0.3) & (R < 0.9)
```

```
ans =
    1     0     0     0     1     1     1
    0     0     0     1     0     1     0
    0     1     0     0     1     1     0
    0     0     1     1     0     1     0
    1     0     1     0     1     0     0
```

## Example 3 – Array AND Scalar

Find those elements of array R that are greater than the scalar value of 40:

```
rng(0, 'twister');
R = rand(3,5) * 50
R =
    40.7362    45.6688    13.9249    48.2444    47.8583
    45.2896    31.6180    27.3441     7.8807    24.2688
     6.3493     4.8770    47.8753    48.5296    40.0140
R > 40
ans =
     1     1     0     1     1
     1     0     0     0     0
     0     0     1     1     1
```

## Example 4 – Check Status with NOT

Throw an error if the return status of a function does NOT indicate success:

```
[Z, status] = myfun(X, Y);
if ~(status == SUCCESS);
    error('Error in function myfun')
end
```

# Logical Operators: Elementwise & | ~

---

## Example 5 – OR of Binary Arrays

This example shows the logical OR of the elements in the vector `u` with the corresponding elements in the vector `v`:

```
u = [0 0 1 1 0 1];  
v = [0 1 1 0 0 1];  
u | v  
  
ans =  
    0    1    1    1    0    1
```

### See Also

`all` | `any` | `find` | `logical` | `xor` | `true` | `false` | Logical Operators: Short-circuit `&&` `||` | Relational Operators `<` `>` `<=` `>=` `==` `~=`

**Purpose** Logical operations, with short-circuiting capability

**Syntax**  
expr1 && expr2  
expr1 || expr2

**Description** expr1 && expr2 represents a logical AND operation that employs short-circuiting behavior. With short-circuiting, the second operand expr2 is evaluated only when the result is not fully determined by the first operand expr1. For example, if A = 0, then the following statement evaluates to `false`, regardless of the value of B, so the MATLAB software does not evaluate B:

```
A && B
```

These two expressions must each be a valid MATLAB statement that evaluates to a scalar logical result.

expr1 || expr2 represents a logical OR operation that employs short-circuiting behavior.

---

**Note** Always use the && and || operators when short-circuiting is required. Using the elementwise operators (& and |) for short-circuiting can yield unexpected results.

---

**Examples** In the following statement, it doesn't make sense to evaluate the relation on the right if the divisor, b, is zero. The test on the left is put in to avoid generating a warning under these circumstances:

```
x = (b ~= 0) && (a/b > 18.5)
```

By definition, if any operands of an AND expression are `false`, the entire expression must be `false`. So, if `(b ~= 0)` evaluates to `false`, MATLAB assumes the entire expression to be `false` and terminates its evaluation of the expression early. This avoids the warning that would be generated if MATLAB were to evaluate the operand on the right.

# Special Characters [ ] ( ) { } = ' . ... , ; : % ! @

## Purpose

Special characters

## Syntax

[ ]  
{ }  
( )  
=  
'  
.  
...  
,  
;  
:  
%  
%{ %}  
!  
@

## Description

[ ] Brackets are used to form vectors and matrices.  $[6.9 \ 9.64 \ \text{sqrt}(-1)]$  is a vector with three elements separated by blanks.  $[6.9, \ 9.64, \ i]$  is the same thing.  $[1+j \ 2-j \ 3]$  and  $[1 \ +j \ 2 \ -j \ 3]$  are not the same. The first has three elements, the second has five.

$[11 \ 12 \ 13; \ 21 \ 22 \ 23]$  is a 2-by-3 matrix. The semicolon ends the first row.

Vectors and matrices can be used inside [ ] brackets.  $[A \ B;C]$  is allowed if the number of rows of A equals the number of rows of B and the number of columns of A plus the number of columns of B equals the number of columns of C. This rule generalizes in a hopefully obvious way to allow fairly complicated constructions.

# Special Characters [ ] ( ) { } = ' . ... , ; : % ! @

---

`A = [ ]` stores an empty matrix in `A`. `A(m,:) = [ ]` deletes row `m` of `A`. `A(:,n) = [ ]` deletes column `n` of `A`. `A(n) = [ ]` reshapes `A` into a column vector and deletes the `n`th element.

`[A1,A2,A3...]` = function assigns function output to multiple variables.

For the use of `[` and `]` on the left of an “=” in multiple assignment statements, see `lu`, `eig`, `svd`, and so on.

`{ }` Curly braces are used in cell array assignment statements. For example, `A(2,1) = {[1 2 3; 4 5 6]}`, or `A{2,2} = ('str')`. See `help paren` for more information about `{ }`.

`( )` Parentheses are used to indicate precedence in arithmetic expressions in the usual way. They are used to enclose arguments of functions in the usual way. They are also used to enclose subscripts of vectors and matrices in a manner somewhat more general than usual. If `X` and `V` are vectors, then `X(V)` is `[X(V(1)), X(V(2)), ..., X(V(n))]`. The components of `V` must be integers to be used as subscripts. An error occurs if any such subscript is less than 1 or greater than the size of `X`. Some examples are

- `X(3)` is the third element of `X`.
- `X([1 2 3])` is the first three elements of `X`.

See `help paren` for more information about `( )`.

If `X` has `n` components, `X(n: 1:1)` reverses them. The same indirect subscripting works in matrices. If `V` has `m` components and `W` has `n` components, then `A(V,W)` is the `m`-by-`n` matrix formed from the elements of `A` whose subscripts are the elements of `V` and `W`. For example, `A([1,5],:) = A([5,1],:)` interchanges rows 1 and 5 of `A`.

`=` Used in assignment statements. `B = A` stores the elements of `A` in `B`. `==` is the relational equals operator. See the [Relational Operators < > <= >= == ~=](#) page.

# Special Characters [ ] ( ) { } = ' . ... , ; : % ! @

---

- ' Matrix transpose.  $X'$  is the complex conjugate transpose of  $X$ .  $X.'$  is the nonconjugate transpose.
- Quotation mark. 'any text' is a vector whose components are the ASCII codes for the characters. A quotation mark within the text is indicated by two quotation marks.
- . Decimal point.  $314/100$ ,  $3.14$ , and  $.314e1$  are all the same.
- . Element-by-element operations. These are obtained using  $.*$ ,  $.^$ ,  $./$ , or  $.\$ . See the Arithmetic Operators page.
- . Field access.  $S(m).f$  when  $S$  is a structure, accesses the contents of field  $f$  of that structure.
- .( ) Dynamic Field access.  $S.(df)$  when  $S$  is a structure, accesses the contents of dynamic field  $df$  of that structure. Dynamic field names are defined at runtime.
- .. Parent folder. See `cd`.
- ... Continuation. Three or more periods at the end of a line continue the current function on the next line. Three or more periods before the end of a line cause the MATLAB software to ignore the remaining text on the current line and continue the function on the next line. This effectively makes a comment out of anything on the current line that follows the three periods. For an example, see “Continue Long Statements on Multiple Lines”.
- , Comma. Used to separate matrix subscripts and function arguments. Used to separate statements in multistatement lines. For multistatement lines, the comma can be replaced by a semicolon to suppress printing.
- ; Semicolon. Used inside brackets to end rows. Used after an expression or statement to suppress printing or to separate statements.
- : Colon. Create vectors, array subscripting, and for loop iterations. See `colon (:)` for details.

# Special Characters [ ] ( ) { } = ' . ... , ; : % ! @

---

- % Percent. The percent symbol denotes a comment; it indicates a logical end of line. Any following text is ignored. MATLAB displays the first contiguous comment lines in a function or script file in response to a `help` command.
- %{  
%} Percent-brace. The text enclosed within the `%{` and `%}` symbols is a comment block. Use these symbols to insert comments that take up more than a single line in your script of function code. Any text between these two symbols is ignored by MATLAB.  
  
With the exception of whitespace characters, the `%{` and `%}` operators must appear alone on the lines that immediately precede and follow the block of help text. Do not include any other text on these lines.
- ! Exclamation point. Indicates that the rest of the input line is issued as a command to the operating system. See “Running External Commands, Scripts, and Programs” for more information.
- @ Function handle. MATLAB data type that is a handle to a function. See `function_handle (@)` for details.

## Tips

Some uses of special characters have function equivalents, as shown:

Horizontal concatenation	<code>[A,B,C...]</code> <code>horzcat(A,B,C...)</code>
Vertical concatenation	<code>[A;B;C...]</code> <code>vertcat(A,B,C...)</code>
Subscript reference	<code>A(i,j,k...)</code> <code>subsref(A,S)</code> . See help <code>subsref</code> .
Subscript assignment	<code>A(i,j,k...)=B</code> <code>subsasgn(A,S,B)</code> . See help <code>subsasgn</code> .

# Special Characters [ ] ( ) { } = ' . ... , ; : % ! @

---

---

**Note** For some toolboxes, the special characters are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given character, type `help` followed by the character name. For example, type `help transpose`. The toolboxes that overload `transpose` ( `'` ) are listed. For information about using the character in that toolbox, see the documentation for the toolbox.

# colon (:)

---

## Purpose

Create vectors, array subscripting, and for-loop iterators

## Description

The colon is one of the most useful operators in MATLAB. It can create vectors, subscript arrays, and specify for iterations.

The colon operator uses the following rules to create regularly spaced vectors for scalar values  $i$ ,  $j$ , and  $k$ :

$j:k$  is the same as  $[j, j+1, \dots, k]$ , or empty when  $j > k$ .

$j:i:k$  is the same as  $[j, j+i, j+2i, \dots, j+m*i]$ , where  $m = \text{fix}((k-j)/i)$ , for integer values. This syntax returns an empty matrix when  $i == 0$ ,  $i > 0$  and  $j > k$ , or  $i < 0$  and  $j < k$ .

If you specify nonscalar arrays, MATLAB interprets  $j:i:k$  as  $j(1):i(1):k(1)$ .

You can use the colon to create a vector of indices to select rows, columns, or elements of arrays, where:

$A(:, j)$  is the  $j$ th column of  $A$ .

$A(i, :)$  is the  $i$ th row of  $A$ .

$A(:, :)$  is the equivalent two-dimensional array. For matrices this is the same as  $A$ .

$A(j:k)$  is  $A(j), A(j+1), \dots, A(k)$ .

$A(:, j:k)$  is  $A(:, j), A(:, j+1), \dots, A(:, k)$ .

$A(:, :, k)$  is the  $k$ th page of three-dimensional array  $A$ .

$A(i, j, k, :)$  is a vector in four-dimensional array  $A$ . The vector includes  $A(i, j, k, 1), A(i, j, k, 2), A(i, j, k, 3)$ , and so on.

$A(:)$  is all the elements of  $A$ , regarded as a single column. On the left side of an assignment statement,  $A(:)$  fills  $A$ , preserving its shape from before. In this case, the right side must contain the same number of elements as  $A$ .

When you create a vector to index into a cell array or structure array (such as `cellName{:}` or `structName(:).fieldName`), MATLAB returns multiple outputs in a comma-separated list. For more information, see “How to Use the Comma-Separated Lists” in the MATLAB Programming Fundamentals documentation.

## Examples

Using the colon with integers,

```
D = 1:4
```

results in

```
D =  
    1    2    3    4
```

---

Using two colons to create a vector with arbitrary real increments between the elements,

```
E = 0:.1:.5
```

results in

```
E =  
    0    0.1000    0.2000    0.3000    0.4000    0.5000
```

---

The command

```
A(:,:,2) = pascal(3)
```

generates a three-dimensional array whose first page is all zeros.

```
A(:,:,1) =  
    0    0    0  
    0    0    0  
    0    0    0
```

## colon (:)

---

```
A(:, :, 2) =  
    1     1     1  
    1     2     3  
    1     3     6
```

---

Using a colon with characters to iterate a for-loop,

```
for x='a':'d', x, end
```

results in

```
x =  
    a  
x =  
    b  
x =  
    c  
x =  
    d
```

**Purpose** Absolute value and complex magnitude

**Syntax** `abs(X)`

**Description** `abs(X)` returns an array Y such that each element of Y is the absolute value of the corresponding element of X.

If X is complex, `abs(X)` returns the complex modulus (magnitude), which is the same as

```
sqrt(real(X).^2 + imag(X).^2)
```

**Examples**

```
abs(-5)
ans =
     5
```

```
abs(3+4i)
ans =
     5
```

**See Also** `angle` | `sign` | `unwrap`

# accumarray

---

**Purpose** Construct array with accumulation

**Syntax**

```
A = accumarray(subs, val)
A = accumarray(subs, val, sz)
A = accumarray(subs, val, sz, fun)
A = accumarray(subs, val, sz, fun, fillval)
A = accumarray(subs, val, sz, fun, fillval, issparse)
A = accumarray({subs1, subs2, ...}, val, ...)
```

**Description** `accumarray` groups elements from a data set and applies a function to each group. `A = accumarray(subs, val)` creates an array `A` by accumulating elements of the vector `val` using the elements of `subs` as indices. The position of an element in `subs` determines which value of `vals` it selects for the accumulated vector; the value of an element in `subs` determines the position of the accumulated vector in the output.

`A = accumarray(subs, val, sz)` creates an array `A` with size `sz`, where `sz` is a vector of positive integers. If `subs` is nonempty with  $N > 1$  columns, then `sz` must have  $N$  elements, where `all(sz >= max(subs, [], 1))`. If `subs` is a nonempty column vector, then `sz` must be `[M 1]`, where  $M \geq \text{MAX}(\text{subs})$ . Specify `sz` as `[]` for the default behavior.

`A = accumarray(subs, val, sz, fun)` applies function `fun` to each subset of elements of `val`. The default accumulating function is `sum`. To specify another function `fun`, use the `@` symbol (e.g., `@max`). The function `fun` must accept a column vector and return a numeric, logical, or character scalar, or a scalar cell. Return value `A` has the same class as the values returned by `fun`. Specify `fun` as `[]` for the default behavior.

`A = accumarray(subs, val, sz, fun, fillval)` puts the scalar value `fillval` in elements of `A` that are not referred to by any row of `subs`. For example, if `subs` is empty, then `A` is `repmat(fillval, sz)`. `fillval` and the values returned by `fun` must belong to the same class. The default value of `fillval` is 0.

`A = accumarray(subs, val, sz, fun, fillval, issparse)` creates an array `A` that is sparse if the scalar input `issparse` is equal to logical 1 (i.e., `true`), or full if `issparse` is equal to logical 0 (`false`). `A` is full by

default. If `issparse` is `true`, then `fillval` must be zero or `[]`, and `val` and the output of `fun` must be double.

`A = accumarray({subs1, subs2, ...}, val, ...)` passes multiple `subs` vectors in a cell array. You can use any of the four optional inputs (`sz`, `fun`, `fillval`, or `issparse`) with this syntax.

---

**Note** If the subscripts in `subs` are not sorted, `fun` should not depend on the order of the values in its input data.

---

The function processes the input as follows:

- 1** Find out how many unique indices there are in `subs`. Each unique index defines a bin in the output array. The maximum index value in `subs` determines the size of the output array.

- 2** Find out how many times each index is repeated.

This determines how many elements of `vals` are going to be accumulated at each bin in the output array.

- 3** Create an output array. The output array is of size `max(subs)` or of size `sz`.

- 4** Accumulate the entries in `vals` into bins using the values of the indices in `subs` and apply `fun` to the entries in each bin.

- 5** Fill the values in the output for positions not referred to by `subs`. Default fill value is zero; use `fillval` to set a different value.

---

**Note** `subs` should contain positive integers. `subs` can also be a cell vector with one or more elements, each element a vector of positive integers. All the vectors must have the same length. In this case, `subs` is treated as if the vectors formed columns of an index matrix. `val` must be a numeric, logical, or character vector with the same length as the number of rows in `subs`. `val` can also be a scalar whose value is repeated for all the rows of `subs`.

---

## Examples

### Example 1

Create a 5-by-1 vector and sum values for repeated 1-D subscripts:

```
val = 101:105;
subs = [1; 2; 4; 2; 4]
subs =
     1
     2
     4
     2
     4
```

```
A = accumarray(subs, val)
A =
    101      % A(1) = val(1) = 101
    206      % A(2) = val(2)+val(4) = 102+104 = 206
     0      % A(3) = 0
    208      % A(4) = val(3)+val(5) = 103+105 = 208
```

### Example 2

Create a 4-by-4 matrix and subtract values for repeated 2-D subscripts:

```
val = 101:106;
subs=[1 2; 1 2; 3 1; 4 1; 4 4; 4 1];
B = accumarray(subs, val, [], @(x)sum(diff(x)))

B =
```

```

0    -1    0    0
0     0    0    0
0     0    0    0
2     0    0    0

```

The order of the subscripts matters:

```

val = 101:106;
subs=[1 2; 3 1; 1 2; 4 4; 4 1; 4 1];
B1 = accumarray(subs,val,[],@(x)sum(diff(x)))

```

B1 =

```

0    -2    0    0
0     0    0    0
0     0    0    0
-1    0    0    0

```

### Example 3

Create a 2-by-3-by-2 array and sum values for repeated 3-D subscripts:

```

val = 101:105;
subs = [1 1 1; 2 1 2; 2 3 2; 2 1 2; 2 3 2];

```

```

A = accumarray(subs, val)

```

A(:,:,1) =

```

101    0    0
0     0    0

```

A(:,:,2) =

```

0     0    0
206    0   208

```

### Example 4

Create a 2-by-3-by-2 array, and sum values natively:

```

val = 101:105;
subs = [1 1 1; 2 1 2; 2 3 2; 2 1 2; 2 3 2];

```

```
A = accumarray(subs, int8(val), [], @(x) sum(x,'native'))
A(:,:,1) =
    101     0     0
     0     0     0
A(:,:,2) =
     0     0     0
    127     0    127

class(A)
ans =
    int8
```

## Example 5

Pass multiple subscript arguments in a cell array.

- 1 Create a 12-element vector V:

```
V = 101:112;
```

- 2 Create three 12-element vectors, one for each dimension of the resulting array A. Note how the indices of these vectors determine which elements of V are accumulated in A:

```
%           index 1   index 6 => V(1)+V(6) => A(1,3,1)
%           |           |
rowsubs = [1 3 3 2 3 1 2 2 3 3 1 2];
colsubs = [3 4 2 1 4 3 4 2 2 4 3 4];
pagsubs = [1 1 2 2 1 1 2 1 1 1 2 2];
%           |
%           index 4 => V(4) => A(2,1,2)
%
% A(1,3,1) = V(1) + V(6) = 101 + 106 = 207
% A(2,1,2) = V(4) = 104
```

- 3 Call `accumarray`, passing the subscript vectors in a cell array:

```
A = accumarray({rowsubs colsubs pagsubs}, V)
```

```
A(:,:,1) =
    0     0   207     0           % A(1,3,1) is 207
    0   108     0     0
    0   109     0   317
A(:,:,2) =
    0     0   111     0
   104     0     0   219           % A(2,1,2) is 104
    0   103     0     0
```

### Example 6

Create an array with the `max` function, and fill all empty elements of that array with `NaN`:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @max, NaN)
A =
    101   NaN   NaN   NaN
    104   NaN   105   NaN
```

### Example 7

Create a sparse matrix using the `prod` function:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @prod, 0, true)
A =
    (1,1)           101
    (2,1)         10608
    (2,3)         10815
```

### Example 8

Count the number of entries accumulated in each bin:

```
val = 1;
```

# accumarray

---

```
subs = [1 1; 2 1; 2 3; 2 1; 2 3];
```

```
A = accumarray(subs, val, [2 4])
```

```
A =  
    1    0    0    0  
    2    0    2    0
```

## Example 9

Create a logical array that shows which bins will accumulate two or more values:

```
val = 101:105;
```

```
subs = [1 1; 2 1; 2 3; 2 1; 2 3];
```

```
A = accumarray(subs, val, [2 4], @(x) length(x) > 1)
```

```
A =  
    0    0    0    0  
    1    0    1    0
```

## Example 10

Group values in a cell array:

```
val = 101:105;
```

```
subs = [1 1; 2 1; 2 3; 2 1; 2 3];
```

```
A = accumarray(subs, val, [2 4], @(x) {x})
```

```
A =  
    [    101]    []    []    []  
    [2x1 double]    []    [2x1 double]    []
```

```
A{2}
```

```
ans =  
    104  
    102
```

**Purpose** Inverse cosine in radians

**Syntax**  $Y = \text{acos}(X)$

**Description**  $Y = \text{acos}(X)$  returns the inverse cosine (arccosine) for each element of  $X$ . For real elements of  $X$  in the domain  $[-1, 1]$ ,  $\text{acos}(X)$  is real and in the range  $[0, \pi]$ . For real elements of  $X$  outside the domain  $[-1, 1]$ ,  $\text{acos}(X)$  is complex.

The `acos` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

**Examples** Graph the inverse cosine function over the domain  $-1 \leq x \leq 1$ .

```
x = -1:.05:1;  
plot(x,acos(x)), grid on
```

**Definitions****Inverse Cosine**

The inverse can be defined as

$$\cos^{-1}(z) = -i \log \left[ z + i(1 - z^2)^{1/2} \right].$$

**Purpose** Inverse hyperbolic cosecant

**Syntax**  $Y = \operatorname{acsch}(X)$

**Description**  $Y = \operatorname{acsch}(X)$  returns the inverse hyperbolic cosecant for each element of  $X$ .

The `acsch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

**Examples** Graph the inverse hyperbolic cosecant over the domains  $-20 \leq x \leq -1$  and  $1 \leq x \leq 20$ .

```
x1 = -20:0.01:-1;  
x2 = 1:0.01:20;  
plot(x1,acsch(x1),x2,acsch(x2)), grid on
```

### Inverse Hyperbolic Cosecant

The inverse hyperbolic cosecant can be defined as

# acsch

---

$$\operatorname{csch}^{-1}(z) = \sinh^{-1}\left(\frac{1}{z}\right).$$

**Purpose**

Create Microsoft ActiveX control in figure window

**Syntax**

```
h = actxcontrol('progid')
h = actxcontrol('progid','param1',value1,...)
h = actxcontrol('progid',position)
h = actxcontrol('progid', position, fig_handle)
h = actxcontrol('progid',position,fig_handle,event_handler)
h = actxcontrol('progid',position,fig_handle,event_handler,
    'filename')
```

**Description**

`h = actxcontrol('progid')` creates an ActiveX® control in a figure window. The programmatic identifier (`progid`) for the control determines the type of control created. (See the documentation provided by the control vendor to get this string.) The returned object, `h`, represents the default interface for the control.

You cannot use an ActiveX server for the `progid` because MATLAB software cannot insert ActiveX servers in a figure. See `actxserver` for use with ActiveX servers.

`h = actxcontrol('progid','param1',value1,...)` creates an ActiveX control using the optional parameter name/value pairs. Parameter names include:

- `position` — MATLAB position vector specifying the control's position. The format is `[left, bottom, width, height]` using pixel units.
- `parent` — Handle to parent figure, model, or command window.
- `callback` — Name of event handler. Specify a single name to use the same handler for all events. Specify a cell array of event name/event handler pairs to handle specific events.
- `filename` — Sets the control's initial conditions to those in the previously saved control.
- `licensekey` — License key to create licensed ActiveX controls that require design-time licenses. See “Deploy ActiveX Controls Requiring Run-Time Licenses” for information on how to use controls that require run-time licenses.

One possible format is:

```
h = actxcontrol('myProgId','newPosition',[0 0 200 200],...  
  'myFigHandle',gcf,...  
  'myCallback',{ 'Click' 'myClickHandler';...  
  'DbtClick' 'myDbtClickHandler';...  
  'MouseDown' 'myMouseDownHandler'});
```

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the previous syntaxes are preferred.

`h = actxcontrol('progid',position)` creates an ActiveX control having the location and size specified in the vector, `position`. The format of this vector is:

```
[x y width height]
```

The first two elements of the vector determine where the control is placed in the figure window, with `x` and `y` being offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control. The last two elements, `width` and `height`, determine the size of the control itself.

The default position vector is `[20 20 60 60]`.

`h = actxcontrol('progid', position, fig_handle)` creates an ActiveX control at the specified position in an existing figure window. This window is identified by the Handle Graphics® handle, `fig_handle`.

The current figure handle is returned by the `gcf` command.

---

**Note** If the figure window designated by `fig_handle` is invisible, the control is invisible. If you want the control you are creating to be invisible, use the handle of an invisible figure window.

---

`h = actxcontrol('progid',position,fig_handle,event_handler)` creates an ActiveX control that responds to events. Controls respond to events by invoking a MATLAB function whenever an event (such

as clicking a mouse button) is fired. The `event_handler` argument identifies one or more functions to be used in handling events. For more information, see “Specifying Event Handlers” on page 1-113.

`h = actxcontrol('progid',position,fig_handle,event_handler,'filename')` creates an ActiveX control with the first four arguments, and sets its initial state to that of a previously saved control. MATLAB loads the initial state from the file specified in the string `filename`.

If you do not want to specify an `event_handler`, you can use an empty string ( `' '` ) as the fourth argument.

The `progid` argument must match the `progid` of the saved control.

### Specifying Event Handlers

There is more than one valid format for the `event_handler` argument. Use this argument to specify one of the following:

- A different event handler routine for each event supported by the control
- One common routine to handle selected events
- One common routine to handle all events

In the first case, use a cell array for the `event_handler` argument, with each row of the array specifying an event and handler pair:

```
{'event' 'eventhandler'; 'event2' 'eventhandler2'; ...}
```

`event` can be either a string containing the event name or a numeric event identifier (see Example 2), and `eventhandler` is a string identifying the function you want the control to use in handling the event. Include only those events that you want enabled.

In the second case, use the same cell array syntax just described, but specify the same `eventhandler` for each event. Again, include only those events that you want enabled.

In the third case, make `event_handler` a string (instead of a cell array) that contains the name of the one function that is to handle all events for the control.

There is no limit to the number of event and handler pairs you can specify in the `event_handler` cell array. However, if you register the same event name to the same callback handler multiple times, MATLAB executes the event only once.

Event handler functions should accept a variable number of arguments.

Strings used in the `event_handler` argument are not case sensitive.

---

**Note** Although using a single handler for all events might be easier in some cases, specifying an individual handler for each event creates more efficient code, resulting in better performance.

---

## Tips

If the control implements any custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

When you no longer need the control, call `release` to release the interface and free memory and other resources used by the interface. Note that releasing the interface does not delete the control itself. Use the `delete` function to do this.

For more information on handling control events, see [Writing Event Handlers](#).

For an example event handler, see the file `sampev.m` in the `toolbox\matlab\winfun\comcli` directory.

COM functions are available on Microsoft® Windows® systems only.

---

**Note** If you encounter problems creating Microsoft Forms 2.0 controls in MATLAB or other non-VBA container applications, see “Use Microsoft Forms 2.0 Controls”.

---

## Examples

### Handling Events

The `event_handler` argument specifies how you want the control to handle any events that occur. The control can handle all events with one common handler function, selected events with a common handler function, or each type of event can be handled by a separate function.

This command creates an `mwsamp` control that uses one event handler, `sampev`, to respond to all events:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
    gcf, 'sampev');
```

The next command also uses a common event handler, but will only invoke the handler when selected events, `Click` and `Db1Click` are fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
    gcf, {'Click' 'sampev'; 'Db1Click' 'sampev'});
```

This command assigns a different handler routine to each event. For example, `Click` is an event, and `myclick` is the routine that executes whenever a `Click` event is fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
    gcf, {'Click', 'myclick'; 'Db1Click' 'my2click'; ...
    'MouseDown' 'mymoused'});
```

The next command does the same thing, but specifies the events using numeric event identifiers:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
    gcf, {-600, 'myclick'; -601 'my2click'; -605 'mymoused'});
```

For examples of event handler functions and how to register them with MATLAB, see “Sample Event Handlers”.

## See Also

`actxserver` | `release` | `delete` (COM) | `save` (COM) | `load` (COM) | `interfaces`

# actxcontrollist

---

**Purpose** List currently installed Microsoft ActiveX controls

**Syntax** `info = actxcontrollist`

**Description** `info = actxcontrollist` returns a list of controls in `info`, a 1-by-3 cell array containing the name, programmatic identifier (ProgID), and file name for the control. Each control has one row, which MATLAB software sorts by file name.

COM functions are available on Microsoft Windows systems only.

**Examples** Show information for two controls:

```
list = actxcontrollist;
for k = 1:2
    sprintf(' Name = %s\n ProgID = %s\n File = %s\n', list{k,:})
end
```

MATLAB displays information like:

```
ans =
    Name = Calendar Control 11.0
    ProgID = MSCAL.Calendar.7
    File = C:\Program Files\MSOffice\OFFICE11\MSCAL.OCX
```

```
ans =
    Name = CTreeView Control
    ProgID = CTREEVIEW.CTreeViewCtrl.1
    File = C:\WINNT\system32\dmocx.dll
```

**See Also** `actxcontrolselect` | `actxcontrol`

**Purpose** Create Microsoft ActiveX control from GUI

**Syntax** `h = actxcontrolselect`  
`[h, info] = actxcontrolselect`

**Description** `h = actxcontrolselect` displays a GUI listing all ActiveX controls installed on the system and creates the one you select from the list. Returns handle `h` for the object. Use the handle to identify this control when calling MATLAB COM functions.

`[h, info] = actxcontrolselect` returns a 1-by-3 cell array `info` containing the name, programmatic identifier (ProgID), and file name for the control.

COM functions are available on Microsoft Windows systems only.

**See Also** `actxcontrollist` | `actxcontrol`

**How To**

- “Creating Control Objects Using a GUI”

# actxGetRunningServer

---

**Purpose** Handle to running instance of Automation server

**Syntax** `h = actxGetRunningServer('progid')`

**Description** `h = actxGetRunningServer('progid')` gets a reference to a running instance of the OLE Automation server. `progid` is the programmatic identifier of the Automation server object and `h` is the handle to the default interface of the server object.

The function returns an error if the server specified by `progid` is not currently running or if the server object is not registered. When multiple instances of the Automation server are running, the operating system controls the behavior of this function.

COM functions are available on Microsoft Windows systems only.

**Examples** Get a handle to the MATLAB application:

```
h = actxGetRunningServer('matlab.application')
```

**See Also** `actxcontrol` | `actxserver`

**How To**

- “MATLAB COM Automation Server Interface”

**Purpose** Create COM server

**Syntax**

```
h = actxserver('progid')
h = actxserver('progid','machine','machineName')
h = actxserver('progid','interface','interfaceName')
h = actxserver('progid','machine','machineName','interface',
    'interfaceName')
h = actxserver('progid',machine)
```

**Description** `h = actxserver('progid')` creates a local OLE Automation server, where `progid` is the programmatic identifier of an OLE-compliant COM server, and `h` is the handle of the server's default interface.

Get `progid` from the control or server vendor's documentation. To see the `progid` values for MATLAB software, refer to "Programmatic Identifiers".

`h = actxserver('progid','machine','machineName')` creates an OLE Automation server on a remote machine, where `machineName` is a string specifying the name of the machine on which to start the server.

`h = actxserver('progid','interface','interfaceName')` creates a Custom interface server, where `interfaceName` is a string specifying the interface name of the COM object. Values for `interfaceName` are

- `IUnknown` — Use the `IUnknown` interface.
- The Custom interface name

You must know the name of the interface and have the server vendor's documentation in order to use the `interfaceName` value. For information about custom COM servers and interfaces, see "COM Server Types".

---

**Note** The MATLAB COM Interface does not support invoking functions with optional parameters.

---

```
h =  
actxserver('progid','machine','machineName','interface',  
'interfaceName') creates a Custom interface server on a  
remote machine.
```

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the syntaxes described earlier are preferred:

```
h = actxserver('progid',machine) creates a COM server running  
on the remote system named by the machine argument. This can be an  
IP address or a DNS name. Use this syntax only in environments that  
support Distributed Component Object Model (for more information,  
see “Using MATLAB Application as DCOM Server”).
```

## Tips

For components implemented in a dynamic link library (DLL), `actxserver` creates an in-process server. For components implemented as an executable (EXE), `actxserver` creates an out-of-process server. Out-of-process servers can be created either on the client system or on any other system on a network that supports DCOM.

If the control implements any Custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

You can register events for COM servers.

COM functions are available on Microsoft Windows systems only.

## Examples

### Microsoft Excel® Workbook Example

This example creates an OLE Automation server, Excel version 9.0, and manipulates a workbook in the application.

Create a COM server running Microsoft Excel.

```
e = actxserver ('Excel.Application')  
  
e =  
    COM.Excel.application
```

Make the Excel frame window visible.

```
e.Visible = 1;
```

Use the `get` method on the Excel object `e` to list all properties of the application.

```
e.get
```

```
Application: [1x1
Interface.Microsoft_Excel_9.0_Object_Library._Application]
  Creator: 'xlCreatorCode'
  .
  .
  .
  Workbooks: [1x1
Interface.Microsoft_Excel_9.0_Object_Library.Workbooks]
  .
  .
  .
  Caption: 'Microsoft Excel - Book1'
  CellDragAndDrop: 0
  ClipboardFormats: {3x1 cell}
  .
  .
  .
  Cursor: 'xlNorthwestArrow'
  .
  .
  .
```

Create an interface `eWorkBooks`.

```
eWorkbooks = e.Workbooks
```

```
eWorkbooks =
  Interface.Microsoft_Excel_9.0_Object_Library.Workbooks
```

List all methods for that interface.

```
eWorkbooks.invoke
```

```
    Add: 'handle Add(handle, [Optional]Variant)'  
    Close: 'void Close(handle)'  
    Item: 'handle Item(handle, Variant)'  
    Open: 'handle Open(handle, string, [Optional]Variant)'  
    OpenText: 'void OpenText(handle, string, [Optional]Variant)'  
    .  
    .  
    .
```

Add a new workbook w, also creating a new interface.

```
w = eWorkbooks.Add
```

```
w =  
    Interface.Microsoft_Excel_9.0_Object_Library._Workbook
```

Close Excel and delete the object.

```
e.Quit;  
e.delete;
```

**Purpose** Create or modify app project file for packaging app into .mlappinstall file using interactive dialog box

**Syntax** matlab.apputil.create  
matlab.apputil.create(prjfile)

**Description** matlab.apputil.create opens the Package App dialog box that steps you through the process of creating an .mlappinstall file.

matlab.apputil.create(prjfile) loads the specified .prj file and populates the Package App dialog box with the information from the specified project file. Use this option if you need to update an existing app.

**Input Arguments**

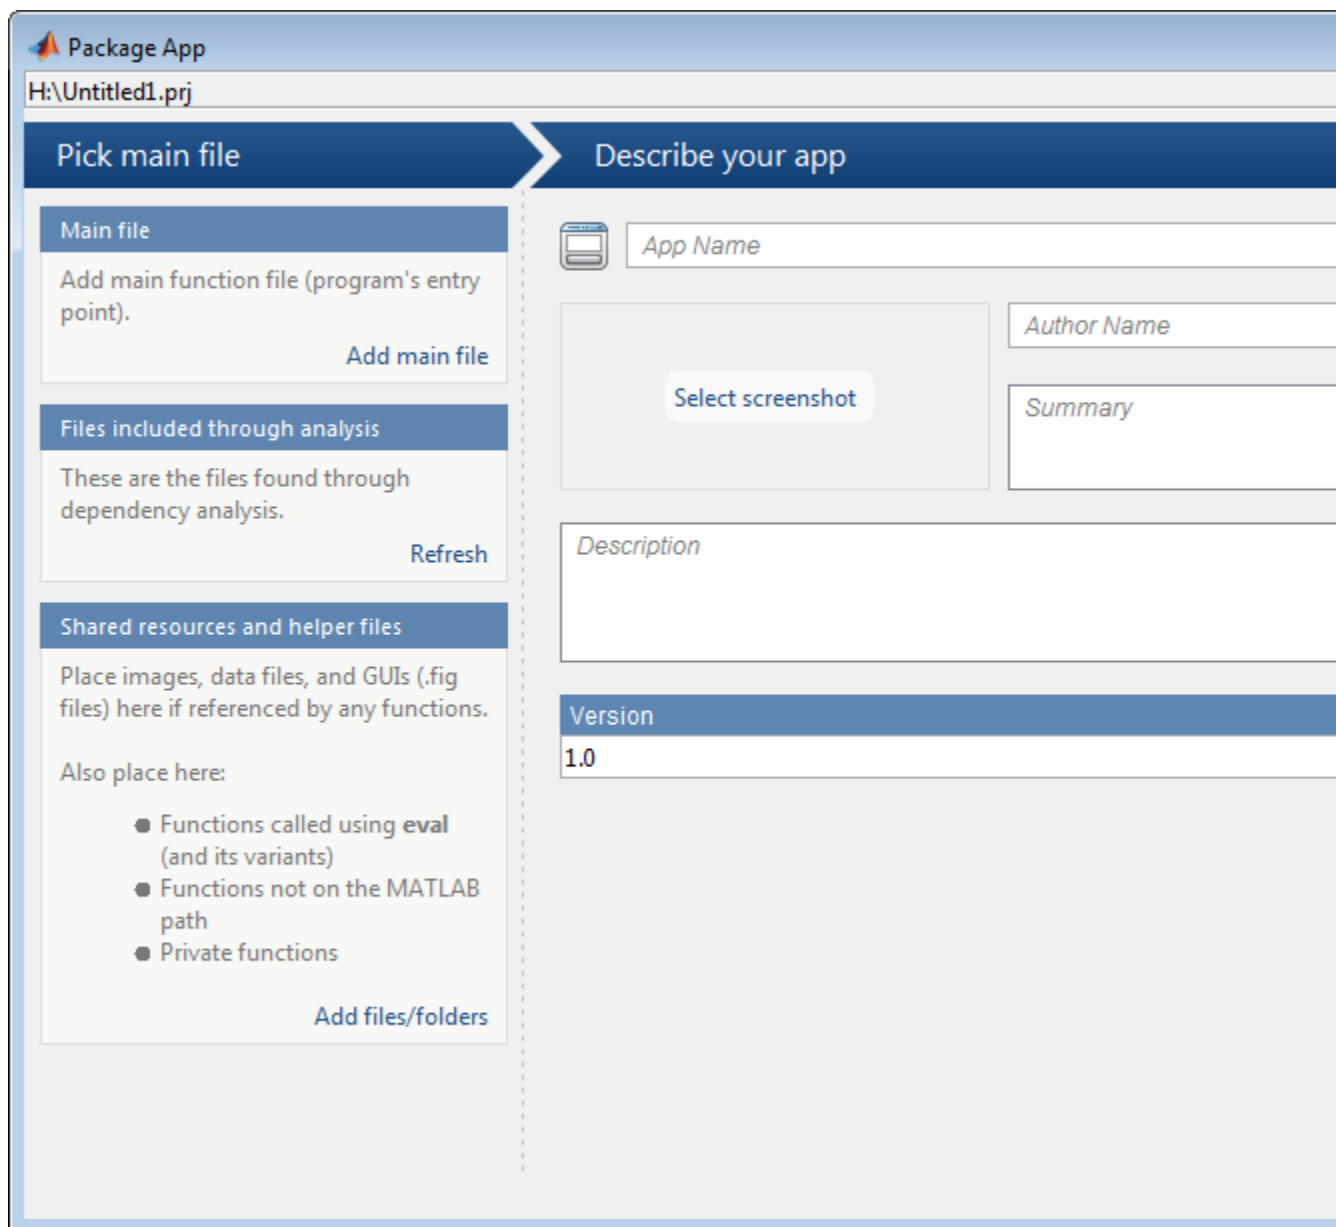

**prjfile - Full or partial path to the .prj file**  
string

Full or partial path to the .prj file you created previously with the Package App dialog box, specified as a string

**Example:** 'C:\myapp.prj'

**Examples** **Open Dialog Box for Creating an App Package**

matlab.apputil.create

Minimally, add a main file and specify an app name. MATLAB creates and continuously saves a .prj file, regardless of whether you click **Package**. However, MATLAB does not create a .mlappinstall file if you do not click **Package**.

## Update Existing App Package

Assume you have an existing project file, myapp.prj. You want to add a file and update the description.

Open the Package App dialog box, specifying the previously created .prj file:

```
matlab.apputil.create('myapp.prj')
```

The dialog box opens populated with the data you previously specified for myapp. Adjust the information in the dialog box, as needed.

**See Also** `matlab.apputil.package`

**Concepts**

- “MATLAB App Installer File — mlappinstall”

# matlab.apputil.getInstalledAppInfo

---

**Purpose** List installed app information

**Syntax** `matlab.apputil.getInstalledAppInfo`

`appinfo = matlab.apputil.getInstalledAppInfo`

**Description** `matlab.apputil.getInstalledAppInfo` displays the ID and name of all installed custom apps. It does not display this information for apps packaged with MathWorks® products.

`appinfo = matlab.apputil.getInstalledAppInfo` returns structure to `appinfo`, which includes the status, ID, location, and name of all installed custom apps. It does not return this information for apps packaged with MathWorks products.

## Output Arguments

### **appinfo - Information about installed apps**

structure array

Information about the installed app, returned as a structure array, with one element for each installed app. Each element of the structure array has the following fields:

#### **status - Installation status**

'installed'

Status of the installation, returned as the string 'installed'.

#### **id - Unique identifier for the installed app**

string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

#### **location - Folder where the app is installed**

string

Folder where the app is installed, returned as a string

## **name - Name of the installed app**

string

Name of the installed app as it appears in the apps gallery, returned as a string

## **Examples**

### **Display Installed Apps Information in the Command Window**

Assume you installed two apps, LinePlotter and PlotRandNumbers. Display the app information in the Command Window.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                               Name
-----
LinePlotterAPP                  LinePlotter
PlotRandNumbersAPP              PlotRandNumbers
```

### **Store Installed App Information in a Variable**

Assume you installed an app, ColorPalette. Get the app information and store it in a variable, myappinfo.

```
myappinfo = matlab.apputil.getInstalledAppInfo;
```

### **Store Installed App Information in a Variable and Display IDs**

Assume you installed two apps, LinePlotter and PlotRandNumbers. Get and store the app information for both installed apps in a variable, myappinfo. Then, get the id for each app.

```
myappinfo = matlab.apputil.getInstalledAppInfo
```

```
myappinfo =
```

```
1x2 struct array with fields:
    id
```

# matlab.apputil.getInstalledAppInfo

---

```
name  
status  
location
```

Get the id of each installed app:

```
appids={myappinfo.id}
```

```
appids =
```

```
    'LinePlotterAPP'    'PlotRandNumbersAPP'
```

<b>Purpose</b>	Package app files into .mlappinstall file
<b>Syntax</b>	<code>matlab.apputil.package(prjfile)</code>
<b>Description</b>	<code>matlab.apputil.package(prjfile)</code> creates a .mlappinstall file based on the information in the specified <code>prjfile</code> .
<b>Input Arguments</b>	<p><b>prjfile</b> - Full or partial path to app project (.prj) file string</p> <p>Full or partial path to app project (.prj) file, specified as a string.</p> <p><b>Example:</b> 'plotdata.prj'</p>
<b>Examples</b>	<p><b>Create mlappinstall File for Previously Created Project File</b></p> <p>Assume you previously created <code>myprjfile.prj</code> using <code>matlab.apputil.create</code>. The following command creates the corresponding .mlappinstall file.</p> <pre>matlab.apputil.package('myprjfile.prj')</pre>
<b>Tips</b>	<ul style="list-style-type: none"><li>• To create a .prj file, use <code>matlab.apputil.create</code>.</li></ul>
<b>See Also</b>	<code>matlab.apputil.create</code>   <code>matlab.apputil.install</code>   <code>matlab.apputil.run</code>

# matlab.apputil.run

---

**Purpose** Run app programmatically

**Syntax** `matlab.apputil.run(appid)`

**Description** `matlab.apputil.run(appid)` runs the custom app specified by the unique identifier, `appid`.

**Input Arguments** **appid - ID of custom app**  
string

ID of custom app you want to run, specified as a string.

**Example:** 'DataExplorationAPP'

## Tips

- The ID of a custom app is returned when you install it. You can use `matlab.apputil.getInstalledAppInfo` to get the ID after you have installed an app.
- When a custom app runs, MATLAB adds any folders it needs to have added to the path, as identified when the app was packaged. When the app exits, MATLAB removes those folders from the path.
- You can run multiple, different custom apps concurrently. However, you cannot run two instances of the same app concurrently.

## Examples

### Run Previously Installed App

Assume you installed two apps, `PlotData` and `setslider`. Run `PlotData` programmatically, using its ID.

Get IDs of all installed apps.

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
-----	-----
setsliderAPP	setslider
PlotDataAPP	PlotData

Run PlotData.

```
matlab.apputil.run('PlotDataAPP')
```

## See Also

```
matlab.apputil.create | matlab.apputil.install |  
matlab.apputil.getInstalledAppInfo
```

# matlab.apputil.uninstall

---

**Purpose** Uninstall app

**Syntax** `matlab.apputil.uninstall(appid)`

**Description** `matlab.apputil.uninstall(appid)` removes the app specified by the unique identifier, `appid`. MATLAB removes all files corresponding to the app and removes the app from the app gallery.

**Input Arguments** **appid - ID of app**  
string

ID of app to be uninstalled, specified as a string.

**Example:** 'DataExplorationAPP'

**Tips**

- To determine the `appid` of an installed app, preserve the value returned when you install the app programmatically with `matlab.apputil.install`, or use `matlab.apputil.getInstalledAppInfo`.

**Examples** **Uninstall App**

Assume you previously installed two apps, `setslider` and `simplegui`. Get the IDs of all installed apps, and then use the ID for `simplegui` to uninstall it.

View the IDs of all apps

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
setsliderAPP	setslider
simpleguiAPP	simplegui

Uninstall the `simplegui` app.

```
matlab.apputil.uninstall('simpleguiAPP')
```

Confirm the app was removed, by running `matlab.apputil.getInstalledAppInfo` again.

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
-----	-----
setsliderAPP	setslider

# addCause (MException)

---

**Purpose** Record additional causes of exception

**Syntax** `baseExcep = addCause(baseExcep, causeExcep)`

**Description** `baseExcep = addCause(baseExcep, causeExcep)` adds information to existing exception `baseExcep` to help determine its cause. The added information is in the form of a second exception `causeExcep`. Both `baseExcep` and `causeExcep` are objects of the `MException` class. The `baseExcep` and `causeExcep` inputs are scalar objects of the `mException` class.

The exception has a property called `cause` in which you can store a series of additional exceptions, each saving information on what caused the initial error. (See the figure in the documentation for “The `MException` Class”.) When your program calls `addCause`, MATLAB appends a new exception `cause` to this field in the base exception `exception`. When your error handling code catches the error in a `try/catch` statement, execution of the `catch` part of this statement makes the base exception, along with all of the appended `cause` records, available to help diagnose the error.

## Examples

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested `try-catch` block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second using `addCause`:

```
function data = read_it(filename);
try
    % Attempt to open and read from a file.
    fid = fopen(filename, 'r');
    data = fread(fid);
catch exception1
    % If the error was caused by an invalid file ID, try
    % reading from another location.
    if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
        msg = sprintf( ...
```

```
        '\nCannot open file %s. Try another location? ', ...
        filename);
    reply = input(msg, 's')
    if reply(1) == 'y'
        newFolder = input('Enter folder name: ', 's');
    else
        throw(exception1);
    end
    oldpath = addpath(newFolder);
    try
        fid = fopen(filename, 'r');
        data = fread(fid);
    catch exception2
        exception3 = addCause(exception2, exception1)
        path(oldpath);
        throw(exception3);
    end
    path(oldpath);
end
end
fclose(fid);

try
    d = read_it('anytextfile.txt');
catch exception
end

exception
exception =
    MException object with properties:

    identifier: 'MATLAB:FileIO:InvalidFid'
    message: 'Invalid file identifier. Use fopen
             to generate a valid file identifier.'
    stack: [1x1 struct]
    cause: {[1x1 MException]}
```

## addCause (MException)

---

```
Cannot open file anytextfile.txt. Try another location?y
Enter folder name: xxxxxxx
Warning: Name is nonexistent or not a directory: xxxxxxx.
> In path at 110
  In addpath at 89
```

### See Also

```

| rethrow(MException) | throwAsCaller(MException) |
getReport(MException) | last(MException)
```

**Purpose** Add event to timeseries object

**Syntax** `ts = addevent(ts,e)`  
`ts = addevent(ts,Name,Time)`

**Description** `ts = addevent(ts,e)` adds one or more `tsdata.event` objects, `e`, to the `timeseries` object `ts`. `e` is either a single `tsdata.event` object or an array of `tsdata.event` objects.

`ts = addevent(ts,Name,Time)` constructs one or more `tsdata.event` objects and adds them to the `Events` property of `ts`. `Name` is a cell array of event name strings. `Time` is a cell array of event times.

**Examples** Create a time-series object and add an event to this object.

```
%% Import the sample data
load count.dat

%% Create time-series object
count1=timeseries(count(:,1),1:24,'name','data');

%% Modify the time units to be 'hours' ('seconds' is default)
count1.TimeInfo.Units = 'hours';

%% Construct and add the first event at 8 AM
e1 = tsdata.event('AMCommute',8);
```

```
%% Specify the time units of the time
e1.Units = 'hours';
```

View the properties (`EventData`, `Name`, `Time`, `Units`, and `StartDate`) of the event object.

```
get(e1)
```

MATLAB software responds with

```
EventData: []
```

# addevent

---

```
        Name: 'AMCommute'  
        Time: 8  
        Units: 'hours'  
        StartDate: ''  
%% Add the event to count1  
count1 = addevent(count1,e1);
```

An alternative syntax for adding two events to the time series count1 is as follows:

```
count1 = addevent(count1,{'AMCommute' 'PMCommute'},{8 18})
```

**Purpose** Information about audio file

**Syntax** `info = audioinfo(filename)`

**Description** `info = audioinfo(filename)` returns information about the contents of the audio file specified by `filename`.

**Input Arguments** **filename - Name of file**  
string

Name of file, specified as a string. If a path is specified, it can be absolute, relative, or partial.

**Example:** `'myFile.mp3'`

**Example:** `'../myFile.mp3'`

**Example:** `'C:\temp\myFile.mp3'`

`audioinfo` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
	AU (.au)
Windows 7 (or later), Macintosh, and Linux®	MP3 (.mp3)
	MPEG-4 AAC (.m4a, .mp4)

On Windows 7 platforms (or later), `audioinfo` might also return information about the contents of any files supported by Windows Media® Foundation.

On Linux platforms, `audioinfo` might also return information about the contents of any files supported by GStreamer.

# audioinfo

---

audioinfo can extract audio metadata from MPEG-4 (.mp4, .m4v) video files on Windows 7 or later, Mac OS X 10.7 Lion or higher, and Linux, and from Windows Media Video (.wmv) and AVI (.avi) files on Windows 7 (or later) and Linux platforms.

## Output Arguments

### info - Information about audio file

structure

Information about audio file, returned as a structure. info can contain the following fields.

Field Name	Description	Data Type
Filename	Filename including the absolute path to the file and the file extension.	string
CompressionMethod	Compression method used.	string
NumChannels	Number of audio channels encoded in	double
SampleRate	Sample rate of the audio data in the file, in hertz.	double
TotalSamples	Total number of audio samples in the file.	double
Duration	Duration of the file, in seconds.	double
BitsPerSample	Number of bits per sample encoded in the audio file.  Only valid for WAVE (.wav) and FLAC (.flac) files.	double

Field Name	Description	Data Type
BitRate	Number of kilobits per second (kbit/s) used for compressed audio files.  Only valid for MP3 (.mp3) and MPEG-4 Audio (.m4a, .mp4) files.	double
Title	Value of 'Title', if any.	string
Artist	Value of 'Artist', if any.	string
Comment	Value of 'Comment', if any.	string

---

**Note** The BitRate property returns the actual bit rate on Mac platforms, and not the encoded bit rate. This means that bit rate values might be lower than specified at the time of the encoding, depending on the source data.

---

---

**Note** On Mac platforms, audioinfo returns metadata from .m4a and .mp4 files only on Mac OS X 10.7 Lion or higher. Previous versions of Mac OS X will not read the 'Title', 'Author', or 'Comment' fields.

---

## Examples

### Get Information About Audio File

Create a WAVE file from the example file handel.mat, and get information about the file.

# audioinfo

---

Create a WAVE (.wav) file in the current folder.

```
load handel.mat
filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Use `audioinfo` to return information about the WAVE file.

```
info = audioinfo(filename)

info =
    Filename: 'S:\handel.wav'
    CompressionMethod: 'Uncompressed'
    NumChannels: 1
    SampleRate: 8192
    TotalSamples: 73113
    Duration: 8.9249
    Title: []
    Comment: []
    Artist: []
    BitsPerSample: 16
```

## Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 and Linux platforms, `audioinfo` might report fewer samples than expected. On Linux platforms, this is due to a limitation in the underlying GStreamer framework.
- On Linux platforms, `audioinfo` interprets single channel data in MPEG-4 AAC files as stereo data.

## See Also

`audioread` | `audiowrite`

## Purpose

Read audio file

## Syntax

```
[y,Fs] = audioread(filename)
[y,Fs] = audioread(filename,samples)

[y,Fs] = audioread( ___,dataType)
```

## Description

`[y,Fs] = audioread(filename)` reads data from the file named `filename`, and returns sampled data, `y`, and a sample rate for that data, `Fs`.

`[y,Fs] = audioread(filename,samples)` reads the selected range of audio samples in the file, where `samples` is a vector of the form `[start,finish]`.

`[y,Fs] = audioread( ___,dataType)` returns sampled data in the data range corresponding to the `dataType` of 'native' or 'double', and can include any of the input arguments in previous syntaxes.

## Input Arguments

### **filename** - Name of file to read

string

Name of file to read, specified as a string that includes the file extension. If a path is specified, it can be absolute, relative or partial.

**Example:** 'myFile.mp3'

**Example:** '../myFile.mp3'

**Example:** 'C:\temp\myFile.mp3'

`audioread` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
	AU (.au)
Windows 7 (or later), Macintosh, and Linux	MP3 (.mp3)
	MPEG-4 AAC (.m4a, .mp4)

On Windows 7 (or later) platforms, `audioread` might also read any files supported by Windows Media Foundation.

On Linux platforms, `audioread` might also read any files supported by GStreamer.

`audioread` can extract audio from MPEG-4 (.mp4, .m4v) video files on Windows 7 or later, Macintosh, and Linux, and from Windows Media Video (.wmv) and AVI (.avi) files on Windows 7 (or later) and Linux platforms.

### **samples - Audio samples to read**

[1, inf] (default) | two-element vector of positive scalar integers

Audio samples to read, specified as a two-element vector of the form [start, finish], where `start` and `finish` are the first and last samples to read, and are positive scalar integers.

- `start` must be less than or equal to `finish`.
- `start` and `finish` must be less than the number of audio samples in the file,
- You can use `inf` to indicate the last sample in the file.

---

**Note** When reading a portion of some MP3 files on Windows 7 platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying Windows Media Foundation framework.

When reading a portion of MP3 and M4A files on Linux platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying GStreamer framework.

---

**Example:** `[1,100]`

### Data Types

`double`

### **dataType** - Data format of audio data, *y*

`'double'` (default) | `'native'`

Data format of audio data,*y*, specified as one of the following strings:

`'double'` Double-precision normalized samples.

`'native'` Samples in the native format found in the file.

For compressed audio formats, such as MP3 and MPEG-4 AAC that do not store data in integer form, `'native'` defaults to `'single'`.

## Output Arguments

### **y** - Audio data

`matrix`

Audio data in the file, returned as an *m*-by-*n* matrix, where *m* is the number of audio samples read and *n* is the number of audio channels in the file.

- If you do not specify `dataType`, or `dataType` is `'double'`, then *y* is of type `double`, and matrix elements are normalized values between `-1.0` and `1.0`.

# audioread

---

- If `dataType` is 'native', then `y` can be one of several MATLAB data types, depending on the file format and the `BitsPerSample` value of the input file. Call `audioinfo` to determine the `BitsPerSample` value of the file.

File Format	BitsPerSample	Data Type of <code>y</code>	Data Range of <code>y</code>
WAVE (.wav)	8	uint8	$0 \leq y \leq 255$
	16	int16	$-32768 \leq y \leq +32767$
	24	int32	$-2^{32} \leq y \leq 2^{32}-1$
	32	int32	$-2^{32} \leq y \leq 2^{32}-1$
	32	single	$-1.0 \leq y \leq +1.0$
	64	double	$-1.0 \leq y \leq +1.0$
FLAC (.flac)	8	uint8	$0 \leq y \leq 255$
	16	int16	$-32768 \leq y \leq +32767$
	24	int32	$-2^{32} \leq y \leq 2^{32}-1$
MP3 (.mp3), MPEG-4 AAC (.m4a, .mp4), and OGG (.ogg)	N/A	single	$-1.0 \leq y \leq +1.0$

---

**Note** Where `y` is `single` or `double` and the `BitsPerSample` is 32 or 64, values in `y` might exceed  $-1.0$  or  $+1.0$ .

---

**Fs - Sample rate**

positive scalar

Sample rate, in hertz, of audio data `y`, returned as a positive scalar.**Examples****Read Complete Audio File**Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.Create a WAVE (`.wav`) file in the current folder.

```
load handel.mat
```

```
filename = 'handel.wav';  
audiowrite(filename,y,Fs);  
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread('handel.wav');
```

Play the audio.

```
sound(y,Fs);
```

**Read Portion of Audio File**Create a FLAC file from the example file `handel.mat`, and then read only the first 2 seconds.Create a FLAC (`.flac`) file in the current folder.

```
load handel.mat
```

```
filename = 'handel.flac';  
audiowrite(filename,y,Fs);
```

Read only the first 2 seconds.

```
samples = [1,2*Fs];  
clear y Fs  
[y,Fs] = audioread(filename,samples);
```

Play the samples.

```
sound(y,Fs);
```

## Return Audio in Native Integer Format

Create a FLAC file and read the first 2 seconds according to the previous Example. Then, view the data type of the sampled data `y`.

```
whos y
```

Name	Size	Bytes	Class	Attributes
y	16384x1	131072	double	

The data type of `y` is `double`.

Request audio data in the native format of the file, and then view the data type of the sampled data `y`.

```
[y,Fs] = audioread(filename,'native');  
whos y
```

Name	Size	Bytes	Class	Attributes
y	16384x1	32768	int16	

The data type of `y` is now `int16`.

## Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 and Linux platforms, `audioread` might read fewer samples than expected. On Windows 7 platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.

- On Linux platforms, `audioread` reads MPEG-4 AAC files that contain single-channel data as stereo data.

## See Also

`audiowrite` | `audioinfo`

# audiowrite

---

**Purpose** Write audio file

**Syntax**  
`audiowrite(filename,y,Fs)`  
`audiowrite(filename,y,Fs,Name,Value)`

**Description** `audiowrite(filename,y,Fs)` writes a matrix of audio data, `y`, with sample rate `Fs` to a file called `filename`. The `filename` input also specifies the output file format. The output data type depends on the output file format and the data type of the audio data, `y`.

`audiowrite(filename,y,Fs,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **filename - Name of file to write**

string

Name of file to write, or the full path to the file, specified as a string that includes the file extension. If a path is specified, it can be absolute or relative. If you do not specify the path, then the destination directory is the current working directory.

`audiowrite` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
Windows and Mac	MPEG-4 AAC (.m4a, .mp4)

**Example:** `'myFile.m4a'`

**Example:** `'../myFile.m4a'`

**Example:** `'C:\temp\myFile.m4a'`

When writing AAC files on Windows, `audiowrite` pads the front and back of the output signal with extra samples of silence. The Windows

AAC encoder also places a very sharp fade-in and fade-out on the audio. This results in audio with an increased number of samples after being written to disk.

### **y - Audio data to write**

matrix

Audio data to write, specified as an  $m$ -by- $n$  matrix, where  $m$  is the number of audio samples to write and  $n$  is the number of audio channels to write.

If either  $m$  or  $n$  is 1, then `audiowrite` assumes that this dimension specifies the number of audio channels, and the other dimension specifies the number of audio samples.

The maximum number of channels depends on the file format.

<b>File Format</b>	<b>Maximum Number of Channels</b>
WAVE (.wav)	256
OGG (.ogg)	255
FLAC (.flac)	8
MPEG-4 AAC (.m4a, .mp4)	2

The valid range for the data in  $y$  depends on the data type of  $y$ .

<b>Data Type of <math>y</math></b>	<b>Valid Range for <math>y</math></b>
uint8	$0 \leq y \leq 255$
int16	$-32768 \leq y \leq +32767$
int32	$-2^{32} \leq y \leq 2^{32}-1$
single	$-1.0 \leq y \leq +1.0$
double	$-1.0 \leq y \leq +1.0$

Data beyond the valid range is clipped.

If `y` is `single` or `double`, then audio data in `y` should be normalized to values in the range  $-1.0$  and  $1.0$ , inclusive.

## Data Types

`single` | `double` | `int16` | `int32` | `uint8`

## **Fs** - Sample rate

positive scalar

Sample rate, in hertz, of audio data `y`, specified as a positive scalar greater than 0. Values of `Fs` are truncated to integer boundaries. When writing to `.m4a` or `.mp4` files on Windows platforms, `audiowrite` supports only samples rates of 44100 and 48000.

**Example:** 44100

## Data Types

`double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Title','Symphony No. 9','Artist','My Orchestra'` instructs `audiowrite` to write an audio file with the title “Symphony No. 9” and the artist information “My Orchestra.”

## **'BitsPerSample'** - Number of output bits per sample

16 (default) | 8 | 24 | 32 | 64

Number of output bits per sample, specified as the comma-separated pair consisting of `'BitsPerSample'` and a number.

Only available for WAVE (`.wav`) and FLAC (`.flac`) files. For FLAC files, only 8, 16, or 24 bits per sample are supported.

**Example:** `'BitsPerSample',32`

**'BitRate' - Kilobits per second (kbit/s)**

128 (default) | 64 | 96 | 160 | 192 | 256 | 320

Number of kilobits per second (kbit/s) used for compressed audio files, specified as the comma-separated pair consisting of 'BitRate' and an integer. Noninteger values are truncated. On Windows 7 platforms, the only valid values are 96, 128, 160, and 192.

In general, a larger BitRate value results in higher compression quality.

Only available for MPEG-4 (.m4a, .mp4) files.

**Example:** 'BitRate',96

**'Quality' - Quality setting for the Ogg Vorbis Compressor**

75 (default) | value in the range [0 100]

Quality setting for the Ogg Vorbis Compressor, specified as the comma-separated pair consisting of 'Quality' and a number in the range [0 100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression.

Only available for OGG (.ogg) files.

**Example:** 'Quality',25

**'Title' - Title information**

[] (default) | string

Title information, specified as the comma-separated pair consisting of 'Title' and a string.

**'Artist' - Artist information**

[] (default) | string

Artist information, specified as the comma-separated pair consisting of 'Artist' and a string.

**'Comment' - Additional information**

[] (default) | string

Additional information, specified as the comma-separated pair consisting of 'Comment' and a string.

---

**Note** On Mac platforms, `audiowrite` writes metadata to WAVE, OGG, and FLAC files only, and will not write the 'Title', 'Author', or 'Comment' fields to MPEG-4 AAC files.

---

## Examples

### Write an Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Write a WAVE (`.wav`) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread(filename);
```

Listen to the audio.

```
sound(y,Fs);
```

### Specify Bits Per Sample and Metadata

Create a FLAC file from the example file `handel.mat` and specify the number of output bits per sample and a comment.

```
load handel.mat

filename = 'handel.flac';
```

```
audiowrite(filename,y,Fs,'BitsPerSample',24,'Comment','This is my new
clear y Fs
```

View information about the new FLAC file.

```
info = audioinfo(filename)
```

```
info =
```

```

      Filename: 'S:\handel.flac'
CompressionMethod: 'FLAC'
      NumChannels: 1
      SampleRate: 8192
TotalSamples: 73113
      Duration: 8.9249
      Title: []
      Comment: 'This is my new audio file.'
      Artist: []
      BitsPerSample: 24
```

## Algorithms

The output data type is determined by the file format, the data type of `y`, and the specified output `BitsPerSample`.

File Formats	Data Type of <code>y</code>	Output <code>BitsPerSample</code>	Output Data Type
WAVE (.wav),	uint8, int16, int32, single, double	8	uint8
		16	int16
		24	int32
	uint8, int16, int32	32	int32
	single, double	32	single
	single, double	64	double

# audiowrite

---

File Formats	Data Type of y	Output BitsPerSample	Output Data Type
FLAC (.flac)	uint8, int16, int32, single, double	8	int8
		16	int16
		24	int32
MPEG-4 (.m4a, .mp4), OGG (.ogg)	uint8, int16, int32, single, double	N/A	single

## See Also

[audioinfo](#) | [audioread](#)

## Purpose

Add frame to Audio/Video Interleaved (AVI) file

## Syntax

```
aviobj = addframe(aviobj,frame)  
aviobj = addframe(aviobj,frame1,frame2,frame3,...)   
aviobj = addframe(aviobj,mov)  
aviobj = addframe(aviobj,h)
```

## Description

*aviobj* = addframe(*aviobj*,*frame*) appends the data in *frame* to the AVI file identified by *aviobj*, which was created by a previous call to `avifile`. *frame* can be either an indexed image (m-by-n) or a truecolor image (m-by-n-by-3) of double or uint8 precision. If *frame* is not the first frame added to the AVI file, it must be consistent with the dimensions of the previous frames.

`addframe` returns a handle to the updated AVI file object, *aviobj*. For example, `addframe` updates the `TotalFrames` property of the AVI file object each time it adds a frame to the AVI file.

*aviobj* = addframe(*aviobj*,*frame1*,*frame2*,*frame3*,...) adds multiple frames to an AVI file.

*aviobj* = addframe(*aviobj*,*mov*) appends the frames contained in the MATLAB movie *mov* to the AVI file *aviobj*. MATLAB movies that store frames as indexed images use the colormap in the first frame as the colormap for the AVI file, unless the colormap has been previously set.

*aviobj* = addframe(*aviobj*,*h*) captures a frame from the figure or axis handle *h* and appends this frame to the AVI file. `addframe` renders the figure into an offscreen array before appending it to the AVI file. This ensures that the figure is written correctly to the AVI file even if the figure is obscured on the screen by another window or screen saver.

## Tips

- `avifile` cannot write files larger than 2 GB. Use `VideoWriter` and `writeVideo` to create larger files.
- If you are creating an animation from a figure with an `EraseMode` property set to 'xor', you must use `getframe` to capture the graphics into a frame of a MATLAB movie. Add the frame to the AVI file using

## addframe (avifile)

---

the syntax `aviobj = addframe(aviobj,mov)`. See the example for an illustration.

### Examples

This example calls `addframe` to add frames to the AVI file object `aviobj`.

```
aviobj = avifile('example.avi','compression','None');

t = linspace(0,2.5*pi,40);
fact = 10*sin(t);
fig=figure;
[x,y,z] = peaks;
for k=1:length(fact)
    h = surf(x,y,fact(k)*z);
    axis([-3 3 -3 3 -80 80])
    axis off
    caxis([-90 90])

    F = getframe(fig);
    aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

### See Also

`VideoWriter` | `avifile` | `close (avifile)` | `movie2avi`

## Purpose

Create event listener

## Syntax

```
lh = addlistener(Hsource, 'EventName', callback)
lh = addlistener(Hsource, property, 'EventName', callback)
```

## Description

`lh = addlistener(Hsource, 'EventName', callback)` creates a listener for the specified event.

`lh = addlistener(Hsource, property, 'EventName', callback)` creates a listener for one of the predefined property events. There are four property events:

- **PreSet** — triggered just before the property value is set, before calling its set access method.
- **PostSet** — triggered just after the property value is set.
- **PreGet** — triggered just before a property value query is serviced, before calling its get access method.
- **PostGet** — triggered just after returning the property value to the query

See “Events and Listeners — Syntax and Techniques” for more information.

## Input Arguments

**Hsource**

Handle of the object that is the source of the event, or an array of source handles.

**EventName**

Name of the event, which is triggered by the source objects.

**callback**

Function handle referencing a function to execute when the event is triggered.

**property**

Character string that can be:

- the name of the property

# addlistener (handle)

---

- a cell array of strings where each string is the name of a property that exists in object array `Hsource`
- a `meta.property` object or an array of `meta.property` objects
- a cell array of `meta.property` objects

If `Hsource` is a scalar, then any of the properties can be dynamic properties. If `Hsource` is non-scalar, then the properties must belong to the class of `Hsource` and can not include dynamic properties (which are not part of the class definition).

For more information, see the following sections:

- The `GetObservable` and `SetObservable` property attributes in the “Property Attributes” table.
- “Creating Property Listeners”
- “Dynamic Properties — Adding Properties to an Instance”

## Output Arguments

`lh`  
Handle of the `event.listener` object returned by `addlistener`.

## Removing a Listener

To remove a listener, delete the listener object returned by `addlistener`. For example,

```
delete(lh)
```

calls the `handle` class `delete` method to delete the object from the workspace and remove the listener.

When you use `addlistener` to create a listener, redefining the variable containing the `handle` to the listener does not delete the listener because the event object still has a reference to the `event.listener` object. `addlistener` ties the listener’s lifecycle to the object that is the source of the event. If you want to define a listener that is not tied to the event object, use the `event.listener` constructor directly to create the listener.

**See Also**

delete (handle) | handle | notify (handle)

**How To**

- “Limiting Listener Scope — Constructing event.listener Objects Directly”

# inputParser.addOptional

---

**Purpose** Add optional positional argument to input parser scheme

**Syntax** `addOptional(p, argName, default)`  
`addOptional(p, argName, default, validationFcn)`

**Description** `addOptional(p, argName, default)` adds optional input, `argName`, to the input parser scheme of `inputParser` object, `p`. When the inputs that you are checking do not include a value for this optional input, the input parser assigns the `default` value to the input.

`addOptional(p, argName, default, validationFcn)` specifies a validation function for the input argument.

- Tips**
- For optional string inputs, specify a validation function. Without a validation function, the input parser interprets valid string inputs as invalid parameter names and throws an error.
  - Use `addOptional` to add an individual argument into the input parser scheme. If you want to parse an optional name-value pair, use `addParameter`.

## Input Arguments

**p**  
Object of class `inputParser`.

**argName**  
String that specifies the internal name for the input argument.

Arguments added with `addOptional` are positional. When you call a function with positional inputs:

- Specify inputs in the same order that they are added into the input parser scheme.
- Specify a value for the  $k$ th argument by assigning values for the first  $(k - 1)$  arguments in the input scheme.

**default**

Default value for the input. This value can be of any data type.

## **validationFcn**

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

## **Examples**

### **Add Optional Input**

Create an `inputParser` object and add an optional input named `myinput` with a default value of 0 to the input scheme.

```
p = inputParser;  
argName = 'myinput';  
default = 0;  
addOptional(p,argName,default);
```

### **Validate Optional Input**

Check whether an optional input named `num` with a default value of 1 is a numeric scalar greater than zero.

```
p = inputParser;  
argName = 'num';  
default = 1;  
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);  
addOptional(p,argName,default,validationFcn);
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as -1:

```
parse(p, -1)
```

The value of 'num' is invalid. It must satisfy the function: `@(x)isnum`

# inputParser.addOptional

---

## Validate Optional Input with validateattributes

Create an inputParser object and define a validation function using validateattributes to test that optional input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;  
argName = 'evenPosNum';  
default = 1;  
validationFcn = @(x) validateattributes(x,{'numeric'},...  
    {'even','positive'});  
addOptional(p,argName,default,validationFcn);
```

Parse an input string. Parse will fail.

```
parse(p,'hello')
```

The value of 'evenPosNum' is invalid. Expected input to be one of these types: double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64. Instead its type was char.

Parse an odd number. Parse will fail.

```
parse(p,13)
```

The value of 'evenPosNum' is invalid. Expected input to be even.

Parse an even, positive number. Parse will pass.

```
parse(p,42)
```

## Concepts

- “Anonymous Functions”

<b>Purpose</b>	Add optional parameter name-value pair argument to input parser scheme
<b>Syntax</b>	<pre>addParameter(p,paramName,default) addParameter(p,paramName,default,validationFcn) addParameter(__,'PartialMatchPriority', matchPriorityValue)</pre>
<b>Description</b>	<p><code>addParameter(p,paramName,default)</code> adds parameter name and value argument <code>paramName</code> to the input parser scheme of <code>inputParser</code> object, <code>p</code>. When the inputs that you are checking do not include a value for this optional parameter, the input parser assigns the default value.</p> <p><code>addParameter(p,paramName,default,validationFcn)</code> specifies a validation function for the input argument.</p> <p><code>addParameter(__,'PartialMatchPriority',matchPriorityValue)</code> allows specification of <code>matchPriorityValue</code> to indicate priority for matching of conflicting partial parameter names and can include any of the input arguments in the previous syntaxes..</p>
<b>Input Arguments</b>	<p><b>p</b> Object of class <code>inputParser</code>.</p> <p><b>paramName</b> String that specifies the internal name for the input parameter.  Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>default</b> Default value for the input. This value can be of any data type.</p> <p><b>matchPriorityValue</b> Positive integer value indicating the priority for matching of conflicting partial parameter names. The input parser selects</p>

# inputParser.AddParameter

---

lower priority values over higher ones. If, within an input parser scheme, partial parameter names are ambiguous and have the same priority, `inputParser` will throw an error. If the names are ambiguous, but have different `PartialMatchPriority` values, `inputParser` issues a warning indicating the matched name.

**Default:** 1

## **validationFcn**

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

## **Examples**

### **Add Optional Parameter Value Input**

Create an `inputParser` object and add an optional input named `myparam` with a default value of 0 to the input scheme.

```
p = inputParser;  
paramName = 'myparam';  
default = 0;  
addParameter(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParameter` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p, 'myparam', 100);  
p.Results
```

```
ans =  
    myparam: 100
```

## Validate Parameter Value

Check whether the value corresponding to myparam is a numeric scalar greater than zero.

```
p = inputParser;
paramName = 'myparam';
default = 1;
errorStr = 'Value must be positive, scalar, and numeric.';
validationFcn = @(x) assert(isnumeric(x) && isscalar(x) && (x > 0),errorStr);
addParameter(p,paramName,default,validationFcn);
```

The syntax @(x) creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as -1:

```
parse(p, 'myparam', -1)
```

The value of 'myparam' is invalid. Value must be positive, scalar, and numeric.

## Validate Parameter Value Input with validateattributes

Create an inputParser object and define a validation function using validateattributes to test that input parameter myName is a nonempty string.

```
p = inputParser;
paramName = 'myName';
default = 'John Doe';
validationFcn = @(x) validateattributes(x,{'char'},{'nonempty'});
addParameter(p,paramName,default,validationFcn);
```

Define myName as a number. The attempt to parse fails.

```
parse(p, 'myName', 1138)
```

The value of 'myName' is invalid. Expected input to be one of these types:

char

# inputParser.addParameter

---

Instead its type was double.

Parse a string. The attempt to parse passes.

```
parse(p, 'myName ', 'George ')
```

## See Also

## Concepts

- “Anonymous Functions”

**Purpose** (Not recommended) Add parameter name and value argument to Input Parser scheme

**Compatibility** addParamValue is not recommended. Use addParameter instead.

**Syntax**  
addParamValue(p,paramName,default)  
addParamValue(p,paramName,default,validationFcn)

**Description**  
addParamValue(p,paramName,default) adds parameter name and value argument paramName to the input scheme of inputParser object p. When the inputs that you are checking do not include a value for this optional parameter, the parser assigns the default value.  
addParamValue(p,paramName,default,validationFcn) specifies a validation function for the input argument.

**Tips**

- If your parameter values do not require validation, you do not have to include them in the input scheme with addParamValue. As an alternative, set the KeepUnmatched property of the inputParser object to true. The parser stores extra parameter names and values in the Unmatched property rather than in the Results property of the object. For an example, see the inputParser reference page.

## Input Arguments

**p**

Object of class inputParser.

**paramName**

String that specifies the internal name for the input parameter.

Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form Name1, Value1, . . . , NameN, ValueN.

**default**

Default value for the input. This value can be of any data type.

**validationFcn**

# inputParser.addParamValue

---

Handle to a function that checks if the input argument is valid.

inputParser accepts two types of validation functions: functions that return true or false, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

## Examples

### Add Optional Parameter Value Input

Create an inputParser object and add an optional input named myparam with a default value of 0 to the input scheme.

```
p = inputParser;  
paramName = 'myparam';  
default = 0;  
addParamValue(p,paramName,default);
```

Unlike the positional inputs added with the addRequired and addOptional methods, each parameter added with addParamValue corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the parse method.

```
parse(p,'myparam',100);  
p.Results
```

```
ans =  
    myparam: 100
```

### Validate Parameter Value

Check whether the value corresponding to myparam is a numeric scalar greater than zero.

```
p = inputParser;  
paramName = 'myparam';  
default = 1;  
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);  
addParamValue(p,paramName,default,validationFcn);
```

The syntax @(x) creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as -1:

```
parse(p, 'myparam', -1)
```

```
Argument 'myparam' failed validation @(x)isnumeric(x)&&isscalar(x)&&(x
```

## Concepts

- “Anonymous Functions”

# addcats

---

## Purpose

Add categories to categorical array

## Syntax

```
B = addcats(A,newcats)
B = addcats(A,newcats, 'Before' ,beforewhere)
B = addcats(A,newcats, 'After' ,afterwhere)
```

## Description

`B = addcats(A,newcats)` adds categories to the end of the category list for the input categorical array, `A`. The output categorical array, `B`, contains the same values as `A`. The output, `B`, does not contain any elements equal to the new categories until you assign values from `newcats` to elements in `B`.

If `A` is an ordinal categorical array, you must specify the `'Before' ,beforewhere` or `'After' ,afterwhere` input arguments.

`B = addcats(A,newcats, 'Before' ,beforewhere)` adds categories before the category specified by `beforewhere`.

`B = addcats(A,newcats, 'After' ,afterwhere)` adds categories after the category specified by `afterwhere`.

## Input Arguments

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### **newcats - New categories**

string | cell array of strings

New categories, specified as a string or a cell array of strings.

### **beforewhere - Category to precede**

string

Category to precede, specified as a string.

**afterwhere - Category to follow**

string

Category to follow, specified as a string.

**Examples****Add Categories at End**

Create a nonordinal categorical array.

```
A = categorical({'republican' 'democrat' 'republican';...
               'democrat' 'republican' 'democrat'})
```

A =

```
      republican      democrat      republican
      democrat      republican      democrat
```

Display the categories of A.

categories(A)

ans =

```
      'democrat'
      'republican'
```

A is a 2-by-3 categorical array with two categories.

Add the categories, independent and undeclared, to the end of the category list

```
B = addcats(A,{'independent' 'undeclared'})
```

B =

```
      republican      democrat      republican
      democrat      republican      democrat
```

B contains the same values as A.

Display the categories of B.

```
categories(B)

ans =

    'democrat'
    'republican'
    'independent'
    'undeclared'
```

B is a 2-by-3 categorical array with four categories.

## Add Categories and Specify Category to Precede

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'},...
    {'small' 'medium' 'large' 'xlarge'}, 'Ordinal', true)
```

```
A =

    medium    large
    small     xlarge
    large     medium
```

Display the categories of A.

```
categories(A)
```

```
ans =

    'small'
    'medium'
    'large'
    'xlarge'
```

Since A is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

Add the category `xsmall` before `small`.

```
B = addcats(A, 'xsmall', 'Before', 'small')
```

```
B =
```

```
      medium      large
      small      xlarge
      large      medium
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'xsmall'
'small'
'medium'
'large'
'xlarge'
```

The categories have the mathematical ordering `xsmall < small < medium < large < xlarge`.

## See Also

```
categories | removecats | iscategory | mergecats |
renamecats | reordercats
```

# addpath

---

## Purpose

Add folders to search path

## Syntax

```
addpath(folderName1,...,folderNameN)
addpath(folderName1,...,folderNameN,position)
```

```
addpath( ____, '-frozen' )
```

```
oldpath = addpath( ____ )
```

## Description

`addpath(folderName1,...,folderNameN)` adds the specified folders to the top of the search path. Use `addpath` statements in a `startup.m` file to modify the search path programmatically at startup.

`addpath(folderName1,...,folderNameN,position)` adds the specified folders to the top or bottom of the search path, as specified by `position`.

`addpath( ____, '-frozen' )` additionally disables folder change detection on Windows for folders being added, which conserves Windows change notification resources (Windows only). Type `help changenotification` in the Command Window for more information.

Add `'-frozen'` to the input arguments in any of the previous syntaxes. You can specify `'-frozen'` and `position` in either order.

`oldpath = addpath( ____ )` additionally returns the path prior to adding the specified folders.

## Input Arguments

**folderName1,...,folderNameN - Names of folders to add to search path**

string

Names of folders to add to the search path, specified as strings. Use the full path name for each folder. Use `genpath` with `addpath` to add all subfolders of `folderName`.

**Example:** 'c:\matlab\work'

**Example:** '/home/user/matlab'

**Example:** '/home/user/matlab', '/home/user/matlab/test'

## position - Position on the search path

'-begin' (default) | '-end'

Position on the search path, specified as one of the following strings.

Value of position	Description
'-begin'	Add specified folders to the top of the search path.
'-end'	Add specified folders to the bottom of the search path.

## Output Arguments

### oldpath - Path prior to addition of folders

string

Path prior to the addition of folders, returned as a string.

## Examples

### Add Folder to Top of Search Path

If you do not have a folder called `c:/matlab/myfiles`, create the folder.

```
mkdir('c:/matlab/myfiles')
```

Add `c:/matlab/myfiles` to the top of the search path.

```
addpath('c:/matlab/myfiles')
```

### Add Folder to End of Search Path

Add `c:/matlab/myfiles` to the end of the search path.

```
addpath('c:/matlab/myfiles', '-end')
```

## Add Folder and Its Subfolders to Search Path

Add `c:/matlab/myfiles` and its subfolders to the search path.

Call `genpath` inside of `addpath` to add all subfolders of `c:/matlab/myfiles` to the search path.

```
addpath(genpath('c:/matlab/myfiles'))
```

## Add Folder to Search Path and Disable Folder Change Notification

On Windows, add the folder `c:/matlab/myfiles` to the top of the search path, disable folder change notification, and return the search path before adding the folder.

```
oldpath = addpath('c:/matlab/myfiles', '-frozen');
```

### Tips

- If you use `addpath` within a local function, the path change persists after program control returns from the function. That is, the scope of the path change is global.

### See Also

[genpath](#) | [path](#) | [pathsep](#) | [rmpath](#) | [savepath](#)

### Concepts

- “What Is the MATLAB Search Path?”
- “Files and Folders that MATLAB Accesses”
- “Path Names in MATLAB”
- “Specifying Startup Options in the MATLAB Startup File”

**Purpose**

Add preference

**Syntax**

```
addpref('group','pref',val)
addpref('group',{'pref1','pref2',... 'prefn'},{val1,val2,
...valn})
```

**Description**

`addpref('group','pref',val)` creates the preference specified by `group` and `pref` and sets its value to `val`. It is an error to add a preference that already exists. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. 'ApplicationOnePrefs'. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`addpref('group',{'pref1','pref2',... 'prefn'},{val1,val2, ...valn})` creates the preferences specified by the cell array of names 'pref1', 'pref2', ..., 'prefn', setting each to the corresponding value.

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

**Examples**

Add a preference called `version` to the `mytoolbox` group of preferences, setting its value to the cell array `{'1.0','beta'}`.

```
addpref('mytoolbox','version',{'1.0','beta'})
```

---

Add a preference called `documentation` to the `mytoolbox` group of preferences, setting its value to a struct you define as having four fields:

```
mydoc.docexists = 1;
```

# addpref

---

```
mydoc.docpath = fullfile(docroot,'techdoc',...
    'matlab_env','examples');
mydoc.demoexists = 1;
mydoc.demopath = fullfile(docroot,'techdoc',...
    'matlab_env','examples','demo_examples');
addpref('mytoolbox','documentation',mydoc)
% Retrieve the preference with GETPREF
p = getpref('mytoolbox','documentation')

p =
    docexists: 1
    docpath: [1x109 char]
    demoexists: 1
    demopath: [1x123 char]
```

## See Also

[getpref](#) | [ispref](#) | [rmpref](#) | [setpref](#) | [uigetpref](#) | [uisetpref](#)

**Purpose** Add dynamic property

**Syntax** `P = addprop(Hobj, 'PropName')`

**Description** `P = addprop(Hobj, 'PropName')` adds a property named `PropName` to each object in array `Hobj`. The class definition is not affected by the addition of dynamic properties. Note that you can add dynamic properties only to objects derived from the `dynamicprops` class. You can set and retrieve the data in dynamic properties as you would any property.

The output argument `P` is an array the same size as `Hobj` of `meta.DynamicProperty` objects, which you can use to assign `SetMethod` and `GetMethod` functions to the property. These functions operate just like property set and get access methods.

See “Dynamic Properties — Adding Properties to an Instance” for more information and examples.

**See Also** `handle` | `dynamicprops`

# addproperty

---

**Purpose** Add custom property to COM object

**Syntax** `h.addproperty('propertyname')`  
`addproperty(h, 'propertyname')`

**Description** `h.addproperty('propertyname')` adds the custom property specified in the string `propertyname` to the object or interface `h`. Use the `COM set` function to assign a value to the property.

`addproperty(h, 'propertyname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Add a custom property to an instance of the MATLAB sample control:

**1** Create an instance of the control:

```
f = figure('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.get
```

MATLAB displays its properties:

```
Label: 'Label'  
Radius: 20
```

**2** Add a custom property named `Position` and assign a value:

```
h.addproperty('Position');  
h.Position = [200 120];  
h.get
```

MATLAB displays (in part):

```
Label: 'Label'  
Radius: 20  
Position: [200 120]
```

**3** Delete the custom property `Position`:

```
h.deleteproperty('Position');  
h.get
```

MATLAB displays the original list of properties:

```
Label: 'Label'  
Radius: 20
```

## See Also

## How To

- “Use Object Properties”

# inputParser.addRequired

---

**Purpose** Add required positional argument to input parser scheme

**Syntax** `addRequired(p, argName)`  
`addRequired(p, argName, validationFcn)`

**Description** `addRequired(p, argName)` adds required argument, `argName`, to the input parser scheme of `inputParser` object, `p`.  
`addRequired(p, argName, validationFcn)` includes a validation function for the input argument.

**Input Arguments** **p**  
Object of class `inputParser`.

**argName**  
String that specifies the internal name for the input argument.  
Arguments added with `addRequired` are positional. When you call a function with positional inputs, you must specify inputs in the order that they are added to the input parser scheme.

**validationFcn**  
Handle to a function that checks if the input argument is valid.  
`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

**Examples** **Add Required Input**

Create an `inputParser` object and add a required input named `myinput` to the input scheme.

```
p = inputParser;  
argName = 'myinput';  
addRequired(p, argName);
```

## Validate Required Input

Check whether a required input named `num` is a numeric scalar greater than zero.

```
p = inputParser;  
argName = 'num';  
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);  
addRequired(p, argName, validationFcn);
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p, -1)
```

The value of `'num'` is invalid. It must satisfy the function: `@(x)isnum`

## Validate Required Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that required input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;  
argName = 'evenPosNum';  
validationFcn = @(x) validateattributes(x, {'numeric'}, ...  
    {'even', 'positive'});  
addRequired(p, argName, validationFcn);
```

Parse an input string. Parse will fail.

```
parse(p, 'hello')
```

The value of `'evenPosNum'` is invalid. Expected input to be one of the  
double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int

Instead its type was `char`.

# inputParser.addRequired

---

Parse an odd number. Parse will fail.

```
parse(p,13)
```

The value of 'evenPosNum' is invalid. Expected input to be even.

Parse an even, positive number. Parse will pass.

```
parse(p,42)
```

## Concepts

- “Anonymous Functions”

<b>Purpose</b>	Add sample to <code>tscollection</code> object
<b>Syntax</b>	<pre>tsc = addsampletocollection(tsc, 'time', Time, TS1Name, TS1Data,     TSnName, TSnData)</pre>
<b>Description</b>	<p><code>tsc = addsampletocollection(tsc, 'time', Time, TS1Name, TS1Data, TSnName, TSnData)</code> adds data samples <code>TSnData</code> to the collection member <code>TSnName</code> in the <code>tscollection</code> object <code>tsc</code> at one or more <code>Time</code> values. Here, <code>TSnName</code> is the string that represents the name of a time series in <code>tsc</code>, and <code>TSnData</code> is an array containing data samples.</p>
<b>Tips</b>	<p>If you do not specify data samples for a time-series member in <code>tsc</code>, that time-series member will contain missing data at the times given by <code>Time</code> (for numerical time-series data), NaN values, or (for logical time-series data) <code>false</code> values.</p> <p>When a time-series member requires <code>Quality</code> values, you can specify data quality codes together with the data samples by using the following syntax:</p> <pre>tsc = addsampletocollection(tsc, 'time', time, TS1Name, ...     ts1cellarray, TS2Name, ts2cellarray, ...)</pre> <p>Specify data in the first cell array element and <code>Quality</code> in the second cell array element.</p> <hr/> <p><b>Note</b> If a time-series member already has <code>Quality</code> values but you only provide data samples, 0s are added to the existing <code>Quality</code> array at the times given by <code>Time</code>.</p> <hr/>
<b>Examples</b>	<p>The following example shows how to create a <code>tscollection</code> that consists of two <code>timeseries</code> objects, where one <code>timeseries</code> does not have quality codes and the other does. The final step of the example adds a sample to the <code>tscollection</code>.</p>

# addsampletocollection

---

- 1 Create two timeseries objects, ts1 and ts2.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...  
                'name','acceleration');  
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...  
                'name','speed');
```

- 2 Define a dictionary of quality codes and descriptions for ts2.

```
ts2.QualityInfo.Code = [0 1];  
ts2.QualityInfo.Description = {'bad','good'};
```

- 3 Assign a quality of code of 1, which is equivalent to 'good', to each data value in ts2.

```
ts2.Quality = ones(5,1);
```

- 4 Create a time-series collection tsc, which includes time series ts1 and ts2.

```
tsc = tscollection({ts1,ts2});
```

- 5 Add a data sample to the collection tsc at 3.5 seconds.

```
tsc = addsampletocollection(tsc,'time',3.5,'acceleration',10,'speed',{5 1});
```

The cell array for the timeseries object 'speed' specifies both the data value 5 and the quality code 1.

---

**Note** If you do not specify a quality code when adding a data sample to a time series that has quality codes, then the lowest quality code is assigned to the new sample by default.

---

**Purpose** Modify date number by field

**Syntax** R = addtodate(D, Q, F)

**Description** R = addtodate(D, Q, F) adds quantity Q to the indicated date field F of a scalar serial date number D, returning the updated date number R.

The quantity Q to be added can be a positive or negative integer. The absolute value of Q must be less than or equal to 1e16. The date field F must be a 1-by-N character array equal to one of the following: 'year', 'month', 'day', 'hour', 'minute', 'second', or 'millisecond'.

If the addition to the date field causes the field to roll over, the MATLAB software adjusts the next more significant fields accordingly. Adding a negative quantity to the indicated date field rolls back the calendar on the indicated field. If the addition causes the field to roll back, MATLAB adjusts the next less significant fields accordingly.

**Examples** Modify the hours, days, and minutes of a given date:

```
t = datenum('07-Apr-2008 23:00:00');
datestr(t)
ans =
    07-Apr-2008 23:00:00
```

```
t= addtodate(t, 2, 'hour');
datestr(t)
ans =
    08-Apr-2008 01:00:00
```

```
t= addtodate(t, -7, 'day');
datestr(t)
ans =
    01-Apr-2008 01:00:00
```

```
t= addtodate(t, 59, 'minute');
datestr(t)
ans =
```

# addtodate

---

```
01-Apr-2008 01:59:00
```

Adding 20 days to the given date in late December causes the calendar to roll over to January of the next year:

```
R = addtodate(datenum('12/24/2007 12:45'), 20, 'day');
```

```
datestr(R)
```

```
ans =
```

```
13-Jan-2008 12:45:00
```

<b>Purpose</b>	Add <code>timeseries</code> object to <code>tscollection</code> object
<b>Syntax</b>	<pre>tsc = addts(tsc,ts) tsc = addts(tsc,ts) tsc = addts(tsc,ts,Name) tsc = addts(tsc,Data,Name)</pre>
<b>Description</b>	<p><code>tsc = addts(tsc,ts)</code> adds the <code>timeseries</code> object <code>ts</code> to <code>tscollection</code> object <code>tsc</code>.</p> <p><code>tsc = addts(tsc,ts)</code> adds a cell array of <code>timeseries</code> objects <code>ts</code> to the <code>tscollection</code> <code>tsc</code>.</p> <p><code>tsc = addts(tsc,ts,Name)</code> adds a cell array of <code>timeseries</code> objects <code>ts</code> to <code>tscollection</code> <code>tsc</code>. <code>Name</code> is a cell array of strings that gives the names of the <code>timeseries</code> objects in <code>ts</code>.</p> <p><code>tsc = addts(tsc,Data,Name)</code> creates a new <code>timeseries</code> object from <code>Data</code> with the name <code>Name</code> and adds it to the <code>tscollection</code> object <code>tsc</code>. <code>Data</code> is a numerical array and <code>Name</code> is a string.</p>
<b>Tips</b>	<p>The <code>timeseries</code> objects you add to the collection must have the same time vector as the collection. That is, the time vectors must have the same time values and units.</p> <p>Suppose that the time vector of a <code>timeseries</code> object is associated with calendar dates. When you add this <code>timeseries</code> to a collection with a time vector without calendar dates, the time vectors are compared based on the units and the values relative to the <code>StartDate</code> property. For more information about properties, see the <code>timeseries</code> reference page.</p>
<b>Examples</b>	<p>The following example shows how to add a time series to a time-series collection:</p> <ol style="list-style-type: none"><li>1 Create two <code>timeseries</code> objects, <code>ts1</code> and <code>ts2</code>.</li></ol> <pre>ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...                 'name','acceleration');</pre>

# addts

---

```
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...  
                'name','speed');
```

**2** Create a time-series collection `tsc`, which includes `ts1`.

```
tsc = tscollection(ts1);
```

**3** Add `ts2` to the `tsc` collection.

```
tsc = addts(tsc, ts2);
```

**4** To view the members of `tsc`, type

```
tsc
```

at the MATLAB prompt. the response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time      1 seconds  
End time        5 seconds
```

```
Member Time Series Objects:
```

```
acceleration  
speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of the `timeseries` objects `ts1` and `ts2`, respectively.

**Purpose** Airy Functions

**Syntax**  
`W = airy(Z)`  
`W = airy(k,Z)`  
`W = airy(k,Z,scale)`

**Description** `W = airy(Z)` returns the Airy function,  $Ai(Z)$ , for each element of  $Z$ .

`W = airy(k,Z)` returns any of four different Airy functions, depending on the value of  $k$ , such as the Airy function of the second kind or the first derivative of an Airy function.

`W = airy(k,Z,scale)` scales the resulting Airy function. `airy` applies a specific scaling function to  $W$  depending on your choice of  $k$  and `scale`.

**Input Arguments**

**Z - System variable**  
 vector | matrix | N-D Array

System variable, specified as a real or complex vector, matrix, or N-D array.

**Data Types**  
 single | double

**Complex Number Support:** Yes

**k - Type of Airy function**  
 0 (default) | 1 | 2 | 3

Type of Airy function, specified as one of four values.

k	Returns
0	Airy function, $Ai(Z)$ , which is the same as <code>airy(Z)</code> .
1	First derivative of Airy function, $Ai'(Z)$ .

# airy

<b>k</b>	<b>Returns</b>
2	Airy function of the second kind, $Bi(Z)$
3	First derivative of Airy function of the second kind, $Bi'(Z)$

## Data Types

single | double

## scale - Scaling option

0 (default) | 1

Scaling option, specified as 0 or 1. Use `scale = 1` to enable the scaling of  $Z$ . The values you specify for `k` and `scale` determine the scaling function `airy` applies to  $Z$ .

<b>scale</b>	<b>k</b>	<b>Scaling applied to output</b>
0	Any	None
1	0 or 1	$e^{\frac{2}{3}Z^{(3/2)}}$
1	2 or 3	$e^{-\left \frac{2}{3}Re(Z^{(3/2)})\right }$

## Data Types

single | double

## Output Arguments

### W - Airy function of z

vector | matrix | N-D Array

Airy function of  $Z$ , returned as an array the same size as  $Z$ .

## Definitions

### Airy Functions

The Airy functions form a pair of linearly independent solutions to

$$\frac{d^2W}{dZ^2} - ZW = 0.$$

The relationship between the Airy and modified Bessel functions is

$$Ai(Z) = \left[ \frac{1}{\pi} \sqrt{\frac{Z}{3}} \right] K_{1/3}(\zeta)$$

$$Bi(Z) = \sqrt{\frac{Z}{3}} [I_{-1/3}(\zeta) + I_{1/3}(\zeta)],$$

where

$$\zeta = \frac{2}{3} Z^{3/2}.$$

## Examples

### Airy Function of Real-Valued x

Define  $x$ .

```
x = -10:0.01:1;
```

Calculate  $Ai(x)$ .

```
ai = airy(x);
```

Calculate  $Bi(x)$  using  $k = 2$ .

```
bi = airy(2,x);
```

Plot both results together on the same axes.

```
figure
plot(x,ai,'-b',x,bi,'-r');
```

```
axis([-10 1 -0.6 1.4]);  
xlabel('x');  
legend('Ai(x)', 'Bi(x)', 'Location', 'NorthWest');
```

## Airy Function of Complex-Valued Input

Compute the Airy function at a slice through the complex plane at  $x+i$ .

Take a slice through the complex plane.

```
x = -4:0.1:4;  
z = x+1i;
```

Calculate  $Ai(z)$ .

```
w = airy(z);
```

Plot the real part of the result.

```
figure  
plot(x, real(w));  
axis([-4 4 -1.5 1]);  
xlabel('real(z)');
```

# airy

## Scaled Airy Function

Define  $x$ .

```
x = -10:0.01:1;
```

---

Calculate the scaled and unscaled Airy function.

```
scaledAi = airy(0,x,1);  
noscaleAi = airy(0,x,0);
```

Plot the real part of each result.

```
rscaled = real(scaledAi);  
rnoscale = real(noscaleAi);  
figure  
plot(x,rscaled,'-b',x,rnoscale,'-r');  
axis([-10 1 -0.60 0.60]);  
xlabel('x');  
legend('scaled','not scaled','Location','SouthEast');
```

# airy

**Purpose**

Align user interface controls (uicontrols) and axes

**Syntax**

```
align(HandleList,'HorizontalAlignment','VerticalAlignment')
Positions = align(HandleList, 'HorizontalAlignment',
    'VerticalAlignment')
Positions = align(CurPositions, 'HorizontalAlignment',
    'VerticalAlignment')
```

**Description**

`align(HandleList,'HorizontalAlignment','VerticalAlignment')` aligns the `uicontrol` and axes objects in `HandleList`, a vector of handles, according to the options `HorizontalAlignment` and `VerticalAlignment`. The following tables show the possible values for `HorizontalAlignment` and `VerticalAlignment`.

<b>HorizontalAlignment</b>	<b>Definition</b>
None	No horizontal alignment
Left	Shifts the objects' left edges to that of the first object selected
Center	Shifts objects to center their positions to the average of the extreme <i>x</i> -values of the group
Right	Shifts the objects' right edges to that of the first object selected
Distribute	Equalizes <i>x</i> -distances between all objects within the span of the extreme <i>x</i> -values
Fixed	Spaces objects to have a specified number of points between them in the <i>y</i> -direction

<b>VerticalAlignment</b>	<b>Definition</b>
None	No vertical alignment
Top	Shifts the objects' top edges to that of the first object selected

VerticalAlignment	Definition
Middle	Shifts objects to center their positions to the average of the extreme <i>y</i> -values of the group
Bottom	Shifts the objects' bottom edges to that of the first object selected
Distribute	Equalizes <i>y</i> -distances between all objects within the span of the extreme <i>y</i> -values
Fixed	Spaces objects to have a specified number of points between them in the <i>x</i> -direction

Aligning objects does not change their absolute sizes. All alignment options align the objects within the bounding box that encloses the objects. `Distribute` and `Fixed` align objects to the bottom left of the bounding box. `Distribute` evenly distributes the objects while `Fixed` distributes the objects with a fixed distance (in points) between them. When you specify both horizontal and vertical distance together, the keywords `'HorizontalAlignment'` and `'VerticalAlignment'` are not necessary.

If you use `Fixed` for `HorizontalAlignment` or `VerticalAlignment`, you must also specify the distance, in points, where 72 points equals 1 inch. For example:

```
align(HandleList, 'Fixed', Distance, 'VerticalAlignment')
```

distributes the specified components *Distance* points horizontally and aligns them vertically as specified.

```
align(HandleList, 'HorizontalAlignment', 'Fixed', Distance)
```

aligns the specified components horizontally as specified and distributes them *Distance* points vertically.

```
align(HandleList, 'Fixed', HorizontalDistance, ...  
      'Fixed', VerticalDistance)
```

distributes the specified components `HorizontalDistance` points horizontally and distributes them `VerticalDistance` points vertically.

`Positions = align(HandleList, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the specified objects as a vector of `Position` vectors. The position of the objects on the figure does not change.

`Positions = align(CurPositions, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the objects whose positions are contained in `CurPositions`, where `CurPositions` is a vector of `Position` vectors. The position of the objects on the figure does not change.

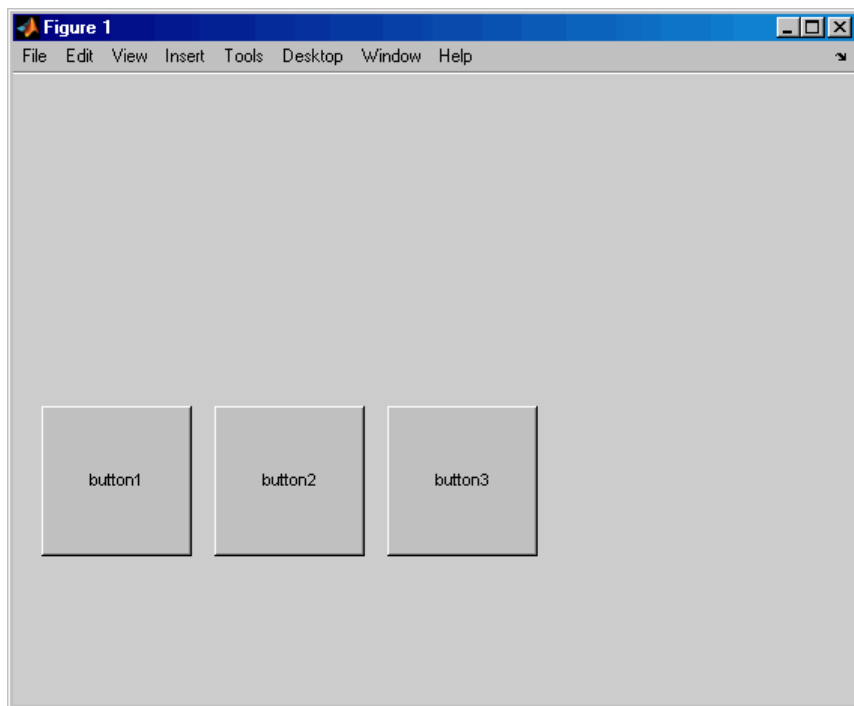

## Examples

Create a GUI with three buttons and use `align` to line up the buttons.

```
% Create a figure window and one button object:
f=figure;
u1 = uicontrol('Style','push', 'parent', f,'pos',...
[20 100 100 100],'string','button1');
% Create two more button objects, not aligned with
% each other or any part of the figure window:
u2 = uicontrol('Style','push', 'parent', f,'pos',...
[150 250 100 100],'string','button2');
u3 = uicontrol('Style','push', 'parent', f,'pos',...
[250 100 100 100],'string','button3');
% Align the button objects with the bottom of the first
% button object, equalizing the distance between the
% objects within the span of the extreme x-values:
align([u1 u2 u3],'distribute','bottom');
```

# align

---

## Alternatives

See “Alignment Tool — Aligning and Distributing Objects” for the GUI alternative.

## See Also

`uicontrol` | `uistack`

**Purpose**

Set or query axes alpha limits

**Syntax**

```
alpha_limits = alim  
alim([amin amax])  
alim_mode = alim('mode')  
alim('alim_mode')  
alim(axes_handle,...)
```

**Description**

`alpha_limits = alim` returns the alpha limits (ALim property) of the current axes.

`alim([amin amax])` sets the alpha limits to the specified values. `amin` is the value of the data mapped to the first alpha value in the `alphamap`, and `amax` is the value of the data mapped to the last alpha value in the `alphamap`. Data values in between are linearly interpolated across the `alphamap`, while data values outside are clamped to either the first or last `alphamap` value, whichever is closest.

`alim_mode = alim('mode')` returns the alpha limits mode (ALimMode property) of the current axes.

`alim('alim_mode')` sets the alpha limits mode on the current axes. `alim_mode` can be

- `auto` — MATLAB automatically sets the alpha limits based on the alpha data of the objects in the axes.
- `manual` — MATLAB does not change the alpha limits.

`alim(axes_handle,...)` operates on the specified axes.

**Examples**

Map transparency to a surface plot of z-data and change the `alim` property to make all values below zero transparent:

```
[x,y] = meshgrid([-2:.2:2]);  
z = x.*exp(-x.^2-y.^2);  
% Plot the data, using the gradient of z as  
% the alphamap:  
surf(x,y,z+.001,'FaceAlpha','flat',...  
'AlphaDataMapping','scaled',...)
```

```
'AlphaData',gradient(z),...  
'FaceColor','blue');  
axis tight  
% Adjust the alim property to see only where  
% the gradient is between 0 and 0.15:  
alim([0 .15])
```

---

<b>Purpose</b>	Determine if all array elements are nonzero or true
<b>Syntax</b>	<pre>B = all(A) B = all(A,dim)</pre>
<b>Description</b>	<p><code>B = all(A)</code> tests along the first array dimension of <code>A</code> whose size does not equal 1, and determines if the elements are all nonzero or logical 1 (true). In practice, <code>all</code> is a natural extension of the logical AND operator.</p> <ul style="list-style-type: none"><li>• If <code>A</code> is a vector, then <code>all(A)</code> returns logical 1 (true) if all the elements are nonzero and returns logical 0 (false) if one or more elements are zero.</li><li>• If <code>A</code> is a nonempty, nonvector matrix, then <code>all(A)</code> treats the columns of <code>A</code> as vectors and returns a row vector of logical 1s and 0s.</li><li>• If <code>A</code> is an empty 0-by-0 matrix, then <code>all(A)</code> returns logical 1 (true).</li><li>• If <code>A</code> is a multidimensional array, then <code>all(A)</code> acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes 1, while the sizes of all other dimensions remain the same.</li></ul> <p><code>B = all(A,dim)</code> tests elements along dimension <code>dim</code>. The <code>dim</code> input is a positive integer scalar.</p>
<b>Input Arguments</b>	<p><b>A - Input Array</b> scalar   vector   matrix   multidimensional array</p> <p>Input array, specified as a scalar, vector, matrix, or multidimensional array.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char</p> <p><b>Complex Number Support:</b> Yes</p> <p><b>dim - Dimension to operate along</b></p>

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `all(A,1)` works on successive elements in the columns of A and returns a row vector of logical values.
- `all(A,2)` works on successive elements in the rows of A and returns a column vector of logical values.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## Output Arguments

### B - Logical array

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of A acted on by `all` has size 1 in B.

## Examples

### Test Matrix Columns

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =  
  
    0     0     3  
    0     0     3  
    0     0     3
```

Test each column for all nonzero elements.

```
B = all(A)  
  
B =  
  
    0     0     1
```

### Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];  
B = (A < 0.5)
```

```
B =  
  
0  0  1  1  1  1  0
```

The output is a vector of logical values. The `all` function reduces such a vector of logical values to a single condition. In this case, `B = all(A < 0.5)` yields logical 0.

This makes `all` particularly useful in `if` statements.

```
if all(A < 0.5)  
    %do something  
else  
    %do something else  
end
```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

## Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if all of its elements are less than 3.

```
A = rand(3,7,5) * 5;  
B = all(A(:) < 3)
```

```
B =
```

```
0
```

You can also test the array for elements that are greater than zero.

```
B = all(A(:) > 0)
```

```
B =
```

```
1
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

## Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
0     0     3  
0     0     3  
0     0     3
```

Test the rows of `A` for all nonzero elements by specifying `dim = 2`.

```
B = all(A,2)
```

```
B =
```

```
0  
0  
0
```

# allchild

---

**Purpose** Find all children of specified objects

**Syntax** `child_handles = allchild(handle_list)`

**Description** `child_handles = allchild(handle_list)` returns the list of all children (including ones with hidden handles) for each handle. If `handle_list` is a single element, `allchild` returns the output in a vector. If `handle_list` is a vector of handles, the output is a cell array.

**Examples** Compare the results these two statements return:

```
axes
get(gca, 'Children')
allchild(gca)
```

**See Also** `findall` | `findobj`

**Purpose** Set transparency properties for objects in current axes

**Syntax**

```
alpha
alpha(object_handle,value)
alpha(face_alpha)
alpha(alpha_data)
alpha(alpha_data)
alpha(alpha_data_mapping)
```

**Description** alpha sets one of three transparency properties, depending on what arguments you specify with the call to this function. For available arguments, see Inputs.

alpha(object\_handle,value) sets the transparency property only on the object identified by object\_handle.

## Input Arguments

### Face Alpha

alpha(face\_alpha) sets the FaceAlpha property of all image, patch, and surface objects in the current axes. You can set face\_alpha to

scalar	Set the FaceAlpha property to the specified value (for images, set the AlphaData property to the specified value).
'flat'	Set the FaceAlpha property to flat.
'interp'	Set the FaceAlpha property to interp.
'texture'	Set the FaceAlpha property to texture.
'opaque'	Set the FaceAlpha property to 1.
'clear'	Set the FaceAlpha property to 0.

See “Specifying Transparency” for more information.

### AlphaData (Surface Objects)

alpha(alpha\_data) sets the AlphaData property of all surface objects in the current axes. You can set alpha\_data to

matrix the same size as CData	Set the AlphaData property to the specified values.
'x'	Set the AlphaData property to be the same as XData.
'y'	Set the AlphaData property to be the same as YData.
'z'	Set the AlphaData property to be the same as ZData.
'color'	Set the AlphaData property to be the same as CData.
'rand'	Set the AlphaData property to a matrix of random values equal in size to CData.

## AlphaData (Image Objects)

`alpha(alpha_data)` sets the AlphaData property of all image objects in the current axes. You can set `alpha_data` to

matrix the same size as CData	Set the AlphaData property to the specified value.
'x'	Ignored.
'y'	Ignored.
'z'	Ignored.
'color'	Set the AlphaData property to be the same as CData.
'rand'	Set the AlphaData property to a matrix of random values equal in size to CData.

## AlphaDataMapping

`alpha(alpha_data_mapping)` sets the AlphaDataMapping property of all image, patch, and surface objects in the current axes. You can set `alpha_data_mapping` to

'scaled'	Set the AlphaDataMapping property to scaled.
'direct'	Set the AlphaDataMapping property to direct.
'none'	Set the AlphaDataMapping property to none.

## Examples

Create a surface plot and change its transparency using alpha:

```
surf(peaks);  
alpha(0.5);
```

## See Also

Surface: AlphaDataMapping

- “Making Objects Transparent”

**Purpose** Specify figure alphamap (transparency)

**Syntax**

```

alphamap(alpha_map)
alphamap('parameter')
alphamap('parameter',length)
alphamap('parameter',delta)
alphamap(figure_handle,...)
alpha_map = alphamap
alpha_map = alphamap(figure_handle)
alpha_map = alphamap('parameter')

```

**Description** `alphamap(alpha_map)` sets the AlphaMap of the current figure to the specified m-by-1 array of alpha values, `alpha_map`.

`alphamap('parameter')` creates a new alphamap or modifies the current alphamap. You can specify the following parameters:

- 'default' — Set the AlphaMap property to the figure's default alphamap.
- 'rampup' — Create a linear alphamap with increasing opacity (default length equals the current alphamap length).
- 'rampdown' — Create a linear alphamap with decreasing opacity (default length equals the current alphamap length).
- 'vup' — Create an alphamap that is opaque in the center and becomes more transparent linearly towards the beginning and end (default length equals the current alphamap length).
- 'vdown' — Create an alphamap that is transparent in the center and becomes more opaque linearly towards the beginning and end (default length equals the current alphamap length).
- 'increase' — Modify the alphamap making it more opaque (default delta is .1, added to the current values).
- 'decrease' — Modify the alphamap making it more transparent (default delta is .1, subtracted from the current values).

# alphamap

---

- 'spin' — Rotate the current alphamap (default delta is 1; delta must be an integer).

`alphamap('parameter',length)` creates a new alphamap with the length specified by the integer `length` (used with parameters 'rampup', 'ramphdown', 'vup', 'vdown').

`alphamap('parameter',delta)` modifies the existing alphamap using the value specified by the integer `delta` (used with parameters 'increase', 'decrease', 'spin').

`alphamap(figure_handle,...)` performs the operation on the alphamap of the figure identified by `figure_handle`.

`alpha_map = alphamap` returns the current alphamap.

`alpha_map = alphamap(figure_handle)` returns the current alphamap from the figure identified by `figure_handle`.

`alpha_map = alphamap('parameter')` returns the alphamap modified by the parameter, but does not set the AlphaMap property.

## Examples

Create a surface plot and change the alphamap

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
% Plot the data, using the gradient of z as
% the alphamap:
surf(x,y,z+.001,'FaceAlpha','flat',...
'AlphaDataMapping','scaled',...
'AlphaData',gradient(z),...
'FaceColor','blue');
% Change the alphamap to be opaque at the middle and
% transparent towards the ends:
alphamap('vup')
```

- “Making Objects Transparent”

**Purpose** Approximate minimum degree permutation

**Syntax**  
`P = amd(A)`  
`P = amd(A,opts)`

**Description** `P = amd(A)` returns the approximate minimum degree permutation vector for the sparse matrix  $C = A + A'$ . The Cholesky factorization of  $C(P,P)$  or  $A(P,P)$  tends to be sparser than that of  $C$  or  $A$ . The `amd` function tends to be faster than `symamd`, and also tends to return better orderings than `symamd`. Matrix  $A$  must be square. If  $A$  is a full matrix, then `amd(A)` is equivalent to `amd(sparse(A))`.

`P = amd(A,opts)` allows additional options for the reordering. The `opts` input is a structure with the two fields shown below. You only need to set the fields of interest:

- **dense** — A nonnegative scalar value that indicates what is considered to be dense. If  $A$  is  $n$ -by- $n$ , then rows and columns with more than  $\max(16, (\text{dense} \cdot \sqrt{n}))$  entries in  $A + A'$  are considered to be "dense" and are ignored during the ordering. MATLAB software places these rows and columns last in the output permutation. The default value for this field is 10.0 if this option is not present.
- **aggressive** — A scalar value controlling aggressive absorption. If this field is set to a nonzero value, then aggressive absorption is performed. This is the default if this option is not present.

MATLAB software performs an assembly tree post-ordering, which is typically the same as an elimination tree post-ordering. It is not always identical because of the approximate degree update used, and because "dense" rows and columns do not take part in the post-order. It is well-suited for a subsequent `chol` operation, however, if you require a precise elimination tree post-ordering, you can use the following code:

```
P = amd(S);  
C = spones(S)+spones(S');  
[ignore, Q] = etree(C(P,P));  
P = P(Q);
```

If  $S$  is already symmetric, omit the second line,  $C = \text{spones}(S) + \text{spones}(S')$ .

## Examples

This example constructs a sparse matrix and computes a two Cholesky factors: one of the original matrix and one of the original matrix preordered by `amd`. Note how much sparser the Cholesky factor of the preordered matrix is compared to the factor of the matrix in its natural ordering:

```
A = gallery('wathen',50,50);
p = amd(A);
L = chol(A,'lower');
Lp = chol(A(p,p),'lower');

figure;
subplot(2,2,1);    spy(A);
title('Sparsity structure of A');

subplot(2,2,2);    spy(A(p,p));
title('Sparsity structure of AMD ordered A');

subplot(2,2,3);    spy(L);
title('Sparsity structure of Cholesky factor of A');

subplot(2,2,4);    spy(Lp);
title('Sparsity structure of Cholesky factor of AMD ordered A');

set(gcf,'Position',[100 100 800 700]);
```

## See Also

`colamd` | `colperm` | `symamd` | `symrcm`

# ancestor

---

**Purpose** Ancestor of graphics object

**Syntax**  
`p = ancestor(h,type)`  
`p = ancestor(h,type,'toplevel')`

**Description** `p = ancestor(h,type)` returns the handle of the closest ancestor of `h`, if the ancestor is one of the types of graphics objects specified by `type`. `type` can be:

- a string that is the name of a single type of object. For example, 'figure'
- a cell array containing the names of multiple objects. For example, {'hgtransform','hgroup','axes'}

If MATLAB cannot find an ancestor of `h` that is one of the specified types, then `ancestor` returns `p` as empty. When `ancestor` searches the hierarchy, it includes the object itself in the search. Therefore, if the object with handle `h` is of one of the types listed in `type`, `ancestor` will return object `h`.

`ancestor` returns `p` as empty but does not issue an error if `h` is not the handle of a Handle Graphics object.

`p = ancestor(h,type,'toplevel')` returns the highest-level ancestor of `h`, if this type appears in the `type` argument.

## Examples

Find the ancestors of a line object:

```
% Create some line objects and parent them
% to an hgroup object.
hgg = hgroup;
hgl = line(randn(5),randn(5),'Parent',hgg);
% Now get the ancestor of the lines:
p = ancestor(hgg,{'figure','axes','hgroup'});
get(p,'Type')
% Now get the top-level ancestor:
ptop=ancestor(hgg,{'figure','axes','hgroup'},'toplevel');
get(ptop,'type')
```

**See Also**

`findobj`

# and

---

**Purpose** Find logical AND of array or scalar inputs

**Syntax** A & B & ...  
and(A, B)

**Description** A & B & ... performs a logical AND of all input arrays A, B, etc., and returns an array containing elements set to either logical 1 (**true**) or logical 0 (**false**). An element of the output array is set to 1 if all input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input A is a 3-by-5 matrix and input B is the number 1, then B is treated as if it were a 3-by-5 matrix of ones.

and(A, B) is called for the syntax A & B when either A or B is an object.

---

**Note** The symbols & and && perform different operations in the MATLAB software. The element-wise AND operator described here is &. The short-circuit AND operator is &&.

---

## Examples

If matrix A is

0.4235	0.5798	0	0.7942	0
0.5155	0	0.7833	0.0592	0.8744
0.3340	0	0	0	0.0150
0.4329	0.6405	0.6808	0.0503	0

and matrix B is

```
    0   1   0   1   0
    1   1   1   0   1
    0   1   1   1   0
    0   1   0   0   1
```

then

A & B

ans =

```
    0   1   0   1   0
    1   0   1   0   1
    0   0   0   0   0
    0   1   0   0   0
```

# angle

---

**Purpose** Phase angle

**Syntax** `P = angle(Z)`

**Description** `P = angle(Z)` returns the phase angles, in radians, for each element of complex array `Z`. The angles lie between  $\pm\pi$ .

For complex `Z`, the magnitude `R` and phase angle `theta` are given by

```
R = abs(Z)
theta = angle(Z)
```

and the statement

```
Z = R.*exp(i*theta)
```

converts back to the original complex `Z`.

## Examples

```
Z = [ 1 - 1i  2 + 1i  3 - 1i  4 + 1i
      1 + 2i  2 - 2i  3 + 2i  4 - 2i
      1 - 3i  2 + 3i  3 - 3i  4 + 3i
      1 + 4i  2 - 4i  3 + 4i  4 - 4i ]
```

```
P = angle(Z)
```

```
P =
-0.7854    0.4636   -0.3218    0.2450
 1.1071   -0.7854    0.5880   -0.4636
-1.2490    0.9828   -0.7854    0.6435
 1.3258   -1.1071    0.9273   -0.7854
```

## Algorithms

The angle function can be expressed as `angle(z) = imag(log(z)) = atan2(imag(z), real(z))`.

## See Also

`abs` | `atan2` | `unwrap`

## Purpose

Create annotation objects

## Syntax

```

annotation(annotation_type)
annotation('line',x,y)
annotation('arrow',x,y)
annotation('doublearrow',x,y)
annotation('textarrow',x,y)
annotation('textbox',[x y w h])
annotation('ellipse',[x y w h])
annotation('rectangle',[x y w h])
annotation(figure_handle,...)
annotation(...,'PropertyName',PropertyValue,...)
anno_obj_handle = annotation(...)

```

## Description

annotation(*annotation\_type*) creates the specified annotation type using default values for all properties. *annotation\_type* can be one of the following strings:

- 'line'
- 'arrow'
- 'doublearrow' (two-headed arrow),
- 'textarrow' (arrow with attached text box),
- 'textbox'
- 'ellipse'
- 'rectangle'

annotation('line',x,y) creates a line annotation object that extends from the point defined by x(1),y(1) to the point defined by x(2),y(2), specified in normalized figure units.

annotation('arrow',x,y) creates an arrow annotation object that extends from the point defined by x(1),y(1) to the point defined by x(2),y(2), specified in normalized figure units.

# annotation

---

`annotation('doublearrow',x,y)` creates a two-headed annotation object that extends from the point defined by  $x(1),y(1)$  to the point defined by  $x(2),y(2)$ , specified in normalized figure units.

`annotation('textarrow',x,y)` creates a `textarrow` annotation object that extends from the point defined by  $x(1),y(1)$  to the point defined by  $x(2),y(2)$ , specified in normalized figure units. The tail end of the arrow is attached to an editable text box.

`annotation('textbox',[x y w h])` creates an editable text box annotation with its lower left corner at the point  $x,y$ , a width  $w$ , and a height  $h$ , specified in normalized figure units. Specify  $x, y, w$ , and  $h$  in a single vector.

To type in the text box, enable plot edit mode (`plotedit`) and double-click within the box.

`annotation('ellipse',[x y w h])` creates an ellipse annotation with the lower left corner of the bounding rectangle at the point  $x,y$ , a width  $w$ , and a height  $h$ , specified in normalized figure units. Specify  $x, y, w$ , and  $h$  in a single vector.

`annotation('rectangle',[x y w h])` creates a rectangle annotation with the lower left corner of the rectangle at the point  $x,y$ , a width  $w$ , and a height  $h$ , specified in normalized figure units. Specify  $x, y, w$ , and  $h$  in a single vector.

`annotation(figure_handle,...)` creates the annotation in the specified figure.

`annotation(...,'PropertyName',PropertyValue,...)` creates the annotation and sets the specified properties to the specified values.

`anno_obj_handle = annotation(...)` returns the handle to the “Annotation Objects”.

## Examples

Annotate a graph with a text box.

```
plot(1:10);
annotation('textbox', [.2 .4 .1 .1],...
           'String', 'Straight Line Plot 1 to 10');
```

Notice that the locations specified are normalized in the figure coordinates. Length of the string automatically adjusts the width of the text box, as, `FitBoxToText` property of the annotation object is on by default.

Insert multiple lines in a text box by creating a cell array of string. Each element is used as a separate line.

```
plot(1:10);
str = {'Straight Line', 'Plot of 1 to 10'};
```

# annotation

---

```
annotation('textbox', [.2 .4, .1, .1],...  
          'String', str);
```

---

Insert a text arrow in a graph.

```
plot(1:10);  
a = annotation('textarrow', [.3 .5], [.6 .5],...  
              'String' , 'Straight Line');
```

The text arrow is defined by points starting from (.3, .6) extending to (.5, .5) in normalized figure coordinates.

### Adding Annotations Interactively

It is often convenient to place annotations interactively. For details, see “Working in Plot Edit Mode”.

## How To

- “How to Annotate Graphs”
- “Annotation Objects”

## Purpose

Define annotation arrow properties

## Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

## Annotation Arrow Property Descriptions

Color

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object’s color. The default value is `[0 0 0]` (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

HeadLength

size in points

*Length of the arrowhead.* Specify this property in points. 1 point =  $\frac{1}{72}$  inch. The default value is 10. See also `HeadWidth`.

HeadStyle

string

*Style of arrowhead.* Specify this property as one of the strings from the following table.

# Annotation Arrow Properties

**Arrow Head Style Table**

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	
cback1		deltoid	
cback2			
cback3			

HeadWidth  
size in points

*Width of arrowhead.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default value is 10. See also HeadLength.

## LineStyle

{-} | -- | : | -. | none

*Style of arrow stem.*

### Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Width of arrow stem.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

## Position

four-element vector [x, y, width, height]

*Size and location of the object.* Specify the lower left corner of the object with the first two elements of the vector defining the point  $x, y$  in units normalized to the figure (when Units property is normalized). width and height specify the object's  $dx$  and  $dy$ , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

## Units

{normalized} | inches | centimeters | characters |  
points | pixels

# Annotation Arrow Properties

---

*Position units.* MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $1/72$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

X

vector [ $X_{\text{begin}}$   $X_{\text{end}}$ ]

*x-coordinates of beginning and ending points for line.* A vector of *x*-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

Y

vector [ $Y_{\text{begin}}$   $Y_{\text{end}}$ ]

*y-coordinates of beginning and ending points for line.* A vector of *y*-axis (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

## Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

## Annotation Doublearrow Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

**Color**

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object’s color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

**Head1Length**

size in points

*Length of first arrowhead.* Specify in points. 1 point =  $1/72$  inch. The default value is 10.

The first arrowhead is located at the end defined by the point `x(1)`, `y(1)`.

See also the `Head1Style`, `Head1Width`, `X` and `Y` properties.

**Head2Length**

size in points

# Annotation Doublearrow Properties

*Length of second arrowhead.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default value is 10.

The first arrowhead is located at the end defined by the point  $x(\text{end}), y(\text{end})$ .

See also the Head1Style, Head1Width, X and Y properties.

Head1Style  
string

*Style of first arrowhead.* Specify this property as one of the strings from the following table.

**Arrow Head Style Table**

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	

# Annotation Doublearrow Properties

Head Style String	Head	Head Style String	Head
cback1		deltoid	
cback2			
cback3			

See also Head1Width, Head1Length, and LineWidth.

Head2Style  
string

*Style of second arrowhead.* Specify this property as one of the strings shown in the table for the Head1Style property.

See also Head2Width, Head2Length, LineWidth.

Head1Width  
size in points

*Width of first arrowhead.* Specify in points. 1 point =  $\frac{1}{72}$  inch.  
See also Head1Length.

Head2Width  
size in points

*Width of second arrowhead.* Specify in points. 1 point =  $\frac{1}{72}$  inch.  
See also Head2Length.

LineStyle  
{-} | -- | : | -. | none

*Style of arrow stem.*

# Annotation Doublearrow Properties

---

**Line Style Specifiers Table**

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

See also `Head1Style`, `Head1Length`, and `LineWidth`.

## `LineWidth`

size in points

*Width of arrow stem.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

## `Position`

four-element vector [`x`, `y`, `width`, `height`]

*Size and location of the object.* Specify the lower left corner of the object with the first two elements of the vector defining the point  $x, y$  in units normalized to the figure (when `Units` property is normalized). `width` and `height` specify the object's  $dx$  and  $dy$ , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

## `Units`

{normalized} | inches | centimeters | characters |  
points | pixels

*Position units.* MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

# Annotation Doublearrow Properties

---

- **normalized** — Interpret **Position** as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- **pixels, inches, centimeters, and points** — Absolute units. 1 point =  $1/72$  inch.
- **characters** — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

X

vector  $[X_{\text{begin}} \ X_{\text{end}}]$

*x-coordinates of beginning and ending points for line.* A vector of *x-axis* (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is  $[0.3 \ 0.4]$ .

Y

vector  $[Y_{\text{begin}} \ Y_{\text{end}}]$

*y-coordinates of beginning and ending points for line.* A vector of *y-axis* (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is  $[0.3 \ 0.4]$ .

**Purpose** Define annotation ellipse properties

**Modifying Properties** You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

**Annotation Ellipse Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

`EdgeColor`  
ColorSpec | none

*Edge color of object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color.

`FaceColor`  
{flat} | none | ColorSpec

*Color of filled areas.*

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- `flat` — The object uses the figure colormap to determine the color of the filled areas.

`LineStyle`  
{-} | -- | : | -. | none

*Line style of ellipse.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
'.'	Dotted line
'-.'	Dash-dot line
'none'	No line

### LineWidth

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

### Position

four-element vector [x, y, width, height]

*Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point  $x, y$  in units normalized to the figure (when Units property is normalized). width and height specify the object's  $dx$  and  $dy$ , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].*

### Units

{normalized} | inches | centimeters | characters | points | pixels

*Position units. MATLAB uses this property to determine the units used by the Position property. All positions are measured from the lower left corner of the figure window.*

# Annotation Ellipse Properties

---

- **normalized** — Interpret **Position** as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.

four-element vector [x, y, width, height]

*Size and location of the object.* Specify the lower left corner of the object with the first two elements of the vector defining the point  $x, y$  in units normalized to the figure (when Units property is normalized). width and height specify the object's  $dx$  and  $dy$ , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

## Units

{normalized} | inches | centimeters | characters |  
points | pixels

*Position units.* MATLAB uses this property to determine the units used by the Position property. All positions are measured from the lower left corner of the figure window.

- **normalized** — Interpret Position as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- **pixels, inches, centimeters, and points** — Absolute units. 1 point =  $1/72$  inch.
- **characters** — Based on the size of characters in the default system font. The width of one characters unit is the width

of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

X

vector  $[X_{\text{begin}} X_{\text{end}}]$

*x-coordinates of beginning and ending points for line.* A vector of *x*-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

Y

vector  $[Y_{\text{begin}} Y_{\text{end}}]$

*y-coordinates of beginning and ending points for line.* A vector of *y*-axis (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

## How To

- “Annotation Objects”
- “Adding Arrows and Lines to Graphs”

# Annotation Rectangle Properties

---

## Purpose

Define annotation rectangle properties

## Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

## Annotation Rectangle Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

**EdgeColor**  
ColorSpec | none

*Edge color of object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color. The default value is [0 0 0] (black).

See the ColorSpec reference page for more information on specifying color.

**FaceAlpha**  
Scalar alpha value in range [0 1]

*Transparency of object background.* Defines the degree to which the object’s background color is transparent. A value of 1 (the default) makes the background opaque, a value of 0 makes the background completely transparent (that is, invisible). The default value is 1.

**FaceColor**  
{flat} | none | ColorSpec

*Color of filled areas.*

# Annotation Rectangle Properties

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- **none** — Do not draw faces. Note that MATLAB draws **EdgeColor** independently of **FaceColor**.
- **flat** — The object uses the figure colormap to determine the color of the filled areas.

## LineStyle

{-} | -- | : | -. | none

*Line style of annotation rectangle object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

## Position

four-element vector [x, y, width, height]

*Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point  $x, y$  in units normalized to the figure (when **Units** property is normalized). width and height specify the object's  $dx$  and  $dy$ ,*

# Annotation Rectangle Properties

---

respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

## Units

{normalized} | inches | centimeters | characters |  
points | pixels

*Position units.* MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter x, and the height of one `characters` unit is the distance between the baselines of two lines of text.

## See Also

`annotation`

## Purpose

Define annotation textarrow properties

## Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

## Annotation Textarrow Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

**Color**  
ColorSpec

*Color of the arrow, text and text border.* A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the arrow, the color of the text (`TextColor` property), and the rectangle enclosing the text (`TextEdgeColor` property). The default value is `[0 0 0]` (black).

Setting the `Color` property also sets the `TextColor` and `TextEdgeColor` properties to the same color. However, if the value of the `TextEdgeColor` is `none`, it remains `none` and the text box is not displayed. You can set `TextColor` or `TextEdgeColor` independently without affecting other properties.

For example, if you want to create a textarrow with a red arrow and black text in a black box, you must:

- 1 Set the `Color` property to red — `set(h, 'Color', 'r')`
- 2 Set the `TextColor` to black — `set(h, 'TextColor', 'k')`
- 3 Set the `TextEdgeColor` to black. —  
`set(h, 'TextEdgeColor', 'k')`

# Annotation Textarrow Properties

---

If you do not want display the text box, set the `TextEdgeColor` to `none`.

See the `ColorSpec` reference page for more information on specifying color.

## FontAngle

`{normal} | italic | oblique`

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

## FontName

string

*Font family.* A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is Helvetica.

## FontSize

size in points

*Approximate size of text characters.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default size is 10.

## FontUnits

`{points} | normalized | inches | centimeters | pixels`

*Font size units.* MATLAB uses this property to determine the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units. 1 point =  $\frac{1}{72}$  inch.

## FontWeight

`{normal} | bold | light | demi`

# Annotation Textarrow Properties

*Weight of text characters.* MATLAB uses this property to select a font from those available on your system. Generally, setting this property to **bold** or **demi** causes MATLAB to use a bold font.

**HeadLength**  
size in points

*Length of the arrowhead.* Specify this property in points. 1 point =  $\frac{1}{72}$  inch. The default value is 10. See also **HeadWidth**.

**HeadStyle**  
string

*Style of arrowhead.* Specify this property as one of the strings from the following table.

**Arrow Head Style Table**

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	

# Annotation Textarrow Properties

---

Head Style String	Head	Head Style String	Head
cback1		deltoid	
cback2			
cback3			

**HeadWidth**  
size in points

*Width of arrowhead.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default value is 10. See also HeadLength.

**HorizontalAlignment**  
{left} | center | right

*Horizontal alignment of text.* Specifies the horizontal justification of the text string. It determines where MATLAB places the string horizontally with regard to the points specified by the Position property.

**Interpreter**  
latex | {tex} | none

*Interpret TeX instructions.* This property controls whether MATLAB interprets certain characters in the String property as TeX instructions (default) or displays all characters literally. The options are:

- latex — Supports a basic subset of the LaTeX markup language.
- tex — Supports a subset of plain TeX markup language. See the String property for a list of supported TeX instructions.

- none — Displays literal characters.

## LineStyle

{-} | -- | : | -. | none

*Line style of arrow stem.*

### Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Width of arrow stem.* Specify in points 1 point =  $1/72$  inch. The default is 0.5 points.

## Position

four-element vector [x, y, width, height]

*Size and location of the object.* Specify the lower left corner of the object with the first two elements of the vector defining the point  $x, y$  in units normalized to the figure (when Units property is normalized). width and height specify the object's  $dx$  and  $dy$ , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

## String

string

# Annotation Textarrow Properties

---

*Text string.* Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

When the text Interpreter property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

**TeX Character Sequence Table**

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	$\alpha$	<code>\upsilon</code>	$\upsilon$	<code>\sim</code>	$\sim$
<code>\angle</code>	$\angle$	<code>\phi</code>	$\Phi$	<code>\leq</code>	$\leq$
<code>\ast</code>	$*$	<code>\chi</code>	$\chi$	<code>\infty</code>	$\infty$
<code>\beta</code>	$\beta$	<code>\psi</code>	$\psi$	<code>\clubsuit</code>	$\clubsuit$
<code>\gamma</code>	$\gamma$	<code>\omega</code>	$\omega$	<code>\diamondsuit</code>	$\diamondsuit$
<code>\delta</code>	$\delta$	<code>\Gamma</code>	$\Gamma$	<code>\heartsuit</code>	$\heartsuit$
<code>\epsilon</code>	$\epsilon$	<code>\Delta</code>	$\Delta$	<code>\spadesuit</code>	$\spadesuit$

# Annotation Textarrow Properties

# Annotation Textarrow Properties

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\rfloor</code>	⌋	<code>\neg</code>	¬	<code>\nabla</code>	∇
<code>\lfloor</code>	⌊	<code>\times</code>	×	<code>\ldots</code>	...
<code>\perp</code>	⊥	<code>\surd</code>	√	<code>\prime</code>	′
<code>\wedge</code>	∧	<code>\varpi</code>	ϖ	<code>\O</code>	∅
<code>\rceil</code>	⌈	<code>\rangle</code>	⟩	<code>\mid</code>	
<code>\vee</code>	∨			<code>\copyright</code>	©
<code>\langle</code>	⟨				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers.

**TextBackgroundColor**  
**ColorSpec** | {none}

*Color of text background rectangle.* A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color.

See the **ColorSpec** reference page for more information on specifying color.

**TextColor**  
**ColorSpec**

*Color of text.* A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color. The default value is `[0 0 0]` (black).

# Annotation Textarrow Properties

---

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextEdgeColor`  
ColorSpec | {none}

*Color of edge of text rectangle.* A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextLineWidth`  
width in points

*Width of text rectangle edge.* Specify in points. 1 point =  $1/72$  inch. The default value is 0.5.

`TextMargin`  
size in pixels

*Space around text.* A value in pixels that defines the space around the text string, but within the rectangle. Default value is 5 pixels.

`TextRotation`  
rotation angle in degrees

*Text orientation.* Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation). Angles are absolute and not relative to previous rotations; a rotation of 0 degrees is always horizontal. Default is 0.

`Units`  
{normalized} | inches | centimeters | characters |  
points | pixels

# Annotation Textarrow Properties

---

*Position units.* MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $1/72$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`VerticalAlignment`

`top` | `cap` | `{middle}` | `baseline` | `bottom`

*Vertical alignment of text.* Specifies the vertical justification of the text string. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

Note that `top` and `cap` both place the text at the top, while `baseline` and `bottom` both align the text on the bottom.

X

vector [ $X_{\text{begin}}$   $X_{\text{end}}$ ]

*x-coordinates of beginning and ending points for line.* A vector of *x*-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

Y

vector [ $Y_{\text{begin}}$   $Y_{\text{end}}$ ]

# Annotation Textarrow Properties

---

*y-coordinates of beginning and ending points for line.* A vector of *y-axis* (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

**See Also** [annotation](#)

# Annotation Textbox Properties

---

**Purpose** Define annotation textbox properties

**Modifying Properties** You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

**Annotation Textbox Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

`BackgroundColor`  
`ColorSpec | {none}`

*Color of text background rectangle.* A three-element RGB vector or one of the MATLAB predefined names, specifying the rectangle background color. The default value is `none`.

See the `ColorSpec` reference page for more information on specifying color.

`Color`  
`ColorSpec`

*Text color.* A three-element RGB vector or one of the predefined names, specifying the text color. The default value is black. See `ColorSpec` for more information on specifying color.

`EdgeColor`  
`ColorSpec | {none}`

*Color of edge of text rectangle.* A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

## FaceAlpha

Scalar alpha value in range [0 1]

*Transparency of object background.* Defines the degree to which the object's background color is transparent. A value of 1 (the default) makes the background opaque, a value of 0 makes the background completely transparent (that is, invisible). The default value is 1.

## FitBoxToText

{on} | off

*Automatically adjust text box width and height to fit text.* When this property is on (the default), MATLAB automatically resizes textboxes to fit the *x*-extents and *y*-extents of the text strings they contain. When it is off, text strings are wrapped to fit the width of their textboxes, which can cause them to extend below the bottom of the box.

If you resize a textbox in plot edit mode or change the width or height of its `Position` property directly, MATLAB sets the object's `FitBoxToText` property to off. You can toggle this property with `set`, with the Property Inspector, or in plot edit mode via the object's context menu.

## FitHeightToText

on | off

*Automatically adjust text box width and height to fit text.* MATLAB automatically wraps text strings to fit the width of the text box. However, if the text string is long enough, it can extend beyond the bottom of the text box.

# Annotation Textbox Properties

---

---

**Note** The property is obsolete. To control line wrapping behavior in textboxes, use `FitBoxToText` instead.

---

When you set this mode to on, MATLAB automatically adjusts the height of the text box to accommodate the string, doing so as you create or edit the string.

The fit-size-to-text behavior turns off if you resize the text box programmatically or manually in plot edit mode.

# Annotation Textbox Properties

However, if you resize the text box from any other handles, the position you set is honored without regard to how the text fits the box.

## FontAngle

{normal} | italic | oblique

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

## FontName

string

*Font family.* A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is Helvetica.

# Annotation Textbox Properties

---

## FontSize

size in points

*Approximate size of text characters.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default size is 10.

## FontUnits

{points} | normalized | inches | centimeters | pixels

*Font size units.* MATLAB uses this property to determine the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units. 1 point =  $\frac{1}{72}$  inch.

## FontWeight

{normal} | bold | light | demi

*Weight of text characters.* MATLAB uses this property to select a font from those available on your system. Generally, setting this property to `bold` or `demi` causes MATLAB to use a bold font.

## HorizontalAlignment

{left} | center | right

*Horizontal alignment of text.* Specifies the horizontal justification of the text string within the textbox. It determines where MATLAB places the string horizontally with regard to the points specified by the `Position` property.

## Interpreter

latex | {tex} | none

*Interpret TeX instructions.* This property controls whether MATLAB interprets certain characters in the `String` property as TeX instructions (default) or displays all characters literally. The options are:

# Annotation Textbox Properties

- `latex` — Supports a basic subset of the LaTeX markup language.
- `tex` — Supports a subset of plain TeX markup language. See the `String` property for a list of supported TeX instructions.
- `none` — Displays literal characters.

## LineStyle

`{-}` | `--` | `:` | `-.`  | `none`

*Line style of annotation textbox object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.

## Margin

size in pixels

*Space around text.* A value in pixels that defines the space around the text string, but within the rectangle. Default value is 5 pixels.

## Position

four-element vector `[x, y, width, height]`

# Annotation Textbox Properties

---

*Size and location of the object.* Specify the lower left corner of the object with the first two elements of the vector defining the point  $x, y$  in units normalized to the figure (when `Units` property is normalized). `width` and `height` specify the object's  $dx$  and  $dy$ , respectively, in units normalized to the figure. The default value is `[0.3 0.3 0.1 0.1]`.

String  
string

*Text string.* Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See *Mathematical Symbols, Greek Letters, and TeX Characters* for an example.

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

When the text `Interpreter` property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

# Annotation Textbox Properties

**TeX Character Sequence Table**

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol

<code>\rceil</code>	$\rceil$	<code>\rangle</code>	$\rangle$	<code>\mid</code>	$\mid$
<code>\vee</code>	$\vee$			<code>\copyright</code>	$\copyright$
<code>\langle</code>	$\langle$				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers.

## Units

{normalized} | inches | centimeters | characters |  
points | pixels

*Position units.* MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

## VerticalAlignment

top | cap | {middle} | baseline |  
bottom

*Vertical alignment of text.* Specifies the vertical justification of the text string within the textbox. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

Note that `top` and `cap` both place the text at the top of the box, while `baseline` and `bottom` both align the text on the bottom.

# ans

---

<b>Purpose</b>	Most recent answer
<b>Syntax</b>	ans
<b>Description</b>	The MATLAB software creates the ans variable automatically when you specify no output argument.
<b>Examples</b>	The statement  2+2  is the same as  ans = 2+2
<b>See Also</b>	display

**Purpose**

Determine if any array elements are nonzero

**Syntax**

`B = any(A)`  
`B = any(A, dim)`

**Description**

`B = any(A)` tests along the first array dimension of `A` whose size does not equal 1, and determines if any element is a nonzero number or logical 1 (true). In practice, `any` is a natural extension of the logical OR operator.

- If `A` is a vector, then `B = any(A)` returns logical 1 (true) if any of the elements of `A` is a nonzero number or is logical 1, and returns logical 0 (false) if all the elements are zero.
- If `A` is a nonempty, nonvector matrix, then `B = any(A)` treats the columns of `A` as vectors, returning a row vector of logical 1s and 0s.
- If `A` is an empty 0-by-0 matrix, `any(A)` returns logical 0 (false).
- If `A` is a multidimensional array, `any(A)` acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes 1, while the sizes of all other dimensions remain the same.

`B = any(A, dim)` tests elements along dimension `dim`. The `dim` input is a positive integer scalar.

**Input Arguments****A - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. The `any` function ignores elements of `A` that are NaN (Not a Number).

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `any(A,1)` works on successive elements in the columns of A and returns a row vector of logical values.
- `any(A,2)` works on successive elements in the rows of A and returns a column vector of logical values.

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## Output Arguments

### B - Logical array

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of A acted on by `any` has size 1 in B.

## Examples

### Test Matrix Columns

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
    0    0    3
    0    0    3
    0    0    3
```

Test each column for nonzero elements.

```
B = any(A)
```

```
B =
```

```
    0    0    1
```

### Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];
```

```
B = (A < 0.5)
```

```
B =
```

```
0  0  1  1  1  1  0
```

The output is a vector of logical values. The any function reduces such a vector of logical values to a single condition. In this case, `B = any(A < 0.5)` yields logical 1.

This makes any particularly useful in if statements.

```
if any(A < 0.5)
    %do something
else
    %do something else
end
```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

## Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if any of its elements are greater than 3.

```
A = rand(3,7,5) * 5;  
B = any(A(:) > 3)
```

```
B =
```

```
1
```

You can also test the array for elements that are less than zero.

```
B = any(A(:) < 0)
```

```
B =
```

```
0
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

## Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
0     0     3  
0     0     3  
0     0     3
```

Test the rows of `A` for nonzero elements by specifying `dim = 2`.

```
B = any(A,2)
```

```
B =
```

```
    1  
    1  
    1
```

# area

---

## Purpose

Filled area 2-D plot

## Syntax

```
area(Y)
area(X,Y)
area(...,basevalue)
area(...,'PropertyName',PropertyValue,...)
area(axes_handle,...)
h = area(...)
```

## Description

An area graph displays elements in  $Y$  as one or more curves and fills the area beneath each curve. When  $Y$  is a matrix, the curves are stacked showing the relative contribution of each row element to the total height of the curve at each  $x$  interval.

`area(Y)` plots the vector  $Y$  or plots each column in matrix  $Y$  as a separate curve and stacks the curves. The  $x$ -axis automatically scales to `1:size(Y,1)`.

`area(X,Y)` For vectors  $X$  and  $Y$ , `area(X,Y)` is the same as `plot(X,Y)` except that the area between 0 and  $Y$  is filled. When  $Y$  is a matrix, `area(X,Y)` plots the columns of  $Y$  as filled areas. For each  $X$ , the net result is the sum of corresponding values from the rows of  $Y$ .

If  $X$  is a vector, `length(X)` must equal `length(Y)`. If  $X$  is a matrix, `size(X)` must equal `size(Y)`.

`area(...,basevalue)` specifies the base value for the area fill. The default basevalue is 0. See the `BaseValue` property for more information.

`area(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the patch graphics object created by `area`.

`area(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = area(...)` returns handles of `areaseries` graphics objects.

Creating an area graph of an  $m$ -by- $n$  matrix creates  $n$  `areaseries` objects (that is, one per column), whereas a 1-by- $n$  vector creates one `areaseries` object.

Some `areaseries` object properties that you set on an individual `areaseries` object set the values for all `areaseries` objects in the graph. See the property descriptions for information on specific properties.

## Examples

### Create Area Graph

Plot the data in matrix `Y` as an area graph.

```
Y = [1, 5, 3;  
     3, 2, 7;  
     1, 5, 3;  
     2, 6, 1];  
figure  
area(Y)
```

## area

### Adjust Base Value of Area Graph

By default, `area` uses the  $y$ -axis as the base value. Change the base value by setting the `basevalue` input argument to `-4`.

```
Y = [1, 5, 3;  
     3, 2, 7;  
     1, 5, 3;  
     2, 6, 1];  
figure
```

```
basevalue = -4;  
area(Y,basevalue)
```

### Specify Color and Line Styles for Area Plot

Create an area plot of the data in matrix  $Y$ . Set the line style and line width for the three areaseries objects created, one for each column in  $Y$ . Store the areaseries object handles in vector  $h$ .

```
Y = [1, 5, 3;
```

## area

```
3, 2, 7;  
1, 5, 3;  
2, 6, 1];  
  
figure  
h = area(Y,'LineStyle',':',...  
        'LineWidth',2);
```

Use the areaseries object handles to specify a different face color for each object.

```
set(h(1), 'FaceColor', [0,0.25,0.25]);  
set(h(2), 'FaceColor', [0,0.5,0.5]);  
set(h(3), 'FaceColor', [0,0.75,0.75]);
```

**How To**

• [“”](#)

# Areaseries Properties

---

**Purpose** Define areaseries properties

**Modifying Properties** You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

Note that you cannot define default properties for areaseries objects.

See “Plot Objects” for more information on areaseries objects.

**Areaseries Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation

hg.Annotation object (read-only)

*Control the display of areaseries objects in legends.* Specifies whether this areaseries object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the areaseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the areaseries object in a legend as one entry, but not its children objects
off	Do not include the areaseries or its children in a legend (default)
children	Include only the children of the areaseries as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BaseValue

double: *y*-axis value

*Value where filled area base is drawn.* Specify the value along the *y*-axis at which the MATLAB software draws the baseline of the bottommost filled area. The default is 0.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

cancel | {queue}

*Callback queuing*

## Areaseries Properties

---

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of this object.* The handle of a patch object that is the child of this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

# Areaseries Properties

---

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The legend function uses the `DisplayName` property to label the areaseries object in the legend. The default is an empty string.

- If you specify string arguments with the legend function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, legend creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, legend does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call legend with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EdgeColor`

`{[0 0 0]} | none | ColorSpec`

*Color of line separating filled areas.* You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default value is `[0 0 0]` (black). See the `ColorSpec` reference page for more information on specifying color.

`EraseMode`

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated

## Areaseries Properties

---

sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

### Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## FaceColor

{flat} | none | ColorSpec

*Color of filled areas.*

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- **none** — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- **flat** — The object uses the figure colormap to determine the color of the filled areas.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- **on** — Handles are always visible.
- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

# Areaseries Properties

---

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

```
HitTest  
  {on} | off
```

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`  
`on` | `{off}`

*Select areaseries object on filled area or extent of graph.* Select plot objects by:

- Clicking an area (default).
- Clicking anywhere in the extent of the area plot.

When `HitTestArea` is `off`, you must click an area to select the `areaseries` object. When `HitTestArea` is `on`, you can select the `areaseries` object by clicking anywhere within the extent of the area graph (that is, anywhere within a rectangle that encloses all the area plots).

`Interruptible`  
`off` | `{on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

## Areaseries Properties

---

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the *gca* or *gcf* command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of edges of filled areas.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

### LineWidth

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

### Parent

handle of parent axes, hggroup, or hgtransform

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

### Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

# Areaseries Properties

---

SelectionHighlight  
{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

Tag  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the Tag property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose Tag is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

Type  
string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For areaseries objects, Type is `'hgroup'`.

The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UIContextMenu

handle of uicontextmenu object

*Associate context menu with object.* Handle of a uicontextmenu object created in the object's parent figure. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

vector | matrix

*x-axis values for graph.* The x-axis values for graphs are specified by the X input argument. If XData is a vector, length(XData) must equal length(YData) and must be monotonic. If XData is a

# Areaseries Properties

---

matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped.

`XDataMode`  
{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`  
MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

vector | matrix

*Area plot data.* YData contains the data plotted as filled areas (the Y input argument). If YData is a vector, area creates a single filled area whose upper boundary is defined by the elements of YData. If YData is a matrix, area creates one filled area per column, stacking each on the previous plot. The default value is the Y input argument.

The input argument Y in the area function calling syntax assigns values to YData.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

# Areaseries Properties

---

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## How To

- “Plot Objects”
- “Setting Default Property Values”

<b>Purpose</b>	Convert homogeneous array to table
<b>Syntax</b>	<pre>T = array2table(A) T = array2table(A,Name,Value)</pre>
<b>Description</b>	<p><code>T = array2table(A)</code> converts the <i>m</i>-by-<i>n</i> array, <i>A</i>, to an <i>m</i>-by-<i>n</i> table, <i>T</i>. Each column of <i>A</i> becomes a variable in <i>T</i>.</p> <p><code>array2table</code> uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, <code>array2table</code> uses strings of the form 'Var1', ..., 'Var<i>N</i>', where <i>N</i> is the number of columns in <i>A</i>.</p> <p><code>T = array2table(A,Name,Value)</code> creates a table from an array, <i>A</i>, with additional options specified by one or more <i>Name,Value</i> pair arguments.</p> <p>For example, you can specify row names or variable names to include in the table.</p>
<b>Input Arguments</b>	<p><b>A - Input array</b> <i>matrix</i></p> <p>Input array, specified as a matrix.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char   struct   cell</p> <p><b>Complex Number Support:</b> Yes</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <i>Name,Value</i> arguments. <i>Name</i> is the argument name and <i>Value</i> is the corresponding value. <i>Name</i> must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as <i>Name1,Value1,...,NameN,ValueN</i>.</p>

# array2table

---

**Example:** 'RowNames', {'row1', 'row2', 'row3'} uses the row names, row1, row2, and row3 for the table, T.

## 'RowNames' - Row names for T

{} (default) | cell array of nonempty, distinct strings

Row names for T, specified as the comma-separated pair consisting of 'RowNames' and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(A,1)`.

## 'VariableNames' - Variable names for T

cell array of nonempty, distinct strings

Variable names for T, specified as the comma-separated pair consisting of 'VariableNames' and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(A,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of  $N$  strings of the form {'Var1' ... 'Var $N$ '} where  $N$  is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

## Output Arguments

### T - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Convert Numeric Array to Table

Create an array of numeric data.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

```
A =
```

```
     1     4     7
```

```
     2     5     8
     3     6     9
```

Convert the array, A, to a table.

```
T = array2table(A)
```

```
T =
```

```
     A1     A2     A3
     —     —     —
     1     4     7
     2     5     8
     3     6     9
```

The table has variable names that append the column number to the input array name, A.

## Convert Array to Table Including Variable Names

Create an array of numeric data.

```
A = [1 12 30.48; 2 24 60.96; 3 36 91.44]
```

```
A =
```

```
     1.0000     12.0000     30.4800
     2.0000     24.0000     60.9600
     3.0000     36.0000     91.4400
```

Convert the array, A, to a table and include variable names.

```
T = array2table(A,...
    'VariableNames',{'Feet' 'Inches' 'Centimeters'})
```

```
T =
```

```
     Feet     Inches     Centimeters
```

# array2table

---

1	12	30.48
2	24	60.96
3	36	91.44

## Tips

- If A is a cell array, use `cell2table(A)` to create a table from the contents of the cells in A. Each variable in the table is numeric or a cell array of strings. `array2table(A)` creates a table where each variable is a column of cells.

## See Also

## Related Examples

- “Access Data in a Table”

**Purpose**

Apply function to each element of array

**Syntax**

```
[B1,...,Bm] = arrayfun(func,A1,...,An)
[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)
```

**Description**

[B1,...,Bm] = arrayfun(func,A1,...,An) calls the function specified by function handle `func` and passes elements from arrays A1,...,An, where `n` is the number of inputs to function `func`. Output arrays B1,...,Bm, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax [B1(i),...,Bm(i)] = func(A1{i},...,An{i}). The `arrayfun` function does not perform the calls to function `func` in a specific order.

[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value) calls function `func` with additional options specified by one or more Name,Value pair arguments. Possible values for Name are 'UniformOutput' or 'ErrorHandler'.

**Input Arguments****func**

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

**A1,...,An**

Arrays that contain the `n` inputs required for function `func`. Each array must have the same dimensions. Arrays can be numeric, character, logical, cell, structure, or user-defined object arrays.

If any input `A` is a user-defined object array, and you overloaded the `subsref` or `size` methods, `arrayfun` requires that:

- The `size` method returns an array of type `double`.
- The object array supports linear indexing.

- The product of the sizes returned by the `size` method does not exceed the limit of the array, as defined by linear indexing into the array.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'UniformOutput'**

Logical value, as follows:

- |                        |   |
|------------------------|---|
| <code>true</code> (1)  | Indicates that for all inputs, each output from function <code>func</code> is a cell array or a scalar value that is always of the same type and size. The <code>arrayfun</code> function combines the outputs in arrays <code>B1, ..., Bm</code> , where <code>m</code> is the number of function outputs. Each output array is of the same type as the individual function outputs. |
| <code>false</code> (0) | Requests that the <code>arrayfun</code> function combine the outputs into cell arrays <code>B1, ..., Bm</code> . The outputs of function <code>func</code> can be of any size or type.  |

**Default:** `true`

## **'ErrorHandler'**

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

identifier	Error identifier.
message	Error message text.
index	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

## Output Arguments

### **B1,...,Bm**

Arrays that collect the  $m$  outputs from function `func`. Each array `B` is the same size as each of the inputs `A1, . . . , An`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

## Examples

To run the examples in this section, create a nonscalar structure array with arrays of different sizes in field `f1`.

```
s(1).f1 = rand(3, 6);
s(2).f1 = magic(12);
s(3).f1 = ones(5, 10);
```

---

Count the number of elements in each `f1` field.

```
counts = arrayfun(@(x) numel(x.f1), s)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
counts =
```

```
18  144  50
```

---

Compute the size of each array in the f1 fields.

```
[nrows, ncols] = arrayfun(@(x) size(x.f1), s)
```

This code returns

```
nrows =  
    3    12    5  
ncols =  
    6    12   10
```

---

Compute the mean of each column in the f1 fields of s. Because the output is nonscalar, set UniformOutput to false.

```
averages = arrayfun(@(x) mean(x.f1), s, 'UniformOutput', false)
```

This code returns

```
averages =  
    [1x6 double]    [1x12 double]    [1x10 double]
```

---

Create additional nonscalar structures t and u, and test for equality between the arrays in fields f1 across structures s, t, and u.

```
t = s; t(1).f1(:)=0;  
u = s; u(2).f1(:)=0;
```

```
same = arrayfun(@(x,y,z) isequal(x.f1, y.f1, z.f1), s, t, u)
```

This code returns

```
same =  
    0    0    1
```

**Tutorials**

- “Anonymous Functions”

# FTP.ascii

---

**Purpose** Set FTP transfer type to ASCII

**Syntax** `ascii(ftpobj)`

**Description** `ascii(ftpobj)` sets the download and upload FTP mode to ASCII, which converts new line characters. Use this method only for text files, including HTML pages and Rich Text Format (RTF) files.

**Input Arguments** **ftpobj**  
FTP object created by `ftp`.

**Examples** Connect to the MathWorks FTP server, and switch from binary (default) to ASCII mode:

```
mw=ftp('ftp.mathworks.com');  
ascii(mw)
```

**See Also** `binary` | `ftp`

**Purpose** Inverse secant in radians

**Syntax**  $Y = \text{asec}(X)$

**Description**  $Y = \text{asec}(X)$  returns the inverse secant (arcsecant) for each element of  $X$ .

The `asec` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

**Examples** Graph the inverse secant over the domains  $1 \leq x \leq 5$  and  $-5 \leq x \leq -1$ .

```
x1 = -5:0.01:-1;  
x2 = 1:0.01:5;  
plot(x1,asec(x1),x2,asec(x2)), grid on
```

### Inverse Secant

The inverse secant can be defined as

$$\sec^{-1}(z) = \cos^{-1}\left(\frac{1}{z}\right).$$

**See Also**

asecd | asech | sec

<b>Purpose</b>	Inverse secant in degrees
<b>Syntax</b>	$Y = \text{asecd}(X)$
<b>Description</b>	$Y = \text{asecd}(X)$ returns the inverse secant of the elements of $X$ in degrees.
<b>Input Arguments</b>	<p><b>X - Secant of angle</b> scalar value   vector   matrix   N-D array</p> <p>Secant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The <code>asecd</code> operation is element-wise when <math>X</math> is nonscalar.</p> <p><b>Data Types</b> single   double</p> <p><b>Complex Number Support:</b> Yes</p>
<b>Output Arguments</b>	<p><b>Y - Angle in degrees</b> scalar value   vector   matrix   N-D array</p> <p>Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as <math>X</math>.</p>

**Purpose** Inverse hyperbolic secant

**Syntax**  $Y = \operatorname{asech}(X)$

**Description**  $Y = \operatorname{asech}(X)$  returns the inverse hyperbolic secant for each element of  $X$ .

The `asech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

**Examples** Graph the inverse hyperbolic secant over the domain  $0.01 \leq x \leq 1$ .

```
x = 0.01:0.001:1;  
plot(x,asech(x)), grid on
```

### Inverse Hyperbolic Secant

The inverse hyperbolic secant can be defined as

# asech

---

$$\operatorname{sech}^{-1}(z) = \cosh^{-1}\left(\frac{1}{z}\right).$$

**Purpose** Inverse sine in radians

**Syntax** `Y = asin(X)`

**Description** `Y = asin(X)` returns the inverse sine (arcsine) for each element of `X`. The `asin` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians. For real elements of `X` in the domain  $[-1, 1]$ , `asin(X)` is in the range

$$\left[-\frac{\pi}{2}, \frac{\pi}{2}\right].$$

For real elements of `x` outside the range  $[-1, 1]$ , `asin(X)` is complex.

**Examples** Graph the inverse sine function over the domain  $-1 \leq x \leq 1$ .

```
x = -1:.01:1;  
plot(x,asin(x)), grid on
```

## Inverse Sine

The inverse sine can be defined as

$$\sin^{-1}(z) = -i \log \left[ iz + (1 - z^2)^{1/2} \right].$$

asin | sinh | acosh

**Purpose**

Generate error when condition is violated

**Syntax**

```
assert(expression)
assert(expression, 'msgString')
assert(expression, 'msgString', value1, value2, ...)
assert(expression, 'msgIdent', 'msgString', value1, value2,
    ...)
```

**Description**

`assert(expression)` evaluates *expression* and, if it is false, generates an exception. Depending on how the program has been designed to respond to the assertion failure, MATLAB either enters a catch block to handle the condition, or exits the program.

`assert(expression, 'msgString')` evaluates *expression* and, if it is false, generates an exception and displays the string contained in *msgString*. This string must be enclosed in single quotation marks. When *msgString* is the last input to `assert`, the MATLAB software displays it literally, without performing any substitutions on the characters in *msgString*.

`assert(expression, 'msgString', value1, value2, ...)` evaluates *expression* and, if it is false, generates an exception and displays the formatted string contained in *msgString*. The *msgString* string can include escape sequences such as `\t` or `\n`, as well as any of the C language conversion operators supported by the `sprintf` function (e.g., `%s` or `%d`). Additional arguments *value1*, *value2*, etc. provide values that correspond to and replace the conversion operators.

See “Formatting Strings” in the MATLAB Programming Fundamentals documentation for more detailed information on using string formatting commands.

MATLAB makes substitutions for escape sequences and conversion operators in *msgString* in the same way that it does for the `sprintf` function.

`assert(expression, 'msgIdent', 'msgString', value1, value2, ...)` evaluates *expression* and, if it is false, generates an exception and displays the formatted string *msgString*, also tagging the error

# assert

---

with the message identifier *msgIdent*. See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for information.

## Examples

This function tests input arguments using `assert`:

```
function write2file(varargin)
min_inputs = 3;
assert(nargin >= min_inputs, ...
    'You must call function %s with at least %d inputs', ...
    mfilename, min_inputs)

infile = varargin{1};
assert(ischar(infile), ...
    'First argument must be a filename.')
assert(exist(infile)~=0, 'File %s not found.', infile)

fid = fopen(infile, 'w');
assert(fid > 0, 'Cannot open file %s for writing', infile)

fwrite(fid, varargin{2}, varargin{3});
```

```

<b>Purpose</b>	Assign value to variable in specified workspace
<b>Syntax</b>	<code>assignin(ws, 'var', val)</code>
<b>Description</b>	<p><code>assignin(ws, 'var', val)</code> assigns the value <code>val</code> to the variable <code>var</code> in the workspace <code>ws</code>. The <code>var</code> input must be the array name only; it cannot contain array indices. If <code>var</code> does not exist in the specified workspace, <code>assignin</code> creates it. <code>ws</code> can have a value of 'base' or 'caller' to denote the MATLAB base workspace or the workspace of the caller function.</p> <p>The <code>assignin</code> function is particularly useful for these tasks:</p> <ul style="list-style-type: none"><li>• Exporting data from a function to the MATLAB workspace</li><li>• Within a function, changing the value of a variable that is defined in the workspace of the caller function (such as a variable in the function argument list)</li></ul>
<b>Tips</b>	<p>The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line. For more information, see “Base and Function Workspaces”.</p>
<b>Examples</b>	<p><b>Example 1</b></p> <p>This example creates a dialog box for the image display function, prompting a user for an image name and a colormap name. The <code>assignin</code> function is used to export the user-entered values to the MATLAB workspace variables <code>imfile</code> and <code>cmap</code>.</p> <pre>prompt = {'Enter image name:', 'Enter colormap name:'}; title = 'Image display - assignin example'; lines = 1; def = {'my_image', 'hsv'}; answer = inputdlg(prompt, title, lines, def);</pre>

# assignin

---

```
assignin('base', 'imfile', answer{1});  
assignin('base', 'cmap', answer{2});
```

## Example 2

`assignin` does not assign to specific elements of an array. The following statement generates an error:

```
X = 1:8;  
assignin('base', 'X(3:5)', -1);
```

However, you can use the `evalin` function to do this:

```
evalin('base', 'X(3:5) = -1')  
X =  
     1     2    -1    -1    -1     6     7     8
```

## See Also

`evalin`

**Purpose** Inverse tangent in radians

**Syntax**  $Y = \text{atan}(X)$

**Description**  $Y = \text{atan}(X)$  returns the inverse tangent (arctangent) for each element of  $X$ . For real elements of  $X$ ,  $\text{atan}(X)$  is in the range  $[-\pi/2, \pi/2]$ .

The `atan` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

**Examples** Graph the inverse tangent function over the domain  $-20 \leq x \leq 20$ .

```
x = -20:0.01:20;  
plot(x,atan(x)), grid on
```

### Inverse Tangent

The inverse tangent can be defined as

# atan

---

$$\tan^{-1}(z) = \frac{i}{2} \log\left(\frac{i+z}{i-z}\right).$$

## See Also

atan2 | tan | atand | atanh

**Purpose** Four-quadrant inverse tangent

**Syntax**  $P = \text{atan2}(Y,X)$

**Description**  $P = \text{atan2}(Y,X)$  returns an array  $P$  the same size as  $X$  and  $Y$  containing the element-by-element, four-quadrant inverse tangent (arctangent) of  $Y$  and  $X$ , which must be real.

Elements of  $P$  lie in the closed interval  $[-\pi, \pi]$ , where  $\pi$  is the MATLAB floating-point representation of  $\pi$ .  $\text{atan}$  uses  $\text{sign}(Y)$  and  $\text{sign}(X)$  to determine the specific quadrant.

$\text{atan2}(Y,X)$  contrasts with  $\text{atan}(Y/X)$ , whose results are limited to the interval  $[-\pi/2, \pi/2]$ , or the right side of this diagram.

**Examples** Any complex number  $z = x + iy$  is converted to polar coordinates with

```
r = abs(z)
theta = atan2(imag(z), real(z))
```

For example,

```
z = 4 + 3i;
```

## atan2

---

```
r = abs(z)
theta = atan2(imag(z),real(z))
```

```
r =
    5
```

```
theta =
    0.6435
```

This is a common operation, so MATLAB software provides a function, `angle(z)`, that computes `theta = atan2(imag(z),real(z))`.

To convert back to the original complex number

```
z = r * exp(i * theta)
z =
```

```
    4.0000 + 3.0000i
```

### See Also

`angle` | `atan` | `atanh` | `atan2d`

**Purpose** Four-quadrant inverse tangent in degrees

**Syntax**  $D = \text{atan2d}(Y,X)$

**Description**  $D = \text{atan2d}(Y,X)$  returns the four-quadrant inverse tangent of points specified in the  $x$ - $y$  plane. The result,  $D$ , is expressed in degrees.

**Input Arguments**

**Y - y-coordinates**

scalar value | vector | matrix | N-D array

$y$ -coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

**Data Types**

single | double

**X - x-coordinates**

scalar value | vector | matrix | N-D array

$x$ -coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

# atan2d

---

## Data Types

single | double

## Output Arguments

### D - Angles in degrees

scalar value | vector | matrix | N-D array

Angles in degrees, returned as a scalar, vector, matrix, or N-D array. These angles correspond to the points defined by X and Y, and they lie in the closed interval  $[-180,180]$ .

## Examples

### Inverse Tangent of Four Points on the Unit Circle

```
x = [1 0 -1 0];  
y = [0 1 0 -1];  
d = atan2d(y,x)
```

d =

```
0    90   180   -90
```

## Tips

- Use `atand(Y/X)` for the inverse tangent with results on the interval  $[-90, 90]$ .

## See Also

`atan2` | `atan` | `atand` | `tan` | `tand`

**Purpose** Inverse tangent in degrees

**Syntax** `Y = atand(X)`

**Description** `Y = atand(X)` returns the inverse tangent of the elements of `X` in degrees.

**Input Arguments** **X - Tangent of angle**  
 scalar value | vector | matrix | N-D array

Tangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `atand` operation is element-wise when `X` is nonscalar.

**Data Types**  
 single | double  
**Complex Number Support:** Yes

**Output Arguments** **Y - Angle in degrees**  
 scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

**Examples** **Inverse Tangent of Vector**

```
x = [-50 -20 0 20 50];
y = atand(x)

y =

    -88.8542   -87.1376         0    87.1376    88.8542
```

The `atand` operation is element-wise when you pass a vector, matrix, or N-D array.

**Inverse Tangent of Complex Value**

```
atand(10+i)
```

# atand

---

ans =

84.3450 + 0.5618i

## See Also

tand | atan | tan | atan2d

**Purpose** Inverse hyperbolic tangent

**Syntax**  $Y = \operatorname{atanh}(X)$

**Description** The `atanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.  $Y = \operatorname{atanh}(X)$  returns the inverse hyperbolic tangent for each element of  $X$ .

**Examples** Graph the inverse hyperbolic tangent function over the domain  $-1 < x < 1$ .

```
x = -0.99:0.01:0.99;
plot(x,atanh(x)), grid on
```

**Inverse Hyperbolic Tangent**

The inverse hyperbolic tangent can be defined as

# atanh

---

$$\tanh^{-1}(z) = \frac{1}{2} \log\left(\frac{1+z}{1-z}\right).$$

atan2 | atan | tanh | asinh | acosh | tan

**Purpose** Information about audio device

**Syntax**

```
devinfo = audiodevinfo
devs = audiodevinfo(IO)
name = audiodevinfo(IO, ID)
ID = audiodevinfo(IO, name)
DriverVersion = audiodevinfo(IO, ID, 'DriverVersion')
ID = audiodevinfo(IO, rate, bits, chans)
doesSupport = audiodevinfo(IO, ID, rate, bits, chans)
```

**Description** `devinfo = audiodevinfo` returns a structure, `devinfo`, containing two fields, `input` and `output`. Each field is an array of structures, with each structure containing information about one of the audio input or output devices on the system. The individual device structure fields are:

- `Name` — A string indicating the name of the device.
- `DriverVersion` — A string indicating the type of the installed device driver.
- `ID` — The ID of the device.

`devs = audiodevinfo(IO)` returns the number of input or output audio devices on the system. Use an `IO` value of 1 to indicate input, and an `IO` value of 0 to indicate output.

`name = audiodevinfo(IO, ID)` returns the name of the input or output audio device identified by device `ID`.

`ID = audiodevinfo(IO, name)` returns the device ID of the input or output audio device identified by the given name (partial matching, case sensitive). If no audio device is found with the given name, -1 is returned.

`DriverVersion = audiodevinfo(IO, ID, 'DriverVersion')` returns a string indicating the type of the specified audio input or output device.

`ID = audiodevinfo(IO, rate, bits, chans)` returns the device ID of the first input or output device that supports the sample rate, number of bits, and number of channels specified by the values of `rate`, `bits`, and `chans`, respectively. If no supporting device is found, -1 is returned.

# audiodevinfo

---

`doesSupport = audiodevinfo(IO, ID, rate, bits, chans)` returns 1 or 0 for whether or not the input or output audio device specified by ID can support the given sample rate, number of bits, and number of channels.

## See Also

`audioplayer` | `audiorecorder`

**Purpose** Create object for playing audio

**Syntax**

```
player = audioplayer(Y,Fs)
player = audioplayer(Y,Fs,nBits)
player = audioplayer(Y,Fs,nBits,ID)
player = audioplayer(recorder)
player = audioplayer(recorder,ID)
```

**Description**

`player = audioplayer(Y,Fs)` creates an `audioplayer` object for signal `Y`, using sample rate `Fs`. The function returns a handle to the `audioplayer` object, `player`.

`player = audioplayer(Y,Fs,nBits)` uses `nBits` bits per sample for signal `Y`.

`player = audioplayer(Y,Fs,nBits,ID)` uses the audio device identified by `ID` for output.

`player = audioplayer(recorder)` creates an `audioplayer` object using audio recorder object `recorder`.

`player = audioplayer(recorder ,ID)` creates an object from `recorder` that uses the audio device identified by `ID` for output.

## Input Arguments

### Y

Audio signal represented by a vector or two-dimensional array containing `single`, `double`, `int8`, `uint8`, or `int16` values.

The value range of the input sample depends on the data type. The following table lists these ranges.

Data Type	Sample Value Range
<code>int8</code>	-128 to 127
<code>uint8</code>	0 to 255
<code>int16</code>	-32768 to 32767

# audioplayer

---

Data Type	Sample Value Range
single	-1 to 1
double	-1 to 1

## **F<sub>s</sub>**

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

## **nBits**

Bits per sample. Specify only when signal Y is represented by floating-point values. Valid values depend on the audio hardware installed: 8, 16, or 24.

**Default:** 16

## **ID**

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

**Default:** -1 (default device)

## **recorder**

Audio recorder object created by `audiorecorder`.

## Methods

---

**Note** When calling any method, include the `audioplayer` object name using function syntax, such as `stop(player)`.

---

<code>get</code>	Query properties of <code>audioplayer</code> object.
<code>isplaying</code>	Query whether playback is in progress: returns true or false.

<code>pause</code>	Pause playback.
<code>play</code>	Play audio from beginning to end.
<code>playblocking</code>	Play, and do not return control until playback completes.
<code>resume</code>	Restart playback from paused position.
<code>set</code>	Set properties of <code>audioplayer</code> object.
<code>stop</code>	Stop playback.

See the reference pages for `get`, `play`, `playblocking`, and `set` for additional syntax options.

## Properties

<code>BitsPerSample</code>	Number of bits per sample. (Read-only)
<code>CurrentSample</code>	Current sample that the audio output device is playing. If the device is not playing, <code>CurrentSample</code> is the next sample to play with <code>play</code> or <code>resume</code> . (Read-only)
<code>DeviceID</code>	Identifier for audio device. (Read-only)
<code>NumberOfChannels</code>	Number of audio channels. (Read-only)
<code>Running</code>	Status of the audio player: 'on' or 'off'. (Read-only)
<code>SampleRate</code>	Sampling frequency in Hz.
<code>TotalSamples</code>	Total length of the audio data in samples. (Read-only)
<code>Tag</code>	String that labels the object.
<code>Type</code>	Name of the class: 'audioplayer'. (Read-only)
<code>UserData</code>	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audioplayer` object and an *event* structure.

# audioplayer

---

StartFcn	Function to execute one time when playback starts.
StopFcn	Function to execute one time when playback stops.
TimerFcn	Function to execute repeatedly during playback. To specify time intervals for the repetitions, use the <code>TimerPeriod</code> property.
TimerPeriod	Time in seconds between <code>TimerFcn</code> callbacks. Default: <code>.05</code>

## Examples

Load and play a sample audio file of Handel’s “Hallelujah Chorus:”

```
load handel;  
player = audioplayer(y, Fs);  
play(player);
```

## See Also

[audiodevinfo](#) | [audiorecorder](#) | [sound](#)

## How To

- “Characteristics of Audio Files”
- “Play Audio”

## Purpose

Create object for recording audio

## Syntax

```
recorder = audiorecorder  
recorder = audiorecorder(Fs,nBits,nChannels)  
recorder = audiorecorder(Fs,nBits,nChannels,ID)
```

## Description

`recorder = audiorecorder` creates an 8000 Hz, 8-bit, 1-channel `audiorecorder` object.

`recorder = audiorecorder(Fs,nBits,nChannels)` sets the sample rate `Fs` (in Hz), the sample size `nBits`, and the number of channels `nChannels`.

`recorder = audiorecorder(Fs,nBits,nChannels,ID)` sets the audio input device to the device specified by `ID`.

## Tips

- To use an `audiorecorder` object, your system must have a properly installed and configured sound card.
- `audiorecorder` is not intended for long, high-sample-rate recording. `audiorecorder` uses system memory for storage and does not use disk buffering. When you attempt a large recording, your MATLAB performance sometimes degrades over time.

## Input Arguments

### **Fs**

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

**Default:** 8000

### **nBits**

Bits per sample. Valid values depend on the audio hardware installed: 8, 16, or 24.

**Default:** 8

# audiorecorder

---

## **nChannels**

The number of channels: 1 (mono) or 2 (stereo).

**Default:** 1

## **ID**

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

**Default:** -1 (default device)

## **Methods**

---

**Note** When calling any method, include the `audiorecorder` object name using function syntax, such as `stop(recorder)`.

---

<code>get</code>	Query properties of <code>audiorecorder</code> object.
<code>getaudiodata</code>	Create an array that stores the recorded signal values.
<code>getplayer</code>	Create an <code>audioplayer</code> object.
<code>isrecording</code>	Query whether recording is in progress: returns <code>true</code> or <code>false</code> .
<code>pause</code>	Pause recording.
<code>play</code>	Play recorded audio. This method returns an <code>audioplayer</code> object.
<code>record</code>	Start recording.
<code>recordblocking</code>	Record, and do not return control until recording completes. This method requires a second input for the length of the recording in seconds: <code>recordblocking(recorder, length)</code>
<code>resume</code>	Restart recording from paused position.
<code>set</code>	Set properties of <code>audiorecorder</code> object.
<code>stop</code>	Stop recording.

See the reference pages for `get`, `getaudiodata`, `play`, `record`, `recordblocking`, and `set` for additional syntax options.

## Properties

<code>BitsPerSample</code>	Number of bits per sample. (Read-only)
<code>CurrentSample</code>	Current sample that the audio input device is recording. If the device is not recording, <code>CurrentSample</code> is the next sample to record with <code>record</code> or <code>resume</code> . (Read-only)
<code>DeviceID</code>	Identifier for audio device. (Read-only)
<code>NumberOfChannels</code>	Number of audio channels. (Read-only)
<code>Running</code>	Status of the audio recorder: 'on' or 'off'. (Read-only)
<code>SampleRate</code>	Sampling frequency in Hz. (Read-only)
<code>TotalSamples</code>	Total length of the audio data in samples. (Read-only)
<code>Tag</code>	String that labels the object.
<code>Type</code>	Name of the class: 'audiorecorder'. (Read-only)
<code>UserData</code>	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audiorecorder` object and an *event* structure.

<code>StartFcn</code>	Function to execute one time when recording starts.
<code>StopFcn</code>	Function to execute one time when recording stops.

# audiorecorder

---

TimerFcn	Function to execute repeatedly during recording. To specify time intervals for the repetitions, use the TimerPeriod property.
TimerPeriod	Time in seconds between TimerFcn callbacks. Default: .05

audiorecorder ignores any specified values for these properties, which will be removed in a future release.

BufferLength	Length of buffer in seconds.
NumberOfBuffers	Number of buffers.

## Examples

Create an audiorecorder object for CD-quality audio in stereo, and view its properties:

```
recObj = audiorecorder(44100, 16, 2);  
get(recObj)
```

---

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.  
recObj = audiorecorder;  
disp('Start speaking.')
```

```
recordblocking(recObj, 5);  
disp('End of Recording.');
```

```
% Play back the recording.  
play(recObj);
```

```
% Store data in double-precision array.  
myRecording = getaudiodata(recObj);
```

```
% Plot the waveform.  
plot(myRecording);
```

# aufinfo

---

**Purpose** Information about NeXT/SUN (.au) sound file

---

**Note** aufinfo will be removed in a future release. Use audioinfo instead.

---

**Syntax** `[m d] = aufinfo(aufile)`

**Description** `[m d] = aufinfo(aufile)` returns information about the contents of the AU sound file specified by the string `aufile`.

`m` is the string 'Sound (AU) file', if `filename` is an AU file. Otherwise, it contains an empty string ('').

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If `filename` is not an AU file, it contains the string 'Not an AU file'.

**See Also** `audioread` | `audioinfo`

**Purpose** Read NeXT/SUN (.au) sound file

---

**Note** auread will be removed in a future release. Use audioread instead.

---

**Syntax**

```
y = auread(afile)
[y,Fs] = auread(afile)
[y,Fs,nbits] = auread(afile)
[ ___ ] = auread(afile,N)
[ ___ ] = auread(afile,[N1 N2])
siz = auread(afile, 'size')
```

**Description** `y = auread(afile)` loads a sound file specified by the string *afile*, returning the sampled data in *y*. The .au extension is appended if no extension is given. Amplitude values are in the range [-1,+1]. auread supports multichannel data in the following formats:

- 8-bit mu-law
- 8-, 16-, and 32-bit linear
- Floating-point

`[y,Fs] = auread(afile)` returns the sample rate (*Fs*) in Hertz used to encode the data in the file.

`[y,Fs,nbits] = auread(afile)` returns the number of bits per sample (*nbits*).

`[ ___ ] = auread(afile,N)` returns only the first *N* samples from each channel in the file.

`[ ___ ] = auread(afile,[N1 N2])` returns only samples *N1* through *N2* from each channel in the file.

`siz = auread(afile, 'size')` returns the size of the audio data contained in the file in place of the actual audio data, returning the vector `siz = [samples channels]`.

## Examples

Create a sound file from the example file `handel.mat`, and read portions of the file back into MATLAB:

```
% Create .au file in current folder.
load handel.mat

hfile = 'handel.au';
auwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits] = auread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = auread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = auread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = auread(hfile, [startpos endpos]);
sound(y3, Fs);
```

## See Also

[audiowrite](#) | [audioinfo](#) | [audioplayer](#) | [audiorecorder](#) | [sound](#) | [audioread](#)

**Purpose** Write NeXT/SUN (.au) sound file

---

**Note** auwrite will be removed in a future release.

---

**Syntax**

```
auwrite(y, aufile)
auwrite(y, Fs, aufile)
auwrite(y, Fs, N, aufile)
auwrite(y, Fs, N, method, aufile)
```

**Description** `auwrite(y, aufile)` writes a sound file specified by the string `aufile`. The data should be arranged with one channel per column. Amplitude values outside the range `[-1, +1]` are clipped prior to writing. `auwrite` supports multichannel data for 8-bit mu-law and 8- and 16-bit linear formats.

`auwrite(y, Fs, aufile)` specifies the sample rate of the data in Hertz.

`auwrite(y, Fs, N, aufile)` selects the number of bits in the encoder. Allowable settings are  $N = 8$  and  $N = 16$ .

`auwrite(y, Fs, N, method, aufile)` allows selection of the encoding method, which can be either 'mu' or 'linear'. Note that mu-law files must be 8-bit. By default, `method = 'mu'`.

**See Also** audioread | audiowrite

# avifile

## Purpose

Create new Audio/Video Interleaved (AVI) file

---

**Note** `avifile` will be removed in a future release. Use `VideoWriter` instead.

---

## Syntax

```
aviobj = avifile(filename)
avifile(filename, ParameterName, ParameterValue)
```

## Description

`aviobj = avifile(filename)` creates an `avifile` object, giving it the name specified in `filename`, using default values for all `avifile` object properties. If `filename` does not include an extension, `avifile` appends `.avi` to the file name. AVI is a file format for storing audio and video data.

`avifile` returns a handle to an AVI file object `aviobj`. Use this object to refer to the AVI file in other functions. An AVI file object supports properties and methods that control aspects of the AVI file created.

`aviobj = avifile(filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. Set parameter values before any calls to `addframe`. The following table lists the available parameters and values.

Parameter Name	Value	Default
'colormap'	An $m$ -by-3 matrix defining the colormap for indexed AVI movies, where $m$ is no more than 256 (236 for Indeo compression).  Valid only when the 'compression' is 'MSVC', 'RLE', or 'None'.	No default
'compression'	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of 'None'.	'Indeo5' on Windows systems.

Parameter Name	Value	Default
	<p>On UNIX<sup>®</sup> operating systems, the only valid value is 'None'.</p> <p>On Windows systems, valid values include:</p> <ul style="list-style-type: none"> <li>• 'MSVC'</li> <li>• 'RLE'</li> <li>• 'Cinepak' on 32-bit systems.</li> <li>• 'Indeo3' or 'Indeo5' on 32-bit Windows XP systems.</li> </ul> <p>Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.</p>	'None' on UNIX systems.
'fps'	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
'keyframe'	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
'quality'	<p>A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.</p> <p>Valid only for compressed movies.</p>	75
'videoname'	A descriptive name for the video stream, no more than 64 characters.	<i>filename</i>

## Tips

- On some Windows systems, including all 64-bit systems, the default Indeo® 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer®. Consider specifying a compression value of 'None'.
- avifile cannot write files larger than 2 GB.
- You can use dot notation to set avifile object properties. For example, set the quality property to 100:

```
aviobj = avifile('myavifile');  
aviobj.quality = 100;
```

All property names of an avifile object are the same as the parameter names, except for the keyframe parameter, which corresponds to the KeyFramePerSec property. For example, change keyframe to 2.5:

```
aviobj.KeyFramePerSec = 2.5;
```

## Examples

Create the AVI file example.avi:

```
aviobj = avifile('example.avi','compression','None');  
  
t = linspace(0,2.5*pi,40);  
fact = 10*sin(t);  
fig=figure;  
[x,y,z] = peaks;  
for k=1:length(fact)  
    h = surf(x,y,fact(k)*z);  
    axis([-3 3 -3 3 -80 80])  
    axis off  
    caxis([-90 90])  
end
```

```
F = getframe(fig);
aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

**Alternatives**

Use `VideoWriter` rather than `avifile` to create AVI files. `VideoWriter` supports files larger than 2 GB, and by default, creates files with Motion JPEG compression, which all platforms support.

**See Also**

`VideoWriter` | `addframe (avifile)` | `close (avifile)` | `movie2avi`

## Purpose

Information about Audio/Video Interleaved (AVI) file

---

**Note** `aviinfo` will be removed in a future release. Use `VideoReader` and the `get` method instead.

---

## Syntax

```
fileinfo = aviinfo(filename)
```

## Description

`fileinfo = aviinfo(filename)` returns a structure whose fields contain information about the AVI file specified in the string `filename`. If `filename` does not include an extension, then `.avi` is used. The file must be in the current working directory or in a directory on the MATLAB path.

The set of fields in the `fileinfo` structure is shown below.

Field Name	Description
AudioFormat	String containing the name of the format used to store the audio data, if audio data is present
AudioRate	Integer indicating the sample rate in Hertz of the audio stream, if audio data is present
Filename	String specifying the name of the file
FileModDate	String containing the modification date of the file
FileSize	Integer indicating the size of the file in bytes
FramesPerSecond	Integer indicating the desired frames per second
Height	Integer indicating the height of the AVI movie in pixels

Field Name	Description
ImageType	String indicating the type of image. Either 'truecolor' for a truecolor (RGB) image, or 'indexed' for an indexed image.
NumAudioChannels	Integer indicating the number of channels in the audio stream, if audio data is present
NumFrames	Integer indicating the total number of frames in the movie
NumColormapEntries	Integer specifying the number of colormap entries. For a truecolor image, this value is 0 (zero).
Quality	Number between 0 and 100 indicating the video quality in the AVI file. Higher quality numbers indicate higher video quality; lower quality numbers indicate lower video quality. This value is not always set in AVI files and therefore can be inaccurate.
VideoCompression	String containing the compressor used to compress the AVI file. If the compressor is not Microsoft Video 1, Run Length Encoding (RLE), Cinepak, or Intel® Indeo, aviinfo returns the four-character code that identifies the compressor.
Width	Integer indicating the width of the AVI movie in pixels

**See also**

mmfileinfo, VideoReader, VideoWriter

# aviread

---

## Purpose

Read Audio/Video Interleaved (AVI) file

---

**Note** `aviread` will be removed in a future release. Use `VideoReader` instead.

---

## Syntax

```
mov = aviread(filename)  
mov = aviread(filename, index)
```

## Description

`mov = aviread(filename)` reads the AVI movie *filename* into the MATLAB movie structure *mov*. If *filename* does not include an extension, then `.avi` is used. Use the `movie` function to view the movie *mov*. On UNIX platforms, *filename* must be an uncompressed AVI file.

*mov* has two fields, `cdata` and `colormap`. The content of these fields varies depending on the type of image.

Image Type	cdata Field	colormap Field
Truecolor	Height-by-width-by-3 array of uint8 values	Empty
Indexed	Height-by-width array of uint8 values	m-by-3 array of double values

`aviread` supports 8-bit frames, for indexed and grayscale images, 16-bit grayscale images, or 24-bit truecolor images. Note, however, that `movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale image frames.

`mov = aviread(filename, index)` reads only the frames specified by *index*. *index* can be a single index or an array of indices into the video stream. In AVI files, the first frame has the index value 1, the second frame has the index value 2, and so on.

## See also

`mmfileinfo`, `movie`, `VideoReader`, `VideoWriter`

**Purpose** Create axes graphics object

**Syntax**

```
axes
axes('PropertyName',propertyvalue,...)
axes(h)
h = axes(...)
```

**Properties** For a list of properties, see Axes Properties.

**Description** `axes` creates an axes graphics object in the current figure using default property values. `axes` is the low-level function for creating axes graphics objects. MATLAB automatically creates an axes, if one does not already exist, when you issue a command that creates a graph.

`axes('PropertyName',propertyvalue,...)` creates an axes object having the specified property values. For a description of the properties, see Axes Properties. MATLAB uses default values for any properties that you do not explicitly define as arguments. The `axes` function accepts property name/property value pairs, structure arrays, and cell arrays as input arguments (see the `set` and `get` commands for examples of how to specify these data types). While the basic purpose of an axes object is to provide a coordinate system for plotted data, axes properties provide considerable control over the way MATLAB displays data.

`axes(h)` makes existing axes `h` the current axes and brings the figure containing it into focus. It also makes `h` the first axes listed in the figure's `Children` property and sets the figure's `CurrentAxes` property to `h`. The current axes is the target for functions that draw image, line, patch, rectangle, surface, and text graphics objects.

If you want to make an axes the current axes without changing the state of the parent figure, set the `CurrentAxes` property of the figure containing the axes:

```
set(figure_handle,'CurrentAxes',axes_handle)
```

This command is useful if you want a figure to remain minimized or stacked below other figures, but want to specify the current axes.

`h = axes(...)` returns the handle of the created axes object.

Use the `set` function to modify the properties of an existing axes or the `get` function to query the current values of axes properties. Use the `gca` command to obtain the handle of the current axes.

The `axis` (not `axes`) function provides simplified access to commonly used properties that control the scaling and appearance of axes.

Set default axes properties on the figure and `root` object levels:

```
set(0, 'DefaultAxesPropertyName', PropertyValue, ...)  
set(gcf, 'DefaultAxesPropertyName', PropertyValue, ...)
```

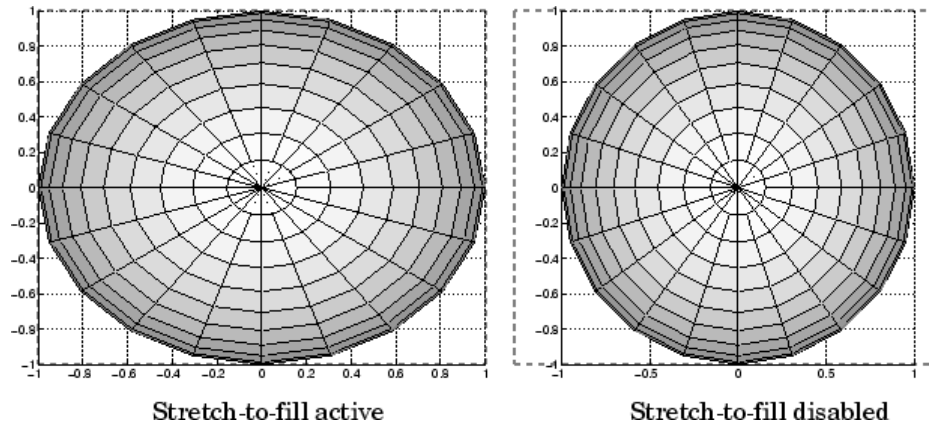

*PropertyName* is the name of the axes property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access axes properties.

### Stretch-to-Fill

By default, MATLAB stretches the axes to fill the axes position rectangle (the rectangle defined by the last two elements in the `Position` property). This results in graphs that use the available space in the rectangle. However, some 3-D graphs (such as a sphere) appear distorted because of this stretching, and are better viewed with a specific three-dimensional aspect ratio.

Stretch-to-fill is active when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto` (the default). However, stretch-to-fill is turned off when the `DataAspectRatio`, `PlotBoxAspectRatio`, or `CameraViewAngle` is user-specified, or when one or more of the corresponding modes is set to `manual` (which happens automatically when you set the corresponding property value).

This picture shows the same sphere displayed both with and without the stretch-to-fill. The dotted lines show the axes rectangle.

When stretch-to-fill is disabled, MATLAB sets the size of the axes to be as large as possible within the constraints imposed by the `Position` rectangle without introducing distortion. In the picture above, the height of the rectangle constrains the axes size.

## Examples

Zoom in and out using the `CameraViewAngle`:

```
sphere
set(gca, 'CameraViewAngle', get(gca, 'CameraViewAngle')-5)
pause(1)
set(gca, 'CameraViewAngle', get(gca, 'CameraViewAngle')+5)
```

Define multiple axes in a single figure window:

```
axes('position',[.1 .1 .8 .6])
mesh(peaks(20));
axes('position',[.1 .7 .8 .2])
pcolor([1:10;1:10]);
```

## Alternatives

To create a figure select **New > Figure** from the figure window **File** menu. To add an axes to a figure, click one of the *New Subplots* icons in the Figure Palette, and slide right to select an arrangement of new axes. For details, see “Plotting Tools — Interactive Plotting”.

## Tutorials

- “Axes Objects — Defining Coordinate Systems for Graphs”
- “Axes Property Operations”

## Purpose

Modify axes properties

## Creating Axes Objects

Use axes to create axes objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands let you set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values” in the Handle Graphics Objects documentation.

## Axes Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`ActivePositionProperty`  
{outerposition} | position

*Use OuterPosition or Position property for resize.* Specifies which property (`Position` or `OuterPosition`) MATLAB holds constant as you resize the figure (interactively or during a printing or exporting operation).

Setting a value for the `Position` property makes `position` the value of the `ActivePositionProperty`. The same is also true of setting a value for the `OuterPosition` property; `outerposition` becomes the value of the `ActivePositionProperty`.

See `OuterPosition` and `Position` for related properties.

See `Automatic Axes Resize` for a discussion of how to use axes positioning properties.

# Axes Properties

---

ALim

[amin, amax]

*Alpha axis limits.* Determines how MATLAB maps the AlphaData values of surface, patch, and image objects to the figure's alphamap.

- **amin** — Value of the data mapped to the first alpha value in the alphamap.
- **amax** — Value of the data mapped to the last alpha value in the alphamap.

MATLAB linearly interpolates data values in between across the alphamap and clamps data values outside to either the first or last alphamap value, whichever is closest.

If the axes contains multiple graphics objects, MATLAB sets ALim to span the range of all objects' AlphaData (or FaceVertexAlphaData for patch objects).

See the alpha function reference page for additional information.

ALimMode

{auto} | manual

*Alpha axis limits mode.*

- **auto** — MATLAB sets the ALim property to span the AlphaData limits of the graphics objects displayed in the axes.
- **manual** — MATLAB does not change the value of ALim when the AlphaData limits of axes children change.

Setting the ALim property sets ALimMode to manual.

AmbientLightColor

ColorSpec

*Background light in a scene.* Ambient light is a directionless light that shines uniformly on all objects in the axes. However, if there are no visible light objects in the axes, MATLAB does not use `AmbientLightColor`. If there are light objects in the axes, MATLAB adds the `AmbientLightColor` to the other light sources.

`AspectRatio`  
(Obsolete)

This property produces a warning message when queried or changed. The `DataAspectRatio[Mode]` and `PlotBoxAspectRatio[Mode]` properties have superseded it.

`BeingDeleted`  
`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

See the `close` and `delete` function reference pages for related information.

`Box`  
`on` | `{off}`

*Axes box mode.* Specifies whether to enclose the axes extent in a box for 2-D views or a cube for 3-D views. The default is to not display the box.

`BusyAction`  
`cancel` | `{queue}`

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is within the axes, but not over another graphics object parented to the axes. For 3-D views, the active area is a rectangle that encloses the axes.

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of axes associated with the button down event and an event structure, which is empty for this property).

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Some Plotting Functions Reset the `ButtonDownFcn`

Most MATLAB plotting functions clear the axes and reset a number of axes properties, including the `ButtonDownFcn` before plotting data. To create an interface that lets users plot data interactively, consider using a control device such as a push button (`uicontrol`), which plotting functions do not affect. See [“Using Function Handles in GUIs”](#) for an example.

If you must use the axes `ButtonDownFcn` to plot data, then you should use low-level functions such as `line`, `patch`, and `surface` and manage the process with the figure and axes `NextPlot` properties.

See [“High-Level Versus Low-Level Functions”](#) for information on how plotting functions behave.

See [“Preparing Figures and Axes for Graphics”](#) for more information.

## Camera Properties

See [View Control with the Camera Toolbar](#) for information related to the Camera properties.

See [Defining Scenes with Camera Graphics](#) for information on the camera properties.

See [View Projection Types](#) for information on orthogonal and perspective projections.

### `CameraPosition`

[*x*, *y*, *z*] axes coordinates

*Location of the camera.* Position from which the camera views the scene. Specify the point in axes coordinates.

# Axes Properties

---

If you fix `CameraViewAngle`, you can zoom in and out on the scene by changing the `CameraPosition`, moving the camera closer to the `CameraTarget` to zoom in and farther away from the `CameraTarget` to zoom out. As you change the `CameraPosition`, the amount of perspective also changes, if `Projection` is perspective. You can also zoom by changing the `CameraViewAngle`; however, this does not change the amount of perspective in the scene.

`CameraPositionMode`  
{auto} | manual

*Auto or manual CameraPosition.* When set to auto, MATLAB automatically calculates the `CameraPosition` such that the camera lies a fixed distance from the `CameraTarget` along the azimuth and elevation specified by `view`. Setting a value for `CameraPosition` sets this property to manual.

`CameraTarget`  
[x, y, z] axes coordinates

*Camera aiming point.* Specifies the location in the axes that the camera points to. The `CameraTarget` and the `CameraPosition` define the vector (the view axis) along which the camera looks.

`CameraTargetMode`  
{auto} | manual

*Auto or manual CameraTarget placement.* When this property is auto, MATLAB automatically positions the `CameraTarget` at the centroid of the axes plot box. Specifying a value for `CameraTarget` sets this property to manual.

`CameraUpVector`  
[x, y, z] axes coordinates

*Camera rotation.* Specifies the rotation of the camera around the viewing axis defined by the `CameraTarget` and the `CameraPosition` properties. Specify `CameraUpVector` as a

three-element array containing the  $x$ ,  $y$ , and  $z$  components of the vector. For example,  $[0\ 1\ 0]$  specifies the positive  $y$ -axis as the up direction.

The default `CameraUpVector` is  $[0\ 0\ 1]$ , which defines the positive  $z$ -axis as the up direction.

`CameraUpVectorMode`  
{auto} | manual

*Default or user-specified up vector.* When `CameraUpVectorMode` is `auto`, MATLAB uses a value of  $[0\ 0\ 1]$  (positive  $z$ -direction is up) for 3-D views and  $[0\ 1\ 0]$  (positive  $y$ -direction is up) for 2-D views. Setting a value for `CameraUpVector` sets this property to `manual`.

`CameraViewAngle`  
scalar greater than 0 and less than or equal to 180 (angle in degrees)

*Field of view.* Determines the camera field of view. Changing this value affects the size of graphics objects displayed in the axes, but does not affect the degree of perspective distortion. The greater the angle, the larger the field of view, and the smaller objects appear in the scene.

`CameraViewAngleMode`  
{auto} | manual

*Auto or manual CameraViewAngle.* When in `auto` mode, MATLAB sets `CameraViewAngle` to the minimum angle that captures the entire scene (up to  $180^\circ$ ).

The following table summarizes MATLAB camera behavior using various combinations of `CameraViewAngleMode`, `CameraTargetMode`, and `CameraPositionMode`:

# Axes Properties

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
auto	auto	auto	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
auto	auto	manual	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene.
auto	manual	auto	Sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
auto	manual	manual	Sets CameraViewAngle to capture entire scene.
manual	auto	auto	Sets CameraTarget to plot box centroid, sets CameraPosition along the view axis.
manual	auto	manual	Sets CameraTarget to plot box centroid.

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
manual	manual	auto	Sets CameraPosition along the view axis.
manual	manual	manual	User specifies all camera properties.

## Children

vector of graphics object handles

*Handles of all graphics objects rendered within the axes (whether visible or not).* The graphics objects that can be children of axes are `image`, `light`, `line`, `patch`, `rectangle`, `surface`, and `text`. Change the order of the handles to change the stacking of the objects on the display.

The text objects used to label the  $x$ -,  $y$ -, and  $z$ -axes and the title are also children of axes, but their `HandleVisibility` properties are set to `off`. This means their handles do not show up in the axes `Children` property unless you set the `Root ShowHiddenHandles` property to `on`.

When an object's `HandleVisibility` property is `off`, its parent's `Children` property does not list it. See `HandleVisibility` for more information.

## CLim

[`cmin`, `cmax`]

*Color axis limits.* Determines how MATLAB maps the `CData` values of surface and patch objects to the figure's `Colormap`. `cmin` is the value of the data mapped to the first color in the `colormap`. `cmax` is the value of the data mapped to the last color in the `colormap`. MATLAB linearly interpolates data values in between across the `colormap` and clamps data values outside to either the first or last `colormap` color, whichever is closest.

# Axes Properties

---

When `CLimMode` is `auto` (the default), MATLAB assigns `cmin` the minimum data value and `cmax` the maximum data value in the graphics object's `CData`. This maps `CData` elements with minimum data value to the first `colormap` entry and with maximum data value to the last `colormap` entry.

If the axes contains multiple graphics objects, MATLAB sets `CLim` to span the range of all objects' `CData`.

See the `caxis` function reference page for related information.

`CLimMode`  
{`auto`} | `manual`

*Color axis limits mode.*

- `auto` — MATLAB sets the `CLim` property to span the `CData` limits of the graphics objects displayed in the axes.
- `manual` — MATLAB does not change the value of `CLim` when the `CData` limits of axes children change.

Setting the `CLim` property sets this property to `manual`.

`Clipping`  
{`on`} | `off`

*Clipping mode.* This property has no effect on axes.

`Color`  
{`[1,1,1]`} | `ColorSpec`

*Color of the axes back planes.* Setting this property to `none` means that the axes is transparent and the figure color shows through. A `ColorSpec` is a three-element RGB vector or one of the MATLAB predefined names.

`ColorOrder`  
m-by-3 matrix of RGB values

*Colors to use for multiline plots.* Defines the colors used by the `plot` and `plot3` functions to color each line plotted. If you do not specify a line color with `plot` and `plot3`, these functions cycle through the `ColorOrder` property to obtain the color for each line plotted. To obtain the current `ColorOrder`, which might be set during startup, get the property value:

```
get(gca, 'ColorOrder')
```

Note that if the axes `NextPlot` property is `replace` (the default), high-level functions like `plot` reset the `ColorOrder` property before determining the colors to use. If you want MATLAB to use a `ColorOrder` that is different from the default, set `NextPlot` to `replacechildren`. You can also specify your own default `ColorOrder`.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates an axes object. You must define this property as a default value for axes. For example, the statement:

```
set(0, 'DefaultAxesCreateFcn', @ax_create)
```

defines a default value on the `Root` level that sets axes properties whenever you (or MATLAB) create an axes.

```
function ax_create(src, evnt)
    set(src, 'Color', 'b', ...
        'XLim', [1 10], ...
        'YLim', [0 100])
end
```

MATLAB executes this function after setting all properties for the axes. Setting the `CreateFcn` property on an existing axes object has no effect.

# Axes Properties

---

MATLAB passes the handle of the object whose `CreateFcn` is being executed as the first argument to the callback function and is also accessible through the `Root CallbackObject` property, which can be queried using `gcbo`.

See `Function Handle Callbacks` for information on how to use function handles to define the callback function.

`CurrentPoint`  
2-by-3 matrix

*Location of last button click, in axes data units.* Contains the coordinates of two points defined by the location of the pointer at the last mouse click. MATLAB returns the coordinates with respect to the requested axes.

## Clicking Within the Axes — Orthogonal Projection

The two points lie on the line that is perpendicular to the plane of the screen and passes through the pointer. This is true for both 2-D and 3-D views.

The 3-D coordinates are the points, in the axes coordinate system, where this line intersects the front and back surfaces of the axes volume (which is defined by the axes  $x$ ,  $y$ , and  $z$  limits).

The returned matrix is of the form:

$$\begin{bmatrix} x_{front} & y_{front} & z_{front} \\ x_{back} & y_{back} & z_{back} \end{bmatrix}$$

where *front* defines the point nearest to the camera position. Therefore, if the `CurrentPoint` property returns the `cp` matrix, then the first row,

`cp(1, :)`

specifies the point nearest the viewer and the second row,

`cp(2, :)`

specifies the point furthest from the viewer.

## **Clicking Outside the Axes — Orthogonal Projection**

When you click outside the axes volume, but within the figure, the returned values are:

- Back point — a point in the plane of the camera target (which is perpendicular to the viewing axis).
- Front point — a point in the camera position plane (which is perpendicular to the viewing axis).

These points lie on a line that passes through the pointer and is perpendicular to the camera target and camera position planes.

## **Clicking Within the Axes — Perspective Projection**

The values of the current point when using perspective project can be different from the same point in orthographic projection because the shape of the axes volume can be different.

## **Clicking Outside the Axes — Perspective Projection**

Clicking outside of the axes volume returns the front point as the current camera position at all times. Only the back point updates with the coordinates of a point that lies on a line extending from the camera position through the pointer and intersecting the camera target at the point.

## **Related Information**

See the figure `CurrentPoint` property for more information.

# Axes Properties

---

DataAspectRatio  
[dx dy dz]

*Relative scaling of data units.* Controls the relative scaling of data units in the  $x$ ,  $y$ , and  $z$  directions. For example, setting this property to [1 2 1] causes the length of one unit of data in the  $x$ -direction to be the same length as two units of data in the  $y$ -direction and one unit of data in the  $z$ -direction.

Note that the DataAspectRatio property interacts with the PlotBoxAspectRatio, XLimMode, YLimMode, and ZLimMode properties to control how MATLAB scales the  $x$ -,  $y$ -, and  $z$ -axis. Setting the DataAspectRatio disables the stretch-to-fill behavior if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto.

The following table describes the interaction between properties when you disable stretch-to-fill behavior.

## Interaction Between Properties With Stretch-to-Fill Disabled

<b>X-, Y-, Z-LimitModes</b>	<b>DataAspectRatio</b>	<b>PlotBoxAspectRatio</b>	<b>Behavior</b>
auto	auto	auto	Limits chosen to span data range in all dimensions.
auto	auto	manual	Limits chosen to span data range in all dimensions. MATLAB modifies DataAspectRatio to achieve the requested PlotBoxAspectRatio

## Axes Properties

<b>X-, Y-, Z-LimitModes</b>	<b>DataAspectRatio</b>	<b>PlotBoxAspectRatio</b>	<b>Behavior</b>
			within the limits the software selected.
auto	manual	auto	Limits chosen to span data range in all dimensions. MATLAB modifies <code>PlotBoxAspectRatio</code> to achieve the requested <code>DataAspectRatio</code> within the limits the software selected.
auto	manual	manual	Limits chosen to completely fit and center the plot within the requested <code>PlotBoxAspectRatio</code> given the requested <code>DataAspectRatio</code> (this might produce empty space around 2 of the 3 dimensions).
manual	auto	auto	MATLAB honors limits and modifies the <code>DataAspectRatio</code> and <code>PlotBoxAspectRatio</code> as necessary.

# Axes Properties

<b>X-, Y-, Z-LimitModes</b>	<b>DataAspectRatio</b>	<b>PlotBoxAspectRatio</b>	<b>Behavior</b>
manual	auto	manual	MATLAB honors limits and PlotBoxAspectRatio and modifies DataAspectRatio as necessary.
manual	manual	auto	MATLAB honors limits and DataAspectRatio and modifies the PlotBoxAspectRatio as necessary.
1 manual 2 auto	manual	manual	MATLAB selects the 2 automatic limits to honor the specified aspect ratios and limit. See "Examples."
2 or 3 manual	manual	manual	MATLAB honors limits and DataAspectRatio while ignoringPlotBoxAspectRatio.

See “Understanding Axes Aspect Ratio” for more information.

DataAspectRatioMode  
{auto} | manual

*User or MATLAB controlled data scaling.* Controls whether the values of the DataAspectRatio property are user-defined or selected automatically by MATLAB. Setting values for the DataAspectRatio property automatically sets this property

to manual. Changing `DataAspectRatioMode` to manual disables the stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete axes callback function.* Executes when you delete the axes object (for example, when you issue a `delete` or `clf` command). MATLAB executes the routine before destroying the object's properties so the callback can query these values.

MATLAB passes the handle of the object whose `DeleteFcn` is executing as the first argument to the callback function. The handle is also accessible through the `Root CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DrawMode

{normal} | fast

*Rendering mode.* Controls the way MATLAB renders graphics objects displayed in the axes when the figure `Renderer` property is `painters`.

- `normal` — Draws objects in back to front ordering based on the current view in order to handle hidden surface elimination and object intersections.
- `fast` — Draws objects in the order in which you specify the drawing commands, without considering the relationships of the objects in three dimensions. This results in faster rendering because it requires no sorting of objects according to location in the view, but can produce undesirable results because it

# Axes Properties

---

bypasses the hidden surface elimination and object intersection handling provided by normal `DrawMode`.

When the figure `Renderer` property is `zbuffer`, MATLAB ignores `DrawMode` and always provides hidden surface elimination and object intersection handling.

## FontAngle

`{normal} | italic | oblique`

*Select italic or normal font.* Selects the character slant for axes text. `normal` specifies a nonitalic font. `italic` and `oblique` specify italic font.

## FontName

`name (such as Courier) | FixedWidth`

*Font family name.* Specifies the font to use for axes labels. To display and print properly, `FontName` must be a font that your system supports. Note that MATLAB does not display the  $x$ -,  $y$ -, and  $z$ -axis labels in a new font until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

## Specifying a Fixed-Width Font

If you want an axes to use a fixed-width font that looks good in any locale, set `FontName` to the string `FixedWidth`:

```
set(axes_handle, 'FontName', 'FixedWidth')
```

This eliminates the need to hardcode the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan, where character sets can be multibyte). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` (note that this string is case sensitive) and rely

on `FixedWidthFontName` to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`.

Note that setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

## FontSize

Font size specified in `FontUnits`

*Font size.* An integer specifying the font size to use for axes labels and titles, in units determined by the `FontUnits` property. The default point size is 12 and the maximum allowable font size depends on your operating system. MATLAB does not display *x*-, *y*-, and *z*-axis text labels in a new font size until you manually reset them (by setting the `XLabel`, `YLabel`, or `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

## FontUnits

{points} | normalized | inches | centimeters | pixels

*Units used to interpret the FontSize property.* When set to `normalized`, MATLAB interprets the value of `FontSize` as a fraction of the height of the axes. For example, a `normalized FontSize` of 0.1 sets the text characters to a font whose height is one tenth of the axes' height. The default units (`points`), are equal to 1/72 of an inch.

If you set both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB correctly interprets the specified `FontSize`.

## FontWeight

{normal} | bold | light | demi

# Axes Properties

---

*Select bold or normal font.* The character weight for axes text. MATLAB does not display the  $x$ -,  $y$ -, and  $z$ -axis text labels in bold until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` commands). Tick mark labels change immediately.

## GridLineStyle

- | -- | {:} | -. | none

*Line style used to draw grid lines.* The line style is a string consisting of a character, in quotes, specifying solid lines (-), dashed lines (--), dotted lines(:), or dash-dot lines (-.). The default grid line style is dotted. To turn on grid lines, use the `grid` command.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, functions that obtain handles by searching the object hierarchy or

querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When you restrict a handle's visibility by using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the Root's `CurrentFigure` property, objects do not appear in the Root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the Root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the axes can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click the axes. If `HitTest` is `off`, clicking the axes selects the object below it (which is usually the figure containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is

## Axes Properties

---

the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see “Control Callback Execution and Interruption”.

Layer

{bottom} | top

*Draw axis lines below or above graphics objects.* Determines whether to draw axis lines and tick marks on top or below axes children objects for any 2-D view (for example, when you are looking along the  $x$ -,  $y$ -, or  $z$ -axis). Use this property to place grid lines and tick marks on top of images.

LineStyleOrder

LineStyleSpec {a solid line '-'} }

*Order of line styles and markers used in a plot.* Specifies which line styles and markers to use and in what order when creating multiple-line plots. For example:

```
set(gca,'LineStyleOrder','-*|:|o')
```

sets `LineStyleOrder` to solid line with asterisk marker, dotted line, and hollow circle marker. The default is `(-)`, which specifies a solid line for all data plotted. Alternatively, you can create a cell array of character strings to define the line styles:

```
set(gca,'LineStyleOrder',{'-*',':','o'})
```

MATLAB supports four line styles, which you can specify any number of times in any order. MATLAB cycles through the line styles only after using all colors defined by the `ColorOrder` property. For example, the first eight lines plotted use the different colors defined by `ColorOrder` with the first line style. MATLAB then cycles through the colors again, using the second line style specified, and so on.

You can also specify line style and color directly with the `plot` and `plot3` functions or by altering the properties of the line or `lineseries` objects after creating the graph.

## High-Level Functions and LineStyleOrder

Note that, if the axes `NextPlot` property is `replace` (the default), high-level functions like `plot` reset the `LineStyleOrder` property before determining the line style to use. If you want MATLAB to use a `LineStyleOrder` that is different from the default, set `NextPlot` to `replacechildren`.

## Specifying a Default LineStyleOrder

You can specify your own default `LineStyleOrder`. For example:

```
set(0, 'DefaultAxesLineStyleOrder', {'-*', ':', 'o'})
```

creates a default value for the axes `LineStyleOrder` that high-level plotting functions will not reset.

### LineWidth

line width in points

*Width of axis lines.* Specifies the width, in points, of the  $x$ -,  $y$ -, and  $z$ -axis lines. The default line width is 0.5 points 1 point =  $1/72$  inch.

### MinorGridLineStyle

- | -- | {:} | -. | none

*Line style used to draw minor grid lines.* The line style is a string consisting of one or more characters, in quotes, specifying solid lines (-), dashed lines (--), dotted lines (:{), or dash-dot lines (-.). The default minor grid line style is dotted. To turn on minor grid lines, use the `grid minor` command.

### NextPlot

add | {replace} | replacechildren

*Where to draw the next plot.* Determines how high-level plotting functions draw into an existing axes.

- `add` — Use the existing axes to draw graphics objects.

- `replace` — Reset all axes properties except `Position` to their defaults and delete all axes children before displaying graphics (equivalent to `cla reset`).
- `replacechildren` — Remove all child objects, but do not reset axes properties (equivalent to `cla`).

The `newplot` function simplifies the use of the `NextPlot` property and is useful for functions that draw graphs using only low-level object creation routines. Note that figure graphics objects also have a `NextPlot` property.

## `OuterPosition`

four-element vector

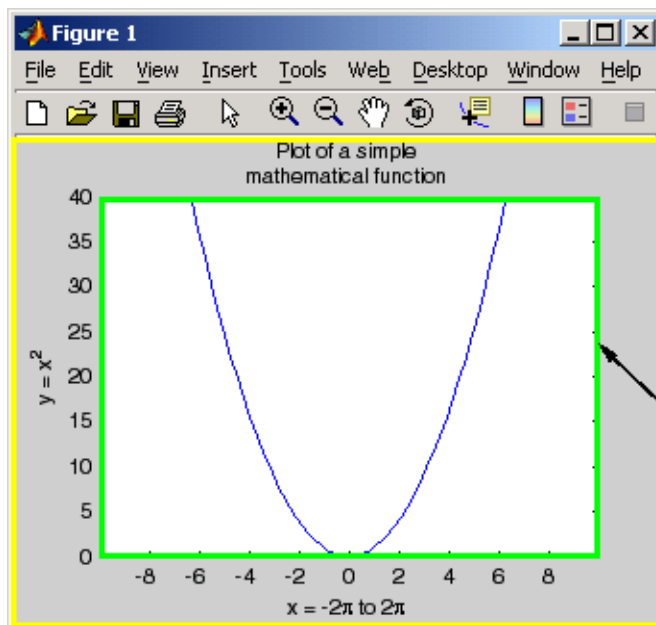

*Position of axes including labels, title, and a margin.* Specifies a rectangle that locates the outer bounds of the axes, including axis labels, the title, and a margin. The vector is as follows:

```
[left bottom width height]
```

where `left` and `bottom` define the distance from the lower-left corner of the figure window to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle.

The following picture shows the region defined by the `OuterPosition` enclosed in a yellow rectangle.

# Axes Properties

The yellow rectangle shows the extent of the OuterPosition.

The green rectangle shows the extent of the Position.

When `ActivePositionProperty` is `OuterPosition` (the default), resizing the figure will not clip any of the text. The default value of `[0 0 1 1]` (normalized units) includes the interior of the figure.

The `Units` property specifies all measurement units.

See the property for related information.

See “Automatic Axes Resize” for a discussion of how to use axes positioning properties.

Parent

figure or uipanel handle

*Axes parent.* The handle of the axes’ parent object. The parent of an axes object is the figure which displays it or the uipanel object that contains it. The utility function `gcf` returns the handle of

the current axes Parent. You can reparent axes to other figure or uipanel objects.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## PlotBoxAspectRatio

[px py pz]

*Relative scaling of axes plot box.* Controls the relative scaling of the plot box in the  $x$ ,  $y$ , and  $z$  directions. The plot box is a box enclosing the axes data region as defined by the  $x$ -,  $y$ -, and  $z$ -axis limits.

Note that the PlotBoxAspectRatio property interacts with the DataAspectRatio, XLimMode, YLimMode, and ZLimMode properties to control the way MATLAB displays graphics objects. Setting the PlotBoxAspectRatio disables stretch-to-fill behavior, if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto.

## PlotBoxAspectRatioMode

{auto} | manual

*User or MATLAB controlled axis scaling.* Controls whether the values of the PlotBoxAspectRatio property are user-defined or selected automatically by MATLAB. Setting values for the PlotBoxAspectRatio property automatically sets this property to manual. Changing the PlotBoxAspectRatioMode to manual disables stretch-to-fill behavior if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto.

## Position

four-element vector

*Position of axes.* Specifies a rectangle that locates the axes within its parent container (figure or uipanel). The vector is of the form:

# Axes Properties

---

`[left bottom width height]`

where `left` and `bottom` define the distance from the lower-left corner of the container to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle. The `Units` property specifies the units for all measurements.

When you enable axes stretch-to-fill behavior (when `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`), MATLAB stretches the axes to fill the `Position` rectangle. When you disable stretch-to-fill, MATLAB makes the axes as large as possible, while obeying all other properties, without extending outside the `Position` rectangle.

See the `OuterPosition` property for related information.

See “Automatic Axes Resize” for a discussion of how to use axes positioning properties.

## Projection

`{orthographic} | perspective`

*Type of projection.* Selects one of the following projection types:

- `orthographic` — Maintains the correct relative dimensions of graphics objects regarding the distance a given point is from the viewer and draws parallel lines in the data parallel on the screen.
- `perspective` — Incorporates foreshortening, which allows you to perceive depth in 2-D representations of 3-D objects. Perspective projection does not preserve the relative dimensions of objects; it displays a distant line segment smaller than a nearer line segment of the same length. Parallel lines in the data might not appear parallel on screen.

## Selected

`on | {off}`

*Is object selected?* When you set this property to on, MATLAB displays selection “handles” at the corners and midpoints if the `SelectionHighlight` property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to on, thereby indicating that the axes has been selected.

`SelectionHighlight`  
{on} | off

*Highlights objects when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

`Tag`  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, suppose you want to direct all graphics output from a file to a particular axes, regardless of user actions that might have changed the current axes. To do this, identify the axes with a `Tag`:

```
axes('Tag','Special Axes')
```

Then make that axes the current axes before drawing by searching for the `Tag` with `findobj`:

```
axes(findobj('Tag','Special Axes'))
```

`TickDir`  
in | out

# Axes Properties

---

*Direction of tick marks.* For 2-D views, the default is to direct tick marks inward from the axis lines; 3-D views direct tick marks outward from the axis line.

TickDirMode  
{auto} | manual

*Automatic tick direction control.* In `auto` mode, MATLAB directs tick marks inward for 2-D views and outward for 3-D views. When you specify a setting for `TickDir`, MATLAB sets `TickDirMode` to `manual`. In `manual` mode, MATLAB does not change the specified tick direction.

TickLength  
[2DLength 3DLength]

*Length of tick marks.* Specifies the length of axes tick marks. The first element is the length of tick marks used for 2-D views and the second element is the length of tick marks used for 3-D views. Specify tick mark lengths in units normalized relative to the longest of the visible  $x$ -,  $y$ -, or  $z$ -axis annotation lines.

TightInset  
[left bottom right top] Read only

*Margins added to Position to include text labels.* The distances between the bounds of the `Position` property and the extent of the axes text labels and title. When added to the `Position` width and height values, the `TightInset` defines the tightest bounding box that encloses the axes and its labels and title.

See “Automatic Axes Resize” for more information.

Title  
handle of text object

*Axes title.* The handle of the `text` object used for the axes title. Use this handle to change the properties of the title text or you can

set `Title` to the handle of an existing text object. For example, the following statement changes the color of the current title to red:

```
set(get(gca,'Title'),'Color','r')
```

To create a new title, set this property to the handle of the text object you want to use:

```
set(gca,'Title',text('String','New Title','Color','r'))
```

However, it is simpler to use the `title` command to create or replace an axes title:

```
title('New Title','Color','r') % Make text color red  
title({'This title','has 2 lines'}) % Two line title
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For axes objects, `Type` is always `'axes'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the axes.* Assign this property the handle of a `uicontextmenu` object created in the axes' parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the axes.

## Units

inches | centimeters | {normalized} | points | pixels  
| characters

# Axes Properties

---

*Axes position units.* The units used to interpret the `Position` property. MATLAB measures all units from the lower left corner of the figure window.

---

**Note** The `Units` property controls the positioning of the axes within the figure. This property does not affect the data units used for graphing. See the axes `XLim`, `YLim`, and `ZLim` properties to set the limits of each axis data units.

---

- `normalized` — Units map the lower left corner of the figure window to (0,0) and the upper right corner to (1.0, 1.0).
- `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

When specifying the units as property/value pairs during object creation, you must set the `Units` property before specifying the properties that you want to use these units.

`UserData`  
matrix

*User-specified data.* Data you want to associate with the axes object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`View`  
Obsolete

The axes camera properties now controls the functionality provided by the `View` property — `CameraPosition`, `CameraTarget`, `CameraUpVector`, and `CameraViewAngle`. See the `view` command.

## Visible

{on} | off

*Visibility of axes.* By default, axes are visible. Setting this property to `off` prevents axis lines, tick marks, and labels from being displayed. The `Visible` property does not affect children of axes.

## XAxisLocation

top | {bottom}

*Location of x-axis tick marks and labels.* Controls where MATLAB displays the *x*-axis tick marks and labels. Setting this property to `top` moves the *x*-axis to the top of the plot from its default position at the bottom. This property applies to 2-D views only.

## YAxisLocation

right | {left}

*Location of y-axis tick marks and labels.* Controls where MATLAB displays the *y*-axis tick marks and labels. Setting this property to `right` moves the *y*-axis to the right side of the plot from its default position on the left side. This property applies to 2-D views only. See the `ploty` function for a simple way to use two *y*-axes.

## Properties That Control the X-, Y-, or Z-Axis

### XColor

### YColor

### ZColor

ColorSpec

*Color of axis lines.* A three-element vector specifying an RGB triple, or a predefined MATLAB color string. This property determines the color of the axis lines, tick marks, tick mark labels, and the axis grid lines of the respective *x*-, *y*-, and *z*-axis. The default axis color is black. See `ColorSpec` for details on specifying colors.

# Axes Properties

---

XDir  
YDir  
ZDir

{normal} | reverse

*Direction of increasing values.* A mode controlling the direction of increasing axis values. Axes form a right-hand coordinate system. By default:

- *x*-axis values increase from left to right. To reverse the direction of increasing *x* values, set this property to `reverse`.

```
set(gca,'XDir','reverse')
```

- *y*-axis values increase from bottom to top (2-D view) or front to back (3-D view). To reverse the direction of increasing *y* values, set this property to `reverse`.

```
set(gca,'YDir','reverse')
```

- *z*-axis values increase pointing out of the screen (2-D view) or from bottom to top (3-D view). To reverse the direction of increasing *z* values, set this property to `reverse`.

```
set(gca,'ZDir','reverse')
```

XGrid  
YGrid  
ZGrid

on | {off}

*Axis gridline mode.* When you set any of these properties to `on`, MATLAB draws grid lines perpendicular to the respective axis (for example, along lines of constant *x*, *y*, or *z* values). Use the `grid` command to set all three properties `on` or `off` at once.

```
set(gca,'XGrid','on')
```

XLabel

YLabel

ZLabel

handle of text object

*Axis labels.* The handle of the text object used to label the  $x$ -,  $y$ -, or  $z$ -axis, respectively. To assign values to any of these properties, you must obtain the handle to the text string you want to use as a label. This statement defines a text object and assigns its handle to the XLabel property:

```
set(get(gca,'XLabel'),'String','axis label')
```

MATLAB places the string 'axis label' appropriately for an  $x$ -axis label and moves any text object whose handle you specify as an XLabel, YLabel, or ZLabel property to the appropriate location for the respective label.

Alternatively, you can use the `xlabel`, `ylabel`, and `zlabel` functions, which generally provide a simpler means to label axis lines.

Note that using a bitmapped font (for example, Courier is usually a bitmapped font) might cause the labels to rotate improperly. As a workaround, use a TrueType font (for example, Courier New) for axis labels. See your system documentation to determine the types of fonts installed on your system.

XLim

YLim

ZLim

[minimum maximum]

*Axis limits.* Specifies the minimum and maximum values of the respective axis. The data you plot determines these values.

# Axes Properties

---

Changing these properties affects the scale of the  $x$ -,  $y$ -, or  $z$ -dimension as well as the placement of labels and tick marks on the axis. The default values for these properties are [0 1].

See the `axis`, `datetick`, `xlim`, `ylim`, and `zlim` commands to set these properties.

```
XLimMode  
YLimMode  
ZLimMode  
    {auto} | manual
```

*MATLAB or user-controlled limits.* The axis limits mode determines whether MATLAB calculates axis limits based on the data plotted (for example, the `XData`, `YData`, or `ZData` of the axes children) or uses the values explicitly set with the `XLim`, `YLim`, or `ZLim` property, in which case, the respective limits mode is set to manual.

```
XMinorGrid  
YMinorGrid  
ZMinorGrid  
    on | {off}
```

*Enable or disable minor gridlines.* When set to on, MATLAB draws gridlines aligned with the minor tick marks of the respective axis. Note that you do not have to enable minor ticks to display minor grids.

```
XMinorTick  
YMinorTick  
ZMinorTick  
    on | {off}
```

*Enable or disable minor tick marks.* When set to on, MATLAB draws tick marks between the major tick marks of the respective axis. MATLAB automatically determines the number of minor ticks based on the space between the major ticks.

XScale

YScale

ZScale

{linear} | log

*Axis scaling.* Linear or logarithmic scaling for the respective axis. See also `loglog`, `semilogx`, and `semilogy`.

XTick

YTick

ZTick

vector of data values locating tick marks

*Tick spacing.* A vector of  $x$ -,  $y$ -, or  $z$ -data values that determine the location of tick marks along the respective axis. If you do not want tick marks displayed, set the respective property to the empty vector, `[]`. These vectors must contain monotonically increasing values.

XTickLabel

YTickLabel

ZTickLabel

string

*Tick labels.* A matrix of strings to use as labels for tick marks along the respective axis. These labels replace the numeric labels generated by MATLAB. If you do not specify enough text labels for all the tick marks, MATLAB uses all of the labels specified, then reuses the specified labels.

For example, the statement:

```
set(gca, 'XTickLabel', {'One'; 'Two'; 'Three'; 'Four'})
```

labels the first four tick marks on the  $x$ -axis and then reuses the labels for the remaining ticks.

# Axes Properties

---

Labels can be cell arrays of strings, padded string matrices, string vectors separated by vertical slash characters, or numeric vectors (where MATLAB implicitly converts each number to the equivalent string using `num2str`). All of the following are equivalent:

```
set(gca, 'XTickLabel', {'1'; '10'; '100'})
set(gca, 'XTickLabel', '1|10|100')
set(gca, 'XTickLabel', [1;10;100])
set(gca, 'XTickLabel', ['1  '; '10  '; '100'])
```

Note that tick labels do not interpret TeX character sequences (however, the `Title`, `XLabel`, `YLabel`, and `ZLabel` properties do).

```
XTickMode
YTickMode
ZTickMode
    {auto} | manual
```

*MATLAB or user-controlled tick spacing.* The axis tick modes determine whether MATLAB calculates the tick mark spacing based on the range of data for the respective axis (auto mode) or uses the values explicitly set for any of the `XTick`, `YTick`, and `ZTick` properties (manual mode). Setting values for the `XTick`, `YTick`, or `ZTick` properties sets the respective axis tick mode to manual.

```
XTickLabelMode
YTickLabelMode
ZTickLabelMode
    {auto} | manual
```

*MATLAB or user-determined tick labels.* The axis tick mark labeling modes determine whether MATLAB uses numeric tick mark labels that span the range of the plotted data (auto mode) or uses the tick mark labels specified with the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property (manual mode). Setting

values for the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property sets the respective axis tick label mode to manual.

**See Also**      `axes`

**Purpose** Axis scaling and appearance

**Syntax**

```
axis([xmin xmax ymin ymax])
axis([xmin xmax ymin ymax zmin zmax cmin cmax])
v = axis
axis auto
axis manual
axis tight
axis fill
axis ij
axis xy
axis equal
axis image
axis square
axis vis3d
axis normal
axis off
axis on
axis(axes_handles,...)
[mode,visibility,direction] = axis('state')
```

**Description** `axis` manipulates commonly used axes properties. (See Algorithm section.)

`axis([xmin xmax ymin ymax])` sets the limits for the  $x$ - and  $y$ -axis of the current axes.

`axis([xmin xmax ymin ymax zmin zmax cmin cmax])` sets the  $x$ -,  $y$ -, and  $z$ -axis limits and the color scaling limits (see `caxis`) of the current axes.

`v = axis` returns a row vector containing scaling factors for the  $x$ -,  $y$ -, and  $z$ -axis. `v` has four or six components depending on whether the current axes is 2-D or 3-D, respectively. The returned values are the current axes `XLim`, `Ylim`, and `ZLim` properties.

`axis auto` sets MATLAB default behavior to compute the current axes limits automatically, based on the minimum and maximum values of  $x$ ,  $y$ , and  $z$  data. You can restrict this automatic behavior to a specific

`axis`. For example, `axis 'auto x'` computes only the  $x$ -axis limits automatically; `axis 'auto yz'` computes the  $y$ - and  $z$ -axis limits automatically.

`axis manual` and `axis(axis)` freezes the scaling at the current limits, so that if `hold` is on, subsequent plots use the same limits. This sets the `XLimMode`, `YLimMode`, and `ZLimMode` properties to `manual`.

`axis tight` sets the axis limits to the range of the data.

`axis fill` sets the axis limits and `PlotBoxAspectRatio` so that the axes fill the position rectangle. This option has an effect only if `PlotBoxAspectRatioMode` or `DataAspectRatioMode` is `manual`.

`axis ij` places the coordinate system origin in the upper left corner. The  $i$ -axis is vertical, with values increasing from top to bottom. The  $j$ -axis is horizontal with values increasing from left to right.

`axis xy` draws the graph in the default Cartesian axes format with the coordinate system origin in the lower left corner. The  $x$ -axis is horizontal with values increasing from left to right. The  $y$ -axis is vertical with values increasing from bottom to top.

`axis equal` sets the aspect ratio so that the data units are the same in every direction. The aspect ratio of the  $x$ -,  $y$ -, and  $z$ -axis is adjusted automatically according to the range of data units in the  $x$ ,  $y$ , and  $z$  directions.

`axis image` is the same as `axis equal` except that the plot box fits tightly around the data.

`axis square` makes the current axes region square (or cubed when three-dimensional). This option adjusts the  $x$ -axis,  $y$ -axis, and  $z$ -axis so that they have equal lengths and adjusts the increments between data units accordingly.

`axis vis3d` freezes aspect ratio properties to enable rotation of 3-D objects and overrides `stretch-to-fill`.

`axis normal` automatically adjusts the aspect ratio of the axes and the relative scaling of the data units so that the plot fits the figure's shape as well as possible.

`axis off` turns off all axis lines, tick marks, and labels.

`axis on` turns on all axis lines, tick marks, and labels.

`axis(axes_handles,...)` applies the `axis` command to the specified axes. For example, the following statements

```
h1 = subplot(221);
h2 = subplot(222);
axis([h1 h2], 'square')
```

set both axes to square.

`[mode,visibility,direction] = axis('state')` returns three strings indicating the current setting of axes properties:

Output Argument	Strings Returned
mode	'auto'   'manual'
visibility	'on'   'off'
direction	'xy'   'ij'

mode is auto if `XLimMode`, `YLimMode`, and `ZLimMode` are all set to auto. If `XLimMode`, `YLimMode`, or `ZLimMode` is manual, mode is manual.

Keywords to `axis` can be combined, separated by a space (e.g., `axis tight equal`). These are evaluated from left to right, so subsequent keywords can overwrite properties set by prior ones.

## Tips

You can create an axes (and a figure for it) if none exists with the `axis` command. However, if you specify non-default limits or formatting for the axes when doing this, such as `[4 8 2 9]`, `square`, `equal`, or `image`, the property is ignored because there are no axis limits to adjust in the absence of plotted data. To use `axis` in this manner, you can set `hold on` to keep preset axes limits from being overridden.

**Examples**

The statements

```
x = 0:.01:pi/2;  
plot(x,tan(x),'-ro')
```

use the automatic scaling of the y-axis based on  $y_{\max} = \tan(1.57)$ , which is well over 1000:

The following figure shows a more satisfactory plot after typing `axis([0 pi/2 0 5])`

## Algorithms

When you specify minimum and maximum values for the  $x$ -,  $y$ -, and  $z$ -axes, `axis` sets the `XLim`, `YLim`, and `ZLim` properties for the current axes to the respective minimum and maximum values in the argument list. Additionally, the `XLimMode`, `YLimMode`, and `ZLimMode` properties for the current axes are set to `manual`.

`axis auto` sets the current axes `XLimMode`, `YLimMode`, and `ZLimMode` properties to `'auto'`.

`axis manual` sets the current axes `XLimMode`, `YLimMode`, and `ZLimMode` properties to 'manual'.

The following table shows the values of the axes properties set by `axis equal`, `axis normal`, `axis square`, and `axis image`.

<b>Axes Property or Behavior</b>	<b>axis equal</b>	<b>axis normal</b>	<b>axis square</b>	<b>axis image</b>
DataAspectRatio property	[1 1 1]	not set	not set	[1 1 1]
DataAspectRatioMode property	manual	auto	auto	manual
PlotBoxAspectRatio property	[3 4 4]	not set	[1 1 1]	auto
PlotBoxAspectRatioMode property	manual	auto	manual	auto
<i>Stretch-to-fill</i> behavior;	disabled	active	disabled	disabled

[axes](#) | [grid](#) | [subplot](#) | [xlim](#) | [ylim](#) | [zlim](#) | [axes properties](#)

# balance

---

**Purpose** Diagonal scaling to improve eigenvalue accuracy

**Syntax**

```
[T,B] = balance(A)
[S,P,B] = balance(A)
B = balance(A)
B = balance(A, 'noperm')
```

**Description** `[T,B] = balance(A)` returns a similarity transformation  $T$  such that  $B = T \backslash A * T$ , and  $B$  has, as nearly as possible, approximately equal row and column norms.  $T$  is a permutation of a diagonal matrix whose elements are integer powers of two to prevent the introduction of roundoff error. If  $A$  is symmetric, then  $B == A$  and  $T$  is the identity matrix.

`[S,P,B] = balance(A)` returns the scaling vector  $S$  and the permutation vector  $P$  separately. The transformation  $T$  and balanced matrix  $B$  are obtained from  $A$ ,  $S$ , and  $P$  by  $T(:,P) = \text{diag}(S)$  and  $B(P,P) = \text{diag}(1./S) * A * \text{diag}(S)$ .

`B = balance(A)` returns just the balanced matrix  $B$ .

`B = balance(A, 'noperm')` scales  $A$  without permuting its rows and columns.

## Tips

- Nonsymmetric matrices can have poorly conditioned eigenvalues. Small perturbations in the matrix, such as roundoff errors, can lead to large perturbations in the eigenvalues. The condition number of the eigenvector matrix,

$$\text{cond}(V) = \text{norm}(V) * \text{norm}(\text{inv}(V))$$

where

$$[V,T] = \text{eig}(A)$$

relates the size of the matrix perturbation to the size of the eigenvalue perturbation. Note that the condition number of  $A$  itself is irrelevant to the eigenvalue problem.

Balancing is an attempt to concentrate any ill conditioning of the eigenvector matrix into a diagonal scaling. Balancing usually cannot turn a nonsymmetric matrix into a symmetric matrix; it only attempts to make the norm of each row equal to the norm of the corresponding column.

---

**Note** The MATLAB eigenvalue function, `eig(A)`, automatically balances  $A$  before computing its eigenvalues. Turn off the balancing with `eig(A, 'nobalance')`.

---

## Examples

This example shows the basic idea. The matrix  $A$  has large elements in the upper right and small elements in the lower left. It is far from being symmetric.

```
A = [1  100  10000; .01  1  100; .0001  .01  1]
A =
    1.0e+04 *
    0.0001    0.0100    1.0000
    0.0000    0.0001    0.0100
    0.0000    0.0000    0.0001
```

Balancing produces a diagonal matrix  $T$  with elements that are powers of two and a balanced matrix  $B$  that is closer to symmetric than  $A$ .

```
[T,B] = balance(A)
T =
    1.0e+03 *
    2.0480         0         0
         0    0.0320         0
         0         0    0.0003
B =
    1.0000    1.5625    1.2207
```

# balance

---

```
0.6400    1.0000    0.7813
0.8192    1.2800    1.0000
```

To see the effect on eigenvectors, first compute the eigenvectors of A, shown here as the columns of V.

```
[V,E] = eig(A); V
V =
0.9999    -0.9999    -0.9999
0.0100     0.0059 + 0.0085i    0.0059 - 0.0085i
0.0001     0.0000 - 0.0001i    0.0000 + 0.0001i
```

Note that all three vectors have the first component the largest. This indicates V is badly conditioned; in fact  $\text{cond}(V)$  is  $8.7766\text{e}+003$ . Next, look at the eigenvectors of B.

```
[V,E] = eig(B); V
V =
0.6933    -0.6993    -0.6993
0.4437     0.2619 + 0.3825i    0.2619 - 0.3825i
0.5679     0.2376 - 0.4896i    0.2376 + 0.4896i
```

Now the eigenvectors are well behaved and  $\text{cond}(V)$  is 1.4421. The ill conditioning is concentrated in the scaling matrix;  $\text{cond}(T)$  is 8192.

This example is small and not really badly scaled, so the computed eigenvalues of A and B agree within roundoff error; balancing has little effect on the computed results.

## Limitations

Balancing can destroy the properties of certain matrices; use it with some care. If a matrix contains small elements that are due to roundoff error, balancing might scale them up to make them as significant as the other elements of the original matrix.

## See Also

`eig`

**Purpose**

Bar graph

**Syntax**

```
bar(Y)
bar(x,Y)

bar( ____,width)
bar( ____,style)
bar( ____,bar_color)
bar( ____,Name,Value)

bar(axes_handle, ____)

h = bar( ____)
```

**Description**

`bar(Y)` draws one bar for each element in `Y`.

`bar(x,Y)` draws bars for each column in `Y` at locations specified in `x`.

`bar( ____,width)` sets the relative bar width and controls the separation of bars within a group and can include any of the input arguments in previous syntaxes.

`bar( ____,style)` specifies the style of the bars and can include any of the input arguments in previous syntaxes.

`bar( ____,bar_color)` displays all bars using the color specified by the single-letter abbreviation of `bar_color` and can include any of the input arguments in previous syntaxes.

`bar( ____,Name,Value)` sets the property names to the specified values and can include any of the input arguments in previous syntaxes.

---

**Note** You cannot specify names and values when using `hist` or `histc` options.

---

`bar(axes_handle, ___)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar(___)` returns a vector of handles to `barseries` graphics objects, one for each created.

Change the colormap to use a different color scheme. Use the `colormap` function to specify the figure colormap.

Use shading `flat` to turn off bar edges. Use shading `faceted` to turn on bar edges. See the `shading` function for more information.

## Input Arguments

### **x - x-axis intervals**

vector | 2-D array

x-axis intervals for vertical bars, specified as a vector or a 2-D array..

The *x*-values can be nonmonotonic, but cannot contain duplicate values.

**Example:** `x = 1:10;`

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Y - Bar lengths**

vector | 2-D array

Bar lengths, specified as a vector or a 2-D array.

- If *Y* is a vector, then `bar` creates `length(Y)` bars. The `bar` function treats all vectors as column vectors.
- If *Y* is a 2-D array, then `bar` groups the bars produced by the elements in each row.

- If  $Y$  is complex, then `bar(Y)` plots the imaginary parts of  $Y$  versus the index of each entry. If either  $x$  or  $Y$  is complex, then `bar(x,Y)` ignores the imaginary parts and plots the real parts of  $Y$  versus the real parts of  $x$ .

**Example:** `y = [10,8,5,7,3,9,1];`

#### **Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |  
`uint16` | `uint32` | `uint64`

#### **width - Bar width**

`0.8` (default) | `scalar`

Bar width of each bar, specified as a fraction of the total width of a bar and the space between bars. The default of 0.8 means the a bar width is 80% of the space from the previous bar to the next bar, with 10% of that space on each side.

If width is 1, the bars within a group touch one another.

**Example:** `bar(y,0.5);`

#### **Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |  
`uint16` | `uint32` | `uint64`

#### **style - Bar style, specified as one of the following strings**

`'grouped'` (default) | `'stacked'` | `'hist'` | `'histc'`

Bar style, specified by one of these values.

# bar

---

Style	Purpose
'grouped'	<p>Displays one group for each row in <math>Y</math>.</p> <ul style="list-style-type: none"><li>• If <math>Y</math> is an <math>m</math>-by-<math>n</math> matrix, then MATLAB displays <math>m</math> groups of <math>n</math> vertical bars, where <math>m</math> is the number of rows and <math>n</math> is the number of columns in <math>Y</math>.</li><li>• If <math>Y</math> is a vector of length <math>n</math>, then MATLAB treats <math>Y</math> as a column vector and displays one group of <math>n</math> bars.</li></ul>
'stacked'	<p>Displays one bar for each row in <math>Y</math>.</p> <ul style="list-style-type: none"><li>• If <math>Y</math> is an <math>m</math>-by-<math>n</math> matrix, then MATLAB displays <math>m</math> bars where each bar height is the sum of the elements in the row. Each bar is multicolored. Colors correspond to distinct elements and show the relative contribution each row element makes to the total sum.</li><li>• If <math>Y</math> is a vector of length <math>n</math>, then MATLAB treats <math>Y</math> as a column vector and displays <math>n</math> bars.</li></ul>

Style	Purpose
'histc'	Displays the graph in histogram format, in which bars touch one another.
'hist'	Displays the graph in histogram format, but centers each bar over the <i>x</i> -ticks, rather than making bars span <i>x</i> -ticks as the <code>histc</code> option does.

**Example:** `bar(Y,'hist')`

### Data Types

char

### bar\_color - Bar color

'b' | 'r' | 'g' | 'b' | 'c' | 'm' | 'y' | 'k' | 'w'

Bar color, specified as a single-letter abbreviation, assigns the color specified to all bars.

**Example:** `bar(Y,'r')`

### Data Types

char

### axes\_handle - Axes handle

Current axes (default) | Axes handle

Axes handle specifying the target axes for the bar graph.

**Example:** `bar(ah,Y);`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

For more information see “Barseries Property Descriptions” on page 1-459.

**Example:** `bar(Y, 'EdgeColor', 'g')`

## **'BarLayout' - Arrangement of bars**

grouped (default) | stacked

Arrangement of bars, specified as the comma-separated pair consisting of 'BarLayout' and one of these values:

- **grouped** — Display  $m$  groups of  $n$  vertical bars, where  $m$  is the number of rows and  $n$  is the number of columns in the input argument  $Y$ . The group contains one bar per column in  $Y$ .
- **stacked** — Display one bar for each row in the input argument  $Y$ . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

## **'BaseValue' - Base line location**

0 (default) | scalar

Base line location, specified as the comma-separated pair consisting of 'BaseValue' and the value along the  $y$ -axis (vertical bars) or  $x$ -axis (horizontal bars) at which MATLAB draws the baseline.

## **'BarWidth' - Relative width of bars**

0.8 (default) | scalar

Relative bar width, specified as the comma-separated pair consisting of 'BarWidth' and a value relative to width and spacing. **BarWidth** controls the separation of bars within a group. By default, the bars within a group have a slight separation. A value of 1 makes bars touch with no space. A value greater than 1 makes the bars overlap.

## **'EdgeColor' - Color of bar edges**

[0,0,0] (default) | none | ColorSpec

Color of bar edges, specified as the comma-separated pair consisting of 'EdgeColor' and a three-element RGB vector, or one of the MATLAB predefined color specifier names.

#### **'FaceColor' - Color of bars**

flat (default) | none | ColorSpec

Color of bars, specified as the comma-separated pair consisting of 'FaceColor' and one of these values:

- flat — Use the figure colormap to determine the color of the bars.
- ColorSpec — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all bars.
- none — Do not draw faces. Note that MATLAB draws EdgeColor independently of FaceColor.

#### **'LineStyle' - Line style of bar edges**

— (default) | - | -- | : | -. | none

Line style of bar edges, specified as the comma-separated pair consisting of 'LineStyle' and one of the predefined line style strings.

#### **'LineWidth' - Width of bar edges**

0.5 points (default) | Scalar width specified in points

Width of bar edges, specified as the comma-separated pair consisting of 'LineWidth' and a scalar value representing the line width in points.

## **Output Arguments**

### **h - Handle to barseries objects**

Array of one or more handles

Handle to barseries objects, returned as an array of one or more handles.

## **Examples**

### **Single Data Series**

Use the bar function to plot vector data.

```
y = [75.995,91.972,105.711,123.203,131.669,...
     150.697,179.323,203.212,226.505,249.633,281.422];
```

# bar

```
figure; bar(y);
```

## X-Axis Tick Labels

Specify the numeric values of the x-axis tick labels.

```
x = 1900:10:2000;  
y = [75.995,91.972,105.711,123.203,131.669,...  
     150.697,179.323,203.212,226.505,249.633,281.422];  
figure; bar(x,y);
```

Plot  $y$  values at each  $x$  value. Notice that the  $\text{length}(x)$  and  $\text{length}(y)$  have to be same.

### Bar Width

Set width of each bar to 40 percent of the total space available for each bar.

```
y = [75.995,91.972,105.711,123.203,131.669,...  
      150.697,179.323,203.212,226.505,249.633,281.422];  
figure; bar(y,0.4);
```

# bar

---

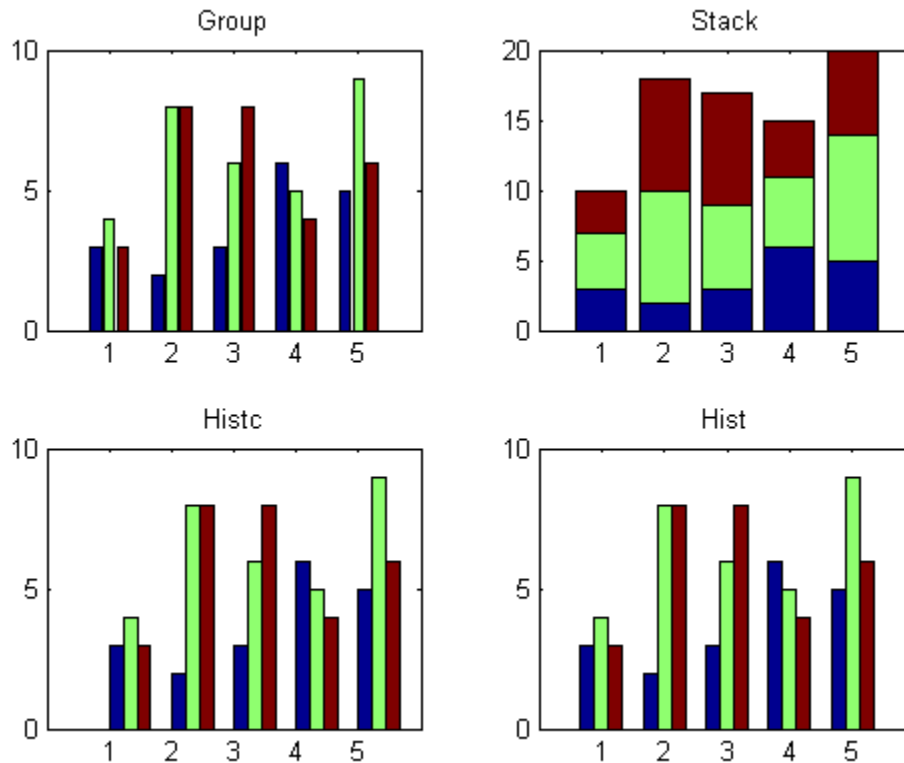

## Bar Graph Styles

Create a 2x2 subplot with different styles applied to each bar graph.

```
Y = round(rand(5,3)*10);  
figure;  
subplot(2,2,1); bar(Y,'grouped'); title('Group')  
subplot(2,2,2); bar(Y,'stacked'); title('Stack')  
subplot(2,2,3); bar(Y,'histc'); title('Histc')  
subplot(2,2,4); bar(Y,'hist'); title('Hist')
```

### Specify Axes

Specify axes handle in the call to `bar`.

```
newY = round(rand(5,3)*10);  
ah = subplot(2,2,2);  
bar(ah,newY,'stacked'); title('New Graph')
```

# bar

## Bar Color

Specify red color for the bar graph.

```
y = [75.995,91.972,105.711,123.203,131.669,...  
      150.697,179.323,203.212,226.505,249.633,281.422];  
figure; bar(y,'r');
```

### Bar Face and Edge Color

Specify green bars and use an RGB color specification for the bar edge color.

```
y = [75.995,91.972,105.711,123.203,131.669,...  
      150.697,179.323,203.212,226.505,249.633,281.422];  
figure; bar(y,'g','EdgeColor',[1,0.5,0.5]);
```

# bar

---

## Bar Graph of 2-D Array

Plot a 6-by-3 array as six groups with three bars each.

```
c = load('count.dat');  
Y = c(1:6,:);  
figure; bar(Y);
```

### Emphasize Subset of Data

Set appearance of one column of data.

Set `LineWidth` and `EdgeColor` for the bars representing the second column in the data array `y`. Pass the handles returned by `bar` to the `set` function to set the barseries properties.

```
c = load('count.dat');  
Y = c(1:6,:);  
hArray = bar(Y);
```

# bar

```
set(hArray(2),'LineWidth',2,'EdgeColor','red');
```

## Related Examples

- [""](#)
- [""](#)
- [""](#)

**Purpose** Plot bar graph horizontally

**Syntax**

```
barh(Y)
barh(X,Y)
barh(...,width)
barh(...,'style')
barh(...,'bar_color')
barh(...,'PropertyName',PropertyValue,...)
barh(axes_handle,...)
h = barh(...)
```

**Description**

A barh graph displays the values in a vector or matrix as horizontal bars.

`barh(Y)` draws one horizontal bar for each element in `Y`. If `Y` is a matrix, `barh` groups the bars produced by the elements in each row. The `x`-axis scale ranges from 1 up to `length(Y)` when `Y` is a vector, and 1 to `size(Y,1)`, which is the number of rows, when `Y` is a matrix. The default is to assign an appropriate progression of tick values according to the data. If you want the `x`-axis scale to end exactly at the last bar, set the axis limits as,

```
set(gca,'XLim',[1 length(Y)])
```

`barh(X,Y)` draws a bar for each element in `Y` at locations specified in `x`, where `X` is a vector defining the `x`-axis intervals for the vertical bars. The `x`-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `barh` groups the elements of each row in `Y` at corresponding locations in `X`.

`barh(...,width)` sets the relative bar width and controls the separation of bars within a group. The default `width` is 0.8, so if you do not specify `X`, the bars within a group have a slight separation. If

# barh

---

`width` is 1, the bars within a group touch one another. The value of `width` must be a scalar.

`barh(..., 'style')` specifies the style of the bars. `'style'` is `'grouped'` or `'stacked'`. Default mode of display is `'grouped'`.

- `'grouped'` displays  $m$  groups of  $n$  vertical bars, where  $m$  is the number of rows and  $n$  is the number of columns in  $Y$ . The group contains one bar per column in  $Y$ .
- `'stacked'` displays one bar for each row in  $Y$ . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.
- `'histc'` displays the graph in histogram format, in which bars touch one another.
- `'hist'` also displays the graph in histogram format, but centers each bar over the  $x$ -ticks, rather than making bars span  $x$ -ticks as the `histc` option does.

---

**Note** When you use either the `hist` or `histc` option, you cannot also use parameter/value syntax. These two options create graphic objects that are patches rather than barseries.

---

`barh(..., 'bar_color')` displays all bars using the color specified by the single-letter abbreviation `'r'`, `'g'`, `'b'`, `'c'`, `'m'`, `'y'`, `'k'`, or `'w'`.

`barh(..., 'PropertyName', PropertyValue, ...)` sets the named property or properties to the specified values. You cannot specify properties when `hist` or `histc` options are used. See the barseries property descriptions for information on what properties you can set.

`barh(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

---

`h = barh(...)` returns a vector of handles to barseries graphics objects, one for each created. When  $Y$  is a matrix, `barh` creates one barseries graphics object per column in  $Y$ .

## Barseries Objects

Creating a bar graph of an  $m$ -by- $n$  matrix creates  $m$  groups of  $n$  barseries objects. Each barseries object contains the data for corresponding  $x$  values of each bar group (as indicated by the coloring of the bars).

## Examples

### Horizontal Bar Graph of Single Data Series

Create a horizontal bar graph of vector data.

```
y = [57,91,105,123,131,150,...  
     170,203,226.5,249,281.4];  
figure;  
barh(y);
```

# barh

`barh` draws one horizontal bar for each element in `y`.

## **Specify Width for Horizontal Bar Graph**

Specify the bar width to 0.4.

```
y = [57,91,105,123,131,150,...  
      170,203,226.5,249,281.4];
```

```
figure;
```

```
width = 0.4;  
barh(y,width);
```

### Specify Style for Horizontal Bar Graph

Create a figure with four subplots. In each subplot, create a horizontal bar graph using a different style option for each graph.

```
x = [2,4];  
y = [1,2,3,4;...]
```

# barh

---

```
    5,6,7,8];

figure;
subplot(2,2,1);
barh(x,y,'grouped'); % groups by row
title('Grouped Style')

subplot(2,2,2);
barh(x,y,'stacked'); % stacks values in each row together
title('Stacked Style')

subplot(2,2,3);
barh(x,y,'hist'); % centers bars over x values
title('hist Style')

subplot(2,2,4);
barh(x,y,'histc'); % spans bars over x values
title('histc Style')
```

### Specify Color for Horizontal Bar Graph

Create a horizontal bar graph and change the color of the bars to red.

```
y = [57,91,105,123,131,150,...
      170,203,226.5,249,281.4];
figure
barh(y, 'r')
```

# barh

---

## Specify Bar Properties Using Name-Value Pairs

Create a horizontal bar graph and set the line width to 2. Use RGB color values to set the face color and the edge color for the bars.

```
y = [57,91,105,123,131,150,...  
      170,203,226.5,249,281.4];
```

```
figure  
barh(y, 'FaceColor', [0,0.5,0.5], ...
```

```
'EdgeColor',[0,0,0.9],...  
'LineWidth',2)
```

### Specify Horizontal Bar Locations

Set up x and y as vectors of data.

```
x = 1900:10:2000;  
y = [57,91,105,123,131,150,...  
     170,203,226.5,249,281.4];
```

# barh

---

Create a horizontal bar graph of the data in `y`. Use `x` to specify the bar locations along the `y`-axis.

```
figure  
barh(x,y)
```

## Horizontal Bar Graph of Matrix Data

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat;  
y = count(1:6,:);
```

Create a horizontal bar graph of matrix `y`.

```
figure;  
barh(y);
```

# barh

---

By default, `barh` groups the bars by row.

## **Specify Bar Properties for Multiple Barseries Objects**

Load the data set, `count.dat`, which returns a three-column array, `count`. Store `y` as the first six rows of `count`.

```
load count.dat;  
y = count(1:6,:);
```

Create a horizontal bar graph of `y` and return the handles to the three barseries objects. Set the line width and line style for all three sets of bars.

```
figure
h = barh(y,'LineWidth',2,...
         'LineStyle',':');
```

# barh

---

Use the barseries object handles to set Name-Value pairs for a specific barseries object. Set the face color for the first barseries object to cyan. Set the face color for the last barseries object to an RGB color value.

```
set(h(1), 'FaceColor', 'c')  
set(h(3), 'FaceColor', [0,0.5,0.5])
```

## Change Baseline Value for Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat;  
y = count(1:6,:);
```

Create a horizontal bar graph of `y` and set the basevalue to 25.

```
figure  
barh(y, 'BaseValue', 25);
```

# barh

Properties

## How To

- `""`
- `""`
- `""`

**Purpose**

Plot 3-D bar graph

**Syntax**

```
bar3(Y)
bar3(x,Y)
bar3(...,width)
bar3(...,'style')
bar3(...,LineStyle)
bar3(axes_handle,...)
h = bar3(...)
```

**Description**

`bar3` draws a three-dimensional bar graph.

`bar3(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the `x`-axis scale ranges from 1 to `length(Y)`. When `Y` is a matrix, the `x`-axis scale ranges from 1 to `size(Y,1)` and the elements in each row are grouped together.

`bar3(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the `y`-axis intervals for vertical bars. The `x`-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3(...,width)` sets the width of the bars and controls the separation of bars within a group. The default width is 0.8, so if you do not specify `x`, bars within a group have a slight separation. If width is 1, the bars within a group touch one another.

`bar3(...,'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. Default mode of display is `'detached'`.

# bar3

---

- 'detached' displays the elements of each row in  $Y$  as separate blocks behind one another in the  $x$  direction.
- 'grouped' displays  $n$  groups of  $m$  vertical bars, where  $n$  is the number of rows and  $m$  is the number of columns in  $Y$ . The group contains one bar per column in  $Y$ .
- 'stacked' displays one bar for each row in  $Y$ . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3(...,LineStyle)` displays all bars using the color specified by `LineStyle`.

`bar3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3(...)` returns a vector of handles to surface objects, one for each created. When  $Y$  is a matrix, `bar3` creates one surface object per column in  $Y$ .

## Examples

### Create 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store  $Y$  as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of  $Y$ . By default, the style is `detached`.

```
figure
bar3(Y)
title('Detached Style')
```

### Specify Bar Width for 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat  
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y` and set the bar width to 0.5.

# bar3

```
width = 0.5;  
  
figure  
bar3(Y,width)  
title('Bar Width of 0.5')
```

## 3-D Bar Graph with Grouped Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat  
Y = count(1:10,:);
```

Create a 3-D bar graph of  $Y$ . Group the elements in each row of  $Y$  by specifying the style option as `grouped`.

```
figure  
bar3(Y, 'grouped')  
title('Grouped Style')
```

## 3-D Bar Graph with Stacked Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat  
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. Stack the elements in each row of `Y` by specifying the style option as `stacked`.

```
figure  
bar3(Y, 'stacked')  
title('Stacked Style')
```

**See Also**

**How To**

• [“”](#)

# bar3h

---

**Purpose** Plot horizontal 3-D bar graph

**Syntax**

```
bar3h(Y)
bar3h(x,Y)
bar3h(...,width)
bar3h(...,'style')
bar3h(...,LineStyle)
bar3h(axes_handle,...)
h = bar3h(...)
```

**Description** bar3h draws three-dimensional horizontal bar charts.

bar3h(Y) draws a three-dimensional bar chart, where each element in Y corresponds to one bar. When Y is a vector, the y-axis scale ranges from 1 to length(Y). When Y is a matrix, the y-axis scale ranges from 1 to size(Y,1) and the elements in each row are grouped together.

bar3h(x,Y) draws a bar chart of the elements in Y at the locations specified in x, where x is a vector defining the y-axis intervals for horizontal bars. The x-values can be nonmonotonic, but cannot contain duplicate values. If Y is a matrix, bar3 clusters elements from the same row in Y at locations corresponding to an element in x. Values of elements in each row are grouped together.

bar3h(...,width) sets the width of the bars and controls the separation of bars within a group. The default width is 0.8, so if you do not specify x, bars within a group have a slight separation. If width is 1, the bars within a group touch one another.

bar3h(...,'style') specifies the style of the bars. 'style' is 'detached', 'grouped', or 'stacked'. Default mode of display is 'detached'.

- 'detached' displays the elements of each row in Y as separate blocks behind one another in the y direction.

- 'grouped' displays  $n$  groups of  $m$  vertical bars, where  $n$  is the number of rows and  $m$  is the number of columns in  $Y$ . The group contains one bar per column in  $Y$ .
- 'stacked' displays one bar for each row in  $Y$ . The bar length is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3h(...,LineStyle)` displays all bars using the color specified by `LineStyle`.

`bar3h(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3h(...)` returns a vector of handles to surface objects, one for each created. When  $Y$  is a matrix, `bar3h` creates one surface object per column in  $Y$ .

## Examples

### Create 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store  $Y$  as the first ten rows of `count`.

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of  $Y$ . By default, the style is `detached`.

```
figure  
bar3h(Y)
```

## Specify Bar Width for 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y` and set the bar width to 0.5.

```
width = 0.5;  
  
figure  
bar3h(Y,width)  
title('Width of 0.5')
```

### 3-D Horizontal Bar Graph with Grouped Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

# bar3h

---

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of Y and specify the style option as grouped.

```
figure  
bar3h(Y, 'grouped')  
title('Grouped Style Option')
```

### 3-D Horizontal Bar Graph with Stacked Option

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y` and specify the style option as `stacked`.

```
figure  
bar3h(Y,'stacked')  
title('Stacked Style Option')
```

# bar3h

---

## See Also

## Purpose

Define barseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for barseries objects.

See “Plot Objects” for more information on barseries objects.

## Barseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of barseries objects in legends.* Specifies whether this barseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the barseries object is displayed in a figure legend.

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Include the barseries object in a legend as one entry, but not its children objects
off	Do not include the barseries or its children in a legend (default)
children	Include only the children of the barseries as separate entries in the legend

# Barseries Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

`BarLayout`  
{grouped} | stacked

*Specify grouped or stacked bars.*

- `grouped` — Display  $m$  groups of  $n$  vertical bars, where  $m$  is the number of rows and  $n$  is the number of columns in the input argument  $Y$ . The group contains one bar per column in  $Y$ .
- `stacked` — Display one bar for each row in the input argument  $Y$ . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`BarWidth`  
scalar in range [0 1]

*Width of individual bars.* `BarWidth` specifies the relative bar width and controls the separation of bars within a group. The default is 0.8, so if you do not specify  $x$ , the bars within a group have a slight separation. If `BarWidth` is 1, the bars within a group touch one another.

`BaseLine`  
handle

*Handle of the baseline line object.* Handle of the line object used as the baseline. You can set the properties of this line using its handle.

Create a bar graph, obtain the handle of the baseline from the barseries object, and then set line properties that make the baseline a dashed, red line:

```
bar_handle = bar(randn(10,1));  
baseline_handle = get(bar_handle,'BaseLine');  
set(baseline_handle,'LineStyle','--','Color','red')
```

BaseValue  
double: y-axis value

# Barseries Properties

---

*Baseline location.* You can specify the value along the *y*-axis (vertical bars) or *x*-axis (horizontal bars) at which the MATLAB software draws the baseline. The default is 0.

**BeingDeleted**  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the **BeingDeleted** property to **on** when the object's delete function callback is called (see the **DeleteFcn** property). It remains set to **on** while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-to-be-deleted object, it can check the object's **BeingDeleted** property before acting.

**BusyAction**  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See `Function Handle Callbacks` for information on how to use function handles to define the callback function.

## `Children`

array of graphics object handles

*Children of the barseries object.* The handle of a patch object that is the child of this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

# Barseries Properties

---

```
set(0, 'ShowHiddenHandles', 'on')
```

Clipping  
{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

CreateFcn  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the barseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

## Barseries Properties

---

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

### EdgeColor

`{[0 0 0]} | none | ColorSpec`

*Color of line separating filled areas.* You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default value is `[0 0 0]` (black). See the `ColorSpec` reference page for more information on specifying color.

### EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However,

the object's color depends on the color of whatever is beneath it on the display.

- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`

`{flat} | none | ColorSpec`

*Color of filled areas.*

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- **none** — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.

# Barseries Properties

---

- `flat` — The object uses the figure colormap to determine the color of the filled areas.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

### HitTest

`{on}` | `off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the bar graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

### HitTestArea

`on` | `{off}`

*Select barseries object on bars or area of extent.* This property enables you to select barseries objects in two ways:

- Select by clicking bars (default).

# Barseries Properties

---

- Select by clicking anywhere in the extent of the bar graph.

When `HitTestArea` is off, you must click the bars to select the `barseries` object. When `HitTestArea` is on, you can select the `barseries` object by clicking anywhere within the extent of the bar graph (that is, anywhere within a rectangle that encloses all the bars).

`Interruptible`  
off | {on}

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of barseries object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

# Barseries Properties

---

## LineWidth

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.

## Parent

handle of parent axes, hgroup, or hgtransform

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hgroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

## SelectionHighlight

{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

## ShowBaseLine

{on} | off

*Turn baseline display on or off.* This property determines whether bar plots display a baseline from which the bars are drawn. By default, the baseline is displayed.

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create a `barseries` object and set the `Tag` property:

```
t = bar(Y, 'Tag', 'bar1')
```

To access the `barseries` object, use `findobj` to find the `barseries` object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `bar1`.

```
set(findobj('Tag', 'bar1'), 'FaceColor', 'red')
```

Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For `barseries` objects, `Type` is `'hgroup'`.

The following statement finds all the `hgroup` objects in the current axes.

```
t = findobj(gca, 'Type', 'hgroup');
```

UIContextMenu

handle of `uicontextmenu` object

# Barseries Properties

---

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

**UserData**  
array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

**Visible**  
{on} | off

*Visibility of object and its children.*

- **on** — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

**XData**  
array

*Location of bars.* The  $x$ -axis intervals for the vertical bars or  $y$ -axis intervals for horizontal bars (as specified by the `X` input argument). If `YData` is a vector, `XData` must be the same size. If `YData` is a matrix, the length of `XData` must be equal to the number of rows in `YData`.

**XDataMode**  
{auto} | manual

*Use automatic or user-specified  $x$ -axis values.* If you specify `XData` (by setting the `XData` property or specifying the `X` input

argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

## `XDataSource`

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## `YData`

scalar | vector | matrix

*Bar plot data.* `YData` contains the data plotted as bars (the *Y* input argument). Each value in `YData` is represented by a bar in the bar graph. If `XYData` is a matrix, the `bar` function creates a "group"

# Barseries Properties

---

or a "stack" of bars for each column in the matrix. See the bar reference page for examples of grouped and stacked bar graphs.

The input argument *Y* in the bar function calling syntax assigns values to *YData*.

## *YDataSource*

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the *YData*. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's *YDataSource* does not change the object's *YData* values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## How To

- “”
- “Plot Objects”
- “Setting Default Property Values”
- “The Property Editor”

**Purpose** (Will be removed) Convert point coordinates from barycentric to Cartesian

---

**Note** `baryToCart(TriRep)` will be removed in a future release. Use `barycentricToCartesian(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `XC = baryToCart(TR, SI, B)`

**Description** `XC = baryToCart(TR, SI, B)` returns the Cartesian coordinates `XC` of each point in `B` that represents the barycentric coordinates with respect to its associated simplex `SI`.

**Input Arguments**

- `TR` Triangulation representation.
- `SI` Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`
- `B` `B` is a matrix that represents the barycentric coordinates of the points to convert with respect to the simplices `SI`. `B` is of size `m-by-k`, where `m = length(SI)`, the number of points to convert, and `k` is the number of vertices per simplex.

**Output Arguments**

- `XC` Matrix of cartesian coordinates of the converted points. `XC` is of size `m-by-n`, where `n` is the dimension of the space where the triangulation resides. That is, the Cartesian coordinates of the point `B(j)` with respect to simplex `SI(j)` is `XC(j)`.

**Definitions** A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';  
y = [0 0 0 0 8 8 8 8]';  
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);  
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure  
subplot(1,2,1);  
triplot(dt); hold on;  
plot(cc(:,1), cc(:,2), '*r'); hold off;  
axis equal;
```

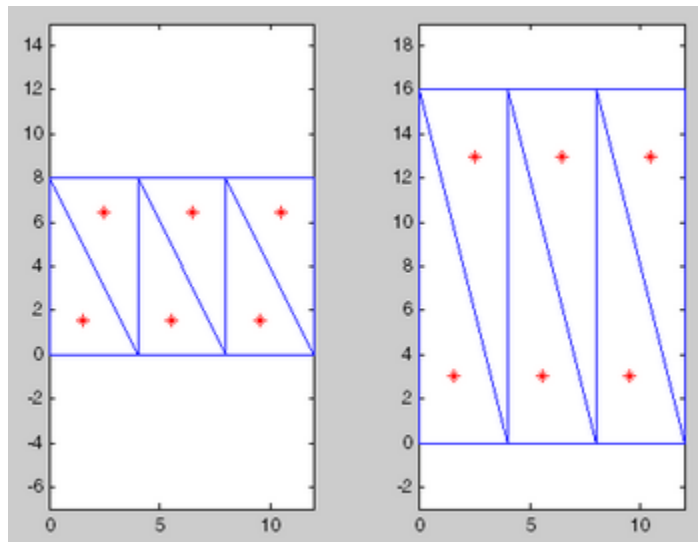

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);  
y = [0 0 0 0 16 16 16 16]';  
tr = TriRep(tri,x,y)  
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);  
triplot(tr); hold on;  
plot(xc(:,1), xc(:,2), '*r'); hold off;  
axis equal;
```

[cartesianToBarycentric](#) | [pointLocation](#) | [delaunayTriangulation](#)  
| [triangulation](#)

# base2dec

---

**Purpose** Convert base N number string to decimal number

**Syntax** `d = base2dec('strn', base)`

**Description** `d = base2dec('strn', base)` converts the string number *strn* of the specified base into its decimal (base 10) equivalent. *base* must be an integer between 2 and 36. If *'strn'* is a character array, each row is interpreted as a string in the specified base.

**Examples** The expression `base2dec('212',3)` converts  $212_3$  to decimal, returning 23.

**See Also** `dec2base`

**Purpose** Produce beep sound

**Syntax**  
beep  
beep on  
beep off  
s = beep

**Description** beep produces your computer's default beep sound.  
beep on turns the beep on.  
beep off turns the beep off.  
s = beep returns the current beep mode (on or off).

# BeginInvoke

---

<b>Purpose</b>	Initiate asynchronous .NET delegate call
<b>Syntax</b>	<code>result = BeginInvoke(arg1, ..., argN, callback, object)</code>
<b>Description</b>	<code>result = BeginInvoke(arg1, ..., argN, callback, object)</code> initiates asynchronous call to a .NET delegate. You must call <code>EndInvoke</code> to complete the asynchronous call.
<b>Input Arguments</b>	<p><b>arg1, ..., argN</b> Input arguments for delegate. The type and number of arguments must agree with the delegate signature.</p> <p><b>callback</b> .NET <code>System.AsyncCallback</code> delegate, or [ ] null value.</p> <p><b>object</b> User-defined object, or [ ] null value.</p>
<b>Output Arguments</b>	<p><b>result</b> .NET <code>System.IAsyncResult</code> object. Used to monitor the progress of the asynchronous call. Input argument to <code>EndInvoke</code>.</p>
<b>See Also</b>	<code>EndInvoke</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Calling .NET Methods Asynchronously”</li></ul>
<b>Related Links</b>	<ul style="list-style-type: none"><li>• MSDN® Calling Synchronous Methods Asynchronously</li></ul>

**Purpose** MATLAB benchmark

**Syntax**  
 bench  
 bench(N)  
 bench(0)  
 t = bench(N)

**Description** bench times six different MATLAB tasks and compares the execution speed with the speed of several other computers. The six tasks are:

Test	Description	Performance Factors
LU	Perform LU of a full matrix	Floating-point, regular memory access
FFT	Perform FFT of a full vector	Floating-point, irregular memory access
ODE	Solve van der Pol equation with ODE45	Data structures and MATLAB function files
Sparse	Solve a symmetric sparse linear system	Mixed integer and floating-point
2-D	Plot Bernstein polynomial graph	2-D line drawing graphics
3-D	Display animated L-shape membrane logo	3-D animated OpenGL graphics

A final bar chart shows speed, which is inversely proportional to time. The longer bars represent faster machines, and the shorter bars represent the slower ones.

bench(N) runs each of the six tasks N times.

bench(0) just displays the results from other machines.

t = bench(N) returns an N-by-6 array with the execution times.

## Tips

---

**Note** A benchmark is intended to compare performance of one particular version of MATLAB on different machines. It does not offer direct comparisons between different versions of MATLAB as tasks and problem sizes change from version to version.

---

The LU and FFT tasks involve large matrices and long vectors. The 2-D and 3-D tasks measure graphics performance, including software or hardware support for OpenGL. The command

```
opengl info
```

describes the OpenGL support available on a particular machine.

Fluctuations of five or ten percent in the measured times of repeated runs on a single machine are not uncommon. Your own mileage may vary.

**Purpose** Bessel function of third kind (Hankel function)

**Syntax**  
 H = besselh(nu,K,Z)  
 H = besselh(nu,Z)  
 H = besselh(nu,K,Z,1)

**Definitions** The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + (z^2 - \nu^2) y = 0,$$

where  $\nu$  is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.  $J_\nu(z)$  and  $J_{-\nu}(z)$  form a fundamental set of solutions of Bessel's equation for noninteger  $\nu$ .  $Y_\nu(z)$  is a second solution of Bessel's equation—linearly independent of  $J_\nu(z)$ —defined by

$$Y_\nu(z) = \frac{J_\nu(z) \cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}.$$

The relationship between the Hankel and Bessel functions is

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z),$$

where  $J_\nu(z)$  is `besselj`, and  $Y_\nu(z)$  is `bessely`.

**Description** H = besselh(nu,K,Z) computes the Hankel function  $H_\nu^{(K)}(z)$  where K = 1 or 2, for each element of the complex array Z. If nu and Z are arrays of the same size, the result is also that size. If either input is a scalar, besselh expands it to the other input's size.

H = besselh(nu,Z) uses K = 1.

H = besselh(nu,K,Z,1) scales  $H_\nu^{(K)}(z)$  by  $\exp(-i*Z)$  if K = 1, and by  $\exp(+i*Z)$  if K = 2.

## Examples

This example generates the contour plots of the modulus and phase of the Hankel function  $H_0^{(1)}(z)$  shown on page 359 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

It first generates the modulus contour plot

```
[X,Y] = meshgrid(-4:0.025:2,-1.5:0.025:1.5);  
H = besselh(0,1,X+i*Y);  
contour(X,Y,abs(H),0:0.2:3.2), hold on
```

then adds the contour plot of the phase of the same function.

```
contour(X,Y,(180/pi)*angle(H),-180:10:180); hold off
```

# besseli

---

**Purpose** Modified Bessel function of first kind

**Syntax**  
`I = besseli(nu,Z)`  
`I = besseli(nu,Z,1)`

**Definitions** The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} - (z^2 + \nu^2) y = 0,$$

where  $\nu$  is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

$I_\nu(z)$  and  $I_{-\nu}(z)$  form a fundamental set of solutions of the modified Bessel's equation.  $I_\nu(z)$  is defined by

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{(k=0)}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k! \Gamma(\nu + k + 1)},$$

where  $\Gamma(a)$  is the gamma function.

$K_\nu(z)$  is a second solution, independent of  $I_\nu(z)$ . It can be computed using `besselk`.

**Description** `I = besseli(nu,Z)` computes the modified Bessel function of the first kind,  $I_\nu(z)$ , for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`I = besseli(nu,Z,1)` computes `besseli(nu,Z) .* exp(-abs(real(Z)))`.

**Examples****Vector of Function Values**

```

# beta

---

**Purpose** Beta function

**Syntax** B = beta(Z,W)

**Definitions** The beta function is

$$B(z,w) = \int_0^1 t^{z-1}(1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

where  $\Gamma(z)$  is the gamma function.

**Description** B = beta(Z,W) computes the beta function for corresponding elements of arrays Z and W. The arrays must be real and nonnegative. They must be the same size, or either can be scalar.

**Examples** In this example, which uses integer arguments,

```
beta(n,3)
= (n-1)!*2!/(n+2)!
= 2/(n*(n+1)*(n+2))
```

is the ratio of fairly small integers, and the rational format is able to recover the exact result.

```
format rat
beta((0:10)',3)
```

```
ans =
    1/0
    1/3
    1/12
    1/30
    1/60
    1/105
    1/168
    1/252
```

1/360

1/495

1/660

**Algorithms**

$\text{beta}(z,w) = \exp(\text{gammaIn}(z) + \text{gammaIn}(w) - \text{gammaIn}(z+w))$

**See Also**

[betainc](#) | [betaIn](#) | [gammaIn](#)

# betainc

---

**Purpose** Incomplete beta function

**Syntax** `I = betainc(X,Z,W)`  
`I = betainc(X,Z,W,tail)`

**Definitions** The incomplete beta function is

$$I_x(z,w) = \frac{1}{B(z,w)} \int_0^x t^{z-1} (1-t)^{w-1} dt$$

where  $B(z,w)$ , the beta function, is defined as

$$B(z,w) = \int_0^1 t^{z-1} (1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

and  $\Gamma(z)$  is the gamma function.

**Description** `I = betainc(X,Z,W)` computes the incomplete beta function for corresponding elements of the arrays `X`, `Z`, and `W`. The elements of `X` must be in the closed interval  $[0,1]$ . The arrays `Z` and `W` must be nonnegative and real. All arrays must be the same size, or any of them can be scalar.

`I = betainc(X,Z,W,tail)` specifies the tail of the incomplete beta function. Choices are:

'lower' (the default)	Computes the integral from 0 to x
'upper'	Computes the integral from x to 1

These functions are related as follows:

$$1 - \text{betainc}(X,Z,W) = \text{betainc}(X,Z,W, \text{'upper'})$$

Note that especially when the upper tail value is close to 0, it is more accurate to use the 'upper' option than to subtract the 'lower' value from 1.

**Examples**

```
format long
betainc(.5,(0:10)',3)
```

```
ans =
    1.000000000000000
    0.875000000000000
    0.687500000000000

    0.089843750000000
    0.054687500000000
    0.032714843750000
    0.019287109375000
```

**See Also**

[beta](#) | [betaIn](#)

# betaincinv

---

**Purpose** Beta inverse cumulative distribution function

**Syntax**  
`x = betaincinv(y,z,w)`  
`x = betaincinv(y,z,w,tail)`

**Description** `x = betaincinv(y,z,w)` computes the inverse incomplete beta function for corresponding elements of `y`, `z`, and `w`, such that `y = betainc(x,z,w)`. The elements of `y` must be in the closed interval `[0,1]`, and those of `z` and `w` must be nonnegative. `y`, `z`, and `w` must all be real and the same size (or any of them can be scalar).

`x = betaincinv(y,z,w,tail)` specifies the tail of the incomplete beta function. Choices are `lower` (the default) to use the integral from 0 to `x`, or `'upper'` to use the integral from `x` to 1. These two choices are related as follows: `betaincinv(y,z,w,'upper') = betaincinv(1-y,z,w,'lower')`. When `y` is close to 0, the `'upper'` option provides a way to compute `x` more accurately than by subtracting from `y` from 1.

**Definitions** The incomplete beta function is defined as

$$I_x(z,w) = \frac{1}{\beta(z,w)} \int_0^x t^{z-1} (1-t)^{w-1} dt$$

`betaincinv` computes the inverse of the incomplete beta function with respect to the integration limit `x` using Newton's method.

## Purpose

Biconjugate gradients method

## Syntax

```
x = bicg(A,b)
bicg(A,b,tol)
bicg(A,b,tol,maxit)
bicg(A,b,tol,maxit,M)
bicg(A,b,tol,maxit,M1,M2)
bicg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicg(A,b,...)
[x,flag,relres] = bicg(A,b,...)
[x,flag,relres,iter] = bicg(A,b,...)
[x,flag,relres,iter,resvec] = bicg(A,b,...)
```

## Description

`x = bicg(A,b)` attempts to solve the system of linear equations  $A*x = b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ .  $A$  can be a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A'*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicg` converges, it displays a message to that effect. If `bicg` fails to converge after the maximum number of iterations or halts for any reason, it prints a warning message that includes the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`bicg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicg` uses the default,  $1e-6$ .

`bicg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicg` uses the default,  $\min(n,20)$ .

`bicg(A,b,tol,maxit,M)` and `bicg(A,b,tol,maxit,M1,M2)` use the preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for  $x$ . If  $M$  is `[]` then `bicg` applies

no preconditioner.  $M$  can be a function handle `mfun`, such that `mfun(x, 'notransp')` returns  $M \backslash x$  and `mfun(x, 'transp')` returns  $M' \backslash x$ .

`bicg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is `[]`, then `bicg` uses the default, an all-zero vector.

`[x,flag] = bicg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>bicg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>bicg</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	<code>bicg</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>bicg</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicg(A,b,...)` also returns the relative residual norm  $\|b - A \cdot x\| / \|b\|$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = bicg(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = bicg(A,b,...)` also returns a vector of the residual norms at each iteration including  $\|b - A \cdot x_0\|$ .

## Examples

### Using `bicg` with a Matrix Input.

This example shows how to use `bicg` with a matrix input. `bicg`. The following code:

```
n = 100;
on = ones(n,1);
```

```
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = bicg(A,b,tol,maxit,M1,M2);
```

displays this message:

```
bicg converged at iteration 9 to a solution with relative
residual 5.3e-009
```

## Using bicg with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_bicg` that

- Calls `bicg` with the `@afun` function handle as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_bicg` are available to `afun`.

Place the following into a file called `run_bicg`:

```
function x1 = run_bicg
n = 100;
on = ones(n,1);
b = afun(on, 'notransp');
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = bicg(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)           % y = A'*x
    if strcmp(transp_flag,'transp')
        y = 4 * x;
```

```

        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
        y(2:n) = y(2:n) - x(1:n-1);
    elseif strcmp(transp_flag,'notransp') % y = A*x
        y = 4 * x;
        y(2:n) = y(2:n) - 2 * x(1:n-1);
        y(1:n-1) = y(1:n-1) - x(2:n);
    end
end
end
end

```

When you enter

```
x1 = run_bicg;
```

MATLAB software displays the message

```

bicg converged at iteration 9 to a solution with ...
relative residual
5.3e-009

```

### Using a Preconditioner

This example demonstrates the use of a preconditioner.

#### 1

Load A = west0479, a real 479-by-479 nonsymmetric sparse matrix:

```

load west0479;
A = west0479;

```

#### 2

Define b so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

#### 3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

## 4

Use `bicg` to find a solution at the requested tolerance and number of iterations:

```
[x0,f10,rr0,it0,rv0] = bicg(A,b,tol,maxit);
```

`f10` is 1 because `bicg` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. In fact, the behavior of `bicg` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

## 5

Plot the behavior of `bicg`:

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

## 6

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = bicg(A,b,tol,maxit,L,U);
```

f11 is 0 because bicg drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

## 8

You can follow the progress of bicg by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

`bicgstab` | `cgs` | `gmres` | `ilu` | `lsqr` | `luinc` | `minres` | `pcg` | `qmr` | `symmlq` | `function_handle` | `mldivide`

# bicgstab

---

**Purpose** Biconjugate gradients stabilized method

**Syntax**

```
x = bicgstab(A,b)
bicgstab(A,b,tol)
bicgstab(A,b,tol,maxit)
bicgstab(A,b,tol,maxit,M)
bicgstab(A,b,tol,maxit,M1,M2)
bicgstab(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstab(A,b,...)
[x,flag,relres] = bicgstab(A,b,...)
[x,flag,relres,iter] = bicgstab(A,b,...)
[x,flag,relres,iter,resvec] = bicgstab(A,b,...)
```

**Description** `x = bicgstab(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ .  $A$  can be a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicgstab` converges, a message to that effect is displayed. If `bicgstab` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`bicgstab(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicgstab` uses the default,  $1e-6$ .

`bicgstab(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicgstab` uses the default,  $\min(n,20)$ .

`bicgstab(A,b,tol,maxit,M)` and `bicgstab(A,b,tol,maxit,M1,M2)` use preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for  $x$ . If  $M$  is `[]` then `bicgstab` applies no preconditioner.  $M$  can be a function handle `mfun`, such that `mfun(x)` returns  $M*x$ .

`bicgstab(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicgstab` uses the default, an all zero vector.

`[x,flag] = bicgstab(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>bicgstab</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>bicgstab</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>bicgstab</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>bicgstab</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicgstab(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = bicgstab(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ . `iter` can be an integer + 0.5, indicating convergence halfway through an iteration.

`[x,flag,relres,iter,resvec] = bicgstab(A,b,...)` also returns a vector of the residual norms at each half iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Using `bicgstab` with a Matrix Input

This example first solves  $Ax = b$  by providing `A` and the preconditioner `M1` directly as arguments.

The code:

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = bicgstab(A,b,tol,maxit,M1);
```

displays the message:

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

## Using bicgstab with a Function Handle

This example replaces the matrix  $A$  in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner  $M1$  with a handle to a backsolve function `mfun`. The example is contained in a file `run_bicgstab` that

- Calls `bicgstab` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_bicgstab` are available to `afun` and `mfun`.

The following shows the code for `run_bicgstab`:

```
function x1 = run_bicgstab
n = 21;
b = afun(ones(n,1));
tol = 1e-12;
maxit = 15;
x1 = bicgstab(@afun,b,tol,maxit,@mfun);

function y = afun(x)
    y = [0; x(1:n-1)] + ...
        [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
        [x(2:n); 0];
end
```

```
function y = mfun(r)
    y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
end
end
```

When you enter

```
x1 = run_bicgstab;
```

MATLAB software displays the message

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

### Using a Preconditioner

This example demonstrates the use of a preconditioner.

#### 1

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

#### 2

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

#### 3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

#### 4

Use `bicgstab` to find a solution at the requested tolerance and number of iterations:

# bicgstab

```
[x0,f10,rr0,it0,rv0] = bicgstab(A,b,tol,maxit);
```

f10 is 1 because `bicgstab` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. In fact, the behavior of `bicgstab` is so bad that the initial guess ( $x_0 = \text{zeros}(\text{size}(A,2),1)$ ) is the best solution and is returned as indicated by  $it_0 = 0$ . MATLAB stores the residual history in `rv0`.

## 5

Plot the behavior of `bicgstab`:

```
semilogy(0:0.5:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

## 6

Create a preconditioner with `ilu`, since  $A$  is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = bicgstab(A,b,tol,maxit,L,U);
```

`f11` is 0 because `bicgstab` drives the relative residual to  $5.9829e-014$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the third iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output `rv1(1)` is `norm(b)` and the output `rv1(7)` is `norm(b-A*x2)` since `bicgstab` uses half iterations.

## 8

You can follow the progress of `bicgstab` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');
xlabel('Iteration Number');
ylabel('Relative Residual');
```

## See Also

bicg | cgs | gmres | lsqr | luinc | minres | pcg | qmr | symmlq  
| function\_handle | mldivide

**Purpose** Biconjugate gradients stabilized (l) method

**Syntax**

```
x = bicgstabl(A,b)
x = bicgstabl(afun,b)
x = bicgstabl(A,b,tol)
x = bicgstabl(A,b,tol,maxit)
x = bicgstabl(A,b,tol,maxit,M)
x = bicgstabl(A,b,tol,maxit,M1,M2)
x = bicgstabl(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstabl(A,b,...)
[x,flag,relres] = bicgstabl(A,b,...)
[x,flag,relres,iter] = bicgstabl(A,b,...)
[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)
```

**Description**

`x = bicgstabl(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and the right-hand side column vector  $b$  must have length  $n$ .

`x = bicgstabl(afun,b)` accepts a function handle `afun` instead of the matrix  $A$ . `afun(x)` accepts a vector input  $x$  and returns the matrix-vector product  $A*x$ . In all of the following syntaxes, you can replace  $A$  by `afun`.

`x = bicgstabl(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `bicgstabl` uses the default,  $1e-6$ .

`x = bicgstabl(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `bicgstabl` uses the default,  $\min(N,20)$ .

`x = bicgstabl(A,b,tol,maxit,M)` and `x = bicgstabl(A,b,tol,maxit,M1,M2)` use preconditioner  $M$  or  $M=M1*M2$  and effectively solve the system  $A*inv(M)*x = b$  for  $x$ . If  $M$  is `[]` then a preconditioner is not applied.  $M$  may be a function handle returning  $M\backslash x$ .

`x = bicgstabl(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]` then `bicgstabl` uses the default, an all zero vector.

`[x,flag] = bicgstabl(A,b,...)` also returns a convergence flag:

# bicgstabl

---

Flag	Convergence
0	bicgstabl converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	bicgstabl iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	bicgstabl stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during bicgstabl became too small or too large to continue computing.

`[x,flag,relres] = bicgstabl(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = bicgstabl(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ . `iter` can be `k/4` where `k` is some integer, indicating convergence at a given quarter iteration.

`[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)` also returns a vector of the residual norms at each quarter iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Using bicgstabl with Inputs or with a Function

You can pass inputs directly to `bicgstabl`:

```
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M = diag([10:-1:1 1 1:10]);
x = bicgstabl(A,b,tol,maxit,M);
```

You can also use a matrix-vector product function:

```
function y = afun(x,n)
y = [0; x(1:n-1)] + [((n-1)/2:-1:0)';
(1:(n-1)/2)'] .* x + [x(2:n); 0];
```

and a preconditioner backsolve function:

```
function y = mfun(r,n)
y = r ./ [((n-1)/2:-1:1)';
1;
(1:(n-1)/2)'];
```

as inputs to `bicgstabl`:

```
x1 = bicgstabl(@(x)afun(x,n),b,tol,maxit,@(x)mfun(x,n));
```

### **Using a Preconditioner**

This example demonstrates the use of a preconditioner.

#### **1**

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

#### **2**

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

#### **3**

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

#### **4**

Use `bicgstabl` to find a solution at the requested tolerance and number of iterations:

# bicgstabl

```
[x0,f10,rr0,it0,rv0] = bicgstabl(A,b,tol,maxit);
```

f10 is 1 because `bicgstabl` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. In fact, the behavior of `bicgstabl` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

## 5

Plot the behavior of `bicgstabl`:

```
semilogy(0:0.25:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

**6**

Create a preconditioner with `ilu`, since  $A$  is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

**7**

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
```

```
[x1,f11,rr1,it1,rv1] = bicgstabl(A,b,tol,maxit,L,U);
```

`f11` is 0 because `bicgstabl` drives the relative residual to  $1.0257e-015$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output `rv1(1)` is `norm(b)`, and the output `rv1(9)` is `norm(b-A*x2)` since `bicgstabl` uses quarter iterations.

**8**

You can follow the progress of `bicgstabl` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:0.25:it1,rv1/norm(b),'-o');
```

```
set(gca,'XTick',0:0.25:it1);
```

```
xlabel('Iteration number');
```

```
ylabel('Relative residual');
```

# bicgstabl

---

[bicgstab](#) | [bicg](#) | [cgs](#) | [gmres](#) | [lsqr](#) | [luinc](#) | [minres](#) | [pcg](#) | [qmr](#) | [symmlq](#) | [function\\_handle](#) | [mldivide](#)

**Purpose** Convert binary number string to decimal number

**Syntax** `bin2dec(binarystr)`

**Description** `bin2dec(binarystr)` interprets the binary string *binarystr* and returns the equivalent decimal number.

`bin2dec` ignores any space ( ' ') characters in the input string.

**Examples** Binary 010111 converts to decimal 23:

```
bin2dec('010111')
ans =
    23
```

Because space characters are ignored, this string yields the same result:

```
bin2dec(' 010 111 ')
ans =
    23
```

**See Also** `dec2bin`

# FTP.binary

---

**Purpose** Set FTP transfer type to binary

**Syntax** `binary(ftpobj)`

**Description** `binary(ftpobj)` sets the FTP download and upload mode to binary, which does not convert new line characters. Binary mode is the default for FTP objects. If you previously called the `ascii` method, use this method before transferring a nontext file, such as an executable or ZIP archive.

**Input Arguments** **ftpobj**  
FTP object created by `ftp`.

**Examples** Connect to the MathWorks FTP server, and set the transfer mode to binary:

```
mw=ftp('ftp.mathworks.com');  
binary(mw)
```

**See Also** `ascii` | `ftp`

<b>Purpose</b>	Bit-wise AND
<b>Syntax</b>	<pre>intout = bitand(integ1,integ2) intout = bitand(integ1,integ2,assumedtype)  objout = bitand(netobj1,netobj2)</pre>
<b>Description</b>	<p><code>intout = bitand(integ1,integ2)</code> returns the bit-wise AND of values <code>integ1</code> and <code>integ2</code>.</p> <p><code>intout = bitand(integ1,integ2,assumedtype)</code> assumes that <code>integ1</code> and <code>integ2</code> are of <code>assumedtype</code>.</p> <p><code>objout = bitand(netobj1,netobj2)</code> returns the bit-wise AND of the .NET enumeration objects <code>netobj1</code> and <code>netobj2</code>.</p>
<b>Input Arguments</b>	<p><b>integ1, integ2 - Input values</b> signed integer arrays   unsigned integer arrays   double arrays</p> <p>Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. <code>integ1</code> and <code>integ2</code> must be the same data type, or one must be a scalar double value.</p> <ul style="list-style-type: none"><li>• If <code>integ1</code> and <code>integ2</code> are double arrays, and <code>assumedtype</code> is not specified, then MATLAB treats <code>integ1</code> and <code>integ2</code> as unsigned 64-bit integers.</li><li>• If <code>assumedtype</code> is specified, then all elements in <code>integ1</code> and <code>integ2</code> must have integer values within the range of <code>assumedtype</code>.</li></ul> <p><b>Data Types</b> double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>assumedtype - Assumed data type of integ1 and integ2</b> 'uint64'   'uint32'   'uint16'   'uint8'   'int64'   'int32'   'int16'   'int8'</p>

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

## Data Types

`char`

## `netobj1`, `netobj2` - Input values

`.NET` enumeration objects

Input values, specified as `.NET` enumeration objects. You must be running a version of Windows to use `.NET` enumeration objects as input arguments.

`bitand` is an instance method for MATLAB enumeration objects created from a `.NET` enumeration.

## Output Arguments

### `intout` - Bit-wise AND result

signed integer array | unsigned integer array | double array

Bit-wise AND result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

### `objout` - Bit-wise AND result

`.NET` enumeration object

Bit-wise AND result, returned as a `.NET` enumeration objects.

## Examples

### Truth Table

Create a truth table for the logical AND operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitand(A, B)
```

```
TTable =

     0     0
     0     1
```

bitand returns 1 only if both bit-wise inputs are 1.

### Negative Values

Explore how bitand handles negative values

MATLAB encodes signed integers using two's complement. Thus, the bit-wise AND of -5 (11111010) and 6 (00000110) is 2 (00000010).

```
C = -5;
D = 6;
bitand(C,D,'int8')
```

```
ans =

     2
```

# bitcmp

---

<b>Purpose</b>	Bit-wise complement
<b>Compatibility</b>	<code>bitcmp(A,N)</code> will not accept <code>N</code> in a future release. Use <code>bitcmp(A)</code> or <code>bitcmp(A,assumedtype)</code> instead.
<b>Syntax</b>	<pre>cmp = bitcmp(A) cmp = bitcmp(A,assumedtype)  cmp = bitcmp(A,N)</pre>
<b>Description</b>	<p><code>cmp = bitcmp(A)</code> returns the bit-wise complement of <code>A</code>.</p> <p><code>cmp = bitcmp(A,assumedtype)</code> assumes that <code>A</code> is of <code>assumedtype</code>.</p> <p><code>cmp = bitcmp(A,N)</code> returns an <code>N</code>-bit complement of <code>A</code>. Elements of <code>A</code> cannot exceed <math>2^N-1</math>.</p>
<b>Input Arguments</b>	<p><b>A - Input value</b> signed integer array   unsigned integer array   double array</p> <p>Input value, specified as a signed integer array, unsigned integer array, or double array.</p> <ul style="list-style-type: none"><li>• If <code>A</code> is a double array, and <code>assumedtype</code> is not specified, then MATLAB treats <code>A</code> as an unsigned 64-bit integer.</li><li>• If <code>assumedtype</code> is specified, then all elements in <code>A</code> must have integer values within the range of <code>assumedtype</code>.</li></ul> <p><b>Data Types</b> double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>assumedtype - Assumed data type of A</b> 'uint64'   'uint32'   'uint16'   'uint8'   'int64'   'int32'   'int16'   'int8'</p>

Assumed data type of A, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If A is a double array, then `assumedtype` can specify any valid integer type, but defaults to 'uint64'.
- If A is an integer type array, then `assumedtype` must specify that same integer type.

#### Data Types

char

#### N - number of returned bits

integer

Number of returned bits, specified as an integer. N cannot exceed the number of bits in the integer type of A.

#### Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

## Output Arguments

### cmp - Bit-wise complement

signed integer array | unsigned integer array | double array

Bit-wise complement, returned as a signed integer array, unsigned integer array, or double array. `cmp` is the same size and type as A.

## Examples

### Complement of a Negative Integer

```
A = int8(-11);
cmp = bitcmp(A)
```

```
cmp =
```

```
    10
```

You can see the complement operation when the numbers are shown in binary.

```
original = bitget(A,8:-1:1)
complement = bitget(bitcmp(A),8:-1:1)
```

```
original =
```

```
    1    1    1    1    0    1    0    1
```

```
complement =
```

```
    0    0    0    0    1    0    1    0
```

## Complement of Unsigned Integers

```
cmp = bitcmp(64,'uint8')
maxint = intmax('uint8') - 64
```

```
cmp =
```

```
    191
```

```
maxint =
```

```
    191
```

The complement of an unsigned integer is equal to itself subtracted from the maximum integer of its data type.

<b>Input Arguments</b>	<p><b>A - Input value</b> signed integer array   unsigned integer array   double array</p> <p>Input value, specified as a signed integer array, unsigned integer array, or double array.</p> <ul style="list-style-type: none"><li>• If <code>A</code> is a double array, and <code>assumedtype</code> is not specified, then MATLAB treats <code>A</code> as an unsigned 64-bit integer.</li><li>• If <code>assumedtype</code> is specified, then all elements in <code>A</code> must have integer values within the range of <code>assumedtype</code>.</li></ul> <p><b>Data Types</b> double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>bit - Bit position</b> integer   integer array</p> <p>Bit position, specified as an integer or integer array. <code>bit</code> must be between 1 (the least-significant bit) and the number of bits in the integer class of <code>A</code>.</p> <p><b>Data Types</b> double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>assumedtype - Assumed data type of A</b></p>

# bitget

---

```
'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' |  
'int16' | 'int8'
```

Assumed data type of A, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If A is a double array, then `assumedtype` can specify any valid integer type, but defaults to 'uint64'.
- If A is an integer type array, then `assumedtype` must specify that same integer type.

## Data Types

char

## Output Arguments

### b - Bit value at bit

0 | 1

Bit value at `bit`, returned as 0 or 1. `b` is the same data type as A.

## Examples

### Maximum Integer

Find the difference in the binary representation between the maximum integer of signed and unsigned integers.

```
a1 = intmax('int8');  
a2 = intmax('uint8');  
b1 = bitget(a1,8:-1:1)  
b2 = bitget(a2,8:-1:1)
```

b1 =

```
0  1  1  1  1  1  1  1
```

b2 =

```
1  1  1  1  1  1  1  1
```

The signed integers require a bit to accommodate negative integers.

## Negative Numbers Using Two's Complement

Find the 8-bit representation of a negative number.

```
A = -29;  
b = bitget(A,8:-1:1,'int8')
```

b =

```
    1    1    1    0    0    0    1    1
```

### See Also

[bitand](#) | [bitcmp](#) | [bitor](#) | [bitshift](#) | [bitset](#) | [bitxor](#) | [intmax](#)

# bitmax

---

- Purpose** Maximum double-precision floating-point integer
- Compatibility** `bitmax` will be removed in a future release. Use `flintmax` instead.
- Syntax** `bitmax`
- Description** `bitmax` returns the maximum unsigned double-precision floating-point integer for your computer. It is the value when all bits are set, namely the value  $2^{53} - 1$ .

---

**Note** Instead of integer-valued double-precision variables, use unsigned integers for bit manipulations and replace `bitmax` with `intmax`.

---

- Examples** Display in different formats the largest floating point integer and the largest 32 bit unsigned integer:

```
format long e
bitmax
ans =
    9.007199254740991e+015
```

```
intmax('uint32')
ans =
    4294967295
```

```
format hex
bitmax
ans =
    433fffffffffffffff
```

```
intmax('uint32')
ans =
    ffffffff
```

In the second `bitmax` statement, the last 13 hex digits of `bitmax` are `f`, corresponding to 52 1's (all 1's) in the mantissa of the binary representation. The first 3 hex digits correspond to the sign bit 0 and the 11 bit biased exponent `10000110011` in binary (1075 in decimal), and the actual exponent is  $(1075 - 1023) = 52$ . Thus the binary value of `bitmax` is  $1.111\dots111 \times 2^{52}$  with 52 trailing 1's, or  $2^{53} - 1$ .

# bitnot

---

<b>Purpose</b>	.NET enumeration object bit-wise NOT instance method
<b>Syntax</b>	<code>objout = bitnot(netobj)</code>
<b>Description</b>	<code>objout = bitnot(netobj)</code> reverses all bits of the .NET enumeration objects <code>netobj</code> .
<b>Input Arguments</b>	<b>netobj - Input value</b> .NET enumeration objects  Input value, specified as .NET enumeration object. You must be running a version of Windows to use .NET enumeration objects as input arguments.
<b>Output Arguments</b>	<b>objout - Bit-wise NOT result</b> .NET enumeration object  Bit-wise NOT result, returned as a .NET enumeration object.
<b>Limitations</b>	<ul style="list-style-type: none"><li>• The method is an instance method for MATLAB enumeration objects created from a .NET enumeration. This method does not have an equivalent MATLAB function.</li></ul>
<b>See Also</b>	<code>bitand</code>   <code>bitor</code>   <code>bitxor</code>
<b>Related Examples</b>	<ul style="list-style-type: none"><li>• “Creating .NET Enumeration Bit Flags”</li></ul>

**Purpose**

Bit-wise OR

**Syntax**

```
intout = bitor(integ1,integ2)
intout = bitor(integ1,integ2,assumedtype)

objout = bitor(netobj1,netobj2)
```

**Description**

`intout = bitor(integ1,integ2)` returns the bit-wise OR of `integ1` and `integ2`.

`intout = bitor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitor(netobj1,netobj2)` returns the bit-wise OR of the .NET enumeration objects `netobj1` and `netobj2`.

**Input Arguments****integ1, integ2 - Input values**

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

**Data Types**

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**assumedtype - Assumed data type of integ1 and integ2**

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

## Data Types

`char`

## `netobj1`, `netobj2` - Input values

`.NET` enumeration objects

Input values, specified as `.NET` enumeration objects. You must be running a version of Windows to use `.NET` enumeration objects as input arguments.

`bitor` is an instance method for MATLAB enumeration objects created from a `.NET` enumeration.

## Output Arguments

### `intout` - Bit-wise OR result

signed integer array | unsigned integer array | double array

Bit-wise OR result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

### `objout` - Bit-wise OR result

`.NET` enumeration object

Bit-wise OR result, returned as a `.NET` enumeration objects.

## Examples

### Truth Table

Create a truth table for the logical OR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitor(A, B)
```

```
TTable =

     0     1
     1     1
```

bitor returns 1 if either bit-wise input is 1.

### Negative Values

Explore how bitor handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise OR of -5 (11111010) and 6 (00000110) is -1 (11111110).

```
C = -5;
D = 6;
bitor(C,D,'int8')
```

```
ans =

    -1
```

### See Also

bitand | bitnot | bitcmp | bitget | bitshift | bitset |  
bitxor | intmax

### Related Examples

- “Creating .NET Enumeration Bit Flags”

# bitset

---

## Purpose

Set bit at specific location

## Syntax

```
intout = bitset(A,bit)
intout = bitset(A,bit,assumedtype)

intout = bitset(A,bit,V)
intout = bitset(A,bit,V,assumedtype)
```

## Description

`intout = bitset(A,bit)` returns the value of `A` with position `bit` set to 1 (on).

`intout = bitset(A,bit,assumedtype)` assumes `A` is of type `assumedtype`.

`intout = bitset(A,bit,V)` returns `A` with position `bit` set to the value of `V`.

- If `V` is zero, then the bit position `bit` is set to 0 (off).
- If `V` is nonzero, then the bit position `bit` is set to 1 (on).

`intout = bitset(A,bit,V,assumedtype)` assumes `A` is of type `assumedtype`.

## Input Arguments

### **A - Input value**

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If `A` is a double array, and `assumedtype` is not specified, then MATLAB treats `A` as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in `A` must have integer values within the range of `assumedtype`.

**Data Types**

double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

**bit - Bit position**

integer | integer array

Bit position, specified as an integer or integer array. **bit** must be between 1 (the least significant bit) and the number of bits in the integer class of **A**.

**Data Types**

double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

**assumedtype - Assumed data type of A**

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' |  
'int16' | 'int8'

Assumed data type of **A**, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If **A** is a double array, then **assumedtype** can specify any valid integer type, but defaults to 'uint64'.
- If **A** is an integer type array, then **assumedtype** must specify that same integer type.

**Data Types**

char

**V - bit value**

scalar | numeric array

Bit value, specified as a scalar or a numeric array. If **V** and **bit** are arrays, they must be the same size.

**Data Types**

double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64 | logical

# bitset

---

## Output Arguments

### **intout - Adjusted integer**

signed integer array | unsigned integer array | double array

Adjusted integer, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same size and type as `A`.

## Examples

### **Set Bits to On**

Add powers of 2 onto a number.

```
A = 4;  
intout = bitset(A,4:6)
```

```
intout =  
  
      12      20      36
```

You can see that `bitset` sequentially turns on bits 4 through 6.

```
c = dec2bin(intout)
```

```
c =  
  
001100  
010100  
100100
```

### **Out of Range of Integer Type**

MATLAB throws an error if you specify an integer outside the range of `assumedtype`.

```
intout = bitset(300,5,'int8')
```

```
Error using bitset  
Double inputs must have integer values in the range of ASSUMEDTYPE.
```

You can avoid this error by limiting your input to the range of the specified datatype.

**Set Bits to Off**

Repeatedly subtract powers of 2 from a number.

```
a = intmax('uint8')
for k = 0:7
    a = bitset(a, 8-k, 0);
    b(1,k+1) = a;
end
b
```

```
a =
```

```
255
```

```
b =
```

```
127  63  31  15  7  3  1  0
```

**Set Multiple Bits**

Set multiple bits to different values

```
bits = 2:6;
val = [1 0 0 1 1];
intout = bitset(0,bits,val,'int8')
```

```
intout =
```

```
2  0  0  16  32
```

**See Also**

bitand | bitcmp | bitget | bitor | bitshift | bitxor |  
intmax

# bitshift

---

**Purpose** Shift bits specified number of places

**Compatibility** `bitshift(A,k,N)` will not accept the argument `N` in a future release. Use `bitshift(A,k)` or `bitcmp(A,k,assumedtype)` instead.

`bitshift` no longer interprets double values as 53-bit unsigned integers by default, but as `uint64` values.

**Syntax**

```
intout = bitshift(A,k)
intout = bitshift(A,k,assumedtype)
```

```
intout = bitshift(A,k,N)
```

**Description** `intout = bitshift(A,k)` returns `A` shifted to the left by `k` bits, equivalent to multiplying by  $2^k$ . Negative values of `k` correspond to shifting bits right or dividing by  $2^{|k|}$  and rounding to the nearest integer towards negative infinite. Any overflow bits are truncated.

- If `A` is an array of signed integers, then `bitshift` returns the arithmetic shift results, preserving the signed bit when `k` is negative, and not preserving the signed bit when `k` is positive.
- If `k` is positive, MATLAB shifts the bits to the left and inserts `k` 0-bits on the right.
- If `k` is negative and `A` is nonnegative, then MATLAB shifts the bits to the right and inserts `|k|` 0-bits on the left.
- If `k` is negative and `A` is negative, then MATLAB shifts the bits to the right and inserts `|k|` 1-bits on the left.

`intout = bitshift(A,k,assumedtype)` assumes `A` is of type `assumedtype`.

`intout = bitshift(A,k,N)` truncates any bits that overflow `N` bits.

## Input Arguments

### A - Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If A is a double array, and `assumedtype` is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in A must have integer values within the range of `assumedtype`.

### Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### k - Number of switched bits

integer | integer array

Number of switched bits, specified as an integer or integer array.

### Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### assumedtype - Assumed data type of A

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of A, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If A is an integer type array, then `assumedtype` must specify that same integer type.
- If A is a double array, then `assumedtype` can specify any valid integer type.

### Data Types

char

# bitshift

---

## **N - Number of bits kept**

nonnegative integer | nonnegative integer array

Number of bits kept, specified as a nonnegative integer or integer array. N must be less than or equal to the number of bits in the unsigned integer class of A.

## **Data Types**

double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

## **Output Arguments**

### **intout - Shifted value**

signed integer array | unsigned integer array | double array

Shifted value, returned as signed integer array, unsigned integer array, or double array. `intout` is the same size and type as A.

## **Examples**

### **Shifted 8-bit Integer**

Repeatedly shift the bits of an unsigned 8-bit value to the left until all the nonzero bits overflow.

```
a = intmax('uint8');
s1 = 'Initial uint8 value %5d is %08s in binary\n';
s2 = 'Shifted uint8 value %5d is %08s in binary\n';
fprintf(s1,a,dec2bin(a))
for i = 1:8
    a = bitshift(a,1);
    fprintf(s2,a,dec2bin(a))
end
```

```
Initial uint8 value    255 is 11111111 in binary
Shifted uint8 value    254 is 11111110 in binary
Shifted uint8 value    252 is 11111100 in binary
Shifted uint8 value    248 is 11111000 in binary
Shifted uint8 value    240 is 11110000 in binary
Shifted uint8 value    224 is 11100000 in binary
Shifted uint8 value    192 is 11000000 in binary
Shifted uint8 value    128 is 10000000 in binary
```

Shifted uint8 value 0 is 00000000 in binary

### **Different Results for Different Integer Types**

Find the shift for a number using different assumed integer types.

```
uintout = bitshift(6,5:7,'uint8')
intout = bitshift(6,5:7,'int8')
```

```
uintout =
```

```
    192    128     0
```

```
intout =
```

```
   -64  -128     0
```

### **See Also**

[bitand](#) | [bitcmp](#) | [bitget](#) | [bitor](#) | [bitset](#) | [bitxor](#) | [intmax](#)

# bitxor

---

## Purpose

Bit-wise XOR

## Syntax

```
intout = bitxor(integ1,integ2)
intout = bitxor(integ1,integ2,assumedtype)

objout = bitxor(netobj1,netobj2)
```

## Description

`intout = bitxor(integ1,integ2)` returns the bit-wise XOR of `integ1` and `integ2`.

`intout = bitxor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitxor(netobj1,netobj2)` returns the bit-wise XOR of the .NET enumeration objects `netobj1` and `netobj2`.

## Input Arguments

### **integ1, integ2 - Input values**

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

### **Data Types**

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **assumedtype - Assumed data type of integ1 and integ2**

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

### Data Types

`char`

### `netobj1`, `netobj2` - Input values

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitxor` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

## Output Arguments

### `intout` - Bit-wise XOR result

signed integer array | unsigned integer array | double array

Bit-wise XOR result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

### `objout` - Bit-wise XOR result

.NET enumeration object

Bit-wise XOR result, returned as a .NET enumeration objects.

## Examples

### Truth Table

Create a truth table for the logical XOR operation.

# bitxor

---

```
A = uint8([0 1; 0 1]);  
B = uint8([0 0; 1 1]);  
TTable = bitxor(A, B)
```

```
TTable =
```

```
    0    1  
    1    0
```

bitxor returns 0 if both bit-wise inputs are equal.

## Negative Values

Explore how bitxor handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise XOR of -5 (11111010) and 6 (00000110) is -3 (11111100).

```
C = -5;  
D = 6;  
bitxor(C,D,'int8')
```

```
ans =
```

```
-3
```

## Related Examples

- “Creating .NET Enumeration Bit Flags”

**Purpose** Create string of blank characters

**Syntax** `blanks(n)`

**Description** `blanks(n)` is a string of `n` blanks.

**Examples** `blanks` is useful with the `display` function. For example,

```
disp(['xxx' blanks(20) 'yyy'])
```

displays twenty blanks between the strings 'xxx' and 'yyy'.  
`disp(blanks(n) '')` moves the cursor down `n` lines.

**See Also** `clc` | `format` | `home`

# blkdiag

---

**Purpose** Construct block diagonal matrix from input arguments

**Syntax** `out = blkdiag(a,b,c,d,...)`

**Description** `out = blkdiag(a,b,c,d,...)`, where `a`, `b`, `c`, `d`, ... are matrices, outputs a block diagonal matrix of the form

$$\begin{bmatrix} a & 0 & 0 & 0 & 0 \\ 0 & b & 0 & 0 & 0 \\ 0 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & \dots \end{bmatrix}$$

The input matrices do not have to be square, nor do they have to be of equal size.

**See Also** `diag` | `horzcat` | `vertcat`

---

<b>Purpose</b>	Axes border
<b>Syntax</b>	<code>box on</code> <code>box off</code> <code>box</code> <code>box(axes_handle,...)</code>
<b>Description</b>	<code>box on</code> displays the boundary of the current axes. <code>box off</code> does not display the boundary of the current axes. <code>box</code> toggles the visible state of the current axes boundary. <code>box(axes_handle,...)</code> uses the axes specified by <code>axes_handle</code> instead of the current axes.
<b>Algorithms</b>	The <code>box</code> function sets the axes <code>Box</code> property to <code>on</code> or <code>off</code> .
<b>See Also</b>	<code>axes</code>   <code>grid</code>

# break

---

<b>Purpose</b>	Terminate execution of for or while loop
<b>Syntax</b>	break
<b>Description</b>	<p>break terminates the execution of a for or while loop. Statements in the loop that appear after the break statement are not executed.</p> <p>In nested loops, break exits only from the loop in which it occurs. Control passes to the statement that follows the end of that loop.</p>
<b>Tips</b>	break is not defined outside a for or while loop. Use return in this context instead.
<b>Examples</b>	<p>The example below shows a while loop that reads the contents of the file <code>fft.m</code> into a MATLAB character array. A break statement is used to exit the while loop when the first empty line is encountered. The resulting character array contains the command line help for the <code>fft</code> program.</p> <pre>fid = fopen('fft.m','r'); s = '';  while ~feof(fid)     line = fgetl(fid);     if isempty(line)    ~ischar(line), break, end     s = sprintf('%s%s\n', s, line); end disp(s);  fclose(fid);</pre>
<b>See Also</b>	for   while   end   continue   return

**Purpose** Brighten or darken colormap

**Syntax**  
`brighten(beta)`  
`brighten(h,beta)`  
`newmap = brighten(beta)`  
`newmap = brighten(cmap,beta)`

**Description** `brighten(beta)` increases or decreases the color intensities in a colormap by replacing the current colormap with a brighter or darker colormap of essentially the same colors. The modified colormap is brighter if  $0 < \text{beta} < 1$  and darker if  $-1 < \text{beta} < 0$ . `brighten(beta)`, followed by `brighten(-beta)`, where  $\text{beta} < 1$ , restores the original map.

`brighten(h,beta)` brightens all objects that are children of the figure having the handle `h`.

`newmap = brighten(beta)` returns a brighter or darker version of the current colormap without changing the display.

`newmap = brighten(cmap,beta)` returns a brighter or darker version of the colormap `cmap` without changing the display.

**Examples** Brighten the current colormap:

```
surf(membrane);
```

# brighten

---

```
beta = .5;  
brighten(beta);
```

## Algorithms

brighten raises values in the colormap to the power of gamma, where gamma is

$$\gamma = \begin{cases} 1 - \beta, & \beta > 0 \\ \frac{1}{1 + \beta}, & \beta \leq 0 \end{cases}$$

brighten has no effect on graphics objects defined with true color.

# brighten

---

- “Altering Colormaps”

---

<b>Purpose</b>	Interactively mark, delete, modify, and save observations in graphs
<b>Syntax</b>	<pre>brush on brush off brush brush color brush(<i>figure_handle</i>,...) brushobj = brush(<i>figure_handle</i>)</pre>
<b>Description</b>	<p>Data brushing is a mode for interacting with graphs in figure windows in which you can click data points or drag a selection rectangle around data points to highlight observations in a color of your choice. Highlighting takes different forms for different types of graphs, and brushing marks persist—even in other interactive modes—until removed by deselecting them.</p> <p><code>brush on</code> turns on interactive data brushing mode.</p> <p><code>brush off</code> turns brushing mode off, leaving any brushed observations still highlighted.</p> <p><code>brush</code> by itself toggles the state of the data brushing tool.</p> <p><code>brush color</code> sets the current color used for brushing graphics to the specified <code>ColorSpec</code>. Changing brush color affects subsequent brushing, but does not change the color of observations already brushed or the brush tool's state.</p> <p><code>brush(<i>figure_handle</i>, ...)</code> applies the function to the specified figure handle.</p> <p><code>brushobj = brush(<i>figure_handle</i>)</code> returns a <i>brush mode object</i> for that figure, useful for controlling and customizing the figure's brushing state. The following properties of such objects can be modified using <code>get</code> and <code>set</code>:</p>

Enable 'on'   {'off'}	Specifies whether this figure mode is currently enabled on the figure.
FigureHandle	The associated figure handle. This property supports <code>get</code> only.
Color	Specifies the color to be used for brushing.

`brush` cannot return a brush mode object at the same time you are calling it to set a brushing option.

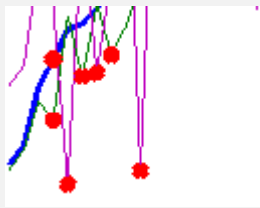

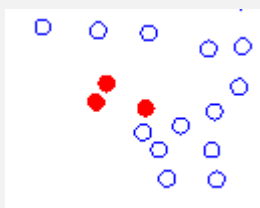

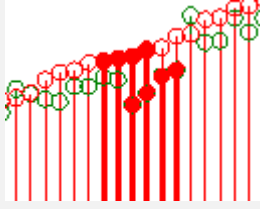

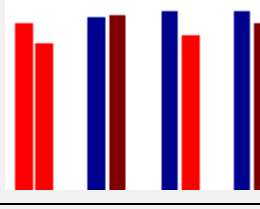

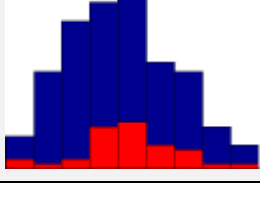

## Tips

- “Types of Plots You Can Brush” on page 1-566
- “Plot Types You Cannot Brush” on page 1-568
- “Mode Exclusivity and Persistence” on page 1-569
- “How Data Linking Affects Data Brushing” on page 1-570
- “Mouse Gestures for Data Brushing” on page 1-571
- “Brush Mode Callbacks” on page 1-572

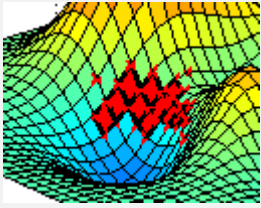

## Types of Plots You Can Brush

Data brushing places lines and patches on plots to create highlighting, marking different types of graphs as follows (brushing marks are shown in red):

Graph Type	Brushing Annotation	Overlays?	Example
lineseries	Colored lines slightly wider than those in the lineseries with a marker distinct from those on the lineseries (filled circles if none) to identify brushed vertices. Only those line segments that connect brushed vertices are highlighted	Y	
scattergroup	Line with LineStyle 'none' and a marker with a color distinct from and slightly larger than the base scattergroup marker.	Y	
stemseries	The brushed stems and stem heads are shaded in the brushing color.	Y	
barseries	The interior of selected bars is filled in the brushing color.	N	
histogram	The bars to which brushed observations contribute are proportionately filled from the bottom up with the brushing color.	N	

# brush

Graph Type	Brushing Annotation	Overlays?	Example
areaseries	Patches filling the region between selected points and the <i>x</i> -axis in the brushing color.	N	
surfaceplot	Patches with edges slightly wider than the surfaceplot line width and with a marker distinct from that of the surfaceplot ( <b>X</b> if none) to identify brushed vertices. Patches are plotted only when all four vertices that define them are brushed. The brushed observations are the set of marked vertices, not the patches.	N	

When using the linked plots feature, a graph can become brushed when you brush another plot that displays some of the same data, potentially brushing the same observations more than once. The overlaid brushing marks (whether lines or markers) are slightly wider than the brushing marks that they overlay; this makes multiply brushed observations visually distinct. The wider brushing marks are placed under the narrower ones, so that if they happen to have different colors, you can see all the colors. See the subsection “How Data Linking Affects Data Brushing” on page 1-570 for more information about brushing linked figures.

As the above table indicates, only lineseries, scatterseries, and stemseries brushing marks can be overlaid in this manner. Although you can brush them, you cannot overlay brushing marks on areaseries, barseries, histograms, or surfaceplots.

## Plot Types You Cannot Brush

Currently, not all plot types enable data brushing. Graph functions that *do not* support brushing are:

- Line plots created with `line`
- Scatter plots created with `spy`
- Contour plots created with `contour`, `contourf`, or `contour3`
- Pie charts created with `pie` or `pie3`
- Radial graphs created with `polar`, `compass`, or `rose`
- Direction graphs created with `feather`, `quiver`, or `comet`
- Area and image plots created with `fill`, `image`, `imagesc`, or `pcolor`
- Bar graphs created with `pareto` or `errorbar`
- Functional plots created with `ezcontour` or `ezcontourf`
- 3-D plot types *other than* `plot3`, `stem3`, `scatter3`, `mesh`, `meshc`, `surf`, `surf1`, and `surfc`

You can use some of these functions to display base data that do not need to be brushable. For example, use `line` to plot mean  $y$ -values as horizontal lines that you do not need or want to brush.

### Mode Exclusivity and Persistence

Data brushing mode is *exclusive*, like zoom, pan, data cursor, or plot edit mode. However, brush marks created in data brushing mode *persist* through all changes in mode. Brush marks that appear in other graphs while they are linked via `linkdata` also persist even when data linking is subsequently turned off. That is, severing connections to a graph's data sources does not remove brushing marks from it. The only ways to remove brushing marks are (in brushing mode):

- Brush an empty area in a brushed graph.
- Right-click and select **Clear all brushing** from the context menu.

Changing the brushing color for a figure does not recolor brushing marks on it until you brush it again. If you hold down the **Shift** key, all existing brush marks change to the new color. All brush marks that appear on linked plots in the same or different figure also change to the new color if the brushing action affects them. The behavior is the same whether you select a brushing color from the Brush Tool dropdown palette, set

it by calling `brush(colorspec)`, or by setting the `Color` property of a brush mode object (e.g., `set(brushobj, 'Color', colorspec)`).

## How Data Linking Affects Data Brushing

When you use the Data Linking tool or call the `linkdata` function, brushing marks that you make on one plot appear on other plots that depict the same variable you are brushing—if those plots are also linked. This happens even if the affected plot is not in Brushing mode. That is, brushing marks appear on a linked plot *in any mode* when you brush another plot linked to it via a common variable or brush that variable in the Variables editor. Be aware that the following conditions apply, however:

- The graph type must support data brushing (see “Types of Plots You Can Brush” on page 1-566 and “Plot Types You Cannot Brush” on page 1-568)
- The graphed variable must not be complex; if you can plot a complex variable you can brush it, but such graphs do not respond when you brush the complex variable in another linked plot. For more information about linking complex variables, see Example 3 in the `linkdata` reference page.
- Observations that you brush display in the same color in all linked graphs. The color is the brush color you have selected in the window you are interacting with, and can differ from the brushing colors selected in the other affected figures. When you brush linked plots, the brushing color is associated with the variable(s) you brush

The last bullet implies that brush marks on an unlinked graph can change color when data linking is turned on for that figure. Brushing marks can, in fact, vanish and be replaced by marks in the same or different color when the plot enters a linked state. In the linked state, brushing is tied to variables (data sources), not just the graphics. If different observations for the same variable on a linked figure are brushed, those variables override the brushed graphics on the newly linked plot. In other words, the newly linked graph loses all its previous brush marks when it “joins the club” of common data sources.

## Mouse Gestures for Data Brushing

You can brush graphs in several ways. The basic operation is to drag the mouse to highlight all observations within the rectangle you define. The following table lists data brushing gestures and their effects.

Action	Gesture	Result
Select data using a region of interest	ROI mouse drag	Region of interest (ROI) rectangle (or rectangular prism for 3-D axes) appears during the gesture and all brushable observations within the rectangle are highlighted. All other brushing marks in the axes are removed. The ROI rectangle disappears when the mouse button is released.
Select a single point	Single left-click on a graphic object that supports data brushing	Produces an equivalent result to ROI rectangle, brushing where the rectangle encloses only the single vertex on the graphical object closest to the mouse. All other brushing annotations in the figure are removed.
Add a point to the selection or remove a highlighted one	Single left-click on a graphic object that supports data brushing, with the <b>Shift</b> key down	Equivalent brushing by dragging an ROI rectangle that encloses only the single vertex on the graphic object closest to the mouse. All other brushed regions in the figure remain brushed.
Select all data associated with a graphic object	Double left-click on a graphic object that supports data brushing	All vertices for the graphic object are brushed.

# brush

Action	Gesture	Result
Add to or subtract from region of interest	Click or ROI drag with the <b>Shift</b> or <b>Ctrl</b> keys down	Region of interest grows; all unbrushed vertices within the rectangle become brushed and all brushed observations in it become unbrushed. All brushed vertices outside the ROI remain brushed.
Copy brushed data to Editor, Command Window, Variables editor, or Workspace Browser	Drag brushed data to another window or to a program/icon on the system desktop	Equivalent to copying brushed data and pasting into other window or an existing/new variable.

## Brush Mode Callbacks

You can program the following callbacks for brush mode operations.

- `ActionPreCallback` `<function_handle>` — Function to execute before brushing

Use this callback to execute code when a brush operation begins. The function handle should reference a function with two implicit arguments:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked
% event_obj    object containing struct of event data
```

The event data struct has the following field:

Axes	The handle of the axes that is being brushed
------	--

- `ActionPostCallback` <function\_handle> — Function to execute after brushing

Use this callback to execute code when a brush operation ends. The function handle should reference a function with two implicit arguments:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

## Examples

### Example 1

On a scatterplot, drag out a rectangle to brush the graph:

```
x = rand(20,1);
y = rand(20,1);
scatter(x,y,80,'s')
brush on
```

# brush

## Example 2

Brush observations from  $-.2$  to  $.2$  on a lineseries plot in dark red:

```
x = [-2*pi:.1:2*pi];  
y = sin(x);  
plot(x,y);  
h = brush;  
set(h, 'Color', [.6 .2 .1], 'Enable', 'on');
```

**How To**

- “Marking Up Graphs with Data Brushing”

# bsxfun

---

**Purpose** Apply element-by-element binary operation to two arrays with singleton expansion enabled

**Syntax** `C = bsxfun(fun,A,B)`

**Description** `C = bsxfun(fun,A,B)` applies the element-by-element binary operation specified by the function handle `fun` to arrays `A` and `B`, with singleton expansion enabled. `fun` can be one of the following built-in functions:

@plus	Plus
@minus	Minus
@times	Array multiply
@rdivide	Right array divide
@ldivide	Left array divide
@power	Array power
@max	Binary maximum
@min	Binary minimum
@rem	Remainder after division
@mod	Modulus after division
@atan2	Four-quadrant inverse tangent; result in radians
@atan2d	Four-quadrant inverse tangent; result in degrees
@hypot	Square root of sum of squares
@eq	Equal
@ne	Not equal
@lt	Less than
@le	Less than or equal to
@gt	Greater than

@ge	Greater than or equal to
@and	Element-wise logical AND
@or	Element-wise logical OR
@xor	Logical exclusive OR

`fun` can also be a handle to any binary element-wise function not listed above. A binary element-wise function of the form `C = fun(A,B)` accepts arrays `A` and `B` of arbitrary, but equal size and returns output of the same size. Each element in the output array `C` is the result of an operation on the corresponding elements of `A` and `B` only. `fun` must also support scalar expansion, such that if `A` or `B` is a scalar, `C` is the result of applying the scalar to every element in the other input array.

The corresponding dimensions of `A` and `B` must be equal to each other or equal to one. Whenever a dimension of `A` or `B` is singleton (equal to one), `bsxfun` virtually replicates the array along that dimension to match the other array. In the case where a dimension of `A` or `B` is singleton, and the corresponding dimension in the other array is zero, `bsxfun` virtually diminishes the singleton dimension to zero.

The size of the output array `C` is equal to:  
`max(size(A),size(B)).*(size(A)>0 & size(B)>0)`.

## Examples

### Deviations from Mean

Use `bsxfun` to subtract the column mean from the corresponding column elements of a matrix, `A`.

```
A = [1 2 10; 1 4 20;1 6 15] ;
C = bsxfun(@minus, A, mean(A))
```

`C =`

```
    0    -2    -5
    0     0     5
    0     2     0
```

## Singleton Expansion with Custom Function

Call a custom-defined binary function with `bsxfun` by specifying a handle to the function.

```
fun = @(A,B) A.*sin(B);  
A = 1:7;  
B = pi*[0 1/4 1/3 1/2 2/3 3/4 1].';  
C = bsxfun(fun,A,B)
```

C =

	0	0	0	0	0	0	0
0.7071	1.4142	2.1213	2.8284	3.5355	4.2426	4.9497	
0.8660	1.7321	2.5981	3.4641	4.3301	5.1962	6.0622	
1.0000	2.0000	3.0000	4.0000	5.0000	6.0000	7.0000	
0.8660	1.7321	2.5981	3.4641	4.3301	5.1962	6.0622	
0.7071	1.4142	2.1213	2.8284	3.5355	4.2426	4.9497	
0.0000	0.0000	0.0000	0.0000	0.0000	0.0000	0.0000	0.0000

Singleton expansion allows `bsxfun` to expand the input vectors into a full matrix.

<b>Purpose</b>	Build searchable documentation database
<b>Syntax</b>	<code>builddocsearchdb(folder)</code>
<b>Description</b>	<code>builddocsearchdb(folder)</code> builds a searchable database from HTML files in the specified folder. The <code>builddocsearchdb</code> function creates a subfolder named <code>helpsearch</code> to contain the database files. The database enables MATLAB to search for content within the HTML files, as long as the version of MATLAB is the same as the version used to create the database.
<b>Input Arguments</b>	<p><b>folder</b> - Full path to folder with HTML files</p> <p>string</p> <p>Full path to a folder with HTML files, specified as a string.</p> <p>To include a particular HTML document in the search database, the <code>builddocsearchdb</code> function requires that:</p> <ul style="list-style-type: none"><li>• The document has a title.</li><li>• The content is different from the title.</li></ul> <p><b>Example:</b> <code>builddocsearchdb('c:\myfiles\html')</code></p>
<b>Examples</b>	<p><b>Search Custom Help Files</b></p> <p>Build a search database for custom help files.</p> <p>MATLAB includes a set of sample files to demonstrate how to create a custom toolbox and supporting documentation. This sample toolbox is called the <i>Upslope Area Toolbox</i>. The <code>upslope</code> folder includes a file named <code>info.xml</code>, which is required to display custom documentation, and a subfolder named <code>html</code>, which contains HTML documentation and supporting files.</p> <p>Copy the sample files to a temporary folder, and add the copied files to the path.</p> <pre>sample = fullfile(...</pre>

# builddocsearchdb

---

```
matlabroot,'help','techdoc','matlab_env','examples','upslope');  
tmp = tempname;  
mkdir(tmp);  
copyfile(sample,tmp);  
addpath(tmp);
```

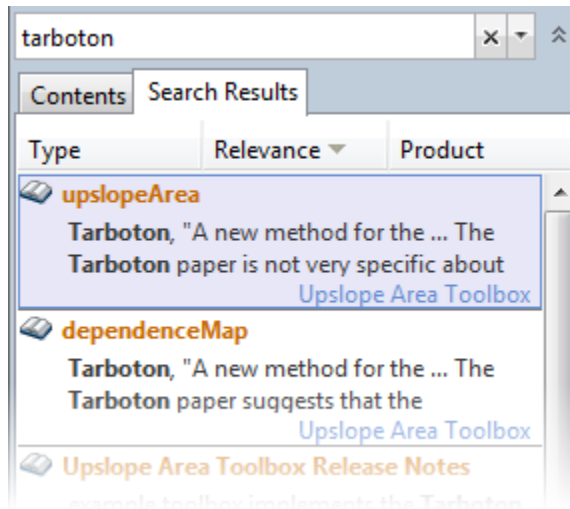

Create a search database.

```
folder = fullfile(tmp,'html');  
builddocsearchdb(folder)
```

Open the Supplemental Software documentation browser. There is a link to this browser at the bottom of the documentation home page.

Search the supplemental documentation for the term *tarboton*, which appears in several of the example help files. The search returns several results from the Upslope Area Toolbox.

Remove the temporary example files.

```
rmpath(tmp)  
rmdir(tmp, 's')
```

## Concepts

- “Display Custom Documentation”

# builtin

---

**Purpose** Execute built-in function from overloaded method

**Syntax** `builtin(function,x1,...,xn)`  
`[y1,...,yn] = builtin(function,x1,...,xn)`

**Description** `builtin(function,x1,...,xn)` executes the built-in function with the input arguments `x1` through `xn`. Use `builtin` to execute the original built-in from within a method that overloads the function. To work properly, you must never overload `builtin`.

`[y1,...,yn] = builtin(function,x1,...,xn)` stores any output from function in `y1` through `yn`.

## Input Arguments

**function - Built-in function name**  
string

Valid built-in function name in the MATLAB path, specified as a string. function cannot be a function handle.

**x1,...,xn - Valid input arguments for function**  
supported data types

Valid input arguments for function, specified by supported data types.

## Examples

### Run an Overloaded Function within a Class Definition

Execute the built-in functionality from within an overloaded method.

Create a simple class describing the speed of a particle and providing a `disp` method by pasting the following code into a file called `MyParticle.m`.

```
classdef MyParticle
    properties
        velocity;
    end
    methods
        function p = MyParticle(x,y,z)
```

```

        p.velocity.x = x;
        p.velocity.y = y;
        p.velocity.z = z;
    end
    function disp(p)
        builtin('disp',p) %call builtin
        if isscalar(p)
            disp(' Velocity')
            disp([' x: ',num2str(p.velocity.x)])
            disp([' y: ',num2str(p.velocity.y)])
            disp([' z: ',num2str(p.velocity.z)])
        end
    end
end
end
end
end

```

Create an instance MyParticle.

```
p = MyParticle(1,2,4)
```

```
p =
```

```
MyParticle
```

```
Properties:
```

```
velocity: [1x1 struct]
```

```
Methods
```

```
Velocity
```

```
x: 1
```

```

## Definitions

### built-in function

A built-in function is part of the MATLAB executable. MATLAB does not implement these functions in the MATLAB language. Although

# builtin

---

most built-in functions have a `.m` file associated with them, this file only supplies documentation for the function.

You can use the syntax `which function` to check whether a function is built-in.

**Purpose** Solve boundary value problems for ordinary differential equations

**Syntax**

```
sol = bvp4c(odefun,bcfun,solinit)
sol = bvp4c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

### Arguments

odefun	<p>A function handle that evaluates the differential equations <math>f(x,y)</math>. It can have the form</p> <pre>dydx = odefun(x,y) dydx = odefun(x,y,parameters)</pre> <p>where <math>x</math> is a scalar corresponding to <math>x</math>, and <math>y</math> is a column vector corresponding to <math>y</math>. <code>parameters</code> is a vector of unknown parameters. The output <code>dydx</code> is a column vector.</p>
bcfun	<p>A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form <math>bc(y(a),y(b))</math>, <code>bcfun</code> can have the form</p> <pre>res = bcfun(ya,yb) res = bcfun(ya,yb,parameters)</pre> <p>where <code>ya</code> and <code>yb</code> are column vectors corresponding to <math>y(a)</math> and <math>y(b)</math>. <code>parameters</code> is a vector of unknown parameters. The output <code>res</code> is a column vector.</p> <p>See “Multipoint Boundary Value Problems” on page 1-588 for a description of <code>bcfun</code> for multipoint boundary value problems.</p>
solinit	<p>A structure containing the initial guess for a solution. You create <code>solinit</code> using the function <code>bvpinit</code>. <code>solinit</code> has the following fields.</p>

	x	Ordered nodes of the initial mesh. Boundary conditions are imposed at $a = \text{solinit.x}(1)$ and $b = \text{solinit.x}(\text{end})$ .
	y	Initial guess for the solution such that $\text{solinit.y}(:,i)$ is a guess for the solution at the node $\text{solinit.x}(i)$ .
	parameters	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named x, y, and parameters. You can form solinit with the helper function bvpinit. See bvpinit for details.	
options	Optional integration argument. A structure you create using the bvpset function. See bvpset for details.	

## Description

`sol = bvp4c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval  $[a,b]$  subject to two-point boundary value conditions  $bc(y(a),y(b)) = 0$ .

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary.

`bvp4c` can also solve multipoint boundary value problems. See “Multipoint Boundary Value Problems” on page 1-588. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`. See the reference page for `bvpinit` for more information.

The `bvp4c` solver can also find unknown parameters  $p$  for problems of the form

$$y' = f(x, y, p)$$

$$0 = bc(y(a), y(b), p)$$

where  $p$  corresponds to parameters. You provide `bvp4c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp4c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp4c` produces a solution that is continuous on  $[a, b]$  and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp4c` to evaluate the solution at specific points `xint` in the interval  $[a, b]$ .

```
sxint = deval(sol, xint)
```

The structure `sol` returned by `bvp4c` has the following fields:

<code>sol.x</code>	Mesh selected by <code>bvp4c</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points of <code>sol.x</code>
<code>sol.yp</code>	Approximation to $y'(x)$ at the mesh points of <code>sol.x</code>
<code>sol.parameters</code>	Values returned by <code>bvp4c</code> for the unknown parameters, if any
<code>sol.solver</code>	' <code>bvp4c</code> '
<code>sol.stats</code>	Computational cost statistics (also displayed when the <code>stats</code> option is set with <code>bvpset</code> ).

The structure `sol` can have any name, and `bvp4c` creates the fields `x`, `y`, `yp`, `parameters`, and `solver`.

`sol = bvp4c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

## Singular Boundary Value Problems

`bvp4c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form

$$y' = S \cdot y/x + F(x,y,p)$$

$$0 = bc(y(0),y(b),p)$$

The interval is required to be  $[0, b]$  with  $b > 0$ . Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the 'SingularTerm' option of `bvpset`, and `odefun` evaluates only  $f(x,y,p)$ . The boundary conditions must be consistent with the necessary condition  $S \cdot y(0) = 0$  and the initial guess should satisfy this condition.

## Multipoint Boundary Value Problems

`bvp4c` can solve multipoint boundary value problems where  $a = a_0 < a_1 < a_2 < \dots < a_n = b$  are boundary points in the interval  $[a,b]$ . The points  $a_1, a_2, \dots, a_{n-1}$  represent interfaces that divide  $[a,b]$  into regions. `bvp4c` enumerates the regions from left to right (from  $a$  to  $b$ ), with indices starting from 1. In region  $k$ ,  $[a_{k-1}, a_k]$ , `bvp4c` evaluates the derivative as

$$yp = \text{odefun}(x,y,k)$$

In the boundary conditions function

$$\text{bcfun}(y_{\text{left}}, y_{\text{right}})$$

`yleft(:,k)` is the solution at the left boundary of  $[a_{k-1}, a_k]$ . Similarly, `yright(:,k)` is the solution at the right boundary of region  $k$ . In particular,

```
yleft(:,1) = y(a)
```

and

```
yright(:,end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit,yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x,k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp4c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

---

**Note** The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If  $S(x)$  approximates the solution  $y(x)$ , `bvp4c` controls the residual  $|S'(x) - f(x,S(x))|$ . This controls indirectly the true error  $|y(x) - S(x)|$ . `bvp5c` controls the true error directly. `bvp5c` is more efficient than `bvp4c` for small error tolerances.

---

## Examples

### Example 1

Boundary value problems can have multiple solutions and one purpose of the initial guess is to indicate which solution you want. The second-order differential equation

$$y'' + |y| = 0$$

has exactly two solutions that satisfy the boundary conditions  $y(0) = 0$ ,  $y(4) = -2$ .

Prior to solving this problem with `bvp4c`, you must write the differential equation as a system of two first-order ODEs

$$y_1' = y_2$$

$$y_2' = -|y_1|.$$

Here  $y_1 = y$  and  $y_2 = y'$ . This system has the required form

$$y' = f(x,y)$$

$$bc(y(a),y(b)) = 0$$

The function  $f$  and the boundary conditions  $bc$  are coded in MATLAB software as functions `twoode` and `twobc`.

```
function dydx = twoode(x,y)
    dydx = [ y(2)
            -abs(y(1))];
```

```
function res = twobc(ya,yb)
    res = [ ya(1)
            yb(1) + 2];
```

Form a guess structure consisting of an initial mesh of five equally spaced points in  $[0,4]$  and a guess of constant values

$$y_1(x) \equiv 0$$

and

$$y_2(x) \equiv 0$$

with the command

```
solinit = bvpinit(linspace(0,4,5),[1 0]);
```

Now solve the problem with

```
sol = bvp4c(@twoode,@twobc,solinit);
```

Evaluate the numerical solution at 100 equally spaced points and plot  $y(x)$  with

```
x = linspace(0,4);  
y = deval(sol,x);  
plot(x,y(1,:));
```

You can obtain the other solution of this problem with the initial guess

```
solinit = bvpinit(linspace(0,4,5),[-1 0]);
```

## Example 2

This boundary value problem involves an unknown parameter. The task is to compute the fourth ( $q = 5$ ) eigenvalue  $\lambda$  of Mathieu's equation

$$y'' + (\lambda - 2q \cos 2x)y = 0.$$

Because the unknown parameter  $\lambda$  is present, this second-order differential equation is subject to *three* boundary conditions:

$$y'(0) = 0$$

$$y'(\pi) = 0$$

$$y(0) = 1$$

It is convenient to use local functions to place all the functions required by bvp4c in a single file.

```

function mat4bvp

lambda = 15;
solinit = bvpinit(linspace(0,pi,10),@mat4init,lambda);
sol = bvp4c(@mat4ode,@mat4bc,solinit);

fprintf('The fourth eigenvalue is approximately %7.3f.\n',...
        sol.parameters)

xint = linspace(0,pi);
Sxint = deval(sol,xint);
plot(xint,Sxint(1,:))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xlabel('x')
ylabel('solution y')
% -----
function dydx = mat4ode(x,y,lambda)
q = 5;
dydx = [ y(2)
        -(lambda - 2*q*cos(2*x))*y(1) ];
% -----
function res = mat4bc(ya,yb,lambda)
res = [ ya(2)
        yb(2)
        ya(1)-1 ];
% -----
function yinit = mat4init(x)
yinit = [ cos(4*x)
        -4*sin(4*x) ];

```

The differential equation (converted to a first-order system) and the boundary conditions are coded as local functions `mat4ode` and `mat4bc`, respectively. Because unknown parameters are present, these functions must accept three input arguments, even though some of the arguments are not used.

The guess structure `solinit` is formed with `bvpinit`. An initial guess for the solution is supplied in the form of a function `mat4init`. We chose  $y = \cos 4x$  because it satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes). In the call to `bvpinit`, the third argument (`lambda = 15`) provides an initial guess for the unknown parameter  $\lambda$ .

After the problem is solved with `bvp4c`, the field `sol.parameters` returns the value  $\lambda = 17.097$ , and the plot shows the eigenfunction associated with this eigenvalue.

## Algorithms

`bvp4c` is a finite difference code that implements the three-stage Lobatto IIIa formula. This is a collocation formula and the collocation

polynomial provides a  $C^1$ -continuous solution that is fourth-order accurate uniformly in  $[a, b]$ . Mesh selection and error control are based on the residual of the continuous solution.

## Arguments

odefun	A function handle that evaluates the differential equations $f(x,y)$ . It can have the form  $dydx = \text{odefun}(x,y)$ $dydx = \text{odefun}(x,y,\text{parameters})$  where $x$ is a scalar corresponding to $x$ , and $y$ is a column vector corresponding to $y$ . $\text{parameters}$ is a vector of unknown parameters. The output $dydx$ is a column vector.	
bcfun	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a),y(b))$ , $\text{bcfun}$ can have the form  $\text{res} = \text{bcfun}(ya,yb)$ $\text{res} = \text{bcfun}(ya,yb,\text{parameters})$  where $ya$ and $yb$ are column vectors corresponding to $y(a)$ and $y(b)$ . $\text{parameters}$ is a vector of unknown parameters. The output $\text{res}$ is a column vector.	
solinit	A structure containing the initial guess for a solution. You create $\text{solinit}$ using the function $\text{bvpinit}$ . $\text{solinit}$ has the following fields.	
	$x$	Ordered nodes of the initial mesh. Boundary conditions are imposed at $a = \text{solinit}.x(1)$ and $b = \text{solinit}.x(\text{end})$ .

	<code>y</code>	Initial guess for the solution such that <code>solinit.y(:,i)</code> is a guess for the solution at the node <code>solinit.x(i)</code> .
	<code>parameters</code>	Optional. A vector that provides an initial guess for unknown parameters.
		The structure can have any name, but the fields must be named <code>x</code> , <code>y</code> , and <code>parameters</code> . You can form <code>solinit</code> with the helper function <code>bvpinit</code> . See <code>bvpinit</code> for details.
<code>options</code>		Optional integration argument. A structure you create using the <code>bvpset</code> function. See <code>bvpset</code> for details.

## Description

`sol = bvp5c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval `[a,b]` subject to two-point boundary value conditions

$$bc(y(a),y(b)) = 0$$

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`.

The `bvp5c` solver can also find unknown parameters  $p$  for problems of the form

$$y' = f(x,y,p)$$

$$0 = bc(y(a),y(b),p)$$

where  $p$  corresponds to parameters. You provide `bvp5c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp5c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp5c` produces a solution that is continuous on  $[a,b]$  and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp5c` to evaluate the solution at specific points `xint` in the interval  $[a,b]$ .

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp5c` has the following fields:

<code>sol.x</code>	Mesh selected by <code>bvp5c</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points of <code>sol.x</code>
<code>sol.parameters</code>	Values returned by <code>bvp5c</code> for the unknown parameters, if any
<code>sol.solver</code>	' <code>bvp5c</code> '
<code>sol.stats</code>	Computational cost statistics (also displayed when the <code>stats</code> option is set with <code>bvpset</code> ).

The structure `sol` can have any name, and `bvp5c` creates the fields `x`, `y`, `parameters`, and `solver`.

`sol = bvp5c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

## Singular Boundary Value Problems

`bvp5c` solves a class of singular boundary value problems, including problems with unknown parameters  $p$ , of the form

$$y' = S \cdot y/x + f(x,y,p)$$

$$0 = bc(y(0),y(b),p)$$

The interval is required to be  $[0, b]$  with  $b > 0$ . Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix  $S$  as the value of the 'SingularTerm' option of `bvpset`, and `odefun` evaluates only  $f(x,y,p)$ . The boundary conditions must be consistent with the necessary condition  $S \cdot y(0) = 0$  and the initial guess should satisfy this condition.

### Multipoint Boundary Value Problems

`bvp5c` can solve multipoint boundary value problems where  $a = a_0 < a_1 < a_2 < \dots < a_n = b$  are boundary points in the interval  $[a,b]$ . The points  $a_1, a_2, \dots, a_{n-1}$  represent interfaces that divide  $[a,b]$  into regions. `bvp5c` enumerates the regions from left to right (from  $a$  to  $b$ ), with indices starting from 1. In region  $k$ ,  $[a_{k-1}, a_k]$ , `bvp5c` evaluates the derivative as

$$yp = \text{odefun}(x,y,k)$$

In the boundary conditions function

$$\text{bcfun}(y_{\text{left}}, y_{\text{right}})$$

$y_{\text{left}}(:, k)$  is the solution at the left boundary of  $[a_{k-1}, a_k]$ . Similarly,  $y_{\text{right}}(:, k)$  is the solution at the right boundary of region  $k$ . In particular,

$$y_{\text{left}}(:, 1) = y(a)$$

and

$$y_{\text{right}}(:, \text{end}) = y(b)$$

When you create an initial guess with

$$\text{solinit} = \text{bvpinit}(x_{\text{init}}, y_{\text{init}}),$$

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x, k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp5c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example of that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

## Algorithms

`bvp5c` is a finite difference code that implements the four-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a  $C^1$ -continuous solution that is fifth-order accurate uniformly in  $[a, b]$ . The formula is implemented as an implicit Runge-Kutta formula. `bvp5c` solves the algebraic equations directly; `bvp4c` uses analytical condensation. `bvp4c` handles unknown parameters directly; while `bvp5c` augments the system with trivial differential equations for unknown parameters.

Kierzenka “Solving Boundary Value Problems for Ordinary Differential Equations in MATLAB with `bvp4c`” [http://www.mathworks.com/bvp\\_tutorial](http://www.mathworks.com/bvp_tutorial). Note that this tutorial uses the `bvp4c` function, however in most cases the solvers can be used interchangeably.

## See Also

@ | `bvp4c` | `bvpget` | `bvpinit` | `bvpset` | `bvpxtend` | `deval`

**Purpose** Extract properties from options structure created with `bvpset`

**Syntax**

```
val = bvpget(options,'name')  
val = bvpget(options,'name',default)
```

**Description**

`val = bvpget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = bvpget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = bvpget(options,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `options`.

**See Also** `bvp4c` | `bvp5c` | `bvpinit` | `bvpset` | `deval`

# bvpinit

---

**Purpose** Form initial guess for BVP solvers

**Syntax**

```
solinit = bvpinit(x,yinit)
solinit = bvpinit(x,yinit,parameters)
solinit = bvpinit(sol,[anew bnew])
solinit = bvpinit(sol,[anew bnew],parameters)
```

**Description** `solinit = bvpinit(x,yinit)` forms the initial guess for a boundary value problem solver.

`x` is a vector that specifies an initial mesh. If you want to solve the BVP on  $[a,b]$ , then specify `x(1)` as  $a$  and `x(end)` as  $b$ . The solver adapts this mesh to the solution, so a guess like `xb=n linspace(a,b,10)` often suffices. However, in difficult cases, you should place mesh points where the solution changes rapidly. The entries of `x` must be in

- Increasing order if  $a < b$
- Decreasing order if  $a > b$

For two-point boundary value problems, the entries of `x` must be distinct. That is, if  $a < b$ , the entries must satisfy `x(1) < x(2) < ... < x(end)`. If  $a > b$ , the entries must satisfy `x(1) > x(2) > ... > x(end)`

For multipoint boundary value problem, you can specify the points in  $[a,b]$  at which the boundary conditions apply, other than the endpoints  $a$  and  $b$ , by repeating their entries in `x`. For example, if you set

```
x = [0, 0.5, 1, 1, 1.5, 2];
```

the boundary conditions apply at three points: the endpoints 0 and 2, and the repeated entry 1. In general, repeated entries represent boundary points between regions in  $[a,b]$ . In the preceding example, the repeated entry 1 divides the interval  $[0,2]$  into two regions:  $[0,1]$  and  $[1,2]$ .

`yinit` is a guess for the solution. It can be either a vector, or a function:

- Vector – For each component of the solution, `bvpinit` replicates the corresponding element of the vector as a constant guess across

all mesh points. That is, `yinit(i)` is a constant guess for the *i*th component `yinit(i,:)` of the solution at all the mesh points in `x`.

- **Function** – For a given mesh point, the guess function must return a vector whose elements are guesses for the corresponding components of the solution. The function must be of the form

```
y = guess(x)
```

where `x` is a mesh point and `y` is a vector whose length is the same as the number of components in the solution. For example, if the guess function is a function, `bvpinit` calls

```
y(:,j) = guess(x(j))
```

at each mesh point.

For multipoint boundary value problems, the guess function must be of the form

```
y = guess(x, k)
```

where `y` an initial guess for the solution at `x` in region `k`. The function must accept the input argument `k`, which is provided for flexibility in writing the guess function. However, the function is not required to use `k`.

`solinit = bvpinit(x,yinit,parameters)` indicates that the boundary value problem involves unknown parameters. Use the vector `parameters` to provide a guess for all unknown parameters.

`solinit` is a structure with the following fields. The structure can have any name, but the fields must be named `x`, `y`, and `parameters`.

<code>x</code>	Ordered nodes of the initial mesh.
<code>y</code>	Initial guess for the solution with <code>solinit.y(:,i)</code> a guess for the solution at the node <code>solinit.x(i)</code> .
<code>parameters</code>	Optional. A vector that provides an initial guess for unknown parameters.

# bvpinit

---

`solinit = bvpinit(sol,[anew bnew])` forms an initial guess on the interval `[anew bnew]` from a solution `sol` on an interval `[a,b]`. The new interval must be larger than the previous one, so either `anew <= a < b <= bnew` or `anew >= a > b >= bnew`. The solution `sol` is extrapolated to the new interval. If `sol` contains parameters, they are copied to `solinit`.

`solinit = bvpinit(sol,[anew bnew],parameters)` forms `solinit` as described above, but uses `parameters` as a guess for unknown parameters in `solinit`.

## See Also

@ | [bvp4c](#) | [bvp5c](#) | [bvpget](#) | [bvpset](#) | [bvpxtend](#) | [deval](#)

**Purpose**

Create or alter options structure of boundary value problem

**Syntax**

```
options = bvpset('name1',value1,'name2',value2,...)
options = bvpset(olddopts,'name1',value1,...)
options = bvpset(olddopts,newopts)
bvpset
```

**Description**

`options = bvpset('name1',value1,'name2',value2,...)` creates a structure `options` that you can supply to the boundary value problem solver `bvp4c`, in which the named properties have the specified values. Any unspecified properties retain their default values. For all properties, it is sufficient to type only the leading characters that uniquely identify the property. `bvpset` ignores case for property names.

`options = bvpset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This overwrites any values in `olddopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = bvpset(olddopts,newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `olddopts`.

`bvpset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `bvpget` to query the options structure for the value of a specific property.

**BVP Properties**

`bvpset` enables you to specify properties for the boundary value problem solver `bvp4c`. There are several categories of properties that you can set:

- “Error Tolerance Properties” on page 1-606
- “Vectorization” on page 1-607
- “Analytical Partial Derivatives” on page 1-608
- “Singular BVPs” on page 1-609
- “Mesh Size Property” on page 1-610

- “Solution Statistic Property” on page 1-611

## Error Tolerance Properties

Because `bvp4c` uses a collocation formula, the numerical solution is based on a mesh of points at which the collocation equations are satisfied. Mesh selection and error control are based on the residual of this solution, such that the computed solution  $S(x)$  is the exact solution of a perturbed problem  $S'(x) = f(x, S(x)) + res(x)$ . On each subinterval of the mesh, a norm of the residual in the  $i$ th component of the solution,  $res(i)$ , is estimated and is required to be less than or equal to a tolerance. This tolerance is a function of the relative and absolute tolerances, `RelTol` and `AbsTol`, defined by the user.

$$\left| \left( res(i) / \max( abs(f(i)), AbsTol(i) / RelTol ) \right) \right| \leq RelTol$$

The following table describes the error tolerance properties.

### BVP Error Tolerance Properties

Property	Value	Description
<code>RelTol</code>	Positive scalar {1e-3}	<p>A relative error tolerance that applies to all components of the residual vector. It is a measure of the residual relative to the size of <math>f(x,y)</math>. The default, 1e-3, corresponds to 0.1% accuracy.</p> <p>The computed solution <math>S(x)</math> is the exact solution of <math>S'(x) = F(x, S(x)) + res(x)</math>. On each subinterval of the mesh, the residual <math>res(x)</math> satisfies</p> $\left  \left( res(i) / \max( abs(F(i)), AbsTol(i) / RelTol ) \right) \right  \leq RelTol$
<code>AbsTol</code>	Positive scalar or vector {1e-6}	<p>Absolute error tolerances that apply to the corresponding components of the residual vector. <code>AbsTol(i)</code> is a threshold below which the values of the corresponding components are unimportant. If a scalar value is specified, it applies to all components.</p>

## Vectorization

The following table describes the BVP vectorization property. Vectorization of the ODE function used by `bvp4c` differs from the vectorization used by the ODE solvers:

- For `bvp4c`, the ODE function must be vectorized with respect to the first argument as well as the second one, so that `F([x1 x2 ...], [y1 y2 ...])` returns `[F(x1,y1) F(x2,y2)...]`.
- `bvp4c` benefits from vectorization even when analytical Jacobians are provided. For stiff ODE solvers, vectorization is ignored when analytical Jacobians are used.

## Vectorization Properties

Property	Value	Description
Vectorized	on   {off}	<p>Set on to inform <code>bvp4c</code> that you have coded the ODE function <code>F</code> so that <code>F([x1 x2 ...], [y1 y2 ...])</code> returns <code>[F(x1,y1) F(x2,y2) ...]</code>. That is, your ODE function can pass to the solver a whole array of column vectors at once. This enables the solver to reduce the number of function evaluations and may significantly reduce solution time.</p> <p>With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. In the <code>shockbvp</code> example shown previously, the <code>shockODE</code> function has been vectorized using colon notation into the subscripts and by using the array multiplication <code>(.*)</code> operator.</p> <pre>function dydx = shockODE(x,y,e)</pre>

## Vectorization Properties (Continued)

Property	Value	Description
		<pre> pix = pi*x; dydx = [ y(2,:)... -x/e.*y(2,)-pi^2*cos(pix)- pix/e.*sin(pix)]; </pre>

## Analytical Partial Derivatives

By default, the `bvp4c` solver approximates all partial derivatives with finite differences. `bvp4c` can be more efficient if you provide analytical partial derivatives  $\partial f/\partial y$  of the differential equations, and analytical partial derivatives,  $\partial bc/\partial ya$  and  $\partial bc/\partial yb$ , of the boundary conditions. If the problem involves unknown parameters, you must also provide partial derivatives,  $\partial f/\partial p$  and  $\partial bc/\partial p$ , with respect to the parameters.

The following table describes the analytical partial derivatives properties.

## BVP Analytical Partial Derivative Properties

Property	Value	Description
FJacobian	Function handle	A function handle that computes the analytical partial derivatives of $f(x,y)$ . When solving $y' = f(x,y)$ , set this property to <code>@fjac</code> if <code>dfdy = fjac(x,y)</code> evaluates the Jacobian $\partial f/\partial y$ . If the problem involves unknown parameters $p$ , <code>[dfdy,dfdp] = fjac(x,y,p)</code> must also return the partial derivative $\partial f/\partial p$ . For problems with constant partial derivatives, set

**BVP Analytical Partial Derivative Properties (Continued)**

Property	Value	Description
		this property to the value of <code>dfdy</code> or to a cell array <code>{dfdy,dfdp}</code> .
BCJacobian	Function handle	A function handle that computes the analytical partial derivatives of $bc(ya,yb)$ . For boundary conditions $bc(ya,yb)$ , set this property to <code>@bcjac</code> if <code>[dbcodya,dbcodyb] = bcjac(ya,yb)</code> evaluates the partial derivatives $\partial bc/\partial ya$ , and $\partial bc/\partial yb$ . If the problem involves unknown parameters $p$ , <code>[dbcodya,dbcodyb,dbcdp] = bcjac(ya,yb,p)</code> must also return the partial derivative $\partial bc/\partial p$ . For problems with constant partial derivatives, set this property to a cell array <code>{dbcodya,dbcodyb}</code> or <code>{dbcodya,dbcodyb,dbcdp}</code> .

**Singular BVPs**

`bvp4c` can solve singular problems of the form

$$y' = S \frac{y}{x} + f(x,y,p)$$

posed on the interval  $[0,b]$  where  $b > 0$ . For such problems, specify the constant matrix  $S$  as the value of `SingularTerm`. For equations of this form, `odefun` evaluates only the  $f(x,y,p)$  term, where  $p$  represents unknown parameters, if any.

**Singular BVP Property**

<b>Property</b>	<b>Value</b>	<b>Description</b>
SingularTerm	Constant matrix	Singular term of singular BVPs. Set to the constant matrix $S$ for equations of the form $y' = S \frac{y}{x} + f(x, y, p)$ posed on the interval $[0, b]$ where $b > 0$ .

**Mesh Size Property**

bvp4c solves a system of algebraic equations to determine the numerical solution to a BVP at each of the mesh points. The size of the algebraic system depends on the number of differential equations ( $n$ ) and the number of mesh points in the current mesh ( $N$ ). When the allowed number of mesh points is exhausted, the computation stops, bvp4c displays a warning message and returns the solution it found so far. This solution does not satisfy the error tolerance, but it may provide an excellent initial guess for computations restarted with relaxed error tolerances or an increased value of  $N_{Max}$ .

The following table describes the mesh size property.

### BVP Mesh Size Property

Property	Value	Description
NMax	positive integer {floor(1000/n)}	Maximum number of mesh points allowed when solving the BVP, where $n$ is the number of differential equations in the problem. The default value of NMax limits the size of the algebraic system to about 1000 equations. For systems of a few differential equations, the default value of NMax should be sufficient to obtain an accurate solution.

### Solution Statistic Property

The Stats property lets you view solution statistics.

The following table describes the solution statistics property.

### BVP Solution Statistic Property

Property	Value	Description
Stats	on   {off}	Specifies whether statistics about the computations are displayed. If the stats property is on, after solving the problem, bvp4c displays: <ul style="list-style-type: none"> <li>• The number of points in the mesh</li> <li>• The maximum residual of the solution</li> <li>• The number of times it called the differential equation function odefun to evaluate <math>f(x,y)</math></li> </ul>

## BVP Solution Statistic Property (Continued)

Property	Value	Description
		<ul style="list-style-type: none"><li>The number of times it called the boundary condition function <code>bcfun</code> to evaluate <math>bc(y(a),y(b))</math></li></ul>

### Examples

To create an options structure that changes the relative error tolerance of `bvp4c` from the default value of  $1e-3$  to  $1e-4$ , enter

```
options = bvpset('RelTol',1e-4);
```

To recover the value of 'RelTol' from `options`, enter

```
bvpget(options, 'RelTol')
```

```
ans =
```

```
1.0000e-004
```

### See Also

`function_handle` | `bvp4c` | `bvp5c` | `bvpget` | `bvpinit` | `deval`

**Purpose** Form guess structure for extending boundary value solutions

**Syntax**

```
solinit = bvpxtend(sol,xnew,ynew)
solinit = bvpxtend(sol,xnew,extrap)
solinit = bvpxtend(sol,xnew)
solinit = bvpxtend(sol,xnew,ynew,pnew)
solinit = bvpxtend(sol,xnew,extrap,pnew)
```

**Description** `solinit = bvpxtend(sol,xnew,ynew)` uses solution `sol` computed on `[a,b]` to form a solution guess for the interval extended to `xnew`. The extension point `xnew` must be outside the interval `[a,b]`, but on either side. The vector `ynew` provides an initial guess for the solution at `xnew`.

`solinit = bvpxtend(sol,xnew,extrap)` forms the guess at `xnew` by extrapolating the solution `sol`. `extrap` is a string that determines the extrapolation method. `extrap` has three possible values:

- 'constant' — `ynew` is a value nearer to end point of solution in `sol`.
- 'linear' — `ynew` is a value at `xnew` of linear interpolant to the value and slope at the nearer end point of solution in `sol`.
- 'solution' — `ynew` is the value of (cubic) solution in `sol` at `xnew`.

The value of `extrap` is case-insensitive and only the leading, unique portion needs to be specified.

`solinit = bvpxtend(sol,xnew)` uses the extrapolating solution where `extrap` is 'constant'. If there are unknown parameters, values present in `sol` are used as the initial guess for parameters in `solinit`.

`solinit = bvpxtend(sol,xnew,ynew,pnew)` specifies a different guess `pnew`. `pnew` can be used with extrapolation, using the syntax `solinit = bvpxtend(sol,xnew,extrap,pnew)`. To modify parameters without changing the interval, use `[]` as place holder for `xnew` and `ynew`.

**See Also** `bvp4c` | `bvp5c` | `bvpinit`

# calendar

---

**Purpose** Calendar for specified month

**Syntax**  
c = calendar  
c = calendar(d)  
c = calendar(y, m)

**Description** c = calendar returns a 6-by-7 matrix containing a calendar for the current month. The calendar runs Sunday (first column) to Saturday.  
c = calendar(d), where d is a serial date number or a date string, returns a calendar for the specified month.  
c = calendar(y, m), where y and m are integers, returns a calendar for the specified month of the specified year.

**Examples** The command  
calendar(1957,10)

reveals that the Space Age began on a Friday (on October 4, 1957, when Sputnik 1 was launched).

```
                Oct 1957
   S      M      Tu      W      Th      F      S
   0      0      1      2      3      4      5
   6      7      8      9      10     11     12
  13     14     15     16     17     18     19
  20     21     22     23     24     25     26
  27     28     29     30     31      0      0
   0      0      0      0      0      0      0
```

---

<b>Purpose</b>	Call function in shared library
<b>Syntax</b>	<code>[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)</code>
<b>Description</b>	<code>[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)</code> calls function, <code>funcname</code> , in library, <code>libname</code> , passing input arguments, <code>arg1,...,argN</code> , and returns output values obtained from <code>funcname</code> in <code>x1,...,xN</code> .
<b>Input Arguments</b>	<p><b>libname - Name of shared library</b> string</p> <p>Name of shared library, specified as a string. If you call <code>loadlibrary</code> using the <code>alias</code> option, then you must use the alias name for the <code>libname</code> argument.</p> <p><b>Data Types</b> char</p> <p><b>funcname - Name of function in library</b> string</p> <p>Name of function in library, specified as a string.</p> <p><b>Data Types</b> char</p> <p><b>arg1,...,argN - Input arguments</b> any type</p> <p>Input arguments, 1 through N, required by <code>funcname</code> (if any), specified by any type. The argument type is specified by the <code>funcname</code> argument list.</p>
<b>Output Arguments</b>	<p><b>x1,...,xN - Output arguments</b> any type</p> <p>Output arguments, 1 through N, from <code>funcname</code> (if any), returned as any type. The argument type is specified by the <code>funcname</code> argument list.</p>

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## Examples

### Call `addStructByRef` Function

Load the library.

```
if ~libisloaded('shrlibsample')
    addpath(fullfile(matlabroot,'extern','examples','shrlib'))
    loadlibrary('shrlibsample')
end
```

Display function signature.

```
libfunctionsview shrlibsample
```

```
[double, c_structPtr] addStructByRef(c_structPtr)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `struct`:

```
struct.p1 = 4; struct.p2 = 7.3; struct.p3 = -290;
```

Call the function.

```
[res,st] = calllib('shrlibsample','addStructByRef',struct);
```

Display the results.

```
res
```

```
res =
    -279
```

Clean up.

```
unloadlibrary shrlibsample
```

# callSoapService

---

**Purpose** Send SOAP message to endpoint

**Syntax** `response = callSoapService(endpoint,soapAction,message)`

**Description** `response = callSoapService(endpoint,soapAction,message)` sends `message`, a Java<sup>®</sup> document object model (DOM), to the `soapAction` service at `endpoint`. Create message using `createSoapMessage`, and extract results from `response` using `parseSoapResponse`.

**Examples** This example uses `callSoapService` in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

---

**Note** The example does not use an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

---

```
% Create the message:
message = createSoapMessage(...
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'},...
'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
'http://test/soap/services/LibraryCatalog',...
'urn:LibraryCatalog#getAuthor',...
message)
%
% Extract MATLAB data from the response
```

```
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

## How To

- “Access Web Services Using MATLAB SOAP Functions”

**Purpose** Move camera position and target

**Syntax**

```
camdolly(dx,dy,dz)
camdolly(dx,dy,dz,'targetmode')
camdolly(dx,dy,dz,'targetmode','coordsys')
camdolly(axes_handle,...)
```

**Description** `camdolly(dx,dy,dz)` moves the camera position and the camera target by the specified amounts `dx`, `dy`, and `dz`.

`camdolly(dx,dy,dz,'targetmode')` uses the `targetmode` argument to determine how the camera moves:

- `movetarget` (default) — Move both the camera and the target.
- `fixtarget` — Move only the camera.

`camdolly(dx,dy,dz,'targetmode','coordsys')` uses the `coordsys` argument to determine how MATLAB interprets `dx`, `dy`, and `dz`:

- `camera` (default) — Move in the coordinate system of the camera. `dx` moves left/right, `dy` moves down/up, and `dz` moves along the viewing axis. MATLAB normalizes the units to the scene.

For example, setting `dx` to 1 moves the camera to the right, which pushes the scene to the left edge of the box formed by the axes position rectangle. A negative value moves the scene in the other direction. Setting `dz` to 0.5 moves the camera to a position halfway between the camera position and the camera target.

- `pixels` — Interpret `dx` and `dy` as pixel offsets and ignore `dz`.
- `data` — Interpret `dx`, `dy`, and `dz` as offsets in axes data coordinates.

`camdolly(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camdolly` operates on the current axes.

`camdolly` sets the axes `CameraPosition` and `CameraTarget` properties, which in turn sets the `CameraPositionMode` and `CameraTargetMode` properties to manual.

**Examples**

Move the camera along the  $x$ - and  $y$ -axes in a series of steps:

```
surf(peaks)
axis vis3d
t = 0:pi/20:2*pi;
dx = sin(t)/40;
dy = cos(t)/40;
for i = 1:length(t);
    camdolly(dx(i),dy(i),0)
    drawnow
end
```

# cameratoolbar

---

**Purpose** Control camera toolbar programmatically

**Syntax**

```
cameratoolbar
cameratoolbar('NoReset')
cameratoolbar('SetMode',mode)
cameratoolbar('SetCoordSys',coordsys)
cameratoolbar('Show')
cameratoolbar('Hide')
cameratoolbar('Toggle')
cameratoolbar('ResetCameraAndSceneLight')
cameratoolbar('ResetCamera')
cameratoolbar('ResetSceneLight')
cameratoolbar('ResetTarget')
mode = cameratoolbar('GetMode')
paxis = cameratoolbar('GetCoordsys')
vis = cameratoolbar('GetVisible')
cameratoolbar(fig,...)
h = cameratoolbar
cameratoolbar('Close')
```

**Description** cameratoolbar creates a toolbar that enables interactive manipulation of the axes camera and light when you drag the mouse on the figure window. Several axes camera properties are set when the toolbar is initialized.

cameratoolbar('NoReset') creates the toolbar without setting any camera properties.

cameratoolbar('SetMode',mode) sets the toolbar mode (depressed button). mode can be 'orbit', 'orbitscenelight', 'pan', 'dollyhv', 'dollyfb', 'zoom', 'roll', 'nomode'. For descriptions of the various modes, see “Camera Toolbar”. You can also set these modes using the toolbar, by clicking the respective buttons.

cameratoolbar('SetCoordSys',coordsys) sets the principal axis of the camera motion. coordsys can be: 'x', 'y', 'z', 'none'.

cameratoolbar('Show') shows the toolbar on the current figure.

`cameratoolbar('Hide')` hides the toolbar on the current figure.

`cameratoolbar('Toggle')` toggles the visibility of the toolbar.

`cameratoolbar('ResetCameraAndSceneLight')` resets the current camera and scenelight.

`cameratoolbar('ResetCamera')` resets the current camera.

`cameratoolbar('ResetSceneLight')` resets the current scenelight.

`cameratoolbar('ResetTarget')` resets the current camera target.

`mode = cameratoolbar('GetMode')` returns the current mode.

`paxis = cameratoolbar('GetCoordsys')` returns the current principal axis.

`vis = cameratoolbar('GetVisible')` returns the visibility of the toolbar (1 if visible, 0 if not visible).

`cameratoolbar(fig, ...)` specifies the figure to operate on by passing the figure handle as the first argument.

`h = cameratoolbar` returns the handle to the toolbar.

`cameratoolbar('Close')` removes the toolbar from the current figure.

In general, the use of OpenGL hardware improves rendering performance.

## Alternatives

Display the toolbar by selecting **Camera Toolbar** from the figure window's **View** menu.

## How To

- “Camera Toolbar”

# camlight

---

**Purpose** Create or move light object in camera coordinates

**Syntax**

```
camlight('headlight')
camlight('right')
camlight('left')
camlight
camlight(az,e1)
camlight(...,'style')
camlight(light_handle,...)
light_handle = camlight(...)
```

**Description**

`camlight('headlight')` creates a light at the camera position.

`camlight('right')` creates a light right and up from camera.

`camlight('left')` creates a light left and up from camera.

`camlight` with no arguments is the same as `camlight('right')`.

`camlight(az,e1)` creates a light at the specified azimuth (`az`) and elevation (`e1`) with respect to the camera position. The camera target is the center of rotation and `az` and `e1` are in degrees.

`camlight(...,'style')` defines the style argument using one of two values:

- `local` (default) — The light is a point source that radiates from the location in all directions.
- `infinite` — The light shines in parallel rays.

`camlight(light_handle,...)` uses the light specified in `light_handle`.

`light_handle = camlight(...)` returns the light object handle.

`camlight` sets the light object `Position` and `Style` properties. A light created with `camlight` does not track the camera. In order for the light to stay in a constant position relative to the camera, call `camlight` whenever you move the camera.

## Examples

Create a light positioned to the left of the camera and then reposition the light each time the camera moves:

```
surf(peaks)
axis vis3d
h = camlight('left');
for i = 1:20;
    camorbit(10,0)
    camlight(h,'left')
    drawnow;
end
```

## See Also

## How To

- “Lighting Overview”

# camlookat

---

**Purpose** Position camera to view object or group of objects

**Syntax** `camlookat(object_handles)`  
`camlookat(axes_handle)`  
`camlookat`

**Description** `camlookat(object_handles)` views the objects identified in the vector `object_handles`. The vector can contain the handles of axes children.

`camlookat(axes_handle)` views the objects that are children of the axes identified by `axes_handle`.

`camlookat` views the objects that are in the current axes by moving the camera position and camera target while preserving the relative view direction and camera view angle. The viewed object (or objects) roughly fill the axes position rectangle. To change the view, `camlookat` sets the axes `CameraPosition` and `CameraTarget` properties.

**Examples** Create three spheres at different locations and then progressively position the camera so that the scene composes around each sphere individually:

```
% Create three spheres using the sphere function:
[x y z] = sphere;
s1 = surf(x,y,z);
hold on
s2 = surf(x+3,y,z+3);
s3 = surf(x,y,z+6);
% Set the data aspect ratio using daspect:
daspect([1 1 1])
% Set the view:
view(30,10)
% Set the projection type using camproj:
camproj perspective
% Compose the scene around the current axes
camlookat(gca)
pause(2)
% Compose the scene around sphere s1
```

```
camlookat(s1)
pause(2)
% Compose the scene around sphere s2
camlookat(s2)
pause(2)
% Compose the scene around sphere s3
camlookat(s3)
pause(2)
camlookat(gca)
```

## See Also

campos | camtarget

## How To

- “Defining Scenes with Cameras”

**Purpose** Rotate camera position around camera target

**Syntax**

```
camorbit(dtheta,dphi)
camorbit(dtheta,dphi,'coordsys')
camorbit(dtheta,dphi,'coordsys','direction')
camorbit(axes_handle,...)
```

**Description** `camorbit(dtheta,dphi)` rotates the camera position around the camera target by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`camorbit(dtheta,dphi,'coordsys')` rotates the camera position around the camera target, using the `coordsys` argument to determine the center of rotation. `coordsys` can take on two values:

- `data` (default) — Rotate the camera around an axis defined by the camera target and the `direction` (default is the positive  $z$  direction).
- `camera` — Rotate the camera about the point defined by the camera target.

`camorbit(dtheta,dphi,'coordsys','direction')` defines the axis of rotation for the `data` coordinate system using the `direction` argument in conjunction with the camera target. Specify `direction` as a three-element vector containing the  $x$ -,  $y$ -, and  $z$ -components of the direction or one of the characters,  $x$ ,  $y$ , or  $z$ , to indicate  $[1\ 0\ 0]$ ,  $[0\ 1\ 0]$ , or  $[0\ 0\ 1]$  respectively.

`camorbit(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camorbit` operates on the current axes.

The behavior of `camorbit` differs from the `rotate3d` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the aspect ratio and modifies the `CameraTarget`, `CameraPosition` and `CameraUpVector` properties of the axes. See `Axes Properties` for more information.

## Examples

Rotate the camera horizontally about a line defined by the camera target point and a direction that is parallel to the  $y$ -axis. Visualize this rotation as a cone formed with the camera target at the apex and the camera position forming the base:

```
surf(peaks)
axis vis3d
for i=1:36
    camorbit(10,0,'data',[0 1 0])
    drawnow
end
```

---

Rotate in the camera coordinate system to orbit the camera around the axes along a circle while keeping the center of a circle at the camera target:

```
surf(peaks)
axis vis3d
for i=1:36
    camorbit(10,0,'camera')
    drawnow
end
```

## Alternatives

Enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

## How To

- “Defining Scenes with Cameras”

# campan

---

**Purpose** Rotate camera target around camera position

**Syntax**

```
campan(dtheta,dphi)
campan(dtheta,dphi,coordsys)
campan(dtheta,dphi,coordsys,direction)
campan(axes_handle,...)
```

**Description** `campan(dtheta,dphi)` rotates the camera target of the current axes around the camera position by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`campan(dtheta,dphi,coordsys)` determine the center of rotation using the `coordsys` argument. It can take on two values:

- 'data' (default) — Rotate the camera target around an axis defined by the camera position and the `direction` (default is the positive `z` direction)
- 'camera' — Rotate the camera about the point defined by the camera target.

`campan(dtheta,dphi,coordsys,direction)` defines the axis of rotation for the data coordinate system using the `direction` argument with the camera position. Specify `direction` as a three-element vector containing the `x`-, `y`-, and `z`-components of the direction or one of the characters, 'x', 'y', or 'z', to indicate [1 0 0], [0 1 0], or [0 0 1] respectively.

`campan(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campan` operates on the current axes.

**Examples** Move the camera target to pan the object in a circular motion.

```
sphere;
axis vis3d
hPan = sin(-pi:1:pi);
vPan = cos(-pi:1:pi);
```

```
for k=1:length(hPan)
    campan(hPan(k),vPan(k))
    drawnow
    pause(.1)
end
```

**How To**

- “Defining Scenes with Cameras”

# campos

---

**Purpose** Set or query camera position

**Syntax**

```
campos
campos([camera_position])
campos('mode')
campos('auto')
campos('manual')
campos(axes_handle,...)
```

**Description**

campos returns the camera position in the current axes.

campos([camera\_position]) sets the position of the camera in the current axes to the specified value. Specify the position as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

campos('mode') returns the value of the camera position mode, which can be either auto (the default) or manual.

campos('auto') sets the camera position mode to auto.

campos('manual') sets the camera position mode to manual.

campos(axes\_handle,...) performs the set or query on the axes identified by the first argument, axes\_handle. When you do not specify an axes handle, campos operates on the current axes.

campos sets or queries values of the axes CameraPosition and CameraPositionMode properties. The camera position is the point in the Cartesian coordinate system of the axes from which you view the scene.

**Examples** Move the camera along the *x*-axis in a series of steps:

```
surf(peaks)
axis vis3d off
for x = -200:5:200
    campos([x,5,10])
    drawnow
end
```

**See Also**

| [Axes: CameraTarget](#) | [Axes: CameraUpVector](#) | [Axes: CameraViewAngle](#) | [Axes: Projection](#)

**How To**

- “Defining Scenes with Cameras”

# camproj

---

**Purpose** Set or query projection type

**Syntax** `camproj`  
`camproj('projection_type')`  
`camproj(axes_handle,...)`

**Description** `camproj` returns the projection type setting in the current axes. The projection type determines whether MATLAB 3-D views use a perspective or orthographic projection.

`camproj('projection_type')` sets the projection type in the current axes to the specified value. Possible values for *projection\_type* are orthographic and perspective.

`camproj(axes_handle,...)` performs the set or query on the axes identified by the first argument, *axes\_handle*. When you do not specify an axes handle, `camproj` operates on the current axes.

`camproj` sets or queries values of the axes object `Projection` property.

**Examples** Compare the different `camproj` settings using `subplot`:

```
subplot(1,2,1); surf(membrane); camproj('perspective')
subplot(1,2,2); surf(membrane); camproj('orthographic')
```

## See Also

## How To

- “Defining Scenes with Cameras”

# camroll

---

**Purpose** Rotate camera about view axis

**Syntax** `camroll(dtheta)`  
`camroll(axes_handle,dtheta)`

**Description** `camroll(dtheta)` rotates the camera around the camera viewing axis by the amounts specified in `dtheta` (in degrees). The viewing axis is the line passing through the camera position and the camera target.

`camroll(axes_handle,dtheta)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camroll` operates on the current axes.

`camroll` sets the axes `CameraUpVector` property and also sets the `CameraUpVectorMode` property to `manual`.

**Examples** Rotate the camera around the viewing axis:

```
surf(peaks)
axis vis3d
for i=1:36
    camroll(10)
    drawnow
end
```

**See Also** `axes` | `axis` | `camdolly` | `camorbit` | `camzoom` | `campan`

**How To** • “Defining Scenes with Cameras”

**Purpose** Set or query location of camera target

**Syntax**

```
camtarget
camtarget([camera_target])
camtarget('mode')
camtarget('auto')
camtarget('manual')
camtarget('manual')
camtarget(axes_handle,...)
```

**Description** `camtarget` returns the location of the camera target in the current axes. The camera target is the location in the axes that the camera points to. The camera remains oriented toward this point regardless of its position.

`camtarget([camera_target])` sets the camera target in the current axes to the specified value. Specify the target as a three-element vector containing the  $x$ -,  $y$ -, and  $z$ -coordinates of the desired location in the data units of the axes.

`camtarget('mode')` returns the value of the camera target mode, which can be either `auto` (default) or `manual`.

`camtarget('auto')` sets the camera target mode to `auto`. When the camera target mode is `auto`, the camera target is the center of the axes plot box.

`camtarget('manual')` sets the camera target mode to `manual`.

`camtarget(axes_handle,...)` performs the set or query on the axes identified by `axes_handle`. When you do not specify an axes handle, `camtarget` operates on the current axes.

`camtarget` sets or queries values of the axes object `CameraTarget` and `CameraTargetMode` properties.

**Examples** Move the camera position and the camera target along the  $x$ -axis in a series of steps:

```
surf(peaks);
axis vis3d
```

# camtarget

---

```
xp = linspace(-150,40,50);
xt = linspace(25,50,50);
for i=1:50
    campos([xp(i),25,5]);
    camtarget([xt(i),30,0])
    drawnow
end
```

## See Also

## How To

- “Defining Scenes with Cameras”

**Purpose** Set or query camera up vector

**Syntax**

```
camup
camup([up_vector])
camup('mode')
camup('auto')
camup('manual')
camup(axes_handle,...)
```

**Description** `camup` returns the camera up vector setting in the current axes. The camera up vector specifies the direction that is oriented up in the scene.

`camup([up_vector])` sets the up vector in the current axes to the specified value. Specify the up vector as  $x$ ,  $y$ , and  $z$  components.

`camup('mode')` returns the current value of the camera up vector mode, which can be either `auto` (default) or `manual`.

`camup('auto')` sets the camera up vector mode to `auto`. In `auto` mode,  $[0\ 1\ 0]$  is the up vector of for 2-D views. This means the  $y$ -axis points up. For 3-D views, the up vector is  $[0\ 0\ 1]$ , meaning the  $z$ -axis points up.

`camup('manual')` sets the camera up vector mode to `manual`. In `manual` mode, the value of the camera up vector does not change unless you set it.

`camup(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camup` operates on the current axes.

**Examples** Set the  $x$ -axis to be the up axis:

```
surf(peaks)
camup([1 0 0]);
```

## See Also

[axis](#) | [campos](#) | [camup](#) | [camtargt](#) | [Axes: CameraPosition](#) | [Axes: CameraTarget](#) | [Axes: CameraUpVector](#) | [Axes: CameraViewAngle](#) | [Axes: Projection](#)

## How To

- “Defining Scenes with Cameras”

**Purpose** Set or query camera view angle

**Syntax**

```
camva
camva(view_angle)
camva('mode')
camva('auto')
camva('manual')
camva(axes_handle,...)
```

**Description** `camva` returns the camera view angle setting in the current axes. The camera view angle determines the field of view of the camera. Larger angles produce a smaller view of the scene. Implement zooming by changing the camera view angle.

`camva(view_angle)` sets the view angle in the current axes to the specified value. Specify the view angle in degrees.

`camva('mode')` returns the current value of the camera view angle mode, which can be either `auto` (the default) or `manual`.

`camva('auto')` sets the camera view angle mode to `auto`.

`camva('manual')` sets the camera view angle mode to `manual`.

`camva(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camva` operates on the current axes.

**Tips** The `camva` function sets or queries values of the axes object `CameraViewAngle` and `CameraViewAngleMode` properties.

When the camera view angle mode is `auto`, the camera view angle adjusts so that the scene fills the available space in the window. If you move the camera to a different position, the camera view angle changes to maintain a view of the scene that fills the available area in the window.

Setting a camera view angle or setting the camera view angle to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes

to fit the window). This means setting the camera view angle to its current value,

```
camva(camva)
```

can cause a change in the way the graph looks. See `axes` for more information.

### Examples

Create two pushbuttons, one that zooms in and another that zooms out:

```
% Set the range checking in the callback statements to keep
% the values for the camera view angle in the range greater
% than zero and less than 180.
uicontrol('Style','pushbutton',...
    'String','Zoom In',...
    'Position',[20 20 60 20],...
    'Callback','if camva <= 1;return;else;camva(camva-1);end');
uicontrol('Style','pushbutton',...
    'String','Zoom Out',...
    'Position',[100 20 60 20],...
    'Callback','if camva >= 179;return;else;camva(camva+1);end');
% Now create a graph to zoom in and out on:
surf(peaks);
```

### How To

- “Defining Scenes with Cameras”

- Purpose** Zoom in and out on scene
- Syntax** `camzoom(zoom_factor)`  
`camzoom(axes_handle,...)`
- Description** `camzoom(zoom_factor)` zooms in or out on the scene depending on the value specified by `zoom_factor`. If `zoom_factor` is greater than 1, the scene appears larger; if `zoom_factor` is greater than zero and less than 1, the scene appears smaller.
- `camzoom(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camzoom` operates on the current axes.
- Tips** `camzoom` sets the axes `CameraViewAngle` property, which in turn causes the `CameraViewAngleMode` property to be set to `manual`. Note that setting the `CameraViewAngle` property disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This may result in a change to the aspect ratio of your graph. See the `axes` function for more information on this behavior.

# TriRep.cartToBary

---

**Purpose** (Will be removed) Convert point coordinates from cartesian to barycentric

---

**Note** `cartToBary(TriRep)` will be removed in a future release. Use `cartesianToBarycentric(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `B = cartToBary(TR, SI, XC)`

**Description** `B = cartToBary(TR, SI, XC)` returns the barycentric coordinates of each point in `XC` with respect to its associated simplex `SI`.

## Input Arguments

`TR` Triangulation representation.

`SI` Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`.

`XC` Matrix that represents the Cartesian coordinates of the points to be converted. `XC` is of size `m-by-n`, where `m` is of `length(SI)`, the number of points to convert, and `n` is the dimension of the space where the triangulation resides.

## Output Arguments

`B` Matrix of dimension `m-by-k` where `k` is the number of vertices per simplex.

**Definitions** A simplex is a triangle/tetrahedron or higher dimensional equivalent.

## Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
```

```
y = [0 0 0 0 8 8 8 8]';  
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);  
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure  
subplot(1,2,1);  
triplot(dt); hold on;  
plot(cc(:,1), cc(:,2), '*r');  
hold off;  
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);  
y = [0 0 0 0 16 16 16 16]';  
tr = TriRep(tri,x,y)  
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);  
triplot(tr);  
hold on;  
plot(xc(:,1), xc(:,2), '*r');  
hold off;  
axis equal;
```

**See Also**

**Purpose** Transform Cartesian coordinates to polar or cylindrical

**Syntax** `[THETA,RHO,Z] = cart2pol(X,Y,Z)`  
`[THETA,RHO] = cart2pol(X,Y)`

**Description** `[THETA,RHO,Z] = cart2pol(X,Y,Z)` transforms three-dimensional Cartesian coordinates stored in corresponding elements of arrays X, Y, and Z, into cylindrical coordinates. THETA is a counterclockwise angular displacement in radians from the positive x-axis, RHO is the distance from the origin to a point in the x-y plane, and Z is the height above the x-y plane. Arrays X, Y, and Z must be the same size (or any can be scalar).

`[THETA,RHO] = cart2pol(X,Y)` transforms two-dimensional Cartesian coordinates stored in corresponding elements of arrays X and Y into polar coordinates.

**Algorithms** The mapping from two-dimensional Cartesian coordinates to polar coordinates, and from three-dimensional Cartesian coordinates to cylindrical coordinates is

**Two-Dimensional Mapping**  
 $\text{theta} = \text{atan2}(y,x)$   
 $\text{rho} = \sqrt{x.^2 + y.^2}$

**Three-Dimensional Mapping**  
 $\text{theta} = \text{atan2}(y,x)$   
 $\text{rho} = \sqrt{x.^2 + y.^2}$   
 $Z = Z$

# cart2pol

---

## See Also

[cart2sph](#) | [pol2cart](#) | [sph2cart](#)

**Purpose** Transform Cartesian coordinates to spherical

**Syntax** `[azimuth,elevation,r] = cart2sph(X,Y,Z)`

**Description** `[azimuth,elevation,r] = cart2sph(X,Y,Z)` transforms Cartesian coordinates stored in corresponding elements of arrays X, Y, and Z into spherical coordinates. `azimuth` and `elevation` are angular displacements in radians. `azimuth` is the counterclockwise angle in the *x-y* plane measured from the positive *x*-axis. `elevation` is the elevation angle from the *x-y* plane. `r` is the distance from the origin to a point.

Arrays X, Y, and Z must be the same size (or any of them can be scalar).

**Algorithms** The mapping from three-dimensional Cartesian coordinates to spherical coordinates is

```
azimuth = atan2(y,x)
elevation = atan2(z,sqrt(x.^2 + y.^2))
r = sqrt(x.^2 + y.^2 + z.^2)
```

## cart2sph

---

The notation for spherical coordinates is not standard. For the `cart2sph` function, `elevation` is measured from the  $x$ - $y$  plane. Notice that if `elevation = 0`, the point is in the  $x$ - $y$  plane. If `elevation = pi/2`, then the point is on the positive  $z$ -axis.

### See Also

`cart2pol` | `pol2cart` | `sph2cart`

**Purpose** Optional keyword in switch statement

**Syntax**

```
switch switch_expression
    case case_expression
        statements
    case case_expression
        statements
    ...
    otherwise
        statements
end
```

**Description** A switch block conditionally executes one set of statements from several choices. Each choice is a case.

An evaluated *switch\_expression* is a scalar or string. An evaluated *case\_expression* is a scalar, a string, or a cell array of scalars or strings. The switch block tests each case until one of the cases is true. A case is true when:

- For numbers, `eq(case_expression,switch_expression)`.
- For strings, `strcmp(case_expression,switch_expression)`.
- For objects that support the eq function, `eq(case_expression,switch_expression)`.
- For a cell array *case\_expression*, at least one of the elements of the cell array matches *switch\_expression*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the switch block.

*otherwise* is optional, and executes only when no case is true.

For more information, see the switch reference page.

## case

---

### Examples

Decide which plot to create based on the value of the string `plottype`:

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
    case 'bar'
        bar(x)
        title('Bar Graph')
    case {'pie','pie3'}
        pie3(x)
        title('Pie Chart')
        legend('First','Second','Third')
    otherwise
        warning('Unexpected plot type. No plot created.');
```

### See Also

`switch` | `end` | `if` | `for` | `while`

**Purpose**

Cast variable to different data type

**Syntax**

```
B = cast(A,newclass)
B = cast(A,'like',p)
```

**Description**

`B = cast(A,newclass)` converts `A` to class `newclass`, where `newclass` is the name of a built-in data type compatible with `A`. The `cast` function truncates any values in `A` that are too large to map into `newclass`.

`B = cast(A,'like',p)` converts `A` to the same data type and sparsity as the variable `p`. If `A` and `p` are both real, then `B` is also real. Otherwise, `B` is complex.

**Examples****Convert Numeric Data Type**

Convert an `int8` value to `uint8`.

Define a scalar 8-bit integer.

```
a = int8(5);
```

Convert `a` to an unsigned 8-bit integer.

```
b = cast(a,'uint8');
class(b)
```

```
ans =
uint8
```

**Match Data Type and Complex Nature of p**

Define a single precision vector `p` that is complex valued.

```
p = single([1+i 2]);
```

Define a 2-by-3 matrix of ones.

```
A = ones(2,3);
```

Convert `A` to the same data type and complexity (real or complex) as `p`.

# cast

---

```
B = cast(A, 'like', p)
```

```
B =
```

```
    1.0000 + 0.0000i    1.0000 + 0.0000i    1.0000 + 0.0000i  
    1.0000 + 0.0000i    1.0000 + 0.0000i    1.0000 + 0.0000i
```

Check the class of B.

```
class(B)
```

```
ans =
```

```
single
```

## See Also

```
class | typecast
```

**Purpose**

Concatenate arrays along specified dimension

**Syntax**

```
C = cat(dim, A, B)
C = cat(dim, A1, A2, A3, A4, ...)
```

**Description**

`C = cat(dim, A, B)` concatenates the arrays `A` and `B` along array the dimension specified by `dim`. The `dim` argument must be a real, positive, integer value.

`C = cat(dim, A1, A2, A3, A4, ...)` concatenates all the input arrays (`A1`, `A2`, `A3`, `A4`, and so on) along array dimension `dim`.

For nonempty arrays, `cat(2, A, B)` is the same as `[A, B]`, and `cat(1, A, B)` is the same as `[A; B]`.

If your input arrays are tables, `dim` must be either 1 or 2. `cat` then concatenates by calling `horzcat` or `vertcat` respectively.

**Tips**

When used with comma-separated list syntax, `cat(dim, C{:})` or `cat(dim, C.field)` is a convenient way to concatenate a cell or structure array containing numeric matrices into a single matrix.

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”

**Examples**

Given

```
A =           B =
     1     2           5     6
     3     4           7     8
```

# cat

---

concatenating along different dimensions produces

1	2
3	4
5	6
7	8

**C = cat(1,A,B)**

1	2	5	6
3	4	7	8

**C = cat(2,A,B)**

	5	6
	7	8
1	2	
3	4	

**C = cat(3,A,B)**

The commands

```
A = magic(3); B = pascal(3);  
C = cat(4, A, B);
```

produce a 3-by-3-by-1-by-2 array.

`vertcat` | `horzcat` | `strcat` | `char` | `num2cell` | `reshape` | `squeeze`  
| `strjoin` | `shiftdim` | `special character`

**Purpose** Handle error detected in try statement

**Syntax**

```
try
    statements
catch exception
    statements
end
```

**Description** try and catch blocks allow you to override the default error behavior for a set of program statements. If any statement in a try block generates an error, program control goes immediately to the catch block, which contains your error handling statements.

*exception* is an optional MException object input to the catch block that allows you to identify the error.

Both try and catch blocks can contain nested try/catch statements.

**Examples** Provide more information about a dimension mismatch error:

```
A = rand(3);
B = ones(5);

try
    C = [A; B];
catch err

    % Give more information for mismatch.
    if (strcmp(err.identifier, 'MATLAB:catenate:dimensionMismatch'))

        msg = sprintf('%s', ...
            'Dimension mismatch occurred: First argument has ', ...
            num2str(size(A,2)), ' columns while second has ', ...
            num2str(size(B,2)), ' columns. ');
        error('MATLAB:myCode:dimensions', msg);

    % Display any other errors as usual.
    else
```

# catch

---

```
        rethrow(err);  
    end  
  
end % end try/catch
```

## See Also

`error` | `assert` | `try` | `MException`

**Purpose**

Create categorical array

**Syntax**

```
B = categorical(A)
B = categorical(A,valueSet)
B = categorical(A,valueSet,catnames)
B = categorical(A, __ ,Name,Value)
```

**Description**

`B = categorical(A)` creates a categorical array from the array, `A`. The categories of `B` are the sorted unique values from `A`.

For more information on creating and using categorical arrays, see “Categorical Arrays”.

`B = categorical(A,valueSet)` creates one category for each value in `valueSet`. The categories of `B` are in the same order as the values of `valueSet`.

You can use `valueSet` to include categories for values not present in `A`. Conversely, if `A` contains any values not present in `valueSet`, the corresponding elements of `B` are undefined.

`B = categorical(A,valueSet,catnames)` names the categories in `B` by matching the category values in `valueSet` with the names in `catnames`.

`B = categorical(A, __ ,Name,Value)` creates a categorical array with additional options specified by one or more `Name,Value` pair arguments. You can include any of the input arguments in previous syntaxes.

For example, you can specify that the categories have a mathematical ordering.

**Input Arguments****A - Input array**

numeric array | logical array | categorical array | cell array of strings  
| ...

Input array, specified as a numeric array, logical array, categorical array, or cell array of strings.

If A contains missing values, the corresponding element of B is `<undefined>`. Missing values are NaN for numeric arrays, the empty string ( `''` ) for cell arrays of strings, and `<undefined>` for categorical arrays. B does not have a category for undefined values. To create an explicit category for missing or undefined values, you must include the desired category name in `catnames`, and NaN, the empty string, or `<undefined>` in `valueset`.

In addition to an array, A can be an object with the following class methods:

- `unique`
- `eq`

### **valueset - Values to define categories**

`unique(A)` (default) | vector of unique values

Values to define categories, specified as a vector of unique values. The data type of `valueset` and the data type of A must be the same.

### **catnames - Category names**

cell array of strings

Category names, specified as a cell array of strings. If you do not specify the `catnames` input argument, `categorical` uses the values in `valueset` as category names.

To merge multiple distinct values in A into a single category in B, include duplicate names corresponding to those values.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** 'Ordinal', true specifies that the categories have a mathematical ordering

## 'Ordinal' - Mathematical ordering indicator

false (default) | true | 0 | 1

Mathematical ordering indicator, specified as the comma-separated pair consisting of 'Ordinal' and either false, true, 0, or 1.

**false**                    categorical creates a categorical array that is not ordinal. This is the default behavior.

The categories of **B** have no mathematical ordering. Therefore, you can only compare the values in **B** for equality.

**true**                    categorical creates an ordinal categorical array.

The categories of **B** have a mathematical ordering, such that the first category specified is the smallest and the last category is the largest. You can compare the values in **B** using relational operators, such as less than and greater than, in addition to comparing the values for equality.

## 'Protected' - Category protection indicator

false | true | 0 | 1

Category protection indicator specified as the comma-separated pair consisting of 'Protected' and either false, true, 0, or 1. The categories of ordinal categorical arrays are always protected. The default value is true when you specify 'Ordinal', true and false otherwise.

- false** When you assign new values to **B**, the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update accordingly to include the categories from both arrays.
- true** When you assign new values to **B**, the values must belong to one of the existing categories. Therefore, you can only combine arrays that have the same categories. To add new categories to **B**, you must use the function `addcats`.

## Examples

### Create Categorical Array from Strings

Convert a cell array of strings to a categorical array.

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

A =

```
    'r'    'b'    'g'  
    'g'    'r'    'b'  
    'b'    'r'    'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B.

```
B = categorical(A)
```

B =

```
    r    b    g  
    g    r    b  
    b    r    g
```

The contents of **B** match the contents of **A**.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
    'b'  
    'g'  
    'r'
```

The categories of B are the unique values from A in alphabetical order.

### Create Categorical Array and Specify Possible Unique Values

Convert a cell array of strings, A, to a categorical array. Specify a list of categories that includes values that are not present in A.

Create a cell array of strings.

```
A = {'republican' 'democrat'; 'democrat' 'democrat'; 'democrat' 'repub
```

```
A =
```

```
    'republican'    'democrat'  
    'democrat'    'democrat'  
    'democrat'    'republican'
```

A is a 3-by-2 cell array containing two unique values.

Convert the cell array of strings, A, to a categorical array, B and include a category for independent.

```
valueset = {'democrat' 'republican' 'independent'}
```

```
B = categorical(A,valueset)
```

```
B =
```

```
    republican    democrat  
    democrat    democrat  
    democrat    republican
```

The contents of B match the contents of A.

Display the categories of B.

```
categories(B)

ans =

    'democrat'
    'republican'
    'independent'
```

The categories of B are in the same order as the values specified in `valueset`.

## Create Categorical Array and Specify Category Names

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
A =

    'r'    'b'    'g'
    'g'    'r'    'b'
    'b'    'r'    'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B, and specify category names.

```
B = categorical(A,{'r' 'g' 'b'},{'red' 'green' 'blue'})
```

```
B =

    red    blue    green
    green  red    blue
```

```
         blue      red      green
```

B uses the specified category names for the contents from A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
    'red'  
    'green'  
    'blue'
```

The categories of B are in the order they were specified.

### Create Categorical Array from Integers

Create a 2-by-3 numeric array.

```
A = gallery('integerdata',3,[2,3],3)
```

```
A =
```

```
     2     1     2  
     1     1     3
```

A contains the values 1, 2, and 3.

Convert the numeric array, A, to a categorical array. Use the values 1, 2, and 3 to define the categories car, bus, and bike, respectively.

```
valueset = 1:3;  
catnames = {'car' 'bus' 'bike'};
```

```
B = categorical(A,valueset,catnames)
```

```
B =
```

```
     bus     car     bus
```

```
      car      car      bike
```

`categorical` maps the numeric values in `valueset` to the category names in `catnames`.

The 2-by-3 categorical array, `B`, is not ordinal. Therefore, you can only compare the values in `B` for equality. To compare the values in `B` using relational operators, such as less than and greater than, you must include the `'Ordinal'`, true name-value pair argument.

## Create Ordinal Categorical Array from Integers

Create a 5-by-2 numeric array.

```
A = gallery('integerdata',3,[5,2],1)
```

```
A =
```

```
     3     2
     3     3
     3     2
     2     1
     3     2
```

`A` contains the values 1, 2, and 3.

Convert the numeric array, `A`, to an ordinal categorical array where 1, 2, and 3 represent child, adult, and senior respectively.

```
valueset = [1:3];
catnames = {'child' 'adult' 'senior'};
```

```
B = categorical(A,valueset,catnames,'Ordinal',true)
```

```
B =
```

```
      senior      adult
      senior      senior
      senior      adult
```

adult	child
senior	adult

Since **B** is ordinal, the categories of **B** have a mathematical ordering, `child < adult < senior`.

**See Also** `categories`

**Concepts**

- “Advantages of Using Categorical Arrays”

# categories

---

**Purpose** Categories of categorical array

**Syntax** `C = categories(A)`

**Description** `C = categories(A)` returns a cell array of strings containing the categories of the categorical array, A.

**Input Arguments** **A - Categorical array**  
vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**Examples** **List Categories in Categorical Array**

Create a categorical array, A.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```
    plane    car    train    car    plane
```

A is a 1-by-5 categorical array.

Display the categories of A.

```
C = categories(A)
```

```
C =
```

```
    'car'  
    'plane'  
    'train'
```

Since you created A by specifying only an input array, the categories appear in alphabetical order.

## List Categories in Ordinal Categorical Array

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'}
               {'small' 'medium' 'large' 'xlarge'}, 'Ordinal', true)
```

A =

```
      medium      large
      small      xlarge
      large      medium
```

A is a 3-by-2 ordinal categorical array.

Display the categories of A.

```
C = categories(A)
```

C =

```
'small'
'medium'
'large'
'xlarge'
```

The categories appear in the order in which you specified them. Since A is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

### Tips

- C includes all categories in A, even if A does not contain any data from a category. To see the unique values in A, use `unique(A)`.
- The order of the categories listed in C is the same order used by functions, such as `summary` and `hist`. To change the order of the categories, use `reordercats`.

### See Also

# caxis

---

**Purpose** Color axis scaling

**Syntax**

```
caxis([cmin cmax])  
caxis auto  
caxis manual  
caxis(caxis) freeze  
v = caxis  
caxis(axes_handle,...)
```

**Description** `caxis` controls the mapping of data values to the colormap. It affects any surfaces, patches, and images with indexed `CData` and `CDataMapping` set to `scaled`. It does not affect surfaces, patches, or images with `true` color `CData` or with `CDataMapping` set to `direct`.

`caxis([cmin cmax])` sets the color limits to specified minimum and maximum values. Data values less than `cmin` or greater than `cmax` map to `cmin` and `cmax`, respectively. Values between `cmin` and `cmax` linearly map to the current colormap.

`caxis auto` computes the color limits automatically using the minimum and maximum data values. This is the default behavior. Color values set to `Inf` map to the maximum color, and values set to `-Inf` map to the minimum color. Faces or edges with color values set to `NaN` are not drawn.

`caxis manual` and `caxis(caxis) freeze` the color axis scaling at the current limits. This enables subsequent plots to use the same limits when `hold` is on.

`v = caxis` returns a two-element row vector containing the `[cmin cmax]` currently in use.

`caxis(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

`caxis` changes the `CLim` and `CLimMode` properties of axes graphics objects.

## Tips

### How Color Axis Scaling Works

Surface, patch, and image graphics objects having indexed CData and CDataMapping set to scaled map CData values to colors in the figure colormap each time they render. CData values equal to or less than cmin map to the first color value in the colormap, and CData values equal to or greater than cmax map to the last color value in the colormap. The following linear transformation is performed on the intermediate values (referred to as C below) to map them to an entry in the colormap (whose length is m, and whose row index is referred to as index below).

```
index = fix((C-cmin)/(cmax-cmin)*m)+1;
%Clamp values outside the range [1 m]
index(index<1) = 1;
index(index>m) = m;
```

## Examples

Create (X,Y,Z) data for a sphere and view the data as a surface.

```
[X,Y,Z] = sphere;
C = Z;
surf(X,Y,Z,C)
```

Values of C have the range [-1 1]. Values of C near -1 are assigned the lowest values in the colormap; values of C near 1 are assigned the highest values in the colormap.

To map the top half of the surface to the highest value in the color table, use

```
caxis([-1 0])
```

To use only the bottom half of the color table, enter

```
caxis([-1 3])
```

which maps the lowest CData values to the bottom of the colormap, and the highest values to the middle of the colormap (by specifying a cmax whose value is equal to cmin plus twice the range of the CData).

The command

```
caxis auto
```

resets axis scaling back to autoranging and you see all the colors in the surface. In this case, entering

```
caxis
```

```
returns
```

```
[-1 1]
```

## Using caxis with Image Data

Adjusting the color axis can be useful when using images with scaled color data. For example, load the image data and colormap for Cape Cod, Massachusetts. This command loads the image's data `X` and the image's colormap `map` into the workspace.

```
load cape
% Display the image with CDataMapping set to scaled and
% install the image's colormap.
image(X,'CDataMapping','scaled')
colormap(map)
% This adjusts the color limits to span the range
% of the image data, which is 1 to 192:
caxis
ans =
     1    192
```

The blue color of the ocean is the first color in the colormap and is mapped to the lowest data value (1). You can effectively move sea level by changing the lower color limit value. For example, The following code compares four settings:

```
figure
load cape
colormap(map)
subplot(2,2,1)
image(X,'CDataMapping','scaled')
```

```
axis image
title('Caxis = [1 192]')
subplot(2,2,2)
image(X,'CDataMapping','scaled')
axis image
title('Caxis = [3 192]')
caxis([3 192])
subplot(2,2,3)
image(X,'CDataMapping','scaled')
axis image
title('Caxis = [5 192]')
caxis([5 192])
subplot(2,2,4)
image(X,'CDataMapping','scaled')
axis image
title('Caxis = [6 192]')
caxis([6 192])
```

- 
- “Axes Color Limits — the CLim Property”

**Purpose**

Change current folder

**Syntax**

```
cd(newFolder)
oldFolder = cd(newFolder)
cd
```

**Description**

`cd(newFolder)` changes the current folder to `newFolder`.

`oldFolder = cd(newFolder)` returns the existing current folder as a string to `oldFolder`, and then changes the current folder to `newFolder`.

`cd` displays the current folder.

**Tips**

- When using the command syntax (`cd newFolder`), if the `newFolder` string contains spaces, enclose the string in single quotation marks.
- On UNIX platforms, use the `~` (tilde) character to represent the user home directory.
- If you use `cd` within a local function, the folder change persists after program control returns from the function. That is, the scope of the folder change is global.

**Input Arguments****newFolder**

A string specifying the folder to which you want to change the current folder. Valid values can be any one of the following:

- A full or relative path.
- `../`, which indicates one level up from the current folder.
- Multiple strings of `../`, which indicates multiple levels up from the current folder.
- `./`, which indicates a path relative to the current folder, although without the `./`, `cd` assumes that the path is relative to the current folder.

**Output Arguments****oldFolder**

A string specifying the current folder that was in place when you issued the `cd` command.

**Definitions**

The current folder is a reference location that MATLAB uses to find files. See “The Current Folder”.

**Examples**

Use `cd` with the `matlabroot` function to change the current folder to the `examples` directory for the currently running version of MATLAB:

```
cd(fullfile(matlabroot, '/help/techdoc/matlab_env/examples'))
```

---

On a Microsoft Windows platform, specify the full path to change the current folder from any location to the `examples` directory for MATLAB Version 7.11 (R2010b), assuming that version is installed on your C: drive:

```
cd('C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples')

% Change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples to
% C:/Program Files/MATLAB/R2010b/help/techdoc:

cd ../../

% Use a relative path to change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc back to
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples:

cd matlab_env/examples

% Change the current folder from its current location to a new location
% but save its previous location. Later, change the current folder to
% previous location.
```

```
% This returns C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/exa  
% to oldFolder, and then changes the current folder to C:/Program Files:
```

```
oldFolder = cd('C:/Program Files')
```

```
% Display current folder:
```

```
pwd
```

```
% Change the current folder to the previous location:  
cd(oldFolder)
```

```
pwd
```

---

On a UNIX platform, change the current folder to the examples directory for the currently running version of MATLAB, assuming it is installed in your home location:

```
cd('~ /help/techdoc/matlab_env/examples')
```

## How To

- “Path Names in MATLAB”
- “Files and Folders that MATLAB Accesses”

**Purpose** (Will be removed) Convex hull

---

**Note** `convexHull(DelaunayTri)` will be removed in a future release. Use `convexHull(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

**Syntax**  
`K = convexHull(DT)`  
`[K AV] = convexHull(DT)`

**Description**  
`K = convexHull(DT)` returns the indices into the array of points `DT.X` that correspond to the vertices of the convex hull.  
`[K AV] = convexHull(DT)` returns the convex hull and the area or volume bounded by the convex hull.

**Input Arguments**  
`DT` Delaunay triangulation.

**Output Arguments**  
`K` If the points lie in 2-D space, `K` is a column vector of length `numf`. Otherwise `K` is a matrix of size `numf-by-ndim`, `numf` being the number of facets in the convex hull, and `ndim` the dimension of the space where the points reside.  
`AV` The area or volume of the convex hull.

**Definitions**  
The convex hull of a set of points `X` is the smallest convex region containing all of the points of `X`.

# DelaunayTri.convexHull

## Examples

### Example 1

Compute the convex hull of a set of random points located within a unit square in 2-D space.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
k = convexHull(dt)
plot(dt.X(:,1),dt.X(:,2), '.', 'markersize',10); hold on;
plot(dt.X(k,1),dt.X(k,2), 'r'); hold off;
```

### Example 2

Compute the convex hull of a set of random points located within a unit cube in 3-D space, and the volume bounded by the convex hull.

```
X = rand(25,3)
dt = DelaunayTri(X)
[ch v] = convexHull(dt)
trisurf(ch, dt.X(:,1),dt.X(:,2),dt.X(:,3), 'FaceColor', 'cyan')
```

# FTP.cd

---

**Purpose** Change or view current folder on FTP server

**Syntax** `cd(ftpobj, folder)`  
`cd(ftpobj)`

**Description** `cd(ftpobj, folder)` changes the current folder on the FTP server.  
`cd(ftpobj)` displays the current folder on the server.

**Input Arguments** **ftpobj**  
FTP object created by `ftp`.

**folder**  
String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

**Examples** Connect to the MathWorks FTP server, change to the `pub` folder, and view its contents:

```
mw=ftp('ftp.mathworks.com');  
cd(mw, 'pub');  
dir(mw)
```

**See Also** `dir` | `ftp`

**Purpose** Convert complex diagonal form to real block diagonal form

**Syntax**  $[V,D] = \text{cdf2rdf}(V,D)$   
 $[V,D] = \text{cdf2rdf}(V,D)$

**Description** If the eigensystem  $[V,D] = \text{eig}(X)$  has complex eigenvalues appearing in complex-conjugate pairs, `cdf2rdf` transforms the system so  $D$  is in real diagonal form, with 2-by-2 real blocks along the diagonal replacing the complex pairs originally there. The eigenvectors are transformed so that

$$X = V*D/V$$

continues to hold. The individual columns of  $V$  are no longer eigenvectors, but each pair of vectors associated with a 2-by-2 block in  $D$  spans the corresponding invariant vectors.

**Examples** The matrix

$$X = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & -5 & 4 \end{bmatrix}$$

has a pair of complex eigenvalues.

$$[V,D] = \text{eig}(X)$$

$$V = \begin{bmatrix} 1.0000 & -0.0191 - 0.4002i & -0.0191 + 0.4002i \\ 0 & 0 - 0.6479i & 0 + 0.6479i \\ 0 & 0.6479 & 0.6479 \end{bmatrix}$$

$$D = \begin{bmatrix} 1.0000 & & \\ & 0 & \\ & & 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 4.0000 + 5.0000i & 0 \\ 0 & 0 & 4.0000 - 5.0000i \end{bmatrix}$$

Converting this to real block diagonal form produces

$$[V,D] = \text{cdf2rdf}(V,D)$$

V =

$$\begin{bmatrix} 1.0000 & -0.0191 & -0.4002 \\ 0 & 0 & -0.6479 \\ 0 & 0.6479 & 0 \end{bmatrix}$$

D =

$$\begin{bmatrix} 1.0000 & 0 & 0 \\ 0 & 4.0000 & 5.0000 \\ 0 & -5.0000 & 4.0000 \end{bmatrix}$$

## Algorithms

The real diagonal form for the eigenvalues is obtained from the complex form using a specially constructed similarity transformation.

<b>Purpose</b>	Convert MATLAB formatted dates to CDF formatted dates
<b>Syntax</b>	<code>E = cdfepoch(date)</code>
<b>Description</b>	<p><code>E = cdfepoch(date)</code> converts the date, specified by <code>date</code>, into a <code>cdfepoch</code> object. <code>date</code> must be a valid date string, returned by <code>datestr</code>, or a serial date number, returned by <code>datenum</code>. <code>date</code> can also be a <code>cdfepoch</code> object.</p> <p>When writing data to a CDF file using <code>cdfwrite</code>, use <code>cdfepoch</code> to convert MATLAB formatted dates to CDF formatted dates. The MATLAB <code>cdfepoch</code> object simulates the <code>CDFEPOCH</code> data type in CDF files.</p> <p>To convert a <code>cdfepoch</code> object into a MATLAB serial date number, use the <code>todatenum</code> function.</p>
<b>Definitions</b>	<p>The MATLAB serial date number calculates dates differently than CDF epochs.</p> <p>A MATLAB serial date number represents the whole and fractional number of days from 1-Jan-0000 to a specific date. The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.</p> <p>A CDF epoch is the number of milliseconds since 1-Jan-0000.</p>
<b>Examples</b>	<p>Convert the current time in serial date number format into a CDF epoch object.</p> <pre>% NOW function returns current time as serial date number dateobj = cdfepoch(now)  dateobj =      cdfepoch object:     11-Mar-2009 15:09:25</pre>

---

Convert the current time in date string format into a CDF epoch object.

```
% DATESTR function returns date as string
dateobj2 = cdfepoch(datestr(now))
```

```
dateobj2 =
```

```
    cdfepoch object:
    11-Mar-2009 15:09:25
```

---

Convert the CDF epoch object into a serial date number.

```
dateobj = cdfepoch(now);
mydatenum = todatenum(dateobj)
```

```
mydatenum =
```

```
    7.3384e+005
```

[datenum](#) | [datestr](#) | [todatenum](#) | [cdfinfo](#) | [cdfread](#)

**Purpose** Information about Common Data Format (CDF) file

**Syntax** `info = cdfinfo(filename)`

**Description** `info = cdfinfo(filename)` returns information about the Common Data Format (CDF) file specified in the string `filename`.

---

**Note** Because `cdfinfo` creates temporary files, the current working directory must be writeable.

---

The following table lists the fields returned in the structure, `info`. The table lists the fields in the order that they appear in the structure.

Field	Description
Filename	Text string specifying the name of the file
FileModDate	Text string indicating the date the file was last modified
FileSize	Double scalar specifying the size of the file, in bytes
Format	Text string specifying the file format
FormatVersion	Text string specifying the version of the CDF library used to create the file
FileSettings	Structure array containing library settings used to create the file
Subfiles	Filenames containing the CDF file's data, if it is a multi-file format CDF

Field	Description	
Variables	N-by-6 cell array, where N is the number of variables, containing information about the variables in the file. The columns present the following information:	
	Column 1	Text string specifying name of variable
	Column 2	Double array specifying the dimensions of the variable, as returned by the <code>size</code> function
	Column 3	Double scalar specifying the number of records assigned for the variable
	Column 4	Text string specifying the data type of the variable, as stored in the CDF file
	Column 5	<p>Text string specifying the record and dimension variance settings for the variable. The single T or F to the left of the slash designates whether values vary by record. The zero or more T or F letters to the right of the slash designate whether values vary at each dimension. Here are some examples.</p> <p>T/ (scalar variable)  F/T (one-dimensional variable)</p> <p>T/TFF (three-dimensional variable)</p>

Field	Description
GlobalAttributes	Structure array that contains one field for each global attribute. The name of each field corresponds to the name of an attribute. The data in each field, contained in a cell array, represents the entry values for that attribute.
VariableAttributes	Structure array that contains one field for each variable attribute. The name of each field corresponds to the name of an attribute. The data in each field is contained in a $n$ -by-2 cell array, where $n$ is the number of variables. The first column of this cell array contains the variable names associated with the entries. The second column contains the entry values.

---

**Note** Attribute names returned by `cdfinfo` might not match the names of the attributes in the CDF file exactly. Attribute names can contain characters that are illegal in MATLAB field names. `cdfinfo` removes illegal characters that appear at the beginning of attributes and replaces other illegal characters with underscores (`'_'`). When `cdfinfo` modifies an attribute name, it appends the attribute's internal number to the end of the field name. For example, the attribute name `Variable%Attribute` becomes `Variable_Attribute_013`.

---

---

**Note** To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

---

## Examples

```
info = cdfinfo('example.cdf')
info =
    Filename: 'example.cdf'
```

# cdfinfo

---

```

**Purpose**

Summary of Common Data Format (CDF) capabilities

**Description**

The MATLAB product provides both high-level and low-level access to Common Data Format (CDF) files. The high-level access functions make it easy to read data from a CDF file or write data from the workspace to a CDF file. The low-level interface provides you with more control over the import and export operations.

---

**Note** For information about MATLAB support for the Network Common Data Form (netCDF), which is a completely separate, incompatible format, see `netcdf`.

---

**High-Level Functions**

MATLAB includes functions that provide high-level access to CDF files:

- `cdfinfo`
- `cdfread`

In addition, MATLAB provides functions that convert time data to and from the CDF epoch data type: `cdfepoch` and `todatenum`.

**Low-Level Functions**

MATLAB provides direct access to dozens of functions in the CDF library. Using these functions, you can read and write data, create variables, attributes, and entries, and take advantage of other features of the CDF library. To use these functions, you must be familiar with the CDF C interface. Documentation about CDF, version 3.3.0, is available at the [CDF Web site](#).

The MATLAB functions correspond to functions in the CDF library new Standard Interface. In most cases, the syntax of a MATLAB function is similar to the syntax of the corresponding CDF library function. To use these functions, you must prefix the function name with the package name, `cdflib`. For example, to use the CDF library function to open an existing CDF file, you would use this syntax:

```
cdfid = cdflib.open('example.cdf');
```

The following tables list all of the functions in the MATLAB CDF library package, grouped by category.

## Library Information

<code>cdflib</code>	Summary of Common Data Format (CDF) capabilities
<code>cdflib.getConstantNames</code>	Names of Common Data Format (CDF) library constants
<code>cdflib.getConstantValue</code>	Numeric value corresponding to Common Data Format (CDF) library constant
<code>cdflib.getFileBackward</code>	Return current backward compatibility mode setting
<code>cdflib.getLibraryCopyright</code>	Copyright notice of Common Data Format (CDF) library
<code>cdflib.getLibraryVersion</code>	Library version and release information
<code>cdflib.getValidate</code>	Library validation mode
<code>cdflib.setFileBackward</code>	Set backward compatibility mode
<code>cdflib.setValidate</code>	Specify library validation mode

## File Operations

<code>cdflib.close</code>	Close Common Data Format (CDF) file
<code>cdflib.create</code>	Create Common Data Format (CDF) file
<code>cdflib.delete</code>	Delete existing Common Data Format (CDF) file
<code>cdflib.getCacheSize</code>	Number of cache buffers used
<code>cdflib.getChecksum</code>	Checksum mode

---

<code>cdflib.getCompression</code>	Compression settings
<code>cdflib.getCompressionCacheSize</code>	Number of compression cache buffers
<code>cdflib.getCopyright</code>	Copyright notice in Common Data Format (CDF) file
<code>cdflib.getFormat</code>	Format of Common Data Format (CDF) file
<code>cdflib.getMajority</code>	Majority of variables
<code>cdflib.getName</code>	Name of Common Data Format (CDF) file
<code>cdflib.getReadOnlyMode</code>	Read-only mode
<code>cdflib.getStageCacheSize</code>	Number of cache buffers for staging
<code>cdflib.getVersion</code>	Common Data Format (CDF) library version and release information
<code>cdflib.inquire</code>	Basic characteristics of Common Data Format (CDF) file
<code>cdflib.open</code>	Open existing Common Data Format (CDF) file
<code>cdflib.setCacheSize</code>	Specify number of dotCDF cache buffers
<code>cdflib.setChecksum</code>	Specify checksum mode
<code>cdflib.setCompression</code>	Specify compression settings
<code>cdflib.setCompressionCacheSize</code>	Specify number of compression cache buffers
<code>cdflib.setFormat</code>	Specify format of Common Data Format (CDF) file
<code>cdflib.setMajority</code>	Specify majority of variables

<code>cdflib.setReadOnlyMode</code>	Specify read-only mode
<code>cdflib.setStageCacheSize</code>	Specify number of staging cache buffers for Common Data Format (CDF) file

## **Variables**

<code>cdflib.closeVar</code>	Close specified variable from multifile format Common Data Format (CDF) file
<code>cdflib.createVar</code>	Create new variable
<code>cdflib.deleteVar</code>	Delete variable
<code>cdflib.deleteVarRecords</code>	Delete range of records from variable
<code>cdflib.getVarAllocRecords</code>	Number of records allocated for variable
<code>cdflib.getVarBlockingFactor</code>	Blocking factor for variable
<code>cdflib.getVarCacheSize</code>	Number of multifile cache buffers
<code>cdflib.getVarCompression</code>	Information about compression used by variable
<code>cdflib.getVarData</code>	Single value from record in variable
<code>cdflib.getVarMaxAllocRecNum</code>	Maximum allocated record number for variable
<code>cdflib.getVarMaxWrittenRecNum</code>	Maximum written record number for variable
<code>cdflib.getVarName</code>	Variable name, given variable number
<code>cdflib.getVarNum</code>	Variable number, given variable name

---

<code>cdflib.getVarNumRecsWritten</code>	Number of records written to variable
<code>cdflib.getVarPadValue</code>	Pad value for variable
<code>cdflib.getVarRecordData</code>	Entire record for variable
<code>cdflib.getVarReservePercent</code>	Compression reserve percentage for variable
<code>cdflib.getVarsMaxWrittenRecNum</code>	Maximum written record number for CDF file
<code>cdflib.getVarSparseRecords</code>	Information about how variable handles sparse records
<code>cdflib.hyperGetVarData</code>	Read hyperslab of data from variable
<code>cdflib.hyperPutVarData</code>	Write hyperslab of data to variable
<code>cdflib.inquireVar</code>	Information about variable
<code>cdflib.putVarData</code>	Write single value to variable
<code>cdflib.putVarRecordData</code>	Write entire record to variable
<code>cdflib.renameVar</code>	Rename existing variable
<code>cdflib.setVarAllocBlockRecords</code>	Specify range of records to be allocated for variable
<code>cdflib.setVarBlockingFactor</code>	Specify blocking factor for variable
<code>cdflib.setVarCacheSize</code>	Specify number of multi-file cache buffers for variable
<code>cdflib.setVarCompression</code>	Specify compression settings used with variable
<code>cdflib.setVarInitialRecs</code>	Specify initial number of records written to variable

<code>cdflib.setVarPadValue</code>	Specify pad value used with variable
<code>cdflib.SetVarReservePercent</code>	Specify reserve percentage for variable
<code>cdflib.setVarsCacheSize</code>	Specify number of cache buffers used for all variables
<code>cdflib.setVarSparseRecords</code>	Specify how variable handles sparse records

## **Attributes**

<code>cdflib.createAttr</code>	Create attribute
<code>cdflib.deleteAttr</code>	Delete attribute
<code>cdflib.deleteAttrEntry</code>	Delete attribute entry
<code>cdflib.deleteAttrgEntry</code>	Delete entry in global attribute
<code>cdflib.getAttrEntry</code>	Value of entry in attribute with variable scope
<code>cdflib.getAttrgEntry</code>	Value of entry in global attribute
<code>cdflib.getAttrMaxEntry</code>	Number of last entry for variable attribute
<code>cdflib.getAttrMaxgEntry</code>	Number of last entry for global attribute
<code>cdflib.getAttrName</code>	Name of attribute, given attribute number
<code>cdflib.getAttrNum</code>	Attribute number, given attribute name
<code>cdflib.getAttrScope</code>	Scope of attribute
<code>cdflib.getNumAttrEntries</code>	Number of entries for attribute with variable scope
<code>cdflib.getNumAttrgEntries</code>	Number of entries for attribute with global scope

---

<code>cdflib.getNumAttributes</code>	Number of attributes with variable scope
<code>cdflib.getNumAttributes</code>	Number of attributes with global scope
<code>cdflib.inquireAttr</code>	Information about attribute
<code>cdflib.inquireAttrEntry</code>	Information about entry in attribute with variable scope
<code>cdflib.inquireAttrgEntry</code>	Information about entry in attribute with global scope
<code>cdflib.putAttrEntry</code>	Write value to entry in attribute with variable scope
<code>cdflib.putAttrgEntry</code>	Write value to entry in attribute with global scope
<code>cdflib.renameAttr</code>	Rename existing attribute

**Utility Functions**

<code>cdflib.computeEpoch</code>	Convert time value to CDF_EPOCH value
<code>cdflib.computeEpoch16</code>	Convert time value to CDF_EPOCH16 value
<code>cdflib.epoch16Breakdown</code>	Convert CDF_EPOCH16 value to time value
<code>cdflib.epochBreakdown</code>	Convert CDF_EPOCH value into time value

# cdflib.close

---

**Purpose** Close Common Data Format (CDF) file

**Syntax** `cdflib.close(cdfId)`

**Description** `cdflib.close(cdfId)` closes the specified CDF file. `cdfId` identifies the CDF file.

You must close a CDF to guarantee that all modifications you made since opening the CDF are actually written to the file.

**Examples** Open the example CDF file and then close it.

```
cdfid = cdflib.open('example.cdf');  
cdflib.close(cdfid)
```

**References** This function corresponds to the CDF library C API routine `CDFcloseCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

- “Exporting to Common Data File Format (CDF) Files”

<b>Purpose</b>	Close specified variable from multifile format Common Data Format (CDF) file
<b>Syntax</b>	<code>cdflib.closeVar(cdfId,varNum)</code>
<b>Description</b>	<p><code>cdflib.closeVar(cdfId,varNum)</code> closes a variable in a multifile format CDF.</p> <p><code>cdfId</code> identifies the CDF file and <code>varNum</code> is a numeric value that specifies the variable. Variable identifiers (variable numbers) are zero-based.</p> <p>For multifile CDFs, you must close all open variable files to guarantee that all modifications you have made are actually written to the CDF file(s). You do not need to call this function for variables in a single-file format CDF.</p>
<b>Examples</b>	<p>Create a multifile CDF, create a variable, and then close the variable. To run this example, you must be in a writable folder.</p> <pre>cdfid = cdflib.create('your_multifile.cdf');  % Make it a multifile format CDF cdflib.setFormat(cdfid,'MULTI_FILE')  % Create a variable in the CDF. varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);  % Close the variable. cdflib.closeVar(cdfid, varnum)  % Clean up cdflib.delete(cdfid) clear cdfid</pre>
<b>References</b>	This function corresponds to the CDF library C API routine <code>CDFclosezVar</code> .

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Convert time value to CDF\_EPOCH value

**Syntax** `epoch = cdflib.computeEpoch(timeval)`

**Description** `epoch = cdflib.computeEpoch(timeval)` converts the time value specified by `timeval` into a CDF\_EPOCH value.

**Input Arguments**

**timeval**

7-by-1 time vector. The following table describes the time components.

Component	Description
year	AD e.g. 1994
month	1 12
day	1 31
hour	0 23
minute	0 59
second	0 59
millisecond	0 999

**Output Arguments**

**epoch**

MATLAB double representing a CDF\_EPOCH time value.

**Examples**

Convert a time value into a CDF\_EPOCH value.

```
timeval = [1999 12 31 23 59 59 0];  
epoch = cdflib.computeEpoch(timeval);
```

**References**

This function corresponds to the CDF library C API routine `computeEPOCH`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.computeEpoch

## Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Convert time value to CDF\_EPOCH16 value

**Syntax** `epoch16 = cdflib.computeEpoch16(timeval)`

**Description** `epoch16 = cdflib.computeEpoch16(timeval)` converts the time value specified by `timeval` into a CDF\_EPOCH16 value.

**Input Arguments** **timeval**

10-by-1 time vector. The following table describes the time components. To specify multiple time values, use additional columns.

Component	Description
year	AD e.g. 1994
month	1 12
day	1 31
hour	0 23
minute	0 59
second	0 59
millisecond	0 999
microsecond	0 999
nanosecond	0 999
picosecond	0 999

**Output Arguments** **epoch16**

CDF Epoch16 time value. If the input argument `timeval` has `m`-by-10 elements, the return value `epoch16` will have size 2-by-`m`

**Examples** Convert the time value into an CDF\_EPOCH16 value:

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
```

# cdflib.computeEpoch16

---

```
epoch16 = cdflib.computeEpoch16(timeval);
```

## References

This function corresponds to the CDF library C API routine `computeEPOCH16`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.createAttr

---

**Purpose** Create attribute

**Syntax** `attrnum = cdflib.createAttr(cdfId,attrName,scope)`

**Description** `attrnum = cdflib.createAttr(cdfId,attrName,scope)` creates an attribute in a CDF file with the specified scope.

**Input Arguments**

**`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`attrName`**

Text string that specifies the name you want to assign to the attribute.

**`scope`**

One of the following text strings, or its numeric equivalent, that specifies the scope of the attribute.

Text String	Description
'global_scope'	Attribute applies to the CDF as a whole.
'variable_scope'	Attribute applies only to the variable

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

**Output Arguments**

**`attrNum`**

Numeric value identifying the attribute. Attribute numbers are zero-based.

**Examples**

Create a CDF, and then create an attribute in the CDF. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute
attrNum = cdflib.createAttr(cdfid, 'Purpose', 'global_scope');

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFcreateAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

# cdflib.createVar

---

**Purpose** Create new variable

**Syntax** `varnum = cdflib.createVar(cdfId, varname, datatype, numElements, dims, recVariance, dimVariance)`

**Description** `varnum = cdflib.createVar(cdfId, varname, datatype, numElements, dims, recVariance, dimVariance)` creates a new variable in the Common Data Format (CDF) file with the specified characteristics.

## Input Arguments

### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **`varname`**

Text string that specifies the name you want to assign to the variable.

### **`datatype`**

Data type of the variable. One of the following text strings, or its numeric equivalent, that specifies a valid CDF data type.

<b>CDF Data Type</b>	<b>Description</b>
CDF_BYTE	1-byte, signed integer
CDF_CHAR	1 byte, signed character data type that maps to the MATLAB <code>char</code> class
CDF_INT1	1-byte, signed integer
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB <code>uint8</code> class
CDF_UINT1	1-byte, unsigned integer
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer

<b>CDF Data Type</b>	<b>Description</b>
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

**numElements**

Number of elements per datum. Value should be 1 for all data types, except CDF\_CHAR and CDF\_UCHAR.

**dims**

A vector of the dimensions extents; empty if there are no dimension extents.

**recVariance**

Specifies record variance: true or false.

**dimVariance**

A vector of logicals; empty if there are no dimensions.

**Output Arguments****varNum**

The numeric identifier for the variable. Variable numbers are zero-based.

# cdflib.createVar

---

## Examples

Create a CDF file and then create a variable named 'Time' in the CDF. The variable has no dimensions and varies across records. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
  majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
  numvAttrs: 0
  numgAttrs: 0

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Retrieve info about the file again to verify variable was created.
% Note value of numVars field is now 1.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
  majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 1
  numvAttrs: 0
  numgAttrs: 0

% Clean up
cdflib.delete(cdfid);
```

```
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFcreatezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.delete

---

**Purpose** Delete existing Common Data Format (CDF) file

**Syntax** `cdflib.delete(cdfId)`

**Description** `cdflib.delete(cdfId)` deletes the existing CDF file specified by the identifier `cdfId`. If the CDF file is a multi-file format CDF, the `cdflib.delete` function also deletes the variable files (having file extensions of `.z0`, `.z1`, etc.).

**Examples** Create a CDF file, and then delete it. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('mytempfile.cdf');
```

```
% Verify that the file was created.  
ls *.cdf
```

```
mytempfile.cdf
```

```
% Delete the file.  
cdflib.delete(cdfId)
```

```
% Verify that the file no longer exists.  
ls *.cdf
```

**References** This function corresponds to the CDF library C API routine `CDFdeleteCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.deleteAttrgEntry

---

**Purpose** Delete entry in global attribute

**Syntax** `cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)`

**Description** `cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)` deletes an entry from a global attribute in a Common Data Format (CDF) file.

**Input Arguments**

**`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`attrNum`**  
Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

**`entryNum`**  
Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

**Examples** Create a CDF and create a global attribute in the file. Write a value to an entry for the attribute and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
```

```
numgAttrs: 0

% Create an attribute with global scope in the file.
attrNum = cdflib.createAttr(cdfid,'my_global_attr','global_scope');

% Write a value to an entry for the attribute
cdflib.putAttrgEntry(cdfid,attrNum,0,'CDF_CHAR','My global attr');

% Get the value of the global attribute entry
value = cdflib.getAttrgEntry(cdfid,attrNum,0)

value =

My global attr

% Delete the entry
cdflib.deleteAttrgEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdflib.getAttrgEntry(cdfid,attrNum,0) % Should fail

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

## Tutorials

- “Importing Common Data File Format (CDF) Files”

## **cdflib.deleteAttrgEntry**

---

- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Delete variable

**Syntax** `cdflib.deleteVar(cdfId,varNum)`

**Description** `cdflib.deleteVar(cdfId,varNum)` deletes a variable from a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that specifies the variable. Variable numbers are zero-based.

**Examples** Create a CDF, create a variable in the CDF, and then delete it.

```
cdfid = cdflib.create('mycdf.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create a variable in the CDF.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Retrieve info about the variable in the CDF.

info = cdflib.inquireVar(cdfid, 0)

info =

    name: 'Time'
    datatype: 'cdf_int1'
```

# cdflib.deleteVar

---

```
        numElements: 1
            dims: []
        recVariance: 1
        dimVariance: []

% Delete the variable from the CDF

cdflib.deleteVar(cdfid,0);

% Check to see if the variable was deleted from the CDF.
info = cdflib.inquire(cdfid)

info =

        encoding: 'IBMPC_ENCODING'
        majority: 'ROW_MAJOR'
        maxRec: -1
        numVars: 0
        numvAttrs: 0
        numgAttrs: 0

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFdeletezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.deleteVarRecords

---

**Purpose** Delete range of records from variable

**Syntax** `cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)`

**Description** `cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)` deletes a range of records from a variable in a Common Data Format (CDF) file.

**Input Arguments**

**`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`varNum`**  
Numeric value that identifies the variable. Variable numbers are zero-based.

**`startRec`**  
Numeric value that specifies the record at which to start deleting records. Record numbers are zero-based.

**`endRec`**  
Numeric value that specifies the record at which to stop deleting records. Record numbers are zero-based.

**Examples** Make a writable copy of the example CDF, get the number of a variable in the CDF, and delete specific records in the variable. To run this example, you must be in a writable folder.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.cdf');
copyfile(srcFile,'myfile.cdf');
fileattrib('myfile.cdf','+w');
cdfid = cdflib.open('myfile.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
cdflib.deleteVarRecords(cdfid,varnum,1,2);
cdflib.close(cdfid);
```

# cdflib.epoch16Breakdown

**Purpose** Convert CDF\_EPOCH16 value to time value

**Syntax** `timeVec = cdflib.epoch16Breakdown(epoch16Time)`

**Description** `timeVec = cdflib.epoch16Breakdown(epoch16Time)` convert a CDF\_EPOCH16 value into a time vector. `timeVec` will have 10-by-*n* elements, where *n* is the number of CDF\_EPOCH16 values.

The following table describes the time value components.

<b>timeVec Element</b>	<b>Description</b>	<b>Valid Values</b>
<code>timeVec(1,:)</code>	Year AD	e.g. 1994
<code>timeVec(2,:)</code>	Month	1 12
<code>timeVec(3,:)</code>	Day	1 31
<code>timeVec(4,:)</code>	Hour	0 23
<code>timeVec(5,:)</code>	Minute	0 59
<code>timeVec(6,:)</code>	Second	0 59
<code>timeVec(7,:)</code>	Millisecond	0 999
<code>timeVec(8,:)</code>	Microsecond	0 999
<code>timeVec(9,:)</code>	Nanosecond	0 999
<code>timeVec(10,:)</code>	Picosecond	0 999

**Examples** Convert CDF\_EPOCH16 value into time value.

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];  
epoch16 = cdflib.computeEpoch16(timeval);
```

```
timevec = cdflib.epoch16Breakdown(epoch16)
```

```
timevec =
```

```
1999
```

12  
31  
23  
59  
59  
50  
100  
500  
999

## References

# cdflib.epochBreakdown

**Purpose** Convert CDF\_EPOCH value into time value

**Syntax** `timeVec = cdflib.epochBreakdown(epochTime)`

**Description** `timeVec = cdflib.epochBreakdown(epochTime)` decomposes the CDF\_EPOCH value, epochTime value into individual time components. timeVec will have 7-by-*n* elements, where *n* is the number of CDF\_EPOCH values in epochTime.

The return value timeVec has the following elements:

timeVec Element	Description	Valid Values
<code>timeVec(1,:)</code>	Year AD	e.g. 1994
<code>timeVec(2,:)</code>	Month	1 12
<code>timeVec(3,:)</code>	Day	1 31
<code>timeVec(4,:)</code>	Hour	0 23
<code>timeVec(5,:)</code>	Minute	0 59
<code>timeVec(6,:)</code>	Second	0 59
<code>timeVec(7,:)</code>	Millisecond	0 999

## Examples

Convert a CDF\_EPOCH value into a time vector.

```
% First convert a time vector into a CDF_EPOCH value
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);
```

```
% Convert the CDF_EPOCH value into a time vector
timevec = cdflib.epochBreakdown(epoch)
```

```
timevec =
    1999
         12
         31
```

- “Exporting to Common Data File Format (CDF) Files”

# cdflib.getAttrMaxEntry

---

**Purpose** Number of last entry for variable attribute

**Syntax** `maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)`

**Description** `maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)` returns the number of the last entry for an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **attrNum**

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

## Output Arguments

### **maxEntry**

Entry number of the last entry in the attribute. Entry numbers are zero-based.

## Examples

Open the example CDF and get the number of the last entry associated with an attribute with variable scope in the file:

```
cdfid = cdflib.open('example.cdf');  
  
% The fourth attribute is of variable scope.  
attrscope = cdflib.getAttrScope(cdfid,3)  
  
attrscope =  
  
VARIABLE_SCOPE
```

```
% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxEntry(cdfid,3)

entrynum =

    3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

# cdflib.getAttrName

---

**Purpose** Name of attribute, given attribute number

**Syntax** `name = cdflib.getAttrName(cdfId,attrNum)`

**Description** `name = cdflib.getAttrName(cdfId,attrNum)` returns the name of an attribute in a Common Data Format (CDF) file.

**Input Arguments**

**`cdfid`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`attrNum`**  
Numeric value that identifies the attribute. Attribute numbers are zero-based.

**Output Arguments**

**`name`**  
Text string specifying the name of the attribute.

**Examples** Open the example CDF and get name of an attribute.

```
cdfid = cdflib.open('example.cdf');  
  
% Get name of the first attribute in the file.  
attrName = cdflib.getAttrName(cdfid,0)  
  
attrName =  
  
SampleAttribute  
  
% Clean up  
cdflib.close(cdfid);  
  
clear cdfid
```

- “Exporting to Common Data File Format (CDF) Files”

# cdflib.getAttrScope

---

**Purpose** Scope of attribute

**Syntax** `scope = cdflib.getAttrScope(cdfId,attrNum)`

**Description** `scope = cdflib.getAttrScope(cdfId,attrNum)` returns the scope of an attribute in a Common Data Format (CDF) file.

**Input Arguments**

**cdfid**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**attrNum**  
Numeric value that specifies the attribute. Attribute numbers are zero-based.

**Output Arguments**

**scope**  
Either of the following text strings, or its numeric equivalent.

Text String	Description
'GLOBAL_SCOPE'	Attribute applies to the CDF as a whole.
'VARIABLE_SCOPE'	Attribute applies only to the variable.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

**Examples** Open example CDF and get the scope of the first attribute in the file:

```
cdfid = cdflib.open('example.cdf');  
  
attrScope = cdflib.getAttrScope(cdfid,0)  
  
attrScope =
```

```
GLOBAL_SCOPE

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

# cdflib.getCacheSize

---

**Purpose**            Number of cache buffers used

**Syntax**            `numBuffers = cdflib.getCacheSize(cdfId)`

**Description**      `numBuffers = cdflib.getCacheSize(cdfId)` returns the number of cache buffers used for the Common Data Format (CDF) file identified by `cdfId`. For a discussion of cache schemes, see the *CDF User's Guide*.

**Examples**            Open the example CDF file and get the cache size:

```
cdfid = cdflib.open('example.cdf');  
  
numBuf = cdflib.getCacheSize(cdfid)  
  
numBuf =  
  
    300  
  
% Clean up  
cdflib.close(cdfid)  
clear cdfid
```

**References**          This function corresponds to the CDF library C API routine `CDFgetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

**Purpose** Checksum mode

**Syntax** `mode = cdflib.getChecksum(cdfId)`

**Description** `mode = cdflib.getChecksum(cdfId)` returns the checksum mode of the Common Data Format (CDF) file.

**Input Arguments** **cdfid**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**Output Arguments** **mode**  
Either of the following text strings or its numeric equivalent.

'MD5_CHECKSUM'	File uses MD5 checksum.
'NO_CHECKSUM'	File does not use a checksum.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

**Examples** Open the example CDF file, and then get the checksum mode of the file:

```
cdfid = cdflib.open('example.cdf');  
  
checksummode = cdflib.getChecksum(cdfid)  
  
checksummode =  
  
NO_CHECKSUM  
  
% Clean up  
cdflib.close(cdfid);  
clear cdfid;
```

# cdflib.getChecksum

---

- “Exporting to Common Data File Format (CDF) Files”

<b>Purpose</b>	Compression settings
<b>Syntax</b>	<code>[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)</code>
<b>Description</b>	<code>[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)</code> returns information about the compression settings of a Common Data Format (CDF) file.
<b>Input Arguments</b>	<b>cdfId</b> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code> .
<b>Output Arguments</b>	<b>ctype</b> Text string specifying compression type, such as <code>'HUFF_COMPRESSION'</code> . If the CDF does not use compression, the function returns the string <code>'NO_COMPRESSION'</code> . For a list of supported compression types, see <code>cdflib.setCompression</code> . <b>cparms</b> The value of the parameter associated with the type of compression. For example, for the <code>'RLE_COMPRESSION'</code> compression type, the parameter specifies the style of run-length encoding. For a list of parameters supported by each compression type, see <code>cdflib.setCompression</code> . <b>cpercentage</b> The rate of compression, expressed as a percentage.
<b>Examples</b>	Open the example CDF file and check the compression settings in the file. <pre>cdfId = cdflib.open('example.cdf');  [ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)</pre>

# cdflib.getCompression

---

```
ctype =  
GZIP_COMPRESSION  
cparms =  
    7

- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Numeric value corresponding to Common Data Format (CDF) library constant

**Syntax** `value = cdflib.getConstantValue(constantName)`

**Description** `value = cdflib.getConstantValue(constantName)` returns the numeric value of the CDF library constant specified by the text string *constantName*. To see a list of constant names, use `cdflib.getConstantNames`.

**Examples** View the list of CDF library constants and get the numeric value corresponding to one of the constants.

```
% Retrieve a list of library constants
names = cdflib.getConstantNames();

value = cdflib.getConstantValue(names{1})

value =

    3
```

# cdflib.getCopyright

---

**Purpose** Copyright notice in Common Data Format (CDF) file

**Syntax** `copyright = cdflib.getCopyright(cdfId)`

**Description** `copyright = cdflib.getCopyright(cdfId)` returns the copyright notice in the CDF file identified by `cdfId`.

**Examples** Create a CDF file, and then get the copyright notice in the file. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');  
  
copyright = cdflib.getCopyright(cdfId)  
  
copyright =  
  
Common Data Format (CDF)  
(C) Copyright 1990-2009 NASA/GSFC  
Space Physics Data Facility  
NASA/Goddard Space Flight Center  
Greenbelt, Maryland 20771 USA  
(Internet -- CDFSUPPORT@LISTSERV.GSFC.NASA.GOV)  
  
% Clean up.  
cdflib.delete(cdfId)  
clear cdfId
```

# cdflib.getFileBackward

---

**Purpose** Return current backward compatibility mode setting

**Syntax** `mode = cdflib.getFileBackward()`

**Description** `mode = cdflib.getFileBackward()` returns the backward compatibility mode.

**Output Arguments** **mode**

One of the following text strings:

BACKWARDFILEon	Backward compatibility mode is on.
BACKWARDFILEoff	Backward compatibility mode is off.

For more information about backward compatibility mode, see `cdflib.setFileBackward`.

**Examples** `mode = cdflib.getFileBackward`

`mode =`

`BACKWARDFILEoff`

**References** This function corresponds to the CDF library C API routine `CDFgetFileBackward`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

**See Also** `cdflib.setFileBackward` | `cdflib.getConstantValue`

**Tutorials**

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”
-

**Purpose** Format of Common Data Format (CDF) file

**Syntax** `format = cdflib.setFormat(cdfId)`

**Description** `format = cdflib.setFormat(cdfId)` returns the format of the CDF file.

**Input Arguments** **`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**Output Arguments** **`format`**  
Either of the following text strings, or its numeric equivalent.

'SINGLE_FILE'	The CDF is stored in a single file.
'MULTI_FILE'	The CDF is made up of multiple files.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

**Examples** Open the example CDF file and determine its file format:

```
cdfId = cdflib.open('example.cdf');  
  
format = cdflib.getFormat(cdfId)  
  
format =  
  
    'SINGLE_FILE'  
  
% Clean up.  
cdflib.close(cdfId)  
clear cdfId
```

# cdflib.getMajority

---

**Purpose** Majority of variables

**Syntax** `majority = cdflib.getMajority(cdfId)`

**Description** `majority = cdflib.getMajority(cdfId)` returns the majority of variables in a Common Data Format (CDF) file.

**Input Arguments** **`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**Output Arguments** **`majority`**  
Either of the following text strings, or its numeric equivalent.

'ROW_MAJOR'	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
'COLUMN_MAJOR'	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

**Examples** Open the example CDF file, and then determine the majority of variables in the file:

```
cdfId = cdflib.open('example.cdf');  
  
majority = cdflib.getMajority(cdfId)  
  
majority =  
  
ROW_MAJOR
```

```
% Clean up
cdflib.close(cdfId)

clear cdfId
```

## References

# cdflib.getName

---

**Purpose** Name of Common Data Format (CDF) file

**Syntax** `name = cdflib.getName(cdfId)`

**Description** `name = cdflib.getName(cdfId)` returns the name of the CDF file identified by `cdfId`.

**Examples** Open the example CDF file and get the name of the file. The path name returned for your installation will be different.

```
cdfId = cdflib.open('example.cdf');  
  
name = cdflib.getName(cdfId)  
  
name =  
  
yourinstallation\matlab\toolbox\matlab\demos\example  
  
% Clean up  
cdflib.close(cdfId)  
  
clear cdfId
```

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

## Purpose

Number of entries for attribute with variable scope

## Syntax

```
nentries = cdflib.getNumAttrEntries(cdfId,attrNum)
```

## Description

`nentries = cdflib.getNumAttrEntries(cdfId,attrNum)` returns the number of entries for the specified attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

## Examples

Open the example CDF, find an attribute with variable scope, and determine how many entries are associated with the attribute:

```
cdfid = cdflib.open('example.cdf');

% Get the number of an attribute
% with variable scope
attrNum = cdflib.getAttrNum(cdfid,'Description');

% Check that scope of attribute is variable
attrScope = cdflib.getAttrScope(cdfid,attrNum)

VARIABLE_SCOPE

% Determine the number of entries for the attribute
attrEntries = cdflib.getNumAttrEntries(cdfid,attrNum)

attrEntries =

    4

% Clean up
cdflib.close(cdfid);
```

# cdflib.getNumAttrEntries

---

## References

This function corresponds to the CDF library C API routine `CDFgetNumAttrzEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

**Purpose** Read-only mode

**Syntax** `mode = cdflib.getReadOnlyMode(cdfId)`

**Description** `mode = cdflib.getReadOnlyMode(cdfId)` returns the read-only mode of a Common Data Format (CDF) file.

**Input Arguments** **`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**Output Arguments** **`mode`**  
Either of the following text strings or its numeric equivalent.

'READONLYon'	CDF is in read-only mode
'READONLYoff'	CDF can be modified.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

**Examples** Open the example CDF file and determine its current read-only status:

```
cdfId = cdflib.open('example.cdf');  
  
mode = cdflib.getReadOnlyMode(cdfId)  
  
mode =  
  
READONLYoff  
  
% Clean up.  
cdflib.close(cdfId);  
clear cdfId
```

## **cdflib.getVarBlockingFactor**

---

- “Exporting to Common Data File Format (CDF) Files”

**Purpose**

Number of multifile cache buffers

**Syntax**

```
numBuffers = cdflib.getVarCacheSize(cdfId,varNum)
```

**Description**

`numBuffers = cdflib.getVarCacheSize(cdfId,varNum)` returns the number of cache buffers used for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable identifiers are zero-based.

This function applies only to multifile format CDFs. For more information about caching, see the *CDF User's Guide*.

**Examples**

Create a multifile CDF and retrieve the number of buffers being used for a variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

% Clean up
```

# cdflib.getVarCacheSize

---

```
cdflib.delete(cdfid);
```

```
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

<b>Purpose</b>	Information about compression used by variable
<b>Syntax</b>	<code>[ ctype, cparams, percent ] = cdflib.getVarCompression(cdfId, varNum)</code>
<b>Description</b>	<code>[ ctype, cparams, percent ] = cdflib.getVarCompression(cdfId, varNum)</code> returns information about the compression used for a variable in a Common Data Format (CDF) File.
<b>Input Arguments</b>	<b>cdfid</b> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code> .
<b>Output Arguments</b>	<b>ctype</b> Text string identifying the type of compression. For a list of compression types, see <code>cdflib.setCompression</code> . <b>cparams</b> Any additional parameter required by the compression type. <b>percent</b> Numeric value indicating the level of compression, expressed as a percentage.
<b>Examples</b>	Open the example CDF file and check the compression settings of any variable. <pre>cdfid = cdflib.open('example.cdf');  % Check the compression setting of any variable in the file % The example checks the first variable (variable numbers are zero-based) [ctype params percent] = cdflib.getVarCompression(cdfid,0)  ctype =</pre>

# cdflib.getVarCompression

---

**Purpose** Maximum allocated record number for variable

**Syntax** `maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)`

**Description** `maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)` returns the record number of the maximum allocated record for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

**Examples** Open example CDF and get the maximum allocated record number for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine maximum record number for variable in file.
maxRecNum = cdflib.getVarMaxAllocRecNum(cdfid,0)

maxRecNum =

    63

% Clean up
cdflib.close(cdfid)

clear cdfid
```

**References** This function corresponds to the CDF library C API routine `CDFgetzVarMaxAllocRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.getVarMaxWrittenRecNum

---

**Purpose** Maximum written record number for variable

**Syntax** `maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)`

**Description** `maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)` returns the record number of the maximum record written for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

**Examples** Open the example CDF, and then determine the maximum number of records written to a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number records written to variable.
numRecs = cdflib.getVarNumRecsWritten(cdfid,0)

numRecs =

    24

% Determine the maximum record number of the records written
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0)

maxRecNum =

    23

% Clean up
cdflib.close(cdfid)

clear cdfid
```

## **cdflib.getVarNum**

---

- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Number of records written to variable

**Syntax** `numrecs = cdflib.getVarNumRecsWritten(cdfId,varNum)`

**Description** `numrecs = cdflib.getVarNumRecsWritten(cdfId,varNum)` returns the total number of records written to a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

**Examples** Open the example CDF, and then determine the number of records written to a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records written to the variable.
numRecs = cdflib.getVarNumRecsWritten(cdfid,0)

numRecs =

    24

% Clean up
cdflib.close(cdfid)

clear cdfid
```

**References** This function corresponds to the CDF library C API routine `CDFgetzVarNumRecsWritten`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

## Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

<b>Purpose</b>	Compression reserve percentage for variable
<b>Syntax</b>	<code>percent = cdflib.getVarReservePercent(cdfId,varNum)</code>
<b>Description</b>	<code>percent = cdflib.getVarReservePercent(cdfId,varNum)</code> returns the compression reserve percentage for a variable in a Common Data Format (CDF) file. This operation only applies to compressed variables.  <code>cdfId</code> identifies the CDF file. <code>varNum</code> is a numeric value that identifies the variable. Variable numbers are zero-based.
<b>Definitions</b>	<b>reserve percentage</b>  Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.  By default, the reserve percent is 0 (no extra space is reserved). You can specify any percentage between 1 and 100 and values greater than 100. The value specifies the percentage of the uncompressed size of the variable.
<b>Examples</b>	Open the example CDF file, get the number of a compressed variable, and then determine the reserve percent for the variable.  <pre>cdfid = cdflib.open('example.cdf'); varnum = cdflib.getVarNum(cdfid,'Temperature'); percent = cdflib.getVarReservePercent(cdfid,varnum); cdflib.close(cdfid);</pre>
<b>References</b>	This function corresponds to the CDF library C API routine <code>CDFgetzVarReservePercent</code> .  To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the <a href="#">CDF Web site</a> .

# **cdflib.getVarReservePercent**

- “Exporting to Common Data File Format (CDF) Files”

## Purpose

Information about how variable handles sparse records

## Syntax

```
stype = cdflib.getVarSparseRecords(cdfId,varNum)
```

## Description

`stype = cdflib.getVarSparseRecords(cdfId,varNum)` returns information about how a variable in the Common Data Format (CDF) file handles sparse records.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **varNum**

Numeric value that identifies the variable. Variable numbers are zero-based.

## Output Arguments

### **stype**

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
'NO_SPARSERECORDS'	No sparse records.
'PAD_SPARSERECORDS'	For sparse records, the library uses the variable's pad value when reading values from a missing record.
'PREV_SPARSERECORDS'	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

# cdflib.getVarSparseRecords

---

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

## Examples

Open the example CDF, and then get the sparse record type of a variable in the file:

```
cdfid = cdflib.open('example.cdf');  
  
stype = cdflib.getVarSparseRecords(cdfid,0)  
  
stype =  
  
NO_SPARSERECORDS  
  
%Clean up  
cdflib.close(cdfid);  
  
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarSparseRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

**Purpose** Common Data Format (CDF) library version and release information

**Syntax** [version,release,increment] = cdflib.getVersion(cdfId)

**Description** [version,release,increment] = cdflib.getVersion(cdfId) returns information about the version of the Common Data Format (CDF) library used to create a CDF file.

**Input Arguments** **cdfId**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**Output Arguments** **version**  
Numeric value indicating the version number of the CDF library.

**release**  
Numeric value indicating the release number of the CDF library.

**increment**  
Numeric value indicating the increment number of the CDF library.

**Examples** Open the example CDF file, and then find out the version of the CDF library used to create it:

```
cdfId = cdflib.open('example.cdf');  
  
[version, release, increment] = cdflib.getVersion(cdfId)  
  
version =  
    2  
  
release =
```

# cdflib.getVersion

---

```
7
increment =
8
% Clean up
cdflib.close(cdfId)
clear cdfId
```

- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Basic characteristics of Common Data Format (CDF) file

**Syntax** `info = cdflib.inquire(cdfId)`

**Description** `info = cdflib.inquire(cdfId)` returns basic information about a Common Data Format (CDF) file.

**Input Arguments** **cdfId**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**Output Arguments** **info**  
A structure containing the following fields:

Field	Description
encoding	Encoding of the variable data and attribute entry data
majority	Majority of the variable data
maxRec	Maximum record number written to a CDF variable
numVars	Number of CDF variables
numvAttrs	Number of attributes with variable scope
numgAttrs	Number of attributes with global scope

**Examples** Open the example CDF file, and then get basic information about the file:

```
cdfId = cdflib.open('example.cdf');

info = cdflib.inquire(cdfId)

info =
```

# cdflib.inquire

---

```
encoding: 'IBMPC_ENCODING'  
majority: 'ROW_MAJOR'

**Purpose** Information about attribute

**Syntax** `info = cdflib.inquireAttr(cdfId,attrNum)`

**Description** `info = cdflib.inquireAttr(cdfId,attrNum)` returns information about an attribute in a Common Data Format (CDF) file.

**Input Arguments**

**`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`attrNum`**  
Numeric value that identifies the attribute in the file. Attribute numbers are zero-based.

**Output Arguments**

**`info`**  
Structure containing the following fields.

Field	Description
<code>name</code>	Attribute's name
<code>scope</code>	Either 'GLOBAL_SCOPE' or 'VARIABLE_SCOPE'
<code>maxgEntry</code>	The maximum entry number used for global attributes.
<code>maxEntry</code>	The maximum entry number used for attributes with variable scope.

**Examples** Open the example CDF, and then get information about the first attribute in the file.

```
cdfid = cdflib.open('example.cdf');
```

# cdflib.inquireAttr

---

```
% Get information about an attribute
info = cdflib.inquireAttr(cdfid,0)

- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Information about variable

**Syntax** `info = cdflib.inquireVar(cdfId,varNum)`

**Description** `info = cdflib.inquireVar(cdfId,varNum)` returns information about a variable in a Common Data Format (CDF) file.

**Input Arguments**

**`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`varNum`**

Numeric value that identifies the variable. Variable numbers are zero-based.

**Output Arguments**

**`info`**

Structure containing the following fields.

Field	Description
<code>name</code>	Name of the variable
<code>datatype</code>	Data type
<code>numElements</code>	Number of elements of the datatype
<code>dims</code>	Sizes of the dimensions
<code>recVariance</code>	Record variance
<code>dimVariance</code>	Dimension variances

Record and dimension variances affect how the library physically stores variable data. For example, if a variable has a record variance of `VARY`, the library physically stores each record. If the record variance is `NOVARY`, the library only stores one record.

# cdflib.inquireVar

---

## Examples

Open the example CDF file and get information about a variable.

```
cdfid = cdflib.open('example.cdf');

% Determine if the file contains variables
info = cdflib.inquireVar(cdfid,1)

info =

         name: 'Longitude'
    datatype: 'cdf_int1'
numElements: 1
         dims: [2 2]
recVariance: 0
dimVariance: [1 0]
```

## References

This function corresponds to the CDF library C API routine `CDFInquirezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.putAttrEntry

---

**Purpose** Write value to entry in attribute with variable scope

**Syntax** `cdflib.putAttrEntry(cdfId, attrNum, entryNum, CDFDataType, entryVal)`

**Description** `cdflib.putAttrEntry(cdfId, attrNum, entryNum, CDFDataType, entryVal)` writes a value to an attribute entry in a Common Data Format (CDF) file.

## Input Arguments

### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **`attrNum`**

Number identifying attribute. The attribute must have variable scope. Attribute numbers are zero-based.

### **`entryNum`**

Number identifying entry. Entry numbers are zero-based.

### **`CDFdatatype`**

One of the following text strings, or its numeric equivalent, that specify the data type of the attribute entry.

<b>CDF Data Type</b>	<b>MATLAB Equivalent</b>
CDF_BYTE	1-byte, signed integer
CDF_CHAR	1 byte, signed character data type that maps to the MATLAB <code>char</code> class
CDF_INT1	1-byte, signed integer.
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB <code>uint8</code> class
CDF_UINT1	1-byte, unsigned integer

CDF Data Type	MATLAB Equivalent
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

## entryVal

Data to be written to attribute entry.

## Examples

Create a CDF and create an attribute with variable scope in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
```

# cdflib.putAttrEntry

---

```
numgAttrs: 0

% Create an attribute of variable scope in the file.
attrNum = cdflib.createAttr(cdfid,'Another Attribute','variable_scope');

% Write a value to an entry for the attribute
cdflib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My Variable Attribute Test');

% Get the value of the global attribute entry
value = cdflib.getAttrEntry(cdfid,attrNum,0)

value =

My Variable Attribute Test

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

## References

## Purpose

Write value to entry in attribute with global scope

## Syntax

```
cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,  
entryVal)
```

## Description

`cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)` writes a value to a global attribute entry in a Common Data Format (CDF) file.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **attrNum**

Number identifying attribute. Attribute numbers are zero-based. The attribute must have global scope.

### **entryNum**

Number identifying entry. Entry numbers are zero-based.

### **CDFdatatype**

One of the following text strings that specify the data type of the attribute entry, or its numeric equivalent.

<b>CDF Data Type</b>	<b>MATLAB Equivalent</b>
CDF_BYTE	1-byte, signed integer
CDF_CHAR	1 byte, signed character data type that maps to the MATLAB <code>char</code> class
CDF_INT1	1-byte, signed integer.
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB <code>uint8</code> class
CDF_UINT1	1-byte, unsigned integer

# cdflib.putAttrgEntry

---

CDF Data Type	MATLAB Equivalent
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

## entryVal

Data to be written to global attribute entry.

## Examples

Create a CDF and create a global attribute in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
```

```
numgAttrs: 0

% Create a global attribute in the file.
attrNum = cdflib.createAttr(cdfid, 'Purpose', 'global_scope');

% Write a value to an entry for the global attribute
cdflib.putAttrgEntry(cdfid, attrNum, 0, 'CDF_CHAR', 'My Test');

% Get the value of the global attribute entry
value = cdflib.getAttrgEntry(cdfid, attrNum, 0)

value =

My Test

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

# cdflib.putVarData

---

**Purpose** Write single value to variable

**Syntax** `cdflib.putVarData(cdfId,varNum,recNum,indices,datum)`

**Description** `cdflib.putVarData(cdfId,varNum,recNum,indices,datum)` writes a single value to a variable in a Common Data File (CDF) file.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **varNum**

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

### **recNum**

Numeric value that identifies the record to which you want to write the datum. Record numbers are zero-based.

### **dims**

Dimension indices within the record. Dimension indices are zero-based.

### **datum**

Data to be written to the variable.

## Examples

Create a CDF, create a variable in the CDF and write data to the variable. To run this example, you must have write permission in the current folder.

```
cdfid = cdflib.create('your_file.cdf');  
  
% Create a variable in the file.  
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);
```

```
% Write some data to the variable
cdflib.putVarData(cdfid,varNum,0,[],int8(98))

% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

    98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

# cdflib.putVarRecordData

---

<b>Purpose</b>	Write entire record to variable
<b>Syntax</b>	<code>cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)</code>
<b>Description</b>	<code>cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)</code> writes data to a record in a variable in a Common Data Format (CDF) file.
<b>Input Arguments</b>	<p><b><code>cdfId</code></b> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p><b><code>varNum</code></b> Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.</p> <p><b><code>recNum</code></b> Numeric value identifying the location of the datum in the variable. Record numbers are zero-based.</p> <p><b><code>recordData</code></b> Data to be written to the variable.</p>

## Examples

Create a CDF, create a variable, and write an entire record of data to the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');  
  
% Create a variable in the file.  
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);  
  
% Write some data to the variable  
cdflib.putVarRecordData(cdfid,varNum,0,int8(98))
```

```
% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

    98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

# cdflib.renameAttr

---

**Purpose** Rename existing attribute

**Syntax** `cdflib.renameAttr(cdfId, attrNum, newName)`

**Description** `cdflib.renameAttr(cdfId, attrNum, newName)` renames an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the attribute.

**Examples** Create a CDF, create an attribute in the CDF, and then rename the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create an attribute
attrNum = cdflib.createAttr(cdfid, 'Purpose', 'global_scope');

% Rename the attribute
cdflib.renameAttr(cdfid, attrNum, 'NewPurpose');

% Check the name of the attribute
attrName = cdflib.getAttrName(cdfid, anum)

attrName =

NewPurpose

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

**References** This function corresponds to the CDF library C API routine `CDFrenameAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.renameVar

---

**Purpose** Rename existing variable

**Syntax** `cdflib.renameVar(cdfId,varNum,newName)`

**Description** `cdflib.renameVar(cdfId,varNum,newName)` renames a variable in a Common Data Format (CDF) file.  
`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the variable.

**Examples** Create a CDF, create a variable in the CDF, and then rename the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Get the name of the variable.
name = cdflib.getVarName(cdfid,varNum)

name =

Time

% Rename the variable
cdflib.renameVar(cdfid,varNum,'NewName');

% Check the new name.
name = cdflib.getVarName(cdfid,varNum)

name =

NewName

% Clean up
```

```
cdflib.delete(cdfid)
```

```
clear cdfid
```

- “Exporting to Common Data File Format (CDF) Files”

# cdflib.setCacheSize

---

**Purpose** Specify number of dotCDF cache buffers

**Syntax** `cdflib.setCacheSize(cdfId,numBuffers)`

**Description** `cdflib.setCacheSize(cdfId,numBuffers)` specifies the number of cache buffers the CDF library uses for an open dotCDF file. A *dotCDF* file is a file with the `.cdf` file extension.

`cdfId` identifies an open CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

For information about cache schemes, see the *CDF User's Guide*.

**Examples** Create a CDF file and set the cache size. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the default cache size
numBuf = cdflib.getCacheSize(cdfid)

numBuf =

    300

% Specify a cache size
cdflib.setCacheSize(cdfid,150)

% Check the cache size again
numBuf = cdflib.getCacheSize(cdfid)

numBuf =

    150

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

# cdflib.setChecksum

---

**Purpose** Specify checksum mode

**Syntax** `cdflib.setChecksum(cdfId,mode)`

**Description** `cdflib.setChecksum(cdfId,mode)` specifies the checksum mode of a Common Data Format (CDF) file.

**Input Arguments**

**`cdfid`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`mode`**

Either of the following text strings, or its numeric equivalent. To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

'MD5_CHECKSUM'	Sets file checksum to MD5 checksum.
'NO_CHECKSUM'	File does not use a checksum.

**Examples** Create a CDF file and set the checksum mode. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('mycdf.cdf');

% Check initial value of checksum.
mode = cdflib.getChecksum(cdfid)

NO_CHECKSUM

cdflib.setChecksum(cdfid,'MD5_CHECKSUM')

% Verify the setting
mode = cdflib.getChecksum(cdfid)

MD5_CHECKSUM
```

## References

This function corresponds to the CDF library C API routine `CDFsetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

- “Exporting to Common Data File Format (CDF) Files”

# cdflib.setCompression

---

**Purpose** Specify compression settings

**Syntax** `cdflib.setCompression(cdfId, ctype, cparms)`

**Description** `cdflib.setCompression(cdfId, ctype, cparms)` specifies compression settings of a Common Data Format (CDF) file.

This function sets the compression for the CDF file itself, not that of any variables in the file.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **ctype**

One of the following text strings, or its numeric equivalent, specifying compression type.

Text String	Compression Type
'NO_COMPRESSION'	No compression
'RLE_COMPRESSION'	Run-length encoding compression
'HUFF_COMPRESSION'	Huffman compression
'AHUFF_COMPRESSION'	Adaptive Huffman compression
'GZIP_COMPRESSION'	GNU's zip compression

To get the numeric equivalent, use `cdflib.getConstantValue`.

### **cparms**

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is 'GZIP\_COMPRESSION'. For this compression type, use `cparms` to specify the level of compression as a numeric value between 1 and 9.

## Examples

Create a CDF file and set the compression setting of the file. To run this example, your current folder must be writable.

```
cdfId = cdflib.create('your_file.cdf');

% Determine the file's default compression setting
[ctype, cparms, cpercent] = cdflib.getCompression(cdfId)

ctype =

NO_COMPRESSION

cparms =

[]

cpercent =

100

% Specify new compression setting
cdflib.setCompression(cdfId,'HUFF_COMPRESSION');

% Check the file's compression setting.
[ctype, cparms, cpercent] = cdflib.getCompression(cdfId)

ctype =

HUFF_COMPRESSION

cparms =

OPTIMAL_ENCODING_TREES

cpercent =
```

# cdflib.setCompression

---

0

```
% Clean up
cdflib.delete(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

- “Exporting to Common Data File Format (CDF) Files”

**Purpose**

Specify number of compression cache buffers

**Syntax**

```
cdflib.setCompressionCacheSize(cdfId,numBuffers)
```

**Description**

`cdflib.setCompressionCacheSize(cdfId,numBuffers)` specifies the number of cache buffers used for the compression scratch CDF file. For more information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` specifies the number of buffers.

**Examples**

Create a CDF file and specify the number of compression cache buffers used. To run this example you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the current number of compression cache buffers
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    80

% Set a new value
cdflib.setCompressionCacheSize(cdfId,100)

% Check the new value
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    100

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

# cdflib.setCompressionCacheSize

---

## Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

**Purpose** Set backward compatibility mode

**Syntax** `cdflib.getFileBackward(mode)`

**Description** `cdflib.getFileBackward(mode)` sets the backward compatibility mode to the value specified by `mode`.

**Tips**

- Setting backward compatibility mode affects only your current MATLAB session, or until you call `cdflib.setFileBackward` again.

**Input Arguments**

**mode**  
One of the following text strings:

BACKWARDFILEon	Set backward compatibility mode on.
BACKWARDFILEoff	Set backward compatibility mode off.

**Default:** BACKWARDFILEoff

**Definitions** **backward compatibility mode**

When specified, ensures that any new CDF file created using CDF V3.0 (or later) will be readable by clients using version 2.7 of the CDF library. CDF 3.0 and later releases use a 64-bit file offset to allow for files greater than 2G bytes in size. CDF library versions released before CDF 3.0 use a 32-bit file offset.

**Examples** Set backward compatibility mode and then check the value.

```
cdflib.setFileBackward('BACKWARDFILEon');
```

```
mode = cdflib.getFileBackward
```

```
mode =
```

```
BACKWARDFILEon
```

# cdflib.setFileBackward

---

**Purpose** Specify format of Common Data Format (CDF) file

**Syntax** `cdflib.setFormat(cdfId, format)`

**Description** `cdflib.setFormat(cdfId, format)` specifies the format of a Common Data Format (CDF) file.

**Input Arguments**

**`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`format`**  
Either of the following text strings, or its numeric equivalent.

'SINGLE_FILE'	The CDF consists of only one file. This is the default file format
'MULTI_FILE'	The CDF consists of one header file for control and attribute data and one additional file for each variable in the CDF.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

**Examples** Create a CDF file and specify its format. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('mycdffile.cdf');

% Specify multifile format.
cdflib.setFormat(cdfId, 'MULTI_FILE');

% Check format.
format = cdflib.getFormat(cdfId)

format =
```

# cdflib.setFormat

**Purpose** Specify majority of variables

**Syntax** `cdflib.setMajority(cdfId,majority)`

**Description** `cdflib.setMajority(cdfId,majority)` specifies the majority of variables in a Common Data Format (CDF) file.

**Input Arguments**

**`cdfId`**  
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

**`majority`**  
Either of the following text strings, or its numeric equivalent.

'ROW_MAJOR'	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
'COLUMN_MAJOR'	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

**Examples** Create a CDF file and specify the majority used by variables in the file. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf')

% Specify the majority used by variables in the file
cdflib.setMajority(cdfId,'COLUMN_MAJOR');

% Check the majority value
majority = cdflib.getMajority(cdfId)
```

# cdflib.setMajority

---

```
majority =

- “Exporting to Common Data File Format (CDF) Files”

## Purpose

Specify read-only mode

## Syntax

```
cdflib.setReadOnlyMode(cdfId,mode)
```

## Description

`cdflib.setReadOnlyMode(cdfId,mode)` specifies the read-only mode of a Common Data Format (CDF) file.

After you open a CDF file, you can put the file into read-only mode to prevent accidental modification.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **mode**

Either of the following text strings or its numeric equivalent.

'READONLYon'	CDF file is read-only
'READONLYoff'	CDF file is modifiable.

To get the numeric equivalent of these mode values, use `cdflib.getConstantValue`.

## Examples

Open the example CDF file and set the file to read-only mode.

```
cdfId = cdflib.open('example.cdf');

% Set the file to READONLY mode
cdflib.setReadOnlyMode(cdfId,'READONLYon')

% Check read-only status of file again.
mode = cdflib.getReadOnlyMode(cdfId)

mode =

READONLYon
```

# cdflib.setReadOnlyMode

---

```
% Clean up
cdflib.close(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

**Purpose** Specify number of staging cache buffers for Common Data Format (CDF) file

**Syntax** `cdflib.setStageCacheSize(cdfId,numBuffers)`

**Description** `cdflib.setStageCacheSize(cdfId,numBuffers)` specifies the number of staging cache buffers for a Common Data Format (CDF) file. For information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

**Examples** Open the example CDF file and specify the number of cache buffers used.

```
cdfId = cdflib.open('example.cdf');

% Get current number of staging cache buffers
size = cdflib.getStageCacheSize(cdfId)

size =

    125

% Specify new cache size value.
cdflib.setStageCacheSize(cdfId, 200)

% Get size again.
size = cdflib.getStageCacheSize(cdfId)

size =

    200

% Clean up
cdflib.close(cdfId)
```

# cdflib.setStageCacheSize

---

`clear cdfId`

## References

This function corresponds to the CDF library C API routine `CDFsetStageCacheSize`.

**Purpose** Specify library validation mode

**Syntax** `cdflib.setValidate(mode)`

**Description** `cdflib.setValidate(mode)` specifies the validation mode of the Common Data Format (CDF) library. Specify the validation mode before opening any files.

**Input Arguments** **mode**  
Either of the following text strings, or its numeric equivalent:

'VALIDATEFILEon'	Turns validation mode on. With validation mode on, the library performs sanity checks on the data fields in the CDF file's internal data structures to make sure that the values are within valid ranges and consistent with the defined values/types/entries. This mode also ensures that variable and attribute associations within the file are valid. Note, however, that enabling this mode will, in most cases, slow down the file opening process, especially for large or very fragmented files.
'VALIDATEFILEoff'	Turns validation mode off.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

**Examples** Set the validation mode of the CDF library.

```
cdflib.setValidate('VALIDATEFILEon');
```

**References** This function corresponds to the CDF library C API routine `CDFsetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

- “Exporting to Common Data File Format (CDF) Files”

## Purpose

Specify number of multi-file cache buffers for variable

## Syntax

```
cdflib.setVarCacheSize(cdfId,varNum,numBuffers)
```

## Description

`cdflib.setVarCacheSize(cdfId,varNum,numBuffers)` specifies the number of cache buffers the CDF library uses for a variable in a Common Data Format (CDF) file.

This function is only used with multifile format CDF files. It does not apply to single-file format CDFs. For more information about caching, see the *CDF User's Guide*.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **varNum**

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

### **numBuffers**

Numeric value identifying the number of cache buffers to use.

## Examples

Create a multifile CDF, and then retrieve the number of buffers being used for a variable:

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
```

# cdflib.setVarCacheSize

---

```
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

    1

% Increase the number of cache buffers used.
cdflib.setVarCacheSize(cdfid,varNum,5)

% Check the number of cache buffers used with the variable.
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

    5

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

## References

# cdflib.setVarCompression

---

**Purpose** Specify compression settings used with variable

**Syntax** `cdflib.setVarCompression(cdfId, varNum, ctype, cparams)`

**Description** `cdflib.setVarCompression(cdfId, varNum, ctype, cparams)` configures the compression setting for a variable in a Common Data Format (CDF) file.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **varNum**

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

### **ctype**

One of the following text strings, or its numeric equivalent, specifying the compression type.

<b>Text String</b>	<b>Compression Type</b>
'NO_COMPRESSION'	No compression.
'RLE_COMPRESSION'	Run-length encoding compression
'HUFF_COMPRESSION'	Huffman compression
'AHUFF_COMPRESSION'	Adaptive Huffman compression
'GZIP_COMPRESSION'	GNU's zip compression

### **cparams**

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is 'GZIP\_COMPRESSION'. For this compression type,

you use `cparms` to specify the level of compression as a numeric value between 1 and 9.

## Examples

Create a CDF, create a variable, and then set the compression used by the variable. To run this example, you must be in a folder with execute permission.

```
cdfid = cdflib.create('mycdf.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Specify the compression used by the variable.
cdflib.setVarCompression(cdfid,0,'GZIP_COMPRESSION',8)

% Check the compression setting of the variable
[ctype params percent] = cdflib.getVarCompression(cdfid,0)

ctype =

GZIP_COMPRESSION

params =

      8

percent =

      0

% Clean up
cdflib.delete(cdfid);
clear cdfid
```

<b>Purpose</b>	Specify reserve percentage for variable
<b>Syntax</b>	<code>cdflib.setVarReservePercent(cdfId,varNum,percent)</code>
<b>Description</b>	<code>cdflib.setVarReservePercent(cdfId,varNum,percent)</code> specifies the compression reserve percentage for a variable in a Common Data Format (CDF) file.
<b>Input Arguments</b>	<p><b>cdfId</b></p> <p>Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p><b>varNum</b></p> <p>Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.</p> <p><b>percent</b></p> <p>Numeric value specifying the amount of extra space to allocate for a compressed variable, expressed as a percentage. You can specify values between 0 (no extra space is reserved) and 100, or values greater than 100. The value specifies the percentage of the uncompressed size of the variable. If you specify a fractional reserve percentages, the library rounds the value down.</p>
<b>Definitions</b>	<p><b>reserve percentage</b></p> <p>Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.</p>

# cdflib.SetVarReservePercent

---

## Examples

Create a CDF, create a variable, set the compression of the variable, and then set the reserve percent for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Set the compression of the variable.
cdflib.setVarCompression(cdfid, varNum, 'GZIP_COMPRESSION', 8);

% Set the compression reserver percentage
cdflib.setVarReservePercent(cdfid, varNum, 80);

cdflib.close(cdfid);
```

## References

- “Exporting to Common Data File Format (CDF) Files”

## Purpose

Specify how variable handles sparse records

## Syntax

```
cdflib.getVarSparseRecords(cdfId, varNum, stype)
```

## Description

`cdflib.getVarSparseRecords(cdfId, varNum, stype)` specifies the sparse records type of a variable in a Common Data Format (CDF) file.

## Input Arguments

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **varNum**

Number that identifies the variable to be set. Variable numbers are zero-based.

### **stype**

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
'NO_SPARSERECORDS'	No sparse records
'PAD_SPARSERECORDS'	For sparse records, the library uses the variable's pad value when reading values from a missing record.
'PREV_SPARSERECORDS'	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

# cdflib.setVarSparseRecords

---

## Examples

Open a multifile CDF and close a variable.

Create a CDF, create a variable, and set the sparse records type of the variable. To run this example you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Set the sparse records type of the variable
cdflib.setVarSparseRecords(cdfid,varNum,'PAD_SPARSERECORDS');

% Check the sparse records type of the variable
stype = cdflib.getVarSparseRecords(cdfid,varNum)

stype =

PAD_SPARSERECORDS

%Clean up
cdflib.delete(cdfid);

clear cdfid
```

## Tutorials

- “Importing Common Data File Format (CDF) Files”
- “Exporting to Common Data File Format (CDF) Files”

**Purpose**

Read data from Common Data Format (CDF) file

**Syntax**

```
data = cdfread(filename)
data = cdfread(filename, param1, val1, param2, val2, ...)
[data, info] = cdfread(filename, ...)
```

**Description**

`data = cdfread(filename)` reads all the data from the Common Data Format (CDF) file specified in the string `filename`. CDF data sets typically contain a set of variables, of a specific data type, each with an associated set of records. The variable might represent time values with each record representing a specific time that an observation was recorded. `cdfread` returns all the data in a cell array where each column represents a variable and each row represents a record associated with a variable. If the variables have varying numbers of associated records, `cdfread` pads the rows to create a rectangular cell array, using pad values defined in the CDF file.

---

**Note** Because `cdfread` creates temporary files, the current working directory must be writeable.

---

`data = cdfread(filename, param1, val1, param2, val2, ...)` reads data from the file, where `param1`, `param2`, and so on, can be any of the parameters listed in the following table.

`[data, info] = cdfread(filename, ...)` returns details about the CDF file in the `info` structure.

Parameter	Value
'Records'	A vector specifying which records to read. Record numbers are zero-based. <code>cdfread</code> returns a cell array with the same number of rows as the number of records read and as many columns as there are variables.
'Variables'	A 1-by- $n$ or $n$ -by-1 cell array specifying the names of the variables to read from the file. $n$ must be less than or equal to the total number of variables in the file. <code>cdfread</code> returns a cell array with the same number of columns as the number of variables read, and a row for each record read.
'Slices'	An $m$ -by-3 array, where each row specifies where to start reading along a particular dimension of a variable, the skip interval to use on that dimension (every item, every other item, etc.), and the total number of values to read on that dimension. $m$ must be less than or equal to the number of dimensions of the variable. If $m$ is less than the total number of dimensions, <code>cdfread</code> reads every value from the unspecified dimensions ( $[0\ 1\ n]$ , where $n$ is the total number of elements in the dimension. Note: Because the 'Slices' parameter describes how to process a single variable, it must be used in conjunction with the 'Variables' parameter.
'ConvertEpochToDatenum'	A Boolean value that determines whether <code>cdfread</code> automatically converts CDF epoch data types to MATLAB serial date numbers. If set to <code>false</code> (the default), <code>cdfread</code> wraps epoch values in MATLAB <code>cdfepoch</code> objects.  Note: For better performance when reading large data sets, set this parameter to <code>true</code> .
'CombineRecords'	A Boolean value that determines how <code>cdfread</code> returns the CDF data sets read from the file. If set to <code>false</code> (the default), <code>cdfread</code> stores the data in an $m$ -by- $n$ cell array, where $m$ is the number of records and $n$ is the number

Parameter	Value
	<p>of variables requested. If set to <code>true</code>, <code>cdfread</code> combines all records for a particular variable into one cell in the output cell array. In this cell, <code>cdfread</code> stores scalar data as a column array. <code>cdfread</code> extends the dimensionality of nonscalar and string data. For example, instead of creating 1000 elements containing 20-by-30 arrays for each record, <code>cdfread</code> stores all the records in one cell as a 1000-by-20-by-30 array</p> <p>Note: If you use the <code>'Records'</code> parameter to specify which records to read, you cannot use the <code>'CombineRecords'</code> parameter.</p> <p>Note: When using the <code>'Variable'</code> parameter to read one variable, if the <code>'CombineRecords'</code> parameter is <code>true</code>, <code>cdfread</code> returns the data as an M-by-N numeric or character array; it does not put the data into a cell array.</p>

---

**Note** To improve performance when working with large data files, use the `'ConvertEpochToDatetime'` and `'CombineRecords'` options.

---

---

**Note** To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

---

## Examples

Read all the data from a CDF file.

```
data = cdfread('example.cdf');
```

Read the data from the variable `'Time'`.

```
data = cdfread('example.cdf', 'Variable', {'Time'});
```

# cdfread

---

Read the first value in the first dimension, the second value in the second dimension, the first and third values in the third dimension, and all values in the remaining dimension of the variable 'multidimensional'.

```
data = cdfread('example.cdf', ...  
             'Variable', {'multidimensional'}, ...  
             'Slices', [0 1 1; 1 1 1; 0 2 2]);
```

This is similar to reading the whole variable into data and then using matrix indexing, as in the following.

```
data{1}(1, 2, [1 3], :)
```

Collapse the records from a data set and convert CDF epoch data types to MATLAB serial date numbers.

```
data = cdfread('example.cdf', ...  
             'CombineRecords', true, ...  
             'ConvertEpochToDatenum', true);
```

`cdfepoch` | `cdfinfo` | `cdflib.setValidate`

## How To

- “Importing Common Data File Format (CDF) Files”

**Purpose**

Write data to Common Data Format (CDF) file

---

**Note** `cdfwrite` is not recommended. Use the `cdflib` low-level functions instead.

---

**Syntax**

```
cdfwrite(filename,variablelist)
cdfwrite(...,'PadValues',padvals)
cdfwrite(...,'GlobalAttributes',gattrib)
cdfwrite(...,'VariableAttributes',vattrib)
cdfwrite(...,'WriteMode',mode)
cdfwrite(...,'Format',format)
```

**Description**

`cdfwrite(filename,variablelist)` writes out a Common Data Format (CDF) file, specified in `filename`. The `filename` input is a string enclosed in single quotes. The `variablelist` argument is a cell array of ordered pairs, each of which comprises a CDF variable name (a string) and the corresponding CDF variable value. To write out multiple records for a variable, put the values in a cell array where each element in the cell array represents a record.

---

**Note** Because `cdfwrite` creates temporary files, both the destination directory for the file and the current working directory must be writeable.

---

`cdfwrite(...,'PadValues',padvals)` writes out pad values for given variable names. `padvals` is a cell array of ordered pairs, each of which comprises a variable name (a string) and a corresponding pad value. Pad values are the default values associated with the variable when an out-of-bounds record is accessed. Variable names that appear in `padvals` must appear in `variablelist`.

`cdfwrite(...,'GlobalAttributes',gattrib)` writes the structure `gattrib` as global metadata for the CDF file. Each field of the structure

is the name of a global attribute. The value of each field contains the value of the attribute. To write out multiple values for an attribute, put the values in a cell array where each element in the cell array represents a record.

---

**Note** To specify a global attribute name that is invalid in your MATLAB application, create a field called 'CDFAttributeRename' in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `GlobalAttributes` structure, and the corresponding name of the attribute to be written to the CDF file.

---

`cdfwrite(..., 'VariableAttributes', vattrib)` writes the structure `vattrib` as variable metadata for the CDF. Each field of the struct is the name of a variable attribute. The value of each field should be an M-by-2 cell array where M is the number of variables with attributes. The first element in the cell array should be the name of the variable and the second element should be the value of the attribute for that variable.

---

**Note** To specify a variable attribute name that is illegal in MATLAB, create a field called 'CDFAttributeRename' in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `VariableAttributes` struct, and the corresponding name of the attribute to be written to the CDF file. If you are specifying a variable attribute of a CDF variable that you are renaming, the name of the variable in the `VariableAttributes` structure must be the same as the renamed variable.

---

`cdfwrite(..., 'WriteMode', mode)`, where *mode* is either 'overwrite' or 'append', indicates whether or not the specified variables should be

appended to the CDF file if the file already exists. By default, `cdfwrite` overwrites existing variables and attributes.

`cdfwrite(..., 'Format', format)`, where *format* is either 'multifile' or 'singlefile', indicates whether or not the data is written out as a multifile CDF. In a multifile CDF, each variable is stored in a separate file with the name \*.vN, where N is the number of the variable that is written out to the CDF. By default, `cdfwrite` writes out a single file CDF. When 'WriteMode' is set to 'Append', the 'Format' option is ignored, and the format of the preexisting CDF is used.

## Examples

Write out a file 'example.cdf' containing a variable 'Longitude' with the value [0:360].

```
cdfwrite('example', {'Longitude', 0:360});
```

Write out a file 'example.cdf' containing variables 'Longitude' and 'Latitude' with the variable 'Latitude' having a pad value of 10 for all out-of-bounds records that are accessed.

```
cdfwrite('example', {'Longitude', 0:360, 'Latitude', 10:20}, ...  
        'PadValues', {'Latitude', 10});
```

Write out a file 'example.cdf', containing a variable 'Longitude' with the value [0:360], and with a variable attribute of 'validmin' with the value 10.

```
varAttribStruct.validmin = {'Longitude' [10]};  
cdfwrite('example', {'Longitude' 0:360}, 'VariableAttributes', ...  
        varAttribStruct);
```

# ceil

---

**Purpose** Round toward positive infinity

**Syntax**  $B = \text{ceil}(A)$

**Description**  $B = \text{ceil}(A)$  rounds the elements of  $A$  to the nearest integers greater than or equal to  $A$ . For complex  $A$ , the imaginary and real parts are rounded independently.

**Examples**  $a = [-1.9, -0.2, 3.4, 5.6, 7, 2.4+3.6i]$

```
a =  
Columns 1 through 4  
-1.9000      -0.2000      3.4000      5.6000  
  
Columns 5 through 6  
7.0000      2.4000 + 3.6000i
```

```
ceil(a)
```

```
ans =  
Columns 1 through 4  
-1.0000      0      4.0000      6.0000  
  
Columns 5 through 6  
7.0000      3.0000 + 4.0000i
```

**See Also** `fix` | `floor` | `round`

---

<b>Purpose</b>	Create cell array
<b>Syntax</b>	<pre>C = cell(dim) C = cell(dim1,...,dimN) D = cell(obj)</pre>
<b>Description</b>	<p><code>C = cell(dim)</code> creates a cell array of empty matrices. If <code>dim</code> is a scalar, <code>C</code> is <code>dim</code>-by-<code>dim</code>. If <code>dim</code> is a vector, <code>C</code> is <code>dim(1)</code>-by-...-<code>dim(N)</code>, where <code>N</code> is the number of elements of <code>dim</code>.</p> <p><code>C = cell(dim1,...,dimN)</code> creates cell array <code>C</code>, where <code>C</code> is <code>dim1</code>-by-...-<code>dimN</code>.</p> <p><code>D = cell(obj)</code> converts a Java array or .NET array of <code>System.String</code> or <code>System.Object</code> into a MATLAB cell array.</p>
<b>Tips</b>	<p>Creating an empty array with the <code>cell</code> function, such as</p> <pre>C = cell(3,4,2);</pre> <p>is exactly equivalent to assigning an empty array to the last index of a new cell array:</p> <pre>C{3,4,2} = [];</pre>
<b>Input Arguments</b>	<p><b>dim</b></p> <p>Scalar integer or vector of integers that specifies the dimensions of cell array <code>C</code>.</p> <p><b>dim1,...,dimN</b></p> <p>Scalar integers that specify the dimensions of <code>C</code>.</p> <p><b>obj</b></p> <p>One of the following:</p> <ul style="list-style-type: none"><li>• Java array or object</li><li>• .NET array of type <code>System.String</code> or <code>System.Object</code></li></ul>

## Output Arguments

### C

Cell array. Each cell contains an empty, 0-by-0 array of type double.

### D

Cell array. Each cell contains a MATLAB type closest to the Java or .NET type. For more information, see:

- “Conversion of Java Return Types”
- “.NET Type to MATLAB Type Mapping”

## Examples

Create an empty 3-by-4-by-2 cell array.

```
mycell = cell(3,4,2);
```

---

Create a cell array that is the same size as `mycell`, created in the previous example.

```
similar = cell(size(mycell));
```

---

Convert an array of `java.lang.String` objects into a MATLAB cell array.

```
strArray = java_array('java.lang.String', 3);  
strArray(1) = java.lang.String('one');  
strArray(2) = java.lang.String('two');  
strArray(3) = java.lang.String('three');
```

```
cellArray = cell(strArray)
```

This code returns

```
cellArray =  
    'one'  
    'two'
```

---

```
'three'
```

---

Create a cell array of folders in the `c:\work` folder, using the .NET Framework `System.IO.Directory` class :

```
myList = cell(System.IO.Directory.GetDirectories('c:\work'));  
celldisp(myList)
```

**See Also**

`num2cell` | `ones` | `rand` | `randn` | `zeros`

**How To**

- “Access Data in a Cell Array”

# cell2mat

---

**Purpose** Convert cell array to numeric array

**Syntax** `A= cell2mat(C)`

**Description** `A= cell2mat(C)` converts cell array `C` with contents of the same data type into a single array, `A`.

**Input Arguments**

**C**

Cell array, where each cell contains the same type of data. The `cell2mat` function accepts numeric or character data within cells of `C`, but not structs, objects, or nested cells.

The contents of `C` must support concatenation into a hyperrectangle. Otherwise, the results are undefined. For example, the contents of cells in the same column must have the same number of columns, although they need not have the same number of rows.

**Output Arguments**

**A**

Array of the same type as the contents of the cells of `C`. The number of dimensions of `A` matches the highest number of dimensions of arrays within `C`.

**Examples**

Combine matrices in the four cells of cell array `c` into matrix `m`.

```
c = {[1],      [2, 3, 4];  
     [5; 9], [6, 7, 8; 10, 11, 12]};
```

```
m = cell2mat(c)
```

`m` is a 3-by-4 matrix:

```
m =  
     1     2     3     4  
     5     6     7     8  
     9    10    11    12
```

**See Also**

[mat2cell](#) | [num2cell](#)

# cell2struct

---

**Purpose** Convert cell array to structure array

**Syntax** `structArray = cell2struct(cellArray, fields, dim)`

**Description** `structArray = cell2struct(cellArray, fields, dim)` creates a structure array, `structArray`, from the information contained within cell array `cellArray`.

The `fields` argument specifies field names for the structure array. This argument is an array of strings or a cell array of strings.

The `dim` argument tells MATLAB which axis of the cell array to use in creating the structure array. Use a numeric double to specify `dim`.

To create a structure array with fields derived from `N` rows of a cell array, specify `N` field names in the `fields` argument, and the number `1` in the `dim` argument. To create a structure array with fields derived from `M` columns of a cell array, specify `M` field names in the `fields` argument and the number `2` in the `dim` argument.

The `structArray` output is a structure array with `N` fields, where `N` is equal to the number of fields in the `fields` input argument. The number of fields in the resulting structure must equal the number of cells along dimension `dim` that you want to convert.

## Examples

Create the following table for use with the examples in this section. The table lists information about the employees of a small Engineering company. Reading the table by rows shows the names of employees by department. Reading the table by columns shows the number of years each employee has worked at the company.

	<b>5 Years</b>	<b>10 Years</b>	<b>15 Years</b>
<b>Development</b>	Lee, Reed, Hill	Dean, Frye	Lane, Fox, King
<b>Sales</b>	Howe, Burns	Kirby, Ford	Hall
<b>Management</b>	Price	Clark, Shea	Sims

	<b>5 Years</b>	<b>10 Years</b>	<b>15 Years</b>
<b>Quality</b>	Bates, Gray	Nash	Kay, Chase
<b>Documentation</b>	Lloyd, Young	Ryan, Hart, Roy	Marsh

Enter the following commands to create the initial cell array `employees`:

```

devel = {'Lee','Reed','Hill'}, {'Dean','Frye'}, ...
        {'Lane','Fox','King'};
sales = {'Howe','Burns'}, {'Kirby','Ford'}, {'Hall'};
mgmt = {'Price'}, {'Clark','Shea'}, {'Sims'};
qual = {'Bates','Gray'}, {'Nash'}, {'Kay','Chase'};
docu = {'Lloyd','Young'}, {'Ryan','Hart','Roy'}, {'Marsh'};

```

```

employees = [devel; sales; mgmt; qual; docu]
employees =
    {1x3 cell}    {1x2 cell}    {1x3 cell}
    {1x2 cell}    {1x2 cell}    {1x1 cell}
    {1x1 cell}    {1x2 cell}    {1x1 cell}
    {1x2 cell}    {1x2 cell}    {1x2 cell}
    {1x2 cell}    {1x2 cell}    {1x1 cell}

```

This is the resulting cell array:

	fiveYears	tenYears	fifteenYears
development	Lee Reed Hill	Dean Frye	Lane Fox King
sales	Howe Burns	Kirby Ford	Hall
management	Price	Clark Shea	Sims
quality	Bates Gray	Nash	Kay Chase
documentation	Young Lloyd	Ryan Hart Roy	Marsh

## 5 x 3 cell array

---

Convert the cell array to a struct along dimension 1:

- 1 Convert the 5-by-3 cell array along its first dimension to construct a 3-by-1 struct array with 5 fields. Each of the rows along dimension 1 of the cell array becomes a field in the struct array:

Traversing the first (i.e., vertical) dimension, there are 5 rows with row headings that read as follows:

```
rowHeadings = {'development', 'sales', 'management', ...
               'quality', 'documentation'};
```

- Convert the cell array to a struct array, `depts`, in reference to this dimension:

```
depts = cell2struct(employees, rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    sales
```

```
management
quality
documentation
```

- 3** Use this row-oriented structure to find the names of the Development staff who have been with the company for up to 10 years:

```
depts(1:2).development
ans =
    'Lee'    'Reed'    'Hill'
ans =
    'Dean'   'Frye'
```

---

Convert the same cell array to a struct along dimension 2:

- 1** Convert the 5-by-3 cell array along its second dimension to construct a 5-by-1 struct array with 3 fields. Each of the columns along dimension 2 of the cell array becomes a field in the struct array:

	fiveYears	tenYears	fifteenYears	
development	Lee Reed Hill	Dean Frye	Lane Fox King	<b>5 x 3 cell array</b>
sales	Howe Burns	Kirby Ford	Hall	
management	Price	Clark Shea	Sims	
quality	Bates Gray	Nash	Kay Chase	
documentation	Young Lloyd	Ryan Hart Roy	Marsh	

**5 x 1 struct array with 3 fields**

y(5)	.fiveYears	Lloyd, Young
	.tenYears	Ryan, Hart, Roy
	.fifteenYears	Marsh
y(4)	.fiveYears	Bates, Gray
	.tenYears	Nash
	.fifteenYears	Kay, Chase
y(3)	.fiveYears	Lauer
	.tenYears	Clark, Shea
	.fifteenYears	Sims
y(2)	.fiveYears	Howe, Burns
	.tenYears	Kirby, Ford
	.fifteenYears	Hall
y(1)	.fiveYears	Lee, Reed, Hill
	.tenYears	Dean, Frye
	.fifteenYears	Lane, Fox, King

- 2** Traverse the cell array along the second (or horizontal) dimension. The column headings become fields of the resulting structure:

```
colHeadings = {'fiveYears' 'tenYears' 'fifteenYears'};

years = cell2struct(employees, colHeadings, 2)
years =
5x1 struct array with fields:
    fiveYears
    tenYears
    fifteenYears
```

- 3** Using the column-oriented structure, show how many employees from the Sales and Documentation departments have worked for the company for at least 5 years:

```
[~, sales_5years, ~, ~, docu_5years] = years.fiveYears
sales_5years =
    'Howe'    'Burns'
docu_5years =
    'Lloyd'   'Young'
```

---

Convert only part of the cell array to a struct:

- 1** Convert only the first and last rows of the cell array. This results in a 3-by-1 struct array with 2 fields:

```
rowHeadings = {'development', 'documentation'};

depts = cell2struct(employees([1,5],:), rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    documentation
```

- 2** Display those employees who belong to these departments for all three periods of time:

```

for k=1:3
    depts(k,:)
end

ans =
    development: {'Lee' 'Reed' 'Hill'}
    documentation: {'Lloyd' 'Young'}

ans =
    development: {'Dean' 'Frye'}
    documentation: {'Ryan' 'Hart' 'Roy'}

ans =
    development: {'Lane' 'Fox' 'King'}
  
```

# cell2struct

---

```
documentation: {'Marsh'}
```

## See Also

[struct2cell](#) | [cell](#) | [iscell](#) | [struct](#) | [isstruct](#) | [fieldnames](#)

## How To

- [dynamic field names](#)

<b>Purpose</b>	Convert cell array to table
<b>Syntax</b>	<pre>T = cell2table(C) T = cell2table(C,Name,Value)</pre>
<b>Description</b>	<p><code>T = cell2table(C)</code> converts the contents of an <i>m</i>-by-<i>n</i> cell array, <i>C</i>, to an <i>m</i>-by-<i>n</i> table, <i>T</i>. Each variable in the table, <i>T</i>, is numeric, with a data type <code>double</code>, or a cell array of strings.</p> <p><code>cell2table</code> uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, <code>cell2table</code> uses strings of the form <code>'Var1'</code>, ..., <code>'VarN'</code> where <i>N</i> is the number of columns in <i>C</i>.</p> <p><code>T = cell2table(C,Name,Value)</code> creates a table from a cell array, <i>C</i>, with additional options specified by one or more <i>Name,Value</i> pair arguments.</p> <p>For example, you can specify row names or variable names to include in the table.</p>
<b>Input Arguments</b>	<p><b>C - Input cell array</b> 2-D cell array</p> <p>Input cell array, specified as a 2-D cell array.</p> <p>If the cell contents have compatible sizes and types, then <code>cell2table</code> vertically concatenates the contents of the cells in each column of <i>C</i> to create each variable in <i>T</i>. If the cell contents have different sizes or incompatible types, then the corresponding variable in the table, <i>T</i>, is a column of cells.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <i>Name,Value</i> arguments. <i>Name</i> is the argument name and <i>Value</i> is the corresponding value. <i>Name</i> must appear inside single quotes (<code>' '</code>). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p>

**Example:** `RowNames', {'row1', 'row2', 'row3'}` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

## **'RowNames' - Row names for T**

`{}` (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(C,1)`.

## **'VariableNames' - Variable names for T**

cell array of nonempty, distinct strings

Variable names for `T`, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(C,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of `N` strings of the form `{'Var1' ... 'VarN'}`, where `N` is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

## **Output Arguments**

### **T - Output table**

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## **Examples**

### **Convert Cell Array to Table**

Create a cell array containing strings and numeric data.

```
C = {5 'cereal' 110 'C+'; 12 'pizza' 140 'B'; ...  
     23 'salmon' 367 'A'; 2 'cookies' 160 'D'}
```

```
C =
```

```
[ 5]    'cereal'    [110]    'C+'
[12]    'pizza'    [140]    'B'
[23]    'salmon'   [367]    'A'
[ 2]    'cookies'  [160]    'D'
```

Convert the cell array, C, to a table and specify variable names.

```
T = cell2table(C,...
    'VariableNames',{'Age' 'FavoriteFood' 'Calories' 'NutritionGrade'})
```

T =

Age	FavoriteFood	Calories	NutritionGrade
5	'cereal'	110	'C+'
12	'pizza'	140	'B'
23	'salmon'	367	'A'
2	'cookies'	160	'D'

The variables T.Age and T.Calories are numeric while the variables T.FavoriteFood and T.NutritionGrade are cell arrays of strings.

### Convert Column Headings to Variable Names

Convert a cell array to a table, and then include the first row from the cell array as variable names for the table.

Create a cell array where the first row contains strings to identify column headings.

```
Patients = {'Gender' 'Age' 'Height' 'Weight' 'Smoker';...
    'M' 38 71 176 true;...
    'M' 43 69 163 false;...
    'M' 38 64 131 false;...
    'F' 38 64 131 false;...
    'F' 40 67 133 false;...
    'F' 49 64 119 false}
```

# cell2table

---

```
Patients =
```

```
      'Gender'      'Age'      'Height'      'Weight'      'Smoker'
      'M'          [ 38]      [  71]      [  176]      [    1]
      'M'          [ 43]      [  69]      [  163]      [    0]
      'M'          [ 38]      [  64]      [  131]      [    0]
      'F'          [ 38]      [  64]      [  131]      [    0]
      'F'          [ 40]      [  67]      [  133]      [    0]
      'F'          [ 49]      [  64]      [  119]      [    0]
```

Exclude the columns headings and convert the contents of the cell array to a table.

```
C = Patients(2:end,:);
T = cell2table(C)
```

```
T =
```

C1	C2	C3	C4	C5
'M'	38	71	176	true
'M'	43	69	163	false
'M'	38	64	131	false
'F'	38	64	131	false
'F'	40	67	133	false
'F'	49	64	119	false

The table, T, has variable names C1, ..., C5.

Change the variable names by setting the table property, T.Properties.VariableNames, to the first row of the cell array.

```
T.Properties.VariableNames = Patients(1,:)
```

```
T =
```

Gender	Age	Height	Weight	Smoker
--------	-----	--------	--------	--------

'M'	38	71	176	true
'M'	43	69	163	false
'M'	38	64	131	false
'F'	38	64	131	false
'F'	40	67	133	false
'F'	49	64	119	false

**See Also**

[table2cell](#) | [array2table](#) | [struct2table](#) | [table](#) | [isvarname](#)

**Related Examples**

- “Access Data in a Table”

# celldisp

---

**Purpose** Cell array contents

**Syntax** `celldisp(C)`  
`celldisp(C, name)`

**Description** `celldisp(C)` recursively displays the contents of a cell array.  
`celldisp(C, name)` uses the string *name* for the display instead of the name of the first input (or ans).

**Examples** Use `celldisp` to display the contents of a 2-by-3 cell array:

```
C = {[1 2] 'Tony' 3+4i; [1 2;3 4] -5 'abc'};  
celldisp(C)
```

```
C{1,1} =  
    1    2
```

```
C{2,1} =  
    1    2  
    3    4
```

```
C{1,2} =  
Tony
```

```
C{2,2} =  
-5
```

```
C{1,3} =  
3.0000+ 4.0000i
```

```
C{2,3} =  
abc
```

**See Also** `cellplot`

**How To** • “Exporting a Cell Array to a Text File”

**Purpose**

Apply function to each cell in cell array

**Syntax**

```
[A1,...,Am] = cellfun(func,C1,...,Cn)
[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)
```

**Description**

`[A1,...,Am] = cellfun(func,C1,...,Cn)` calls the function specified by function handle `func` and passes elements from cell arrays `C1,...,Cn`, where `n` is the number of inputs to function `func`. Output arrays `A1,...,Am`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax `[A1(i),...,Am(i)] = func(C{i},...,Cn{i})`. The `cellfun` function does not perform the calls to function `func` in a specific order.

`[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

**Input Arguments****func**

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

**Backward Compatibility**

`cellfun` accepts function name strings for function `func`, rather than a function handle, for these function names: `isempty`, `islogical`, `isreal`, `length`, `ndims`, `prodofsize`, `size`, `isclass`. Enclose the function name in single quotes.

If you specify a function name string rather than a function handle:

- `cellfun` does not call any overloaded versions of the function.

- The `size` and `isclass` functions require additional inputs to the `cellfun` function:

`A = cellfun('size', C, k)` returns the size along the `k`th dimension of each element of `C`.

`A = cellfun('isclass', C, classname)` returns logical 1 (true) for each element of `C` that matches the `classname` string. This syntax returns logical 0 (false) for objects that are a subclass of `classname`.

## **C1,...,Cn**

Cell arrays that contain the `n` inputs required for function `func`. Each cell array must have the same dimensions.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'UniformOutput'**

Logical value, as follows:

- |                        |  |
|------------------------|--|
| <code>true</code> (1)  | Indicates that for all inputs, each output from function <code>func</code> is a cell array or a scalar value that is always of the same type and size. The <code>cellfun</code> function combines the outputs in arrays <code>A1, ..., Am</code> , where <code>m</code> is the number of function outputs. Each output array is of the same type as the individual function outputs. |
| <code>false</code> (0) | Requests that the <code>cellfun</code> function combine the outputs into cell arrays <code>A1, ..., Am</code> . The outputs of function <code>func</code> can be of any size or type.  |

**Default:** `true`

**'ErrorHandler'**

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

**Output Arguments****A1,...,Am**

Arrays that collect the  $m$  outputs from function `func`. Each array  $A$  is the same size as each of the inputs  $C_1, \dots, C_n$ .

Function `func` can return output arguments of different classes. However, if `UniformOutput` is true (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

**Examples**

Compute the mean of each vector in cell array `C`.

```
C = {1:10, [2; 4; 6], []};
```

```
averages = cellfun(@mean, C)
```

This code returns

```
averages =  
    5.5000    4.0000    NaN
```

---

Compute the size of each array in C, created in the previous example.

```
[nrows, ncols] = cellfun(@size, C)
```

This code returns

```
nrows =  
     1     3     0  
ncols =  
    10     1     0
```

---

Create a cell array that contains strings, and abbreviate those strings to the first three characters. Because the output strings are nonscalar, set `UniformOutput` to `false`.

```
days = {'Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday'};  
abbrev = cellfun(@(x) x(1:3), days, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
abbrev =  
    'Mon'    'Tue'    'Wed'    'Thu'    'Fri'
```

---

Compute the covariance between arrays in two cell arrays C and D. Because the covariance output is nonscalar, set `UniformOutput` to `false`.

```
c1 = rand(5,1); c2 = rand(10,1); c3 = rand(15,1);  
d1 = rand(5,1); d2 = rand(10,1); d3 = rand(15,1);
```

```
C = {c1, c2, c3};
D = {d1, d2, d3};

covCD = cellfun(@cov, C, D, 'UniformOutput', false)
```

This code returns

```
covCD =
    [2x2 double]    [2x2 double]    [2x2 double]
```

---

Define and call a custom error handling function.

```
function result = errorfun(S, varargin)
    warning(S.identifier, S.message);
    result = NaN;
end

A = {rand(3)};
B = {rand(5)};
AgtB = cellfun(@(x,y) x > y, A, B, 'ErrorHandler', @errorfun, ...
    'UniformOutput', false)
```

## Tutorials

- “Anonymous Functions”

# cellplot

---

**Purpose** Graphically display structure of cell array

**Syntax**  
`cellplot(c)`  
`cellplot(c, 'legend')`  
`handles = cellplot(c)`

**Description** `cellplot(c)` displays a figure window that graphically represents the contents of `c`. Filled rectangles represent elements of vectors and arrays, while scalars and short text strings are displayed as text.

`cellplot(c, 'legend')` places a colorbar next to the plot labelled to identify the data types in `c`.

`handles = cellplot(c)` displays a figure window and returns a vector of surface handles.

**Limitations** The `cellplot` function can display only two-dimensional cell arrays.

**Examples** Consider a 2-by-2 cell array containing a matrix, a vector, and two text strings:

```
c{1,1} = '2-by-2';  
c{1,2} = 'eigenvalues of eye(2)';  
c{2,1} = eye(2);  
c{2,2} = eig(eye(2));
```

The command `cellplot(c)` produces

**See Also**`celldisp`**How To**

- “Editing Plots”
- “Exporting a Cell Array to a Text File”

# cellstr

---

**Purpose** Create cell array of strings from character array

**Syntax** `c = cellstr(S)`

**Description** `c = cellstr(S)` places each row of the character array `S` into separate cells of `c`. Any trailing spaces in the rows of `S` are removed.

Use the `char` function to convert back to a string matrix.

**Examples** Given the string matrix

```
S = ['abc '; 'defg'; 'hi  ']
```

```
S =  
    abc  
    defg  
    hi
```

```
whos S  
  Name      Size      Bytes  Class  
  S          3x4          24   char array
```

The following command returns a 3-by-1 cell array.

```
c = cellstr(S)
```

```
c =  
    'abc'  
    'defg'  
    'hi'
```

```
whos c  
  Name      Size      Bytes  Class  
  c          3x1          198   cell array
```

**See Also** `iscellstr` | `strings` | `char` | `isstrprop` | `strsplit`

**Purpose**

Conjugate gradients squared method

**Syntax**

```
x = cgs(A,b)
cgs(A,b,tol)
cgs(A,b,tol,maxit)
cgs(A,b,tol,maxit,M)
cgs(A,b,tol,maxit,M1,M2)
cgs(A,b,tol,maxit,M1,M2,x0)
[x,flag] = cgs(A,b,...)
[x,flag,relres] = cgs(A,b,...)
[x,flag,relres,iter] = cgs(A,b,...)
[x,flag,relres,iter,resvec] = cgs(A,b,...)
```

**Description**

`x = cgs(A,b)` attempts to solve the system of linear equations  $A*x = b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `cgs` converges, a message to that effect is displayed. If `cgs` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$  and the iteration number at which the method stopped or failed.

`cgs(A,b,tol)` specifies the tolerance of the method, `tol`. If `tol` is `[]`, then `cgs` uses the default,  $1e-6$ .

`cgs(A,b,tol,maxit)` specifies the maximum number of iterations, `maxit`. If `maxit` is `[]` then `cgs` uses the default,  $\min(n,20)$ .

`cgs(A,b,tol,maxit,M)` and `cgs(A,b,tol,maxit,M1,M2)` use the preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for  $x$ . If  $M$  is `[]` then `cgs` applies no preconditioner.  $M$  can be a function handle `mfun` such that `mfun(x)` returns  $M \setminus x$ .

`cgs(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess `x0`. If `x0` is `[]`, then `cgs` uses the default, an all-zero vector.

`[x,flag] = cgs(A,b,...)` returns a solution `x` and a flag that describes the convergence of `cgs`.

Flag	Convergence
0	<code>cgs</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>cgs</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>cgs</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>cgs</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = cgs(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is 0, then `relres <= tol`.

`[x,flag,relres,iter] = cgs(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = cgs(A,b,...)` also returns a vector of the residual norms at each iteration, including `norm(b-A*x0)`.

## Examples

### Using `cgs` with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12; maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x = cgs(A,b,tol,maxit,M1);
```

displays the message

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

### Using cgs with a Function Handle

This example replaces the matrix  $A$  in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner  $M1$  with a handle to a backsolve function `mfun`. The example is contained in the file `run_cgs` that

- Calls `cgs` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_cgs` are available to `afun` and `mfun`.

The following shows the code for `run_cgs`:

```
function x1 = run_cgs
n = 21;
b = afun(ones(n,1));
tol = 1e-12; maxit = 15;
x1 = cgs(@afun,b,tol,maxit,@mfun);

    function y = afun(x)
        y = [0; x(1:n-1)] + ...
            [((n-1)/2:-1:0)'; (1:(n-1)/2)'] .* x + ...
            [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_cgs
```

MATLAB software returns

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

### **Using a Preconditioner**

This example demonstrates the use of a preconditioner.

**1**

Load west0479, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

**2**

Define **b** so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

**3**

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

**4**

Use **cgs** to find a solution at the requested tolerance and number of iterations:

```
[x0,f10,rr0,it0,rv0] = cgs(A,b,tol,maxit);
```

**f10** is 1 because **cgs** does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. In fact, the behavior of **cgs** is so poor that the initial guess ( $x0 = \text{zeros}(\text{size}(A,2),1)$ ) is the best solution and is returned as indicated by  $it0 = 0$ . MATLAB stores the residual history in **rv0**.

**5**

Plot the behavior of cgs:

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

## 6

Create a preconditioner with `ilu`, since  $A$  is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the

drop tolerance or consider using the 'udiag' option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = cgs(A,b,tol,maxit,L,U);
```

f11 is 0 because cgs drives the relative residual to  $4.3851e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the third iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b) and the output rv1(14) is norm(b-A\*x2).

## 8

You can follow the progress of cgs by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0)

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

# char

---

**Purpose** Convert to character array (string)

**Syntax**  
S = char(X)  
S = char(C)  
S = char(T1,T2,...,TN)

**Description** S = char(X) converts array X of nonnegative integer codes into a character array. Valid codes range from 0 to 65535, where codes 0 through 127 correspond to 7-bit ASCII characters. The characters that MATLAB can process (other than 7-bit ASCII characters) depend upon your current locale setting. To convert characters into a numeric array, use the `double` function.

S = char(C), when C is a cell array of strings, places each element of C into the rows of the character array s. Use `cellstr` to convert back.

S = char(T1,T2,...,TN) forms the character array S containing the text strings T1, T2, ..., TN as rows, automatically padding each string with blanks to form a valid matrix. Each text parameter, Ti, can itself be a character array. This allows the creation of arbitrarily large character arrays. Empty strings are significant.

## Examples **Convert Integers to Characters**

Create a 3-by-32 array of the printable ASCII characters.

```
asc = char(reshape(32:127,32,3)')
```

```
asc =
```

```
! "#$%&'()*+,-./0123456789:;<=>?  
@ABCDEFGHIJKLMNPQRSTUVWXYZ[\]^_  
`abcdefghijklmnopqrstuvwxyz{|}~
```

**Tutorials** • “How the MATLAB Process Uses Locale Settings”

<b>Purpose</b>	Check MATLAB code files for possible problems
<b>Alternatives</b>	For information on using the graphical user interface for checking code, see “Check Code for Errors and Warnings”.
<b>Syntax</b>	<pre>checkcode('filename') checkcode('filename', '-config=settings.txt') checkcode('filename', '-config=factory') inform=checkcode('filename', '-struct') msg=checkcode('filename', '-string') [inform, filepaths]=checkcode('filename') inform=checkcode('filename', '-id') inform=checkcode('filename', '-fullpath') inform=checkcode('filename', '-notok') checkcode('filename', '-cyc') checkcode('filename', '-codegen') checkcode('filename', '-eml')</pre>

**Description** `checkcode('filename')` displays messages, sometimes referred to as Code Analyzer messages, about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `checkcode(F1,F2,F3,...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `checkcode` messages is subject to some change between versions.

`checkcode('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

---

**Note** If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

---

# checkcode

---

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `checkcode` returns a message indicating that it cannot open or read the file you specified. In that case, `checkcode` uses the factory default settings.

`checkcode('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=checkcode('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
<code>message</code>	Message describing the suspicious construct that code analysis caught.
<code>line</code>	Vector of file line numbers to which the message refers.
<code>column</code>	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=checkcode('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each file’s information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the `-struct` or `-string` argument and you specify an output argument, the default behavior is `-struct`. If you omit the argument

and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepath]=checkcode('filename')` additionally returns `filepath`, the absolute paths to the file names, in the same order as you specified them.

`inform=checkcode('filename','-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=checkcode('filename','-fullpath')` assumes that the input file names are absolute paths, so that `checkcode` does not try to locate them.

`inform=checkcode('filename','-notok')` runs `checkcode` for all lines in `filename`, even those lines that end with the `checkcode` suppression directive, `%#ok`.

`checkcode('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`checkcode('filename','-codegen')` enables code generation messages for display in the Command Window.

`checkcode('filename','-em1')` '-em1' is not recommended. Use '-codegen' instead.

## Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in `matlabroot/help/techdoc/matlab_env/examples`. If you want to run

the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

## Running checkcode on a File with No Options

To run `checkcode` on the example file, `lengthofline.m`, run

```
checkcode('lengthofline')
```

MATLAB displays the Code Analyzer messages for `lengthofline.m` in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
                Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop.Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

## Running checkcode with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=checkcode('lengthofline', '-id')
```

MATLAB returns

```
inform =
```

```
19x1 struct array with fields:
```

```
    message  
     line  
   column  
     id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =
```

```
    message: 'The value assigned here to variable 'nohandle' might never be used.'  
         line: 22  
    column: [1 9]  
         id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned here to variable 'nohandle' might never be used.'.

## Displaying McCabe Complexity with checkcode

To display the McCabe complexity of a MATLAB code file, run checkcode with the -cyc option, as shown in the following example (assuming you have saved lengthofline.m to a local folder).

```
checkcode lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the Code Analyzer messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more in

## How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

## Purpose

Check files into source control system (UNIX platforms)

## Syntax

```
checkin('filename', 'comments', 'comment_text')
checkin({'filename1', 'filename2'}, 'comments', 'comment_text')
checkin('filename', 'comments', 'comment_text', 'option',
        'value')
```

## Description

`checkin('filename', 'comments', 'comment_text')` checks in the file named `filename` to the source control system. Use the full path for `filename` and include the file extension. You must save the file before checking it in, but the file can be open or closed. The `comment_text` is a MATLAB string containing checkin comments for the source control system. You must supply **comments** and `comment_text`.

`checkin({'filename1', 'filename2'}, 'comments', 'comment_text')` checks in the files `filename1` through `filename2` to the source control system. Use the full paths for the files and include file extensions. Comments apply to all files checked in.

`checkin('filename', 'comments', 'comment_text', 'option', 'value')` provides additional checkin options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1', 'filename2', ...}`. Options apply to all file names. The *option* and *value* arguments are shown in the following table.

option Argument	value Argument	Purpose
'force'	'on'	<code>filename</code> is checked in even if the file has not changed since it was checked out.
'force'	'off' (default)	<code>filename</code> is not checked in if there were no changes since checkout.

# checkin

---

option Argument	value Argument	Purpose
'lock'	'on'	filename is checked in with comments, and is automatically checked out.
'lock'	'off' (default)	filename is checked in with comments but does not remain checked out.

## Examples

### Check In a File

Check the file `/myserver/myfiles/clock.m` into the source control system, with the comment `Adjustment for leapyear`:

```
checkin('/myserver/myfiles/clock.m', 'comments', ...  
'Adjustment for leapyear')
```

### Check In Multiple Files

Check two files into the source control system, using the same comment for each:

```
checkin({'/myserver/myfiles/clock.m', ...  
'/myserver/myfiles/calendar.m'}, 'comments', ...  
'Adjustment for leapyear')
```

### Check In a File and Keep It Checked Out

Check the file `/myserver/myfiles/clock.m` into the source control system and keep the file checked out:

```
checkin('/myserver/myfiles/clock.m', 'comments', ...  
'Adjustment for leapyear', 'lock', 'on')
```

## See Also

`checkout` | `cmopts` | `undocheckout` | `verctrl`

## How To

- “Check In Files (UNIX Platforms)”

**Purpose** Check files out of source control system (UNIX platforms)

**Syntax**

```
checkout('filename')
checkout({'filename1','filename2', ...})
checkout('filename','option','value',...)
```

**Description** `checkout('filename')` checks out the file named `filename` from the source control system. Use the full path for `filename` and include the file extension. The file can be open or closed when you use `checkout`.

`checkout({'filename1','filename2', ...})` checks out the files named `filename1` through `filename2` from the source control system. Use the full paths for the files and include the file extensions.

`checkout('filename','option','value',...)` provides additional `checkout` options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1','filename2', ...}`. Options apply to all file names. The *option* and *value* arguments are shown in the following table.

option Argument	value Argument	Purpose
'force'	'on'	The checkout is forced, even if you already have the file checked out. This is effectively an <code>undocheckout</code> followed by a <code>checkout</code> .
'force'	'off' (default)	Prevents you from checking out the file if you already have it checked out.

# checkout

---

option Argument	value Argument	Purpose
'lock'	'on' (default)	The checkout gets the file, allows you to write to it, and locks the file so that access to the file for others is read only.
'lock'	'off'	The checkout gets a read-only version of the file, allowing another user to check out the file for updating. You do not have to check the file in after checking it out with this option.
'revision'	'version_num'	Checks out the specified revision of the file.

If you end the MATLAB session, the file remains checked out. You can check in the file from within the MATLAB desktop during a later session, or directly from your source control system.

## Examples

### Check Out a File

Check out the file `/myserver/myfiles/clock.m` from the source control system:

```
checkout('/myserver/myfiles/clock.m')
```

### Check Out Multiple Files

Check out `/matlab/myfiles/clock.m` and `/matlab/myfiles/calendar.m` from the source control system:

```
checkout({'/myserver/myfiles/clock.m', ...
```

```
'/myserver/myfiles/calendar.m'})
```

## **Force a Checkout, Even If File Is Already Checked Out**

Check out `/matlab/myfiles/clock.m` even if `clock.m` is already checked out to you:

```
checkout('/myserver/myfiles/clock.m', 'force', 'on')
```

## **Check Out Specified Revision of File**

Check out revision 1.1 of `clock.m`:

```
checkout('/matlab/myfiles/clock.m', 'revision', '1.1')
```

## **See Also**

`checkin` | `cmopts` | `undocheckout` | `customverctrl` | `verctrl`

## **How To**

- “Check Out Files (UNIX Platforms)”

**Purpose** Cholesky factorization

**Syntax**

```
R = chol(A)
L = chol(A, 'lower')
R = chol(A, 'upper')
[R,p] = chol(A)
[L,p] = chol(A, 'lower')
[R,p] = chol(A, 'upper')
[R,p,S] = chol(A)
[R,p,s] = chol(A, 'vector')
[L,p,s] = chol(A, 'lower', 'vector')
[R,p,s] = chol(A, 'upper', 'vector')
```

**Description**  $R = \text{chol}(A)$  produces an upper triangular matrix  $R$  from the diagonal and upper triangle of matrix  $A$ , satisfying the equation  $R' * R = A$ . The `chol` function assumes that  $A$  is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the upper triangle as the lower triangle. Matrix  $A$  must be positive definite.

$L = \text{chol}(A, 'lower')$  produces a lower triangular matrix  $L$  from the diagonal and lower triangle of matrix  $A$ , satisfying the equation  $L * L' = A$ . The `chol` function assumes that  $A$  is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the lower triangle as the upper triangle. When  $A$  is sparse, this syntax of `chol` is typically faster. Matrix  $A$  must be positive definite.  $R = \text{chol}(A, 'upper')$  is the same as  $R = \text{chol}(A)$ .

$[R,p] = \text{chol}(A)$  for positive definite  $A$ , produces an upper triangular matrix  $R$  from the diagonal and upper triangle of matrix  $A$ , satisfying the equation  $R' * R = A$  and  $p$  is zero. If  $A$  is not positive definite, then  $p$  is a positive integer and MATLAB does not generate an error. When  $A$  is full,  $R$  is an upper triangular matrix of order  $q = p - 1$  such that  $R' * R = A(1:q, 1:q)$ . When  $A$  is sparse,  $R$  is an upper triangular matrix of size  $q$ -by- $n$  so that the L-shaped region of the first  $q$  rows and first  $q$  columns of  $R' * R$  agree with those of  $A$ .

$[L,p] = \text{chol}(A, 'lower')$  for positive definite  $A$ , produces a lower triangular matrix  $L$  from the diagonal and lower triangle of matrix  $A$ ,

satisfying the equation  $L*L' = A$  and  $p$  is zero. If  $A$  is not positive definite, then  $p$  is a positive integer and MATLAB does not generate an error. When  $A$  is full,  $L$  is a lower triangular matrix of order  $q = p - 1$  such that  $L*L' = A(1:q, 1:q)$ . When  $A$  is sparse,  $L$  is a lower triangular matrix of size  $q$ -by- $n$  so that the L-shaped region of the first  $q$  rows and first  $q$  columns of  $L*L'$  agree with those of  $A$ .  $[R, p] = chol(A, 'upper')$  is the same as  $[R, p] = chol(A)$ .

The following three-output syntaxes require sparse input  $A$ .

$[R, p, S] = chol(A)$ , when  $A$  is sparse, returns a permutation matrix  $S$ . Note that the reordering  $S$  may differ from that obtained from `amd` since `chol` will slightly change the ordering for increased performance. When  $p=0$ ,  $R$  is an upper triangular matrix such that  $R'*R = S'*A*S$ . When  $p$  is not zero,  $R$  is an upper triangular matrix of size  $q$ -by- $n$  so that the L-shaped region of the first  $q$  rows and first  $q$  columns of  $R'*R$  agree with those of  $S'*A*S$ . The factor of  $S'*A*S$  tends to be sparser than the factor of  $A$ .

$[R, p, s] = chol(A, 'vector')$ , when  $A$  is sparse, returns the permutation information as a vector  $s$  such that  $A(s, s) = R'*R$ , when  $p=0$ . You can use the 'matrix' option in place of 'vector' to obtain the default behavior.

$[L, p, s] = chol(A, 'lower', 'vector')$ , when  $A$  is sparse, uses only the diagonal and the lower triangle of  $A$  and returns a lower triangular matrix  $L$  and a permutation vector  $s$  such that  $A(s, s) = L*L'$ , when  $p=0$ . As above, you can use the 'matrix' option in place of 'vector' to obtain a permutation matrix.  $[R, p, s] = chol(A, 'upper', 'vector')$  is the same as  $[R, p, s] = chol(A, 'vector')$ .

---

**Note** Using `chol` is preferable to using `eig` for determining positive definiteness.

---

## Examples

### Example 1

The gallery function provides several symmetric, positive, definite matrices.

```
A=gallery('moler',5)
```

```
A =
```

```
    1   -1   -1   -1   -1
   -1    2    0    0    0
   -1    0    3    1    1
   -1    0    1    4    2
   -1    0    1    2    5
```

```
C=chol(A)
```

```
ans =
```

```
    1   -1   -1   -1   -1
    0    1   -1   -1   -1
    0    0    1   -1   -1
    0    0    0    1   -1
    0    0    0    0    1
```

```
isequal(C'*C,A)
```

```
ans =
```

```
    1
```

For sparse input matrices, chol returns the Cholesky factor.

```
N = 100;
A = gallery('poisson', N);
```

N represents the number of grid points in one direction of a square N-by-N grid. Therefore, A is  $N^2$  by  $N^2$ .

```
L = chol(A, 'lower');
D = norm(A - L*L', 'fro');
```

The value of D will vary somewhat among different versions of MATLAB but will be on order of  $10^{-14}$ .

## Example 2

The binomial coefficients arranged in a symmetric array create a positive definite matrix.

```
n = 5;
X = pascal(n)
X =
    1    1    1    1    1
    1    2    3    4    5
    1    3    6   10   15
    1    4   10   20   35
    1    5   15   35   70
```

This matrix is interesting because its Cholesky factor consists of the same coefficients, arranged in an upper triangular matrix.

```
R = chol(X)
R =
    1    1    1    1    1
    0    1    2    3    4
    0    0    1    3    6
    0    0    0    1    4
    0    0    0    0    1
```

Destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element.

```
X(n,n) = X(n,n) - 1
X =
    1    1    1    1    1
    1    2    3    4    5
```

# chol

---

```
1   3   6  10  15
1   4  10  20  35
1   5  15  35  69
```

Now an attempt to find the Cholesky factorization of X fails.

```
chol(X)
Error using chol
Matrix must be positive definite.
```

## See Also

[cholinc](#) | [cholupdate](#)

**Purpose** Sparse incomplete Cholesky and Cholesky-Infinity factorizations

---

**Note** cholinc has been removed.

- You can replace most instances of cholinc with ichol. Note that cholinc returned upper triangular factors, while ichol returns lower triangular factors by default.
  - Remove any instances that use the syntax cholinc(X, 'inf'). There is no replacement for this syntax.
- 

**Syntax**

```
R = cholinc(X,droptol)
R = cholinc(X,options)
R = cholinc(X,'0')
[R,p] = cholinc(X,'0')
R = cholinc(X,'inf')
```

**Description** cholinc produces two different kinds of incomplete Cholesky factorizations: the drop tolerance and the 0 level of fill-in factorizations. These factors may be useful as preconditioners for a symmetric positive definite system of linear equations being solved by an iterative method such as pcg (Preconditioned Conjugate Gradients). cholinc works only for sparse matrices.

`R = cholinc(X,droptol)` performs the incomplete Cholesky factorization of `X`, with drop tolerance `droptol`.

`R = cholinc(X,options)` allows additional options to the incomplete Cholesky factorization. `options` is a structure with up to three fields:

<code>droptol</code>	Drop tolerance of the incomplete factorization
<code>michol</code>	Modified incomplete Cholesky
<code>rdiag</code>	Replace zeros on the diagonal of <code>R</code>

Only the fields of interest need to be set.

`droptol` is a non-negative scalar used as the drop tolerance for the incomplete Cholesky factorization. This factorization is computed by performing the incomplete LU factorization with the pivot threshold option set to 0 (which forces diagonal pivoting) and then scaling the rows of the incomplete upper triangular factor,  $U$ , by the square root of the diagonal entries in that column. Since the nonzero entries  $U(i, j)$  are bounded below by  $\text{droptol} \cdot \text{norm}(X(:, j))$  (see `luinc`), the nonzero entries  $R(i, j)$  are bounded below by the local drop tolerance  $\text{droptol} \cdot \text{norm}(X(:, j)) / R(i, i)$ .

Setting `droptol = 0` produces the complete Cholesky factorization, which is the default.

`michol` stands for modified incomplete Cholesky factorization. Its value is either 0 (unmodified, the default) or 1 (modified). This performs the modified incomplete LU factorization of  $X$  and scales the returned upper triangular factor as described above.

`rdiag` is either 0 or 1. If it is 1, any zero diagonal entries of the upper triangular factor  $R$  are replaced by the square root of the local drop tolerance in an attempt to avoid a singular factor. The default is 0.

`R = cholinc(X, '0')` produces the incomplete Cholesky factor of a real sparse matrix that is symmetric and positive definite using no fill-in. The upper triangular  $R$  has the same sparsity pattern as `triu(X)`, although  $R$  may be zero in some positions where  $X$  is nonzero due to cancellation. The lower triangle of  $X$  is assumed to be the transpose of the upper. Note that the positive definiteness of  $X$  does not guarantee the existence of a factor with the required sparsity. An error message results if the factorization is not possible. If the factorization is successful,  $R' * R$  agrees with  $X$  over its sparsity pattern.

`[R, p] = cholinc(X, '0')` with two output arguments, never produces an error message. If  $R$  exists,  $p$  is 0. If  $R$  does not exist, then  $p$  is a positive integer and  $R$  is an upper triangular matrix of size  $q$ -by- $n$  where  $q = p - 1$ . In this latter case, the sparsity pattern of  $R$  is that of the  $q$ -by- $n$  upper triangle of  $X$ .  $R' * R$  agrees with  $X$  over the sparsity pattern of its first  $q$  rows and first  $q$  columns.

`R = cholinc(X, 'inf')` produces the Cholesky-Infinity factorization. This factorization is based on the Cholesky factorization, and additionally handles real positive semi-definite matrices. It may be useful for finding a solution to systems which arise in interior-point methods. When a zero pivot is encountered in the ordinary Cholesky factorization, the diagonal of the Cholesky-Infinity factor is set to `Inf` and the rest of that row is set to `0`. This forces a `0` in the corresponding entry of the solution vector in the associated system of linear equations. In practice, `X` is assumed to be positive semi-definite so even negative pivots are replaced with a value of `Inf`.

## Tips

The incomplete factorizations may be useful as preconditioners for solving large sparse systems of linear equations. A single `0` on the diagonal of the upper triangular factor makes it singular. The incomplete factorization with a drop tolerance prints a warning message if the upper triangular factor has zeros on the diagonal. Similarly, using the `rdiag` option to replace a zero diagonal only gets rid of the symptoms of the problem, but it does not solve it. The preconditioner may not be singular, but it probably is not useful, and a warning message is printed.

The Cholesky-Infinity factorization is meant to be used within interior-point methods. Otherwise, its use is not recommended.

## Examples

### Example 1

Start with a symmetric positive definite matrix, `S`.

```
S = delsq(numgrid('C',15));
```

`S` is the two-dimensional, five-point discrete negative Lapacian on the grid generated by `numgrid('C',15)`.

Compute the Cholesky factorization and the incomplete Cholesky factorization of level 0 to compare the fill-in. Make `S` singular by zeroing out a diagonal entry and compute the (partial) incomplete Cholesky factorization of level 0.

```
C = chol(S);  
R0 = cholinc(S,'0');
```

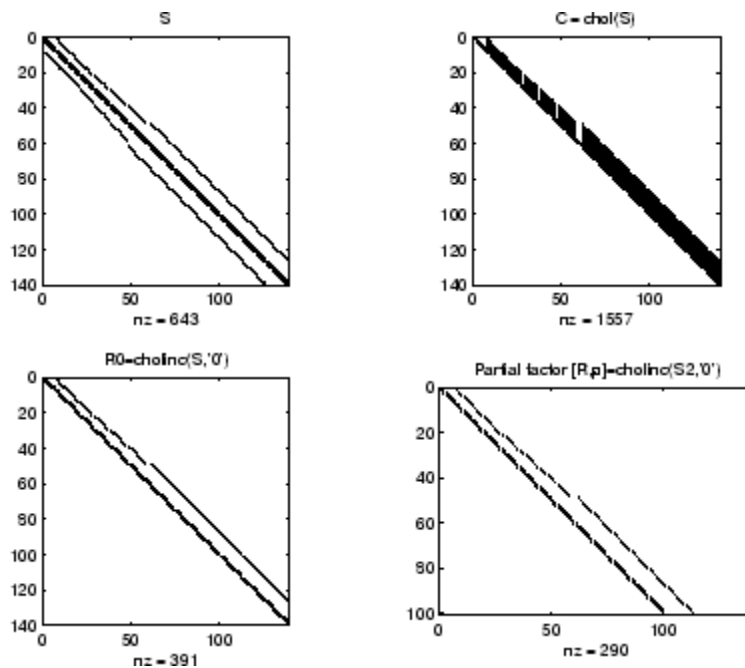

# cholinc

```
S2 = S; S2(101,101) = 0;  
[R,p] = cholinc(S2,'0');
```

Fill-in occurs within the bands of S in the complete Cholesky factor, but none in the incomplete Cholesky factor. The incomplete factorization of the singular S2 stopped at row  $p = 101$  resulting in a 100-by-139 partial factor.

```
D1 = (R0' * R0) .* spones(S) - S;  
D2 = (R' * R) .* spones(S2) - S2;
```

D1 has elements of the order of `eps`, showing that  $R0' * R0$  agrees with S over its sparsity pattern. D2 has elements of the order of `eps` over its first 100 rows and first 100 columns,  $D2(1:100, :)$  and  $D2(:, 1:100)$ .

## Example 2

The first subplot below shows that `cholinc(S,0)`, the incomplete Cholesky factor with a drop tolerance of 0, is the same as the Cholesky factor of  $S$ . Increasing the drop tolerance increases the sparsity of the incomplete factors, as seen below.

Unfortunately, the sparser factors are poor approximations, as is seen by the plot of drop tolerance versus  $\text{norm}(R' * R - S, 1) / \text{norm}(S, 1)$  in the next figure.

### Example 3

The Hilbert matrices have (i,j) entries  $1/(i+j-1)$  and are theoretically positive definite:

```
H3 = hilb(3)
H3 =
    1.0000    0.5000    0.3333
    0.5000    0.3333    0.2500
    0.3333    0.2500    0.2000
R3 = chol(H3)
R3 =
    1.0000    0.5000    0.3333
         0    0.2887    0.2887
         0         0    0.0745
```

In practice, the Cholesky factorization breaks down for larger matrices:

```
H20 = sparse(hilb(20));
```

```
[R,p] = chol(H20);
p =
    14
```

For `hilb(20)`, the Cholesky factorization failed in the computation of row 14 because of a numerically zero pivot. You can use the Cholesky-Infinity factorization to avoid this error. When a zero pivot is encountered, `cholinc` places an `Inf` on the main diagonal, zeros out the rest of the row, and continues with the computation:

```
Rinf = cholinc(H20,'inf');
```

In this case, all subsequent pivots are also too small, so the remainder of the upper triangular factor is:

```
full(Rinf(14:end,14:end))
ans =
    Inf     0     0     0     0     0     0
     0    Inf     0     0     0     0     0
     0     0    Inf     0     0     0     0
     0     0     0    Inf     0     0     0
     0     0     0     0    Inf     0     0
     0     0     0     0     0    Inf     0
     0     0     0     0     0     0    Inf
```

## Limitations

`cholinc` works on square sparse matrices only. For `cholinc(X,'0')` and `cholinc(X,'inf')`, `X` must be real.

## Algorithms

`R = cholinc(X,droptol)` is obtained from `[L,U] = luinc(X,options)`, where `options.droptol = droptol` and `options.thresh = 0`. The rows of the uppertriangular `U` are scaled by the square root of the diagonal in that row, and this scaled factor becomes `R`.

`R = cholinc(X,options)` is produced in a similar manner, except the `rdiag` option translates into the `udiag` option and the `milu` option takes the value of the `michol` option.

# cholinc

---

`R = cholinc(X, '0')` is based on the “KJI” variant of the Cholesky factorization. Updates are made only to positions which are nonzero in the upper triangle of  $X$ .

`R = cholinc(X, 'inf')` is based on the algorithm in Zhang [2].

**Purpose** Rank 1 update to Cholesky factorization

**Syntax**

```
R1 = cholupdate(R,x)
R1 = cholupdate(R,x,'+')
R1 = cholupdate(R,x,'-')
[R1,p] = cholupdate(R,x,'-')
```

**Description**

`R1 = cholupdate(R,x)` where  $R = \text{chol}(A)$  is the original Cholesky factorization of  $A$ , returns the upper triangular Cholesky factor of  $A + x*x'$ , where  $x$  is a column vector of appropriate length. `cholupdate` uses only the diagonal and upper triangle of  $R$ . The lower triangle of  $R$  is ignored.

`R1 = cholupdate(R,x,'+')` is the same as `R1 = cholupdate(R,x)`.

`R1 = cholupdate(R,x,'-')` returns the Cholesky factor of  $A - x*x'$ . An error message reports when  $R$  is not a valid Cholesky factor or when the downdated matrix is not positive definite and so does not have a Cholesky factorization.

`[R1,p] = cholupdate(R,x,'-')` will not return an error message. If  $p$  is 0,  $R1$  is the Cholesky factor of  $A - x*x'$ . If  $p$  is greater than 0,  $R1$  is the Cholesky factor of the original  $A$ . If  $p$  is 1, `cholupdate` failed because the downdated matrix is not positive definite. If  $p$  is 2, `cholupdate` failed because the upper triangle of  $R$  was not a valid Cholesky factor.

**Tips** `cholupdate` works only for full matrices.

**Examples**

```
A = pascal(4)
A =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    20

R = chol(A)
R =
```

# cholupdate

---

```
      1      1      1      1
      0      1      2      3
      0      0      1      3
      0      0      0      1
x = [0 0 0 1]';
```

This is called a rank one update to A since  $\text{rank}(x*x')$  is 1:

```
A + x*x'
ans =
```

```
      1      1      1      1
      1      2      3      4
      1      3      6     10
      1      4     10     21
```

Instead of computing the Cholesky factor with  $R1 = \text{chol}(A + x*x')$ , we can use cholupdate:

```
R1 = cholupdate(R,x)
R1 =
```

```
  1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    1.4142
```

Next destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element of A. The downdated matrix is:

```
A - x*x'
ans =
```

```
      1      1      1      1
      1      2      3      4
```

```

1     3     6    10
1     4    10    19

```

Compare chol with cholupdate:

```

R1 = chol(A-x*x')
Error using chol
Matrix must be positive definite.
R1 = cholupdate(R,x,'-')
Error using cholupdate
Downdated matrix must be positive definite.

```

However, subtracting 0.5 from the last element of A produces a positive definite matrix, and we can use cholupdate to compute its Cholesky factor:

```

x = [0 0 0 1/sqrt(2)]';
R1 = cholupdate(R,x,'-')
R1 =
    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    0.7071

```

## Algorithms

cholupdate uses the algorithms from the LINPACK subroutines ZCHUD and ZCHDD. cholupdate is useful since computing the new Cholesky factor from scratch is an  $O(N^3)$  algorithm, while simply updating the existing factor in this way is an  $O(N^2)$  algorithm.

# circshift

---

**Purpose** Shift array circularly

**Syntax** `B = circshift(A,shiftsize)`

**Description** `B = circshift(A,shiftsize)` circularly shifts the values in the array, `A`, by `shiftsize` elements. `shiftsize` is a vector of integer scalars where the `n`-th element specifies the shift amount for the `n`-th dimension of array `A`. If an element in `shiftsize` is positive, the values of `A` are shifted down (or to the right). If it is negative, the values of `A` are shifted up (or to the left). If it is 0, the values in that dimension are not shifted.

**Examples** Circularly shift first dimension values down by 1.

```
A = [ 1 2 3;4 5 6; 7 8 9]
```

```
A =  
    1     2     3  
    4     5     6  
    7     8     9
```

```
B = circshift(A,1)
```

```
B =  
    7     8     9  
    1     2     3  
    4     5     6
```

Circularly shift first dimension values down by 1 and second dimension values to the left by 1.

```
B = circshift(A,[1 -1]);
```

```
B =  
    8     9     7  
    2     3     1  
    5     6     4
```

**See Also** `fftshift` | `shiftdim` | `permute` | `reshape`

**Purpose** (Will be removed) Circumcenters of specified simplices

---

**Note** `circumcenters(TriRep)` will be removed in a future release. Use `circumcenter(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax**  
`CC = circumcenters(TR, SI)`  
`[CC RCC] = circumcenters(TR, SI)`

**Description**  
`CC = circumcenters(TR, SI)` returns the coordinates of the circumcenter of each specified simplex `SI`. `CC` is an `m`-by-`n` matrix, where `m` is of length `length(SI)`, the number of specified simplices, and `n` is the dimension of the space where the triangulation resides.  
`[CC RCC] = circumcenters(TR, SI)` returns the circumcenters and the corresponding radii of the circumscribed circles or spheres.

**Input Arguments**

TR	Triangulation object.
SI	Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If <code>SI</code> is not specified the circumcenter information for the entire triangulation is returned, where the circumcenter associated with simplex <code>i</code> is the <code>i</code> 'th row of <code>CC</code> .

# TriRep.circumcenters

---

## Output Arguments

**CC** m-by-n matrix. *m* is the number of specified simplices and *n* is the dimension of the space where the triangulation resides. Each row `CC(i,:)` represents the coordinates of the circumcenter of simplex `SI(i)`.

**RCC** Vector of length `length(SI)`, the number of specified simplices containing radii of the circumscribed circles or spheres.

## Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## Examples

### Example 1

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y)
```

Compute the circumcenters.

```
cc = circumcenters(trep);
triplot(trep);
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
```

The circumcenters represent points on the medial axis of the polygon.

### Example 2

Query a 3-D triangulation created with `DelaunayTri`. Compute the circumcenters of the first five tetrahedra.

```
X = rand(10,3);  
dt = DelaunayTri(X);  
cc = circumcenters(dt, [1:5]')
```

`incenter` | `deLaunayTriangulation` | `triangulation`

# cla

---

<b>Purpose</b>	Clear current axes
<b>Syntax</b>	<pre>cla cla reset cla(ax) cla(ax, 'reset')</pre>
<b>Description</b>	<p>cla deletes from the current axes all graphics objects whose handles are not hidden (i.e., their <code>HandleVisibility</code> property is set to <code>on</code>).</p> <p>cla reset deletes from the current axes all graphics objects regardless of the setting of their <code>HandleVisibility</code> property and resets all axes properties, except <code>Position</code> and <code>Units</code>, to their default values.</p> <p>cla(ax) or cla(ax, 'reset') clears the single axes with handle ax.</p>
<b>Tips</b>	<p>The cla command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the <code>HandleVisibility</code> setting of callback. This means that when issued from within a callback routine, cla deletes only those objects whose <code>HandleVisibility</code> property is set to <code>on</code>.</p>
<b>Alternatives</b>	<p>Remove axes and clear objects from them in <i>plot edit</i> mode. For details, see “Working in Plot Edit Mode”.</p>
<b>See Also</b>	<pre>clf   hold   newplot   reset</pre>

**Purpose** Contour plot elevation labels

**Syntax**

```

clabel(C)
clabel(C,h)
clabel(C,v)
clabel(C,h,v)
clabel( __ ,Name,Value)

clabel(C,'manual')
clabel(C,h,'manual')

text_handles = clabel( __ )

```

**Description** `clabel(C)` labels all contours displayed in the current contour plot. Labels are upright and displayed with '+' symbols. `clabel` randomly selects label positions.

`clabel(C,h)` rotates the labels and inserts them in the contour lines. This syntax inserts only those labels that fit within the contour, depending on the size of the contour.

`clabel(C,v)` labels only the contour levels specified by the vector, `v`.

`clabel(C,h,v)` labels only the contour levels specified by vector `v`, rotates the labels, and inserts them in the contour lines.

`clabel( __ ,Name,Value)` specifies the text object properties and the 'LabelSpacing' contourgroup property, using one or more `Name,Value` pair arguments, in addition to any of the input arguments in previous syntaxes.

`clabel(C,'manual')` places contour labels at locations you select with a mouse. Click the mouse or press the space bar to label the contour

# clabel

---

closest to the center of the crosshair. Press the **Return** key while the cursor is within the figure window to terminate labeling.

`clabel(C,h,'manual')` places contour labels at locations you select with a mouse. Press the **Return** key while the cursor is within the figure window to terminate labeling. The labels are rotated and inserted in the contour lines.

`text_handles = clabel( __ )` additionally returns an array containing the handles of the text objects created, using any of the input arguments in the previous syntaxes. If you call `clabel` without the `h` argument, `text_handles` also contains the handles of line objects used to create the '+' symbols.

## Input Arguments

### **C - Contour matrix**

2-by-n matrix

Contour matrix containing the data that defines the contour lines. `C` is returned by the `contour`, `contour3`, or `contourf` function.

### **h - Handle to the `contourgroup` object**

value returned by `contour` functions

Handle to the `contourgroup` object specified as the value returned by the `contour`, `contour3`, or `contourf` function.

### **v - Contour level values**

vector

Contour level values, specified as a row or column vector of individual values.

**Example:** `[0,10,20]`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can

specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Color','red','Rotation',45` adds red labels to a contour plot, where each label is rotated 45 degrees.

In addition to the following, you can specify other text object properties using `Name,Value` pair arguments. See [Text Properties](#).

### 'Color' - Text color

`[0 0 0]` (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
<code>[1 1 0]</code>	y	yellow
<code>[1 0 1]</code>	m	magenta
<code>[0 1 1]</code>	c	cyan
<code>[1 0 0]</code>	r	red
<code>[0 1 0]</code>	g	green
<code>[0 0 1]</code>	b	blue
<code>[1 1 1]</code>	w	white
<code>[0 0 0]</code>	k	black

**Example:** `'Color',[0 1 0]`

**Example:** `'Color','green'`

### 'FontName' - Font name

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName', 'Courier'

### **'FontSize' - Font size**

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize', 12.5

### **'FontUnits' - Font size units**

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize

accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $\frac{1}{72}$  inch

---

**Note** When setting both the `FontSize` and the `FontUnits`, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`. For example, to set the font size to 0.3 inches, call `'FontUnits', 'inches', 'FontSize', 0.3` in the argument list.

---

### **'FontWeight' - Weight of text characters**

`'normal'` (default) | `'bold'` | `'light'` | `'demi'`

Weight of text characters, specified as the comma-separated pair consisting of `'FontWeight'` and one of the following strings:

- `'normal'`
- `'bold'`
- `'light'`
- `'demi'`

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to `'bold'` or `'demi'` causes MATLAB to use a bold font.

**Example:** `'FontWeight', 'bold'`

### **'LabelSpacing' - Spacing between labels**

144 (default) | scalar

Spacing between labels on each contour line, specified as the comma-separated pair consisting of `'LabelSpacing'` and a scalar. Specify the label spacing in points, where 1 point =  $\frac{1}{72}$  inch.

**Example:** `'LabelSpacing', 72`

### **'Rotation' - Text orientation**

0 (default) | scalar

# clabel

---

Text orientation, specified as the comma-separated pair consisting of 'Rotation' and a scalar. Specify values of rotation in degrees. Positive values result in counterclockwise rotation.

**Example:** 'Rotation',45

## Output Arguments

### **text\_handles - Handles of text objects**

handle

Handles of the text objects that `clabel` creates. The `UserData` properties of the text objects contain the contour values displayed.

If you call `clabel` without the `h` argument, `text_handles` also contains the handles of line objects used to create the '+' symbols.

## Examples

### **Label Contour Plot with Vertical Text and '+' Symbols**

Generate a contour plot and obtain the contour matrix, `C`.

```
[x,y,z] = peaks;  
figure  
C = contour(x,y,z);
```

Label the contour plot.

```
clabel(C)
```

### Label Contour Plot with Rotated Text Inserted in Contour Lines

Generate a contour plot and obtain the contour matrix, C, and the handle to the contourgroup object, h.

```
[x,y,z] = peaks;  
figure  
[C,h] = contour(x,y,z);
```

# clabel

Label the contour plot.

```
clabel(C,h);
```

## Label Specific Contour Levels

Label only the contours with contour levels 2 or 6.

```
[x,y,z] = peaks;  
figure  
[C,h] = contour(x,y,z);
```

```
v = [2,6];
clabel(C,h,v)
```

### Set Label Spacing

Set the label spacing to 72 points (1 inch).

```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
clabel(C,h,'LabelSpacing',72)
```

## Label Contour Plot and Set Text Properties

Use Name, Value arguments to set the font size, font color, and text orientation of the labels.

```
[x,y,z] = peaks;  
figure  
[C,h] = contour(x,y,z);  
clabel(C,h,'FontSize',15,'Color','r','Rotation',0)
```

'FontSize',15,'Color','r' adds 15-point red labels to the contour plot. 'Rotation',0 makes the text upright.

### Label Contour Plot and Return Object Handles

Label a contour plot and return the handles of the objects created.

```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
text_handles = clabel(C,h);
```

# clabel

---

MATLAB returns an array containing the handles of the text objects created.

Set the color of the labels to blue, using the handle to the text objects.

```
set(text_handles, 'Color', 'blue')
```

## Related Examples

- “Drawing Text in a Box”

## Concepts

[Text Properties](#)

**Purpose**

Determine class of object

**Syntax**

```
ClassName = class(object)
obj = class(s, 'class_name')
obj = class(s, 'class_name', parent1, parent2, ...)
obj = class(struct([]), 'class_name', parent1, parent2, ...)
obj_struct = class(struct_array, 'class_name', parent_array)
```

**Description**

*ClassName* = `class(object)` returns a string specifying the class of object. See “Fundamental MATLAB Classes” for more information on MATLAB classes.

---

**Note** Before MATLAB 7.6 (classes defined without a `classdef` statement), class constructors called the `class` function to create the object. The following `class` function syntaxes apply only within classes defined before Version 7.6.

---

`obj = class(s, 'class_name')` creates an array of class *class\_name* objects using the struct *s* as a pattern to determine the size of *obj*.

`obj = class(s, 'class_name', parent1, parent2, ...)` inherits the methods and fields of the parent objects *parent1*, *parent2*, and so on. The size of the parent objects must match the size of *s* or be a scalar (1-by-1), in which case, MATLAB performs scalar expansion.

`obj = class(struct([]), 'class_name', parent1, parent2, ...)` constructs object containing only fields that it inherits from the parent objects. All parents must have the same, nonzero size, which determines the size of the returned object *obj*.

`obj_struct = class(struct_array, 'class_name', parent_array)` maps every element of the *parent\_array* to a corresponding element in the *struct\_array* to produce the output array of objects, *obj\_struct*.

All arrays must be of the same size. If either the *struct\_array* or the *parent\_array* is of size 1-by-1, then MATLAB performs scalar expansion to match the array sizes.

# class

---

To create an object array of size 0-by-0, set the size of the `struct_array` and `parent_array` to 0-by-0.

## Examples

Return the class of Java object `obj`:

```
import java.lang.*;
obj = String('mystring');
class(obj)
```

```
ans =
```

```
java.lang.String
```

Return class of any MATLAB variable:

```
h = @sin;
class(h)
```

```
ans =
```

```
function_handle
```

- “Class Syntax Fundamentals”

**Purpose** Class definition keywords

**Syntax**

```
classdef classname
    properties
        PropName
    end
    methods
        methodName
    end
    events
        EventName
    end
    enumeration
        EnumName (arg)
    end
end
```

**Description** `classdef classname` begins the class definition and an `end` keyword terminates the `classdef` block. Only blank lines and comments can precede `classdef`. Enter a class definition in a file having the same name as the class, with a filename extension of `.m`. Class definition files can be in folders on the MATLAB path or in `@` folders whose parent folder is on the MATLAB path. See “Class Files” for more information. See “Classdef Block” and “Class Definition” for more information on classes.

`properties` begins a property definition block, an `end` keyword terminates the `properties` block. Class definitions can contain multiple property definition blocks, each specifying different attribute settings that apply to the properties in that particular block. See “Defining Properties” for more information.

`methods` begins a methods definition block, an `end` keyword terminates the `methods` block. This block contains functions that implement class methods. Class definitions can contain multiple method blocks, each specifying different attribute settings that apply to the methods in that particular block. It is possible to define method functions in separate files. See “How to Use Methods” for more information.

# classdef

---

`events` begins an events definition block, an `end` keyword terminates the `events` block. This block contains event names defined by the class. Class definitions can contain multiple event blocks, each specifying different attribute settings that apply to the events in that particular block. See “Events and Listeners — Syntax and Techniques” for more information.

`enumeration` begins an enumeration definition block, an `end` keyword terminates the enumeration block. See “Enumerations” for more information.

`properties`, `methods`, `events`, and `enumeration` are also the names of MATLAB functions used to query the respective class members for a given object or class name.

To see the attributes of all class components in a popup window, click this link: [Attribute Tables](#)

## Examples

Use these keywords to define classes.

```
classdef (Attributes) class_name
    properties (Attributes)
        PropertyName
    end
    methods (Attributes)
        function obj = methodName(obj, arg2, ...)
            ...
        end
    end
    events (Attributes)
        EventName
    end
    enumeration
        EnumName
    end
end
```

# clc

---

**Purpose** Clear Command Window

**Syntax** `clc`

**Description** `clc` clears all input and output from the Command Window display, giving you a “clean screen.”

After using `clc`, you cannot use the scroll bar to see the history of functions, but you still can use the up arrow key, ↑, to recall statements from the command history.

**Examples** Use `clc` in a MATLAB code file to always display output in the same starting position on the screen.

**See Also** `clear` | `clf` | `close` | `home`

---

<b>Purpose</b>	Remove items from workspace, freeing up system memory
<b>Syntax</b>	<pre>clear clear name1 ... nameN clear -regexp expr1 ... exprN clear ItemType</pre>

# clear

display method for polynom objects, leaving any other implementations in memory.

## **expr1 ... exprN - Regular expressions matching names of variables to clear**

string

Regular expressions matching names of variables to clear, specified as strings.

## **ItemType - Type of items to clear**

all | classes | functions | global | import | java | mex | variables

Type of items to clear, specified as one of the following strings. Click the linked strings below for additional information.

Value of ItemType	Items Cleared								
	Variables in scope	Scripts and functions	Class definitions	Persistent variables	Debug breakpoints	MEX files	Global variables	Imports	Java classes on the dynamic path
all	✓	✓		✓	✓	✓	✓	From command prompt only	
classes	✓	✓	✓	✓	✓	✓	✓		
functions		✓		✓	✓	✓			
global							✓		
import								✓	
java	✓	✓		✓	✓	✓	✓		✓

Value of ItemType	Items Cleared							
	Variables in scope	Scripts and function definitions	Class definitions	Persistent variables	Debug breakpoints	MEX Global variables	Imports	Java classes on the dynamic path
mex						✓		
variables								

The following applies to clearing types of items.

**all:**

- `clear all` also removes the import list when issued from the command prompt.

**classes:**

- `clear classes` issues a warning and does not clear a class of objects if any of those objects still exists after the workspace is cleared. For example, objects can still exist in persistent variables of functions or figure windows.
- `clear classes` does not clear a class if its file is locked using the `mlock` command. No warning is issued in this case.
- Call `clear classes` whenever you change a class definition.

**global:**

- `clear global` removes all global variables in the base and global workspaces. If called from a function, `clear global` also removes all global variables in the function workspace.
- Use `clear global name1 ... nameN` to clear the global variables with the specified names.
- Use `clear global regexp expr1 ... exprN` to clear all global variables that match any of the regular expressions listed.

## **import:**

- Call `clear import` only from the command prompt. Calling `clear import` in a function returns an error.

## **java:**

- `clear java` issues a warning and does not remove the Java class definition if any Java objects exist outside the workspace (for example, in user data or persistent variables in a locked code file).
- Issue a `clear java` command after modifying any files on the dynamic Java path.

## **mex:**

- `clear mex` does not clear locked MEX functions or functions that are currently in use.

If the name of a variable is a value of `ItemType`, then calling `clear` followed by that name deletes the variable with that name. `clear` does not interpret the name as a keyword in this context. For example, if the workspace contains variables `a`, `all`, `b`, and `ball`, `clear all` removes the variable `all` only.

## **Tips**

- The `clear` function can remove variables that you specify. To remove all but some specified variables, use `clearvars` instead.
- You can clear the handle of a figure or graphics object, but the object itself is not removed. Use `delete` to remove objects. Deleting an object does not delete the variable (if any) used for storing its handle.
- The `clear` function does not clear Simulink® models. Use `bdclose` instead.
- On UNIX systems, `clear` does not affect the amount of memory allocated to the MATLAB process.

## **Examples**

### **Clear a Single Variable**

Define two variables `a` and `b`, and then clear `a`.

```
a = 1;
b = 2;
clear a
whos
```

Name	Size	Bytes	Class	Attributes
b	1x1	8	double	

Only variable `b` remains in the workspace.

### Clear Specific Variables by Name

Using regular expressions, clear those variables with names that begin with `Mon`, `Tue`, or `Wed`.

```
clear -regexp ^Mon ^Tue ^Wed;
```

### Clear List of Variables

Create a cell array, `varlist`, that contains the names of variables to clear. Then, clear those variables.

```
varlist = {'v1', 'v2', 'time'};
clear(varlist{:})
```

### Clear All Compiled Scripts, Functions, and MEX-functions

```
clear functions
```

If a function is locked, it will not be cleared from memory.

# clearvars

---

**Purpose** Clear variables from memory

**Alternatives** As an alternative to the `clearvars` function, in the Workspace browser, select variables to clear and then press **Delete**.

**Syntax**

```
clearvars v1 v2 ...
clearvars -global
clearvars -global v1 v2 ...
clearvars -regexp p1 p2 ...
clearvars -except v1 v2 ...
clearvars -except -regexp p1 p2 ...
clearvars v1 v2 ... -except -regexp p1 p2 ...
clearvars -regexp p1 p2 ... -except v1 v2 ...
```

**Description** `clearvars v1 v2 ...` clears variables `v1`, `v2`, and so on from the currently active workspace. Each input must be an unquoted string specifying the variable to be cleared. This string may include the wildcard character (`*`) to clear all variables that match a pattern. For example, `clearvars X*` clears all the variables in the current workspace that start with the letter `X`.

If any of the variables `v1`, `v2`, and so on, are global, `clearvars` removes these variables from the current workspace only, leaving them accessible to any functions that declare them as global.

`clearvars -global` removes all global variables, including those made global within functions.

`clearvars -global v1 v2 ...` completely removes the specified global variables.

The `-global` flag may be used with any of the following syntaxes. When used in this way, it must immediately follow the function name.

`clearvars -regexp p1 p2 ...` clears all variables that match regular expression patterns `p1`, `p2`, and so on.

`clearvars -except v1 v2 ...` clears all variables except for those specified following the `-except` flag. Use the wildcard character `'*'`

in a variable name to exclude variables that match a pattern from being cleared. `clearvars -except X*` clears all the variables in the current workspace, except for those that start with `X`, for instance. Use `clearvars -except` to keep the variables you want and remove all others.

`clearvars -except -regexp p1 p2 ...` clears all variables except those that regular expression patterns `p1`, `p2`. If used in this way, the `-regexp` flag must immediately follow the `-except` flag.

`clearvars v1 v2 ... -except -regexp p1 p2 ...` can be used to specify variables to clear that do not match specified regular expression patterns.

`clearvars -regexp p1 p2 ... -except v1 v2 ...` clears variables that match `p1`, `p2`, ..., except for variables `v1`, `v2`, ...

## Examples

Clear variables starting with `a`, except for the variable `ab`:

```
clearvars a* -except ab
```

Clear all global variables except those starting with `x`:

```
clearvars -global -except x*
```

Clear variables that start with `b` and are followed by 3 digits, for the variable `b106`:

```
clearvars -regexp ^b\d{3}$ -except b106
```

Clear variables that start with `a`, except those ending with `a`:

```
clearvars a* -except -regexp a$
```

## See Also

## How To

- “What Is the MATLAB Workspace?”

# clear (serial)

---

**Purpose** Remove serial port object from MATLAB workspace

**Syntax** `clear obj`

**Description** `clear obj` removes `obj` from the MATLAB workspace, where `obj` is a serial port object or an array of serial port objects.

**Tips** If `obj` is connected to the device and it is cleared from the workspace, then `obj` remains connected to the device. You can restore `obj` to the workspace with the `instrfind` function. A serial port object connected to the device has a `Status` property value of `open`.

To disconnect `obj` from the device, use the `fclose` function. To remove `obj` from memory, use the `delete` function. You should remove invalid serial port objects from the workspace with `clear`.

**Examples** This example creates the serial port object `s` on a Windows platform, copies `s` to a new variable `scopy`, and clears `s` from the MATLAB workspace. `s` is then restored to the workspace with `instrfind` and is shown to be identical to `scopy`.

```
s = serial('COM1');
scopy = s;
clear s
s = instrfind;
isequal(scopy,s)
ans =
     1
```

**See Also** `delete` | `fclose` | `instrfind` | `isvalid` | `Status`

---

<b>Purpose</b>	Clear current figure window
<b>Syntax</b>	<pre>clf clf('reset') clf(fig) clf(fig, 'reset') figure_handle = clf(...)</pre>
<b>Description</b>	<p>clf deletes from the current figure all graphics objects whose handles are not hidden (i.e., their <code>HandleVisibility</code> property is set to on).</p> <p>clf('reset') deletes from the current figure all graphics objects regardless of the setting of their <code>HandleVisibility</code> property and resets all figure properties except <code>Position</code>, <code>Units</code>, <code>PaperPosition</code>, and <code>PaperUnits</code> to their default values.</p> <p>clf(fig) or clf(fig, 'reset') clears the single figure with handle fig.</p> <p>figure_handle = clf(...) returns the handle of the figure. This is useful when the figure <code>IntegerHandle</code> property is off because the noninteger handle becomes invalid when the reset option is used (i.e., <code>IntegerHandle</code> is reset to on, which is the default).</p>
<b>Tips</b>	The clf command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the <code>HandleVisibility</code> setting of callback. This means that when issued from within a callback routine, clf deletes only those objects whose <code>HandleVisibility</code> property is set to on.
<b>Alternatives</b>	Use <b>Clear Figure</b> from the figure window's <b>Edit</b> menu to clear the contents of a figure. You can also create a <i>desktop shortcut</i> to clear the current figure with one mouse click. See “Create Shortcuts to Rerun Commands”.
<b>See Also</b>	cla   clc   hold   reset

# clipboard

---

**Purpose** Copy and paste strings to and from system clipboard

**Syntax**

```
clipboard('copy', data)
str = clipboard('paste')
data = clipboard('pastespecial')
```

**Description** `clipboard('copy', data)` sets the clipboard contents to *data*. If *data* is not a character array, the clipboard uses `mat2str` to convert *data* to a string.

`str = clipboard('paste')` returns the current contents of the clipboard as a string or, if MATLAB cannot convert the current clipboard contents to a string, as an empty string (' ').

`data = clipboard('pastespecial')` returns the current contents of the clipboard as an array by using `uiimport`.

**Definitions** The clipboard function requires Oracle® Java software.

**See Also** `load` | `mat2str` | `uiimport`

**Purpose** Current date and time as date vector

**Syntax** `c = clock`

**Description** `c = clock` returns a six-element date vector containing the current date and time in decimal form:

```
[year month day hour minute seconds]
```

### Examples **Round clock Output to Integer Display**

Use `clock` to return the current date and time.

```
format shortg  
c = clock
```

```
c =  
      2012          3          27          13          58
```

The sixth element of the date vector output (seconds) is accurate to several digits beyond the decimal point.

Use the `fix` function to round to integer display format.

```
fix(c)
```

```
ans =  
      2012          3          27          13          58
```

### Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

### See Also

`date` | `now` | `tic` | `toc` | `cputime` | `etime` | `fix` | `timeit`

# close

---

**Purpose** Remove specified figure

**Syntax**

```
close
close(h)
close name
close all
close all hidden
close all force
status = close(...)
```

**Description** `close` deletes the current figure or the specified figure(s). It optionally returns the status of the close operation.

`close` deletes the current figure (equivalent to `close(gcf)`).

`close(h)` deletes the figure identified by `h`. If `h` is a vector or matrix, `close` deletes all figures identified by `h`.

`close name` deletes the figure with the specified name.

`close all` deletes all figures whose handles are not hidden.

`close all hidden` deletes all figures including those with hidden handles.

`close all force` deletes all figures, including GUIs for which `CloseRequestFcn` has been altered to not close the window.

`status = close(...)` returns 1 if the specified windows have been deleted and 0 otherwise.

**Algorithms** The `close` function works by evaluating the specified figure's `CloseRequestFcn` property with the statement

```
eval(get(h, 'CloseRequestFcn'))
```

The default `CloseRequestFcn`, `closereq`, deletes the current figure using `delete(get(0, 'CurrentFigure'))`. If you specify multiple figure handles, `close` executes each figure's `CloseRequestFcn` in turn. If an error that terminates the execution of a `CloseRequestFcn` occurs, the

figure is not deleted. Note that using your computer's window manager (i.e., the **Close** menu item) also calls the figure's `CloseRequestFcn`.

If a figure's handle is hidden (i.e., the figure's `HandleVisibility` property is set to `callback` or `off` and the root `ShowHiddenHandles` property is set to `on`), you must specify the `hidden` option when trying to access a figure using the `all` option.

To delete all figures unconditionally, use the statements

```
set(0, 'ShowHiddenHandles', 'on')
delete(get(0, 'Children'))
```

The figure `CloseRequestFcn` allows you to either delay or abort the closing of a figure once the `close` function has been issued. For example, you can display a dialog box to see if the user really wants to delete the figure or save and clean up before closing.

When coding a `CloseRequestFcn` callback, make sure that it does not call `close`, because this sets up a recursion that results in a MATLAB warning. Instead, the callback should destroy the figure with `delete`. The `delete` function does not execute the figure's `CloseRequestFcn`; it simply deletes the specified figure.

## See Also

`delete` | `figure` | `gcf` | Figure: `HandleVisibility` | Root: `ShowHiddenHandles`

# Tiff.close

---

**Purpose** Close Tiff object

**Syntax** `tiffobj.close()`

**Description** `tiffobj.close()` closes a Tiff object.

**Examples** **Close Tiff Object**

Open a Tiff object and then close it.

```
t = Tiff('example.tif', 'r');  
t.close();
```

**References** This method corresponds to the `TIFFClose` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Close Audio/Video Interleaved (AVI) file

**Syntax** `aviobj = close(aviobj)`

**Description** `aviobj = close(aviobj)` finishes writing and closes the AVI file associated with `aviobj`, which is an AVI file object created using the `avifile` function.

To close all open AVI files, use the `clear mex` command.

**See Also** `avifile` | `addframe (avifile)` | `movie2avi`

# FTP.close

---

**Purpose** Close connection to FTP server

**Syntax** `close(ftpobj)`

**Description** `close(ftpobj)` closes the connection to the FTP server.

- Tips**
- If you do not run `close` at the end of your session, the connection either times out automatically or terminates when you exit MATLAB.
  - After calling `close`, calling any other FTP method on the same object automatically reopens the connection.
  - `close` does not return any output to indicate success or failure.

**Input Arguments**

**ftpobj**  
FTP object created by `ftp`.

**Examples** Connect to the MathWorks FTP server, and then disconnect:

```
mw=ftp('ftp.mathworks.com');  
close(mw)
```

**See Also** `ftp`

<b>Purpose</b>	Close file after writing video data
<b>Syntax</b>	<code>close(writerObj)</code>
<b>Description</b>	<code>close(writerObj)</code> closes the file associated with object <code>writerObj</code> . The object remains in the workspace. If you call the <code>open</code> method after closing, <code>open</code> discards any existing contents of the file.
<b>Input Arguments</b>	<b>writerObj</b> VideoWriter object created by the <code>VideoWriter</code> function.
<b>Examples</b>	<b>AVI File from Animation</b> Write a sequence of frames to a compressed AVI file, <code>peaks.avi</code> .  Prepare the new file.  <pre>writerObj = VideoWriter('peaks.avi'); open(writerObj);</pre> Generate initial data and set axes and figure properties.  <pre>Z = peaks; surf(Z); axis tight set(gca, 'nextplot', 'replacechildren'); set(gcf, 'Renderer', 'zbuffer');</pre> Setting the <code>Renderer</code> property to <code>zbuffer</code> or <code>Painters</code> works around limitations of <code>getframe</code> with the OpenGL <sup>®</sup> renderer on some Windows systems.  Create a set of frames and write each frame to the file.  <pre>for k = 1:20     surf(sin(2*pi*k/20)*Z,Z)     frame = getframe;     writeVideo(writerObj,frame);</pre>

# VideoWriter.close

---

```
end  
close(writerObj);
```

**Purpose** Default figure close request function

**Syntax** `closereq`

**Description** `closereq` deletes the current figure.

**See Also** | `CloseRequestFcn`

# cmopts

---

**Purpose** Name of source control system

**Syntax** cmopts

**Description** cmopts returns the name of your version control system.

## Output Arguments

Value Returned by cmopts	Description	Platform Supported On
clearcase	ClearCase® software from IBM® Rational®	UNIX platforms
customverctrl	Custom interface created using customverctrl function	UNIX platforms
cvcs	Concurrent Version System (CVS)	UNIX platforms
none	No source control system selected	
pvcs	PVCS® and ChangeMan® software	UNIX platforms
rscs	Revision Control System (RCS)	UNIX platforms
Any SCC-compliant source control system, for example, Microsoft Visual SourceSafe	Varies	Windows platforms

**Alternatives**

To view the currently selected source control system, click the **Preferences** button on the **Home** tab, and select **General > Source Control**.

**How To**

- “Source Control Interface on Microsoft Windows”
- “Source Control Interface on UNIX Platforms”

# cmpermute

---

## Purpose

Rearrange colors in colormap

## Syntax

```
[Y,newmap] = cmpermute(X,map)
[Y,newmap] = cmpermute(X,map,index)
```

## Description

[Y,newmap] = cmpermute(X,map) randomly reorders the colors in map to produce a new colormap, newmap. The cmpermute function also modifies the values in X to maintain correspondence between the indices and the colormap, and returns the result in Y. The image Y and associated colormap, newmap, produce the same image as X and map.

[Y,newmap] = cmpermute(X,map,index) uses an ordering matrix (such as the second output of sort) to define the order of colors in the new colormap.

## Class Support

The input image X can be of class uint8 or double. Y is returned as an array of the same class as X.

## Examples

Randomly reorder a colormap and compare the two images:

```
load trees
image(X)
[Y, newmap] = cmpermute(X,map);
figure
image(Y)
```

## See Also

randperm | sort

---

<b>Purpose</b>	Eliminate duplicate colors in colormap; convert grayscale or truecolor image to indexed image
<b>Syntax</b>	<pre>[Y,newmap] = cmunique(X,map) [Y,newmap] = cmunique(RGB) [Y,newmap] = cmunique(I)</pre>
<b>Description</b>	<p>[Y,newmap] = cmunique(X,map) returns the indexed image Y and associated colormap, newmap, that produce the same image as (X,map) but with the smallest possible colormap. The cmunique function removes duplicate rows from the colormap and adjusts the indices in the image matrix accordingly.</p> <p>[Y,newmap] = cmunique(RGB) converts the truecolor image RGB to the indexed image Y and its associated colormap, newmap. The return value newmap is the smallest possible colormap for the image, containing one entry for each unique color in RGB.</p> <hr/> <p><b>Note</b> newmap might be very large, because the number of entries can be as many as the number of pixels in RGB.</p> <hr/>
<b>Class Support</b>	<p>[Y,newmap] = cmunique(I) converts the grayscale image I to an indexed image Y and its associated colormap, newmap. The return value, newmap, is the smallest possible colormap for the image, containing one entry for each unique intensity level in I.</p> <p>The input image can be of class uint8, uint16, or double. The class of the output image Y is uint8 if the length of newmap is less than or equal to 256. If the length of newmap is greater than 256, Y is of class double.</p>
<b>Examples</b>	<ol style="list-style-type: none"><li>1 Use the magic function to create a sample 4-by-4 image that uses every value in the range between 1 and 16. <pre>X = magic(4)</pre></li></ol>

```
X =  
  
    16     2     3    13  
     5    11    10     8  
     9     7     6    12  
     4    14    15     1
```

- 2** Concatenate two 8-entry grayscale colormaps created using the `gray` function. The resultant colormap, `map`, has 16 entries. Entries 9 through 16 are duplicates of entries 1 through 8.

```
map = [gray(8); gray(8)]  
size(map)
```

```
ans =  
  
    16     3
```

- 3** Use `cmunique` to eliminate duplicate entries in the colormap.

```
[Y, newmap] = cmunique(X, map);  
size(newmap)
```

```
ans =  
  
     8     3
```

`cmunique` adjusts the values in the original image `X` to index the new colormap.

```
Y =  
  
     7     1     2     4  
     4     2     1     7  
     0     6     5     3  
     3     5     6     0
```

- 4** View both images to verify that their appearance is the same.

```
figure, imshow(X, map, 'InitialMagnification', 'fit')  
figure, imshow(Y, newmap, 'InitialMagnification', 'fit')
```

**See Also** [rgb2ind](#)

# colamd

---

**Purpose** Column approximate minimum degree permutation

**Syntax** `p = colamd(S)`

**Description** `p = colamd(S)` returns the column approximate minimum degree permutation vector for the sparse matrix `S`. For a non-symmetric matrix `S`, `S(:,p)` tends to have sparser LU factors than `S`. The Cholesky factorization of `S(:,p)' * S(:,p)` also tends to be sparser than that of `S' * S`.

`knobs` is a two-element vector. If `S` is `m`-by-`n`, then rows with more than `(knobs(1))*n` entries are ignored. Columns with more than `(knobs(2))*m` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs(1) = knobs(2) = spparms('wh_frac')`.

`stats` is an optional vector that provides data about the ordering and the validity of the matrix `S`.

<code>stats(1)</code>	Number of dense or empty rows ignored by <code>colamd</code>
<code>stats(2)</code>	Number of dense or empty columns ignored by <code>colamd</code>
<code>stats(3)</code>	Number of garbage collections performed on the internal data structure used by <code>colamd</code> (roughly of size <code>2.2*nnz(S) + 4*m + 7*n</code> integers)
<code>stats(4)</code>	0 if the matrix is valid, or 1 if invalid
<code>stats(5)</code>	Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists

<code>stats(6)</code>	Last seen duplicate or out-of-order row index in the column index given by <code>stats(5)</code> , or 0 if no such row index exists
<code>stats(7)</code>	Number of duplicate and out-of-order row indices

Although MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `colamd`. For this reason, `colamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `colamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `colamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `colamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a column elimination tree post-ordering.

## Examples

The Harwell-Boeing collection of sparse matrices and the MATLAB demos directory include a test matrix `west0479`. It is a matrix of order 479 resulting from a model due to Westerberg of an eight-stage chemical distillation column. The spy plot shows evidence of the eight stages. The `colamd` ordering scrambles this structure.

```
load west0479
A = west0479;
p = colamd(A);
subplot(1,2,1), spy(A,4), title('A')
subplot(1,2,2), spy(A(:,p),4), title('A(:,p)')
```

# colamd

Comparing the spy plot of the LU factorization of the original matrix with that of the reordered matrix shows that minimum degree reduces the time and storage requirements by better than a factor of 2.8. The nonzero counts are 16777 and 5904, respectively.

```
spy(lu(A),4)
spy(lu(A(:,p)),4)
```

## References

[1] The authors of the code for “colamd” are Stefan I. Larimore and Timothy A. Davis (davis@cise.ufl.edu), University of Florida. # colorbar

---

**Purpose** Colorbar showing color scale

**Syntax**

```
colorbar
colorbar('off')
colorbar('hide')
colorbar('delete')
colorbar(...,'peer',axes_handle)
colorbar(...,'location')
colorbar(...,'PropertyName',propertyvalue)
cbar_axes = colorbar(...)
colorbar('option')
colorbar(cbar_handle,'option')
```

**Description** The colorbar function displays the current colormap in the current figure and resizes the current axes to accommodate the colorbar.

`colorbar` adds a new vertical colorbar on the right side of the current axes. If a colorbar exists in that location, `colorbar` replaces it with a new one. If a colorbar exists at a nondefault location, it is retained along with the new colorbar.

`colorbar('off')`, `colorbar('hide')`, and `colorbar('delete')` delete all colorbars associated with the current axes.

`colorbar(...,'peer',axes_handle)` creates a colorbar associated with the axes `axes_handle` instead of the current axes.

`colorbar(...,'location')` adds a colorbar in the specified orientation with respect to the axes. If a colorbar exists at the location specified, it is replaced. Any colorbars not occupying the specified location are retained. Possible values for *location* are

North	Inside plot box near top
South	Inside bottom
East	Inside right
West	Inside left

NorthOutside	Outside plot box near top
SouthOutside	Outside bottom
EastOutside	Outside right
WestOutside	Outside left

Using one of the `...Outside` values for *location* ensures that the colorbar does not overlap the plot, whereas overlaps can occur when you specify any of the other four values.

`colorbar(..., 'PropertyName', propertyvalue)` specifies property names and values for the axes object used to create the colorbar. See [Axes Properties](#) for a description of the properties you can set. The *location* property applies only to colorbars and legends, not to axes.

`cbar_axes = colorbar(...)` returns a handle to a new colorbar object, which is a child of the current figure. If a colorbar exists, a new one is still created.

`colorbar('option')` specifies options for colorbar visibility. *'option'* is one of `'off'`, `'hide'` or `'delete'`. All of the options delete the colorbar in the current axes.

`colorbar(cbar_handle, 'option')` specifies options for colorbar visibility. *'option'* is one of `'off'`, `'hide'` or `'delete'`. All of the options delete the colorbar specified by the `cbar_handle`.

You can use `colorbar` with 2-D and 3-D plots.

## Tips

To obtain the handle to an existing colorbar, use the command

```
cbar_handle = findobj(figure_handle, 'tag', 'Colorbar')
```

where `figure_handle` is the handle of the figure containing the colorbar you want to modify. If the figure contains more than one colorbar, `cbar_handle` is returned as a vector, and you must choose which of the handles to specify to `colorbar`.

## Examples

Display a colorbar beside the axes and use descriptive text strings as *y*-tick labels. Labels repeat cyclically when the number of *y*-ticks is greater than the number of labels, and not all labels will appear if there are fewer *y*-ticks than labels you have specified. Also note that when colorbars are horizontal, their ticks and labels are governed by the `XTick` property rather than the `YTick` property. For more information, see “Labeling Colorbar Ticks”.

```
surf(peaks(30))
colorbar('YTickLabel',...
        {'Freezing','Cold','Cool','Neutral',...
         'Warm','Hot','Burning','Nuclear'})
```

# colorbar

---

Display a horizontal colorbar beneath the axes of a filled contour plot:

```
contourf(peaks(60))  
colormap cool  
colorbar('location','southoutside')
```

## Alternatives

Add a colorbar to a plot with the colorbar tool  on the figure toolbar, or use **Insert** > **Colorbar** from the figure menu. Use the Property

Editor to modify the position, font and other properties of a legend. .  
For details, see “Working in Plot Edit Mode”.

**See Also** `colormap`

# colordef

---

**Purpose** Set default property values to display different color schemes

**Syntax**

```
colordef white
colordef black
colordef none
colordef(fig,color_option)
h = colordef('new',color_option)
```

**Description** `colordef` enables you to select either a white or black background for graphics display. It sets axis lines and labels so that they contrast with the background color.

`colordef white` sets the axis background color to white, the axis lines and labels to black, and the figure background color to light gray.

`colordef black` sets the axis background color to black, the axis lines and labels to white, and the figure background color to dark gray.

`colordef none` sets the figure coloring to that used by MATLAB Version 4. The most noticeable difference is that the axis background is set to 'none', making the axis background and figure background colors the same. The figure background color is set to black.

`colordef(fig,color_option)` sets the color scheme of the figure identified by the handle `fig` to one of the color options 'white', 'black', or 'none'. When you use this syntax to apply `colordef` to an existing figure, the figure must have no graphic content. If it does, you should first clear it (via `clf`) before using this form of the command.

`h = colordef('new',color_option)` returns the handle to a new figure created with the specified color options (i.e., 'white', 'black', or 'none'). This form of the command is useful for creating GUIs when you may want to control the default environment. The figure is created with 'visible', 'off' to prevent flashing.

**Tips** `colordef` affects only subsequently drawn figures, not those currently on the display. This is because `colordef` works by setting default property values (on the root or figure level). You can list the currently set default values on the root level with the statement

```
get(0, 'defaults')
```

You can remove all default values using the `reset` command:

```
reset(0)
```

See the `get` and `reset` references pages for more information.

**See Also**

```
whitebg | clf
```

# colormap

---

**Purpose** Set and get current colormap

**Syntax**

```
colormap(map)
colormap('default')
cmap = colormap
colormap(ax,...)
```

**Description** A colormap is an  $m$ -by-3 matrix of real numbers between 0.0 and 1.0. Each row is an RGB vector that defines one color. The  $k$ th row of the colormap defines the  $k$ th color, where  $\text{map}(k, :) = [r(k) \ g(k) \ b(k)]$  specifies the intensity of red, green, and blue.

`colormap(map)` sets the colormap to the matrix `map`. If any values in `map` are outside the interval  $[0 \ 1]$ , you receive the error `Colormap must have values in [0,1]`.

`colormap('default')` sets the current colormap to the default colormap.

`cmap = colormap` retrieves the current colormap. The values returned are in the interval  $[0 \ 1]$ .

`colormap(ax, ...)` uses the figure corresponding to axes `ax` instead of the current figure.

## Specifying Colormaps

Files in the `color` folder generate a number of colormaps. Each file accepts the colormap size as an argument. For example,

```
colormap(hsv(128))
```

creates an `hsv` colormap with 128 colors. If you do not specify a size, a colormap the same size as the current colormap is created.

## Supported Colormaps

The built-in MATLAB colormaps are illustrated and described below. In addition to specifying built-in colormaps programmatically, you can use the **Colormap** menu in the **Figure Properties** pane of the Plot Tools GUI to select one interactively.

The named built-in colormaps are the following:

- autumn varies smoothly from red, through orange, to yellow.
- bone is a grayscale colormap with a higher value for the blue component. This colormap is useful for adding an “electronic” look to grayscale images.
- colorcube contains as many regularly spaced colors in RGB color space as possible, while attempting to provide more steps of gray, pure red, pure green, and pure blue.
- cool consists of colors that are shades of cyan and magenta. It varies smoothly from cyan to magenta.
- copper varies smoothly from black to bright copper.
- flag consists of the colors red, white, blue, and black. This colormap completely changes color with each index increment.
- gray returns a linear grayscale colormap.

# colormap

---

- `hot` varies smoothly from black through shades of red, orange, and yellow, to white.
- `hsv` varies the hue component of the hue-saturation-value color model. The colors begin with red, pass through yellow, green, cyan, blue, magenta, and return to red. The colormap is particularly appropriate for displaying periodic functions. `hsv(m)` is the same as `hsv2rgb([h ones(m,2)])` where `h` is the linear ramp,  $h = (0:m-1)'/m$ .
- `jet` ranges from blue to red, and passes through the colors cyan, yellow, and orange. It is a variation of the `hsv` colormap. The `jet` colormap is associated with an astrophysical fluid jet simulation from the National Center for Supercomputer Applications. See “Examples” on page 1-1012.
- `lines` produces a colormap of colors specified by the axes `ColorOrder` property and a shade of gray.
- `pink` contains pastel shades of pink. The `pink` colormap provides sepia tone colorization of grayscale photographs.
- `prism` repeats the six colors red, orange, yellow, green, blue, and violet.
- `spring` consists of colors that are shades of magenta and yellow.
- `summer` consists of colors that are shades of green and yellow.
- `white` is an all white monochrome colormap.
- `winter` consists of colors that are shades of blue and green.

## Examples

The `rgbplot` function plots colormap values. Try `rgbplot(hsv)`, `rgbplot(gray)`, and `rgbplot(hot)`.

The following commands display the `flujet` data using the `jet` colormap:

```
load flujet
image(X)
colormap(jet)
```

---

The demos folder contains a CAT scan image of a human spine. Use the `image` function to view the data:

```
load spine
image(X)
colormap bone
```

# colormap

---

## Algorithms

Each figure has its own `colormap` property. `colormap` is a function that sets and gets this property.

## Alternatives

Select a built-in colormap with the Property Editor. To modify the current colormap, use the Colormap Editor, accessible from **Edit > Colormap** on the figure menu.

## See Also

**How To**

- “Coloring Mesh and Surface Plots”

# colormapeditor

---

**Purpose** Open colormap editor

**Syntax** colormapeditor

**Description** colormapeditor displays the current figure's colormap as a strip of rectangular cells in the colormap editor. Node pointers are colored cells below the colormap strip that indicate points in the colormap where the rate of the variation of R, G, and B values changes. You can also work in the HSV colorspace by setting the **Interpolating Colorspace** selector to HSV.

You can also start the colormap editor by selecting **Colormap** from the **Edit** menu.

## Node Pointer Operations

You can select and move node pointers to change a range of colors in the colormap. The color of a node pointer remains constant as you move it, but the colormap changes by linearly interpolating the RGB values between nodes.

Change the color at a node by double-clicking the node pointer. A color picker box appears, from which you can select a new color. After you select a new color at a node, the colors between nodes are reinterpolated.

You can select a different color map using the **Standard Colormaps** submenu of the GUI **Tools** menu. The Plotting Tools Property Editor has a dropdown menu that also lets you select from standard colormaps, but does not help you to modify a colormap.

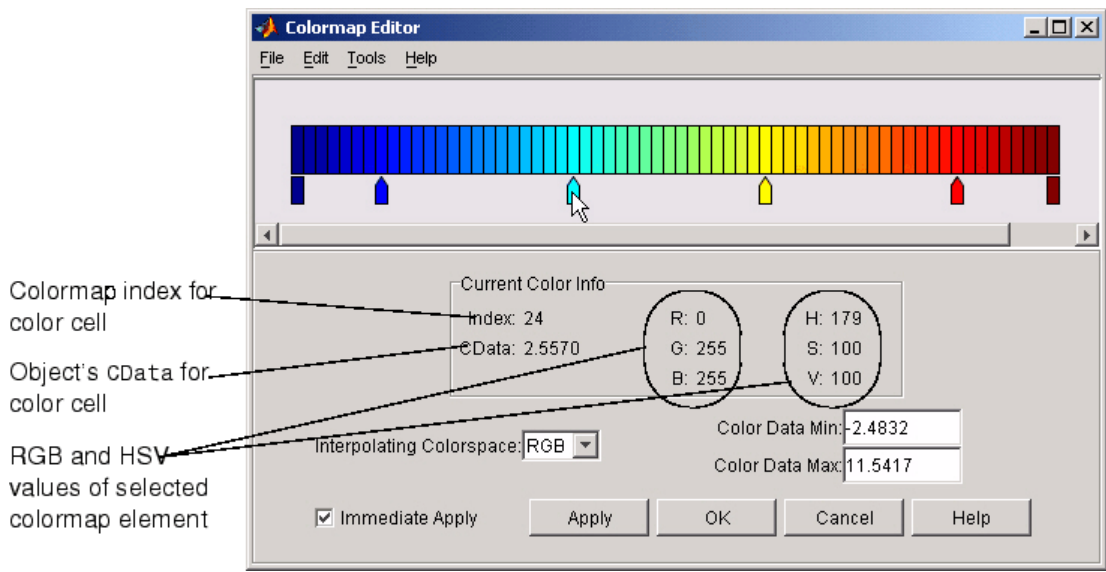

Operation	How to Perform
Select a built-in colormap	<b>Tools &gt; Standard Colormaps</b>
Add a node	Click below the corresponding cell in the colormap strip.
Select a node	Left-click the node.

Operation	How to Perform
Select multiple nodes	Adjacent: left-click first node, <b>Shift+click</b> the last node.  Nonadjacent: left-click first node, <b>Ctrl+click</b> subsequent nodes.
Move a node	Select and drag with the mouse or select and use the left and right arrow keys.
Move multiple nodes	Select multiple nodes and use the left and right arrow keys to move nodes as a group. Movement stops when one of the selected nodes hits an unselected node or an end node.
Delete a node	Select the node and then press the <b>Delete</b> key, or select <b>Delete</b> from the <b>Edit</b> menu, or type <b>Ctrl+x</b> .
Delete multiple nodes	Select the nodes and then press the <b>Delete</b> key, or select <b>Delete</b> from the <b>Edit</b> menu, or type <b>Ctrl+x</b> .
Display color picker for a node	Double-click the node pointer.

## Current Color Info

When you put the mouse over a color cell or node pointer, the colormap editor displays the following information about that colormap element:

- The element's index in the colormap
- The value from the graphics object color data that is mapped to the node's color (i.e., data from the `CData` property of any image, patch, or surface objects in the figure)
- The color's RGB and HSV color value

## Interpolating Colorspace

The colorspace determines what values are used to calculate the colors of cells between nodes. For example, in the RGB colorspace, internode colors are calculated by linearly interpolating the red, green, and blue intensity values from one node to the next. Switching to the HSV colorspace causes the colormap editor to recalculate the colors between nodes using the hue, saturation, and value components of the color definition.

Note that when you switch from one colorspace to another, the color editor preserves the number, color, and location of the node pointers, which can cause the colormap to change.

**Interpolating in HSV.** Since hue is conceptually mapped about a color circle, the interpolation between hue values can be ambiguous. To minimize this ambiguity, the interpolation uses the shortest distance around the circle. For example, interpolating between two nodes, one with hue of 2 (slightly orange red) and another with a hue of 356 (slightly magenta red), does not result in hues 3,4,5...353,354,355 (orange/red-yellow-green-cyan-blue-magenta/red). Taking the shortest distance around the circle gives 357,358,1,2 (orange/red-red-magenta/red).

### Color Data Min and Max

The **Color Data Min** and **Color Data Max** text fields enable you to specify values for the axes `CLim` property. These values change the mapping of object color data (the `CData` property of images, patches, and surfaces) to the colormap. See “Axes Color Limits — the `CLim` Property” for discussion and examples of how to use this property.

## Examples

This example modifies a default MATLAB colormap so that ranges of data values are displayed in specific ranges of color. The graph is a slice plane illustrating a cross section of fluid flow through a jet nozzle. See the `slice` reference page for more information on this type of graph.

### Example Objectives

The objectives are as follows:

- Regions of flow from left to right (positive data) are mapped to colors from yellow through orange to dark red. Yellow is slowest and dark red is the fastest moving fluid.
- Regions that have a speed close to zero are colored green.
- Regions where the fluid is actually moving right to left (negative data) are shades of blue (darker blue is faster).

The following picture shows the desired coloring of the slice plane. The colorbar shows the data to color mapping.

## Running the Example

---

**Note** If you are viewing this documentation in the MATLAB help browser, you can display the graph used in this example by running this file from the MATLAB editor (select **Run** from the **Debug** menu).

---

Initially, the default colormap (`jet`) colored the slice plane, as illustrated in the following picture. Note that this example uses a colormap that is 48 elements to display wider bands of color (the default is 64 elements).

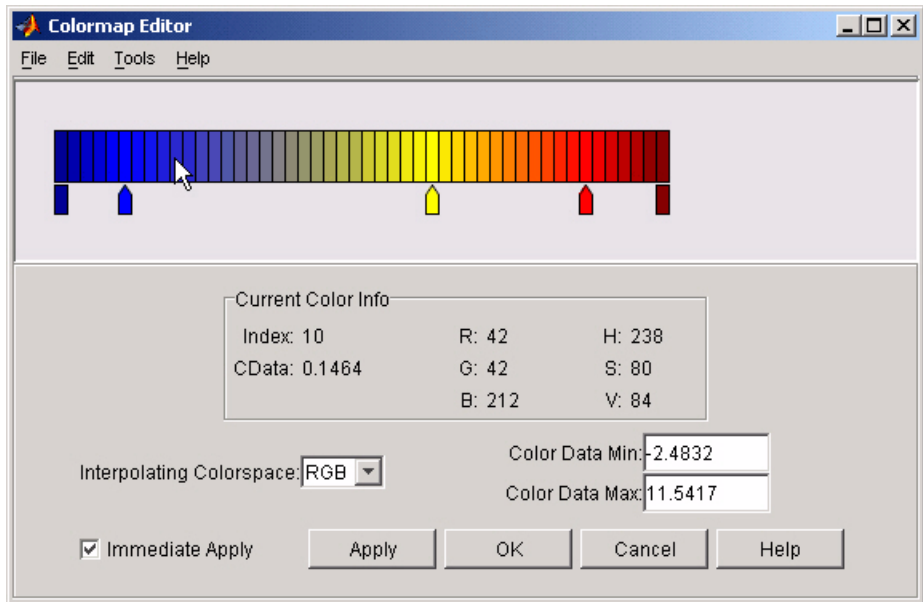

- 1 Start the colormap editor using the `colormapeditor` command. The color map editor displays the current figure's colormap, as shown in the following picture.

# colormapeditor

- 2 Since we want the regions of left-to-right flow (positive speed) to range from yellow to dark red, we can delete the cyan node pointer. To do this, first select it by clicking with the left mouse button and press **Delete**. The colormap now looks like this.

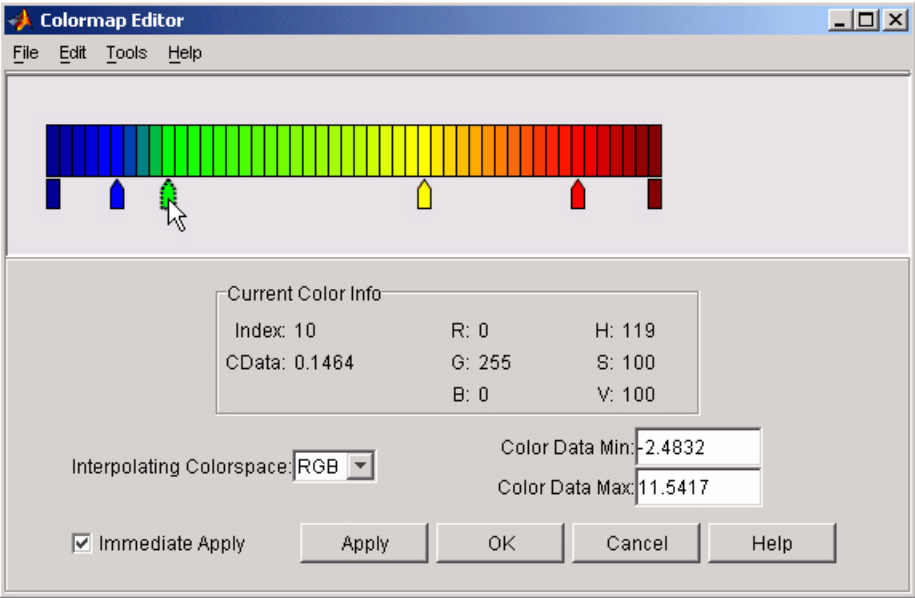

The **Immediate Apply** box is checked, so the graph displays the results of the changes made to the colormap.

- 3** We want the fluid speed values around zero to stand out, so we need to find the color cell where the negative-to-positive transition occurs. Dragging the cursor over the color strip enables you to read the data values in the **Current Color Info** panel.

In this case, cell 10 is the first positive value, so we click below that cell and create a node pointer. Double-clicking the node pointer displays the color picker. Set the color of this node to green.

The graph continues to update to the modified colormap.

# colormapeditor

---

- 4 In the current state, the colormap colors are interpolated from the green node to the yellowish node about 20 cells away. We actually want only the single cell that is centered around zero to be colored green. To limit the color green to one cell, move the blue and yellow node pointers next to the green pointer.

- 5 Before making further adjustments to the colormap, we need to move the green cell so that it is centered around zero. Use the colorbar to locate the green cell.

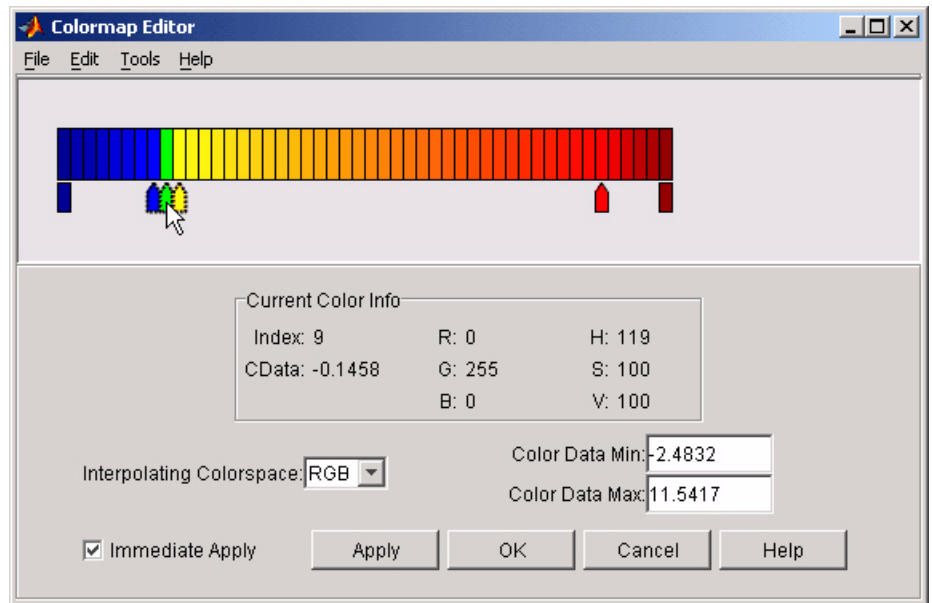

# colormapeditor

---

Note that green cell is not centered around zero.

To recenter the green cell around zero, select the blue, green, and yellow node pointers (left-click blue, **Shift+click** yellow) and move them as a group using the left arrow key. Watch the colorbar in the figure window to see when the green color is centered around zero.

The slice plane now has the desired range of colors for negative, zero, and positive data.

# colormapeditor

---

- 6 Increase the orange-red coloring in the slice by moving the red node pointer toward the yellow node.

- 7 Darken the endpoints to bring out more detail in the extremes of the data. Double-click the end nodes to display the color picker. Set the red endpoint to the RGB value [50 0 0] and set the blue endpoint to the RGB value [0 0 50].

The slice plane coloring now matches the example objectives.

## Saving the Modified Colormap

You can save the modified colormap using the `colormap` function or the figure `Colormap` property.

After you have applied your changes, save the current figure colormap in a variable:

```
mycmap = get(fig,'Colormap'); % fig is figure  
handle or use(gcf)
```

To use this colormap in another figure, set that figure's `Colormap` property:

```
set(new_fig,'Colormap',mycmap)
```

To save your modified colormap in a MAT-file, use the `save` command to save the `mycmap` workspace variable:

```
save('MyColormaps','mycmap')
```

To use your saved colormap in another MATLAB session, load the variable into the workspace and assign the colormap to the figure:

```
load('MyColormaps','mycmap')  
set(fig,'Colormap',mycmap)
```

## How To

- “Colormaps”

# ColorSpec (Color Specification)

---

**Purpose** Color specification

**Description** ColorSpec is not a function; it refers to the three ways in which you specify color for MATLAB graphics:

- RGB triple
- Short name
- Long name

The short names and long names are MATLAB strings that specify one of eight predefined colors. The RGB triple is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color; the intensities must be in the range [0 1]. The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

**Tips** The eight predefined colors and any colors you specify as RGB values are not part of a figure's colormap, nor are they affected by changes to the figure's colormap. They are referred to as *fixed* colors, as opposed to *colormap* colors.

Some high-level functions (for example, `scatter`) accept a colorspec as an input argument and use it to set the CData of graphic objects they create. When using such functions, take care not to specify a colorspec

in a property/value pair that sets CData; values for CData are always n-length vectors or n-by-3 matrices, where n is the length of XData and YData, never strings.

## Examples

To change the background color of a figure to green, specify the color with a short name, a long name, or an RGB triple. These statements generate equivalent results:

```
whitebg('g')
whitebg('green')
whitebg([0 1 0]);
```

You can use ColorSpec anywhere you need to define a color. For example, this statement changes the figure background color to pink:

```
set(gcf, 'Color', [1,0.4,0.6])
```

## See Also

[bar](#) | [bar3](#) | [colordef](#) | [colormap](#) | [fill](#) | [fill3](#) | [whitebg](#)

# colperm

---

**Purpose** Sparse column permutation based on nonzero count

**Syntax** `j = colperm(S)`

**Description** `j = colperm(S)` generates a permutation vector `j` such that the columns of `S(:, j)` are ordered according to increasing count of nonzero entries. This is sometimes useful as a reordering for LU factorization; in this case use `lu(S(:, j))`.

If `S` is symmetric, then `j = colperm(S)` generates a permutation `j` so that both the rows and columns of `S(j, j)` are ordered according to increasing count of nonzero entries. If `S` is positive definite, this is sometimes useful as a reordering for Cholesky factorization; in this case use `chol(S(j, j))`.

**Algorithms** The algorithm involves a sort on the counts of nonzeros in each column.

**Examples** The *n*-by-*n* *arrowhead* matrix

```
A = [ones(1, n); ones(n-1, 1) speye(n-1, n-1)]
```

has a full first row and column. Its LU factorization, `lu(A)`, is almost completely full. The statement

```
j = colperm(A)
```

returns `j = [2:n 1]`. So `A(j, j)` sends the full row and column to the bottom and the rear, and `lu(A(j, j))` has the same nonzero structure as `A` itself.

On the other hand, the Bucky ball example,

```
B = bucky
```

has exactly three nonzero elements in each row and column, so `j = colperm(B)` is the identity permutation and is no help at all for reducing fill-in with subsequent factorizations.

`chol` | `colamd` | `lu` | `spparms` | `symamd` | `symrcm`

# Combine

---

**Purpose** Convenience function for static `.NET System.Delegate` `Combine` method

**Syntax** `result = Combine(delegateA,delegateB)`

**Description** `result = Combine(delegateA,delegateB)` combines two delegates into a new delegate.

**Input Arguments**

**delegateA**  
`.NET System.Delegate` object. The first delegate in the new delegate.

**delegateB**  
`.NET System.Delegate` object. The last delegate in the new delegate.

**Output Arguments**

**result**  
`.NET System.Delegate` object. A new delegate that delegates to the input delegate `delegateA`, then `delegateB`

**Alternatives** Use the static `Combine` method of the `System.Delegate` class.

**See Also** `Remove` | `RemoveAll`

**How To**

- “Combine and Remove .NET Delegates”

**Related Links**

- MSDN `System.Delegate.Combine` Method reference page

**Purpose** 2-D comet plot

**Syntax**

```
comet(y)
comet(x,y)
comet(x,y,p)
comet(axes_handle,...)
```

**Description** `comet(y)` displays a comet graph of the vector `y`. A comet graph is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet(x,y)` displays a comet graph of vector `y` versus vector `x`.

`comet(x,y,p)` specifies a comet body of length `p*length(y)`. `p` defaults to 0.1.

`comet(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

**Examples** Create a simple comet graph:

```
t = 0:.01:2*pi;
x = cos(2*t).*(cos(t).^2);
y = sin(2*t).*(sin(t).^2);
comet(x,y);
```

## See Also

[comet3](#)

**Purpose** 3-D comet plot

**Syntax**

```
comet3(z)
comet3(x,y,z)
comet3(x,y,z,p)
comet3(axes_handle,...)
```

**Description** A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet3(z)` displays a 3-D comet graph of the vector `z`.

`comet3(x,y,z)` displays a comet graph of the curve through the points `[x(i),y(i),z(i)]`.

`comet3(x,y,z,p)` specifies a comet body of length `p*length(y)`. `p` must be between 0 and 1.

`comet3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

**Tips** The trace left by `comet3` is created by using an `EraseMode` of `none`, which means you cannot print the graph (you get only the comet head), and it disappears if you cause a redraw (for example, by resizing the window).

**Examples** Create a 3-D comet graph.

```
t = -10*pi:pi/250:10*pi;
comet3((cos(2*t).^2).*sin(t),(sin(2*t).^2).*cos(t),t);
```

**See Also** `comet`

# commandhistory

---

**Purpose** Open Command History window, or select it if already open

**Syntax** `commandhistory`

**Description** `commandhistory` opens the MATLAB Command History window when it is closed, and selects the Command History window when it is open. The Command History window presents a log of the statements most recently run in the Command Window.

**See Also** `diary` | `prefdir` | `startup`

**How To**

- “Command History”

<b>Purpose</b>	Open Command Window, or select it if already open
<b>Syntax</b>	<code>commandwindow</code>
<b>Description</b>	<code>commandwindow</code> opens the MATLAB Command Window when it is closed, and selects the Command Window when it is open.
<b>Tips</b>	<p>To determine the number of columns and rows that display in the Command Window, given its current size, use</p> <pre>matlab.desktop.commandwindow.size</pre> <p>The number of columns is based on the width of the Command Window. # compan

---

**Purpose** Companion matrix

**Syntax** `A = compan(u)`

**Description** `A = compan(u)` returns the corresponding companion matrix whose first row is  $-u(2:n)/u(1)$ , where  $u$  is a vector of polynomial coefficients. The eigenvalues of `compan(u)` are the roots of the polynomial.

**Examples** The polynomial  $(x - 1)(x - 2)(x + 3) = x^3 - 7x + 6$  has a companion matrix given by

```
u = [1 0 -7 6]
A = compan(u)
A =
     0     7    -6
     1     0     0
     0     1     0
```

The eigenvalues are the polynomial roots:

```
eig(compan(u))

ans =
   -3.0000
    2.0000
    1.0000
```

This is also `roots(u)`.

**See Also** `eig` | `poly` | `polyval` | `roots`

**Purpose**

Plot arrows emanating from origin

**Syntax**

```
compass(U,V)
compass(Z)
compass(...,LineStyle)
compass(axes_handle,...)
h = compass(...)
```

**Description**

A compass graph displays the vectors with components  $(U,V)$  as arrows emanating from the origin.  $U$ ,  $V$ , and  $Z$  are in Cartesian coordinates and plotted on a circular grid.

`compass(U,V)` displays a compass graph having  $n$  arrows, where  $n$  is the number of elements in  $U$  or  $V$ . The location of the base of each arrow is the origin. The location of the tip of each arrow is a point relative to the base and determined by  $[U(i),V(i)]$ .

`compass(Z)` displays a compass graph having  $n$  arrows, where  $n$  is the number of elements in  $Z$ . The location of the base of each arrow is the origin. The location of the tip of each arrow is relative to the base as determined by the real and imaginary components of  $Z$ . This syntax is equivalent to `compass(real(Z),imag(Z))`.

`compass(...,LineStyle)` draws a compass graph using the line type, marker symbol, and color specified by `LineStyle`.

`compass(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = compass(...)` returns handles to line objects.

**Examples****Create Compass Graph**

Create a compass graph of the eigenvalues of a random matrix.

```
rng(0,'twister') % initialize random number generator
```

# compass

---

```
M = randn(20,20);  
Z = eig(M);
```

```
figure  
compass(Z)
```

## How To

- “Compass Plots”

**Purpose** Construct complex data from real and imaginary components

**Syntax** `c = complex(a,b)`

**Description** `c = complex(a,b)` creates a complex output, `c`, from the two real inputs.

`c = a + bi`

The output is the same size as the inputs, which must be scalars or equally sized vectors, matrices, or multi-dimensional arrays.

---

**Note** If `b` is all zeros, `c` is complex and the value of all its imaginary components is 0. In contrast, the result of the addition `a+0i` returns a strictly real result.

---

The following describes when `a` and `b` can have different data types, and the resulting data type of the output `c`:

- If either of `a` or `b` has type `single`, `c` has type `single`.
- If either of `a` or `b` has an integer data type, the other must have the same integer data type or type `scalar double`, and `c` has the same integer data type.

`c = complex(a)` for real `a` returns the complex result `c` with real part `a` and 0 as the value of all imaginary components. Even though the value of all imaginary components is 0, `c` is complex and `isreal(c)` returns false.

The `complex` function provides a useful substitute for expressions such as

`a + i*b` or `a + j*b`

# complex

---

in cases when the names “i” and “j” may be used for other variables (and do not equal  $\sqrt{-1}$ ), when a and b are not `single` or `double`, or when b is all zero.

## Examples

Create complex `uint8` vector from two real `uint8` vectors.

```
a = uint8([1;2;3;4])
b = uint8([2;2;7;7])
c = complex(a,b)
c =
    1.0000 + 2.0000i
    2.0000 + 2.0000i
    3.0000 + 7.0000i
    4.0000 + 7.0000i
```

## See Also

`abs` | `angle` | `conj` | `i` | `imag` | `isreal` | `j` | `real`

**Purpose** Index number of strip containing specified coordinate

**Syntax**

```
stripNumber = tiffobj.computeStrip(row)
stripNumber = tiffobj.computeStrip(row,plane)
```

**Description** `stripNumber = tiffobj.computeStrip(row)` returns the index number of the strip containing the given row. The value of `row` must be one-based.

`stripNumber = tiffobj.computeStrip(row,plane)` returns the index number of the strip containing the given row in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The values of `row` and `plane` must be one-based.

`computeStrip` clamps out-of-range coordinate values to the bounds of the image.

## **Examples** **Determine Index Number of Strip**

Determine the index number of the strip containing a row in the second image of a file.

Create a `Tiff` object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');
t.setDirectory(2);
```

Get the number of rows in the image. Then, get the index of the strip containing the middle row.

```
numRows = t.getTag('ImageLength');
stripNumber = t.computeStrip(numRows/2)
```

```
stripNumber =
```

4

# Tiff.computeStrip

---

Close the Tiff object.

```
t.close();
```

## References

This method corresponds to the TIFFComputeStrip function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## Purpose

Index number of tile containing specified coordinates

## Syntax

```
tileNumber = tiffobj.computeTile([row col])  
tileNumber = tiffobj.computeTile([row col], plane)
```

## Description

`tileNumber = tiffobj.computeTile([row col])` returns the index number of the tile containing the row and column pixel coordinates. The row and column coordinate values are one-based.

`tileNumber = tiffobj.computeTile([row col], plane)` returns the index number of the tile containing the row and column pixel coordinates in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The row, column, and plane coordinate values are one-based.

`computeTile` clamps out-of-range coordinate values to the bounds of the image.

## Examples

### Get Index Number of Tile Containing Last Pixel

Open a Tiff object and get the dimensions of the image to calculate coordinates.

```
t = Tiff('example.tif', 'r');  
numRows = t.getTag('ImageLength');  
numCols = t.getTag('ImageWidth');
```

Get the ID number of the tile containing the coordinates.

```
tileNum = t.computeTile([numRows numCols])
```

```
tileNum =
```

```
    110
```

Close the Tiff object.

```
t.close();
```

# Tiff.computeTile

---

- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Information about computer on which MATLAB software is running

**Syntax**

```
str = computer
archstr = computer('arch')
[str,maxsize] = computer
[str,maxsize,endianness] = computer
```

**Description**

`str = computer` returns the string `str` with the computer type on which MATLAB is running.

`archstr = computer('arch')` returns the string `archstr` which is used by the mex command `-arch` switch.

`[str,maxsize] = computer` returns the integer `maxsize`, the maximum number of elements allowed in an array with this version of MATLAB.

`[str,maxsize,endianness] = computer` returns either 'L' for little-endian byte ordering or 'B' for big-endian byte ordering.

Platform	Word Size	archstr	maxsize	endianness	ispc	isunix	ismac
Microsoft Windows	32-bit	PCWIN	win32	2 <sup>31</sup> - 1	L	1	0
	64-bit	PCWIN64	win64	2 <sup>48</sup> - 1	L	1	0
Linux	64-bit	GLNXA64	glnxa64	2 <sup>48</sup> - 1	L	0	1
Apple Macintosh	64-bit	MACI64	maci64	2 <sup>48</sup> - 1	L	0	1

**Tips**

In some cases, both 32-bit and 64-bit versions of MATLAB can run on the same platform. In this case, the value returned by `computer` reflects which of these is running. For example, if you run a 32-bit version of MATLAB on a Windows x64 platform, `computer` returns `PCWIN`, indicating that the 32-bit version is running. You can get this information and the value of `archstr` from the **Help** menu, as described

# computer

---

in “Information About your Installation” in the Desktop Tools and Development Environment documentation.

`getenv` | `setenv` | `ispc` | `isunix` | `ismac`

**Purpose** Condition number with respect to inversion

**Syntax**  
`c = cond(X)`  
`c = cond(X,p)`

**Description** The *condition number* of a matrix measures the sensitivity of the solution of a system of linear equations to errors in the data. It gives an indication of the accuracy of the results from matrix inversion and the linear equation solution. Values of `cond(X)` and `cond(X,p)` near 1 indicate a well-conditioned matrix.

`c = cond(X)` returns the 2-norm condition number, the ratio of the largest singular value of  $X$  to the smallest.

`c = cond(X,p)` returns the matrix condition number in  $p$ -norm:

`norm(X,p) * norm(inv(X),p)`

If $p$ is...	Then <code>cond(X,p)</code> returns the...
1	1-norm condition number
2	2-norm condition number
'fro'	Frobenius norm condition number
inf	Infinity norm condition number

**Algorithms** The algorithm for `cond` (when  $p = 2$ ) uses the singular value decomposition, `svd`. When the input matrix is sparse, `cond` ignores any specified  $p$  value and calls `condest`.

**See Also** `condeig` | `condest` | `norm` | `normest` | `rank` | `rcond` | `svd`

# condeig

---

**Purpose** Condition number with respect to eigenvalues

**Syntax** `c = condeig(A)`  
`[V,D,s] = condeig(A)`

**Description** `c = condeig(A)` returns a vector of condition numbers for the eigenvalues of A. These condition numbers are the reciprocals of the cosines of the angles between the left and right eigenvectors.

`[V,D,s] = condeig(A)` is equivalent to

```
[V,D] = eig(A);  
s = condeig(A);
```

Large condition numbers imply that A is near a matrix with multiple eigenvalues.

**See Also** `balance` | `cond` | `eig`

**Purpose** 1-norm condition number estimate

**Syntax**  
`c = condest(A)`  
`c = condest(A,t)`  
`[c,v] = condest(A)`

**Description** `c = condest(A)` computes a lower bound `c` for the 1-norm condition number of a square matrix `A`.

`c = condest(A,t)` changes `t`, a positive integer parameter equal to the number of columns in an underlying iteration matrix. Increasing the number of columns usually gives a better condition estimate but increases the cost. The default is `t = 2`, which almost always gives an estimate correct to within a factor 2.

`[c,v] = condest(A)` also computes a vector `v` which is an approximate null vector if `c` is large. `v` satisfies  $\text{norm}(A*v,1) = \text{norm}(A,1)*\text{norm}(v,1)/c$ .

**Note** `condest` invokes `rand`. If repeatable results are required then use `rng` to set the random number generator to its startup settings before using `condest`.

`rng('default')`

**Tips** This function is particularly useful for sparse matrices.

**Algorithms** `condest` is based on the 1-norm condition estimator of Hager [1] and a block-oriented generalization of Hager's estimator given by Higham and Tisseur [2]. The heart of the algorithm involves an iterative search to

estimate  $\|A^{-1}\|_1$  without computing  $A^{-1}$ . This is posed as the convex but nondifferentiable optimization problem  $\max \|A^{-1}\mathbf{x}\|_1$  subject to  $\|\mathbf{x}\|_1 = 1$

cond | norm | normest

**Purpose**

Plot velocity vectors as cones in 3-D vector field

**Syntax**

```
coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)
coneplot(U,V,W,Cx,Cy,Cz)
coneplot(...,s)
coneplot(...,color)
coneplot(...,'quiver')
coneplot(...,'method')
coneplot(X,Y,Z,U,V,W,'nointerp')
coneplot(axes_handle,...)
h = coneplot(...)
```

**Description**

`coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)` plots velocity vectors as cones pointing in the direction of the velocity vector and having a length proportional to the magnitude of the velocity vector. `X`, `Y`, `Z` define the coordinates for the vector field. `U`, `V`, `W` define the vector field. These arrays must be the same size, monotonic, and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). `Cx`, `Cy`, `Cz` define the location of the cones in the vector field. The section “Specifying Starting Points for Stream Plots” in *Visualization Techniques* provides more information on defining starting points.

`coneplot(U,V,W,Cx,Cy,Cz)` (omitting the `X`, `Y`, and `Z` arguments) assumes `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(U)`.

`coneplot(...,s)` automatically scales the cones to fit the graph and then stretches them by the scale factor `s`. If you do not specify a value for `s`, `coneplot` uses a value of 1. Use `s = 0` to plot the cones without automatic scaling.

`coneplot(...,color)` interpolates the array `color` onto the vector field and then colors the cones according to the interpolated values. The size of the `color` array must be the same size as the `U`, `V`, `W` arrays. This option works only with cones (that is, not with the `quiver` option).

`coneplot(...,'quiver')` draws arrows instead of cones (see `quiver3` for an illustration of a quiver plot).

`coneplot(..., 'method')` specifies the interpolation method to use. *method* can be `linear`, `cubic`, or `nearest`. `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`coneplot(X,Y,Z,U,V,W, 'nointerp')` does not interpolate the positions of the cones into the volume. The cones are drawn at positions defined by `X`, `Y`, `Z` and are oriented according to `U`, `V`, `W`. Arrays `X`, `Y`, `Z`, `U`, `V`, `W` must all be the same size.

`coneplot(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = coneplot(...)` returns the handle to the patch object used to draw the cones. You can use the `set` command to change the properties of the cones.

`coneplot` automatically scales the cones to fit the graph, while keeping them in proportion to the respective velocity vectors.

## Examples

Plot the velocity vector cones for vector volume data representing the motion of air through a rectangular region of space:

```
% Load the data. The winds data set contains six 3-D arrays: u, v, and w specify
% the vector components at each of the coordinates specified in x, y, and z. The
% coordinates define a lattice grid structure where the data is sampled within the
% volume.
load wind

% Now establish the range of the data to place the slice planes and to specify
% where you want the cone plots (min, max):
xmin = min(x(:));
xmax = max(x(:));
ymin = min(y(:));
ymax = max(y(:));
zmin = min(z(:));

% Use daspect to set the data aspect ratio of the axes before calling coneplot.
daspect([2,2,1])
```

```

% Decide where in data space you want to plot cones. This example selects the
% full range of x and y in eight steps and the range 3 to 15 in four steps in z
% using linspace and meshgrid.
xrange = linspace(xmin,xmax,8);
yrange = linspace(ymin,ymax,8);
zrange = 3:4:15;
[cx cy cz] = meshgrid(xrange,yrange,zrange);

% Draw the cones, setting the scale factor to 5 to make the cones larger than
% the default size:
hcones = coneplot(x,y,z,u,v,w,cx,cy,cz,5);
% Set the coloring of each cone using FaceColor and EdgeColor:
set(hcones,'FaceColor','red','EdgeColor','none')

% Calculate the magnitude of the vector field (which represents wind speed) to
% generate scalar data for the slice command:
hold on
wind_speed = sqrt(u.^2 + v.^2 + w.^2);
% Create slice planes along the x-axis at xmin and xmax, along the y-axis at
% ymax, and along the z-axis at zmin:
hsurfaces = slice(x,y,z,wind_speed,[xmin,xmax],ymax,zmin);
% Specify interpolated face color so the slice coloring indicates wind speed,
% and do not draw edges (hold, slice, FaceColor, EdgeColor):
set(hsurfaces,'FaceColor','interp','EdgeColor','none')
hold off

% Use the axis command to set the axis limits equal to the range of the data.
axis tight;
% Orient the view to azimuth = 30 and elevation = 40. (rotate3d is a useful
% command for selecting the best view.)
view(30,40);axis off
% Select perspective projection to provide a more realistic looking volume
% using camproj:
camproj perspective;
% Zoom in on the scene a little to make the plot as large as possible using camzoom:
camzoom(1.5)

```

# coneplot

---

```
% The light source affects both the slice planes (surfaces) and the cone plots
% (patches). However, you can set the lighting characteristics of each independently:

% Add a light source to the right of the camera and use Phong lighting to give the
% cones and slice planes a smooth, three-dimensional appearance using camlight and lighting:
camlight right; lighting phong

% Increase the value of the AmbientStrength property for each slice plane to improve
% the visibility of the dark blue colors:
set(hsurfaces,'AmbientStrength',.6)
% Increase the value of the DiffuseStrength property of the cones to brighten particularly
% those cones not showing specular reflections:
set(hcones,'DiffuseStrength',.8)
```

<b>Purpose</b>	Pass control to next iteration of <code>for</code> or <code>while</code> loop
<b>Syntax</b>	<code>continue</code>
<b>Description</b>	<p><code>continue</code> temporarily interrupts the execution of a program loop, skipping any remaining statements in the body of the loop for the current pass. The <code>continue</code> statement does not cause an immediate exit from the loop as a <code>break</code> or <code>return</code> statement would do, but instead continues within the loop for as long as the stated <code>for</code> or <code>while</code> condition holds true.</p> <p>A <code>continue</code> statement in a <i>nested</i> loop behaves in the same manner. Execution resumes at the <code>for</code> or <code>while</code> statement of the loop in which the <code>continue</code> statement was encountered, and reenters the loop if the stated condition evaluates to true.</p>
<b>Examples</b>	<p>Count the number of lines of code in the file <code>magic.m</code>, skipping all blank lines and comments.</p> <pre>fid = fopen('magic.m','r'); count = 0; while ~feof(fid)     line = fgetl(fid);     if isempty(line)    strncmp(line,'% ',1)    ~ischar(line)         continue     end     count = count + 1; end fprintf('%d lines\n',count); fclose(fid);</pre>
<b>See Also</b>	<code>for</code>   <code>while</code>   <code>end</code>   <code>break</code>   <code>return</code>

# contour

---

## Purpose

Contour plot of matrix

## Syntax

```
contour(Z)
contour(Z,n)
contour(Z,v)
contour(X,Y,Z)
contour(X,Y,Z,n)
contour(X,Y,Z,v)
contour(...,LineStyle)
contour(axes_handle,...)
[C,h] = contour(...)
```

## Description

A contour plot displays isolines of matrix  $Z$ . Label the contour lines using `clabel`.

`contour(Z)` draws a contour plot of matrix  $Z$ , where  $Z$  is interpreted as heights with respect to the  $x$ - $y$  plane.  $Z$  must be at least a 2-by-2 matrix that contains at least two different values. The number of contour lines and the values of the contour lines are chosen automatically based on the minimum and maximum values of  $Z$ . The ranges of the  $x$ - and  $y$ -axis are  $[1:n]$  and  $[1:m]$ , where  $[m,n] = \text{size}(Z)$ .

`contour(Z,n)` draws a contour plot of matrix  $Z$  with  $n$  contour levels where  $n$  is a scalar.

`contour(Z,v)` draws a contour plot of matrix  $Z$  with contour lines at the data values specified in the monotonically increasing vector  $v$ . The number of contour levels is equal to `length(v)`. Specifying the vector  $v$  sets the `LevelListMode` to manual to allow user control over contour levels. To display a single contour line at a particular value, define  $v$  as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level  $i$ , use `contour(Z,[i i])`.

`contour(X,Y,Z)`, `contour(X,Y,Z,n)`, and `contour(X,Y,Z,v)` draw contour plots of  $Z$  using  $X$  and  $Y$  to determine the  $x$ - and  $y$ -axis limits.

- If  $X$  and  $Y$  are vectors, then the length of  $X$  must equal the number of columns in  $Z$  and the length of  $Y$  must equal the number of rows in  $Z$ .
- If  $X$  and  $Y$  are matrices, then their sizes must equal the size of  $Z$ .

If  $X$  or  $Y$  is irregularly spaced, then `contour` calculates contours using a regularly spaced contour grid, and then transforms the data to  $X$  or  $Y$ .

`contour(...,LineStyle)` draws the contours using the line type and color specified by `LineStyle`. `contour` ignores marker symbols.

`contour(axes_handle,...)` plots into axes `axes_handle` instead of `gca`.

`[C,h] = contour(...)` returns a contour matrix,  $C$ , that contains the data that defines the contour lines, and a handle,  $h$ , to a `contourgroup` object. The `clabel` function uses contour matrix  $C$  to label the contour lines. `ContourMatrix` is also a read-only `contourgroup` property that you can obtain from the returned handle.

Use contour object properties to control the contour plot appearance.

## Examples

### Create Contour Plot

Use the `meshgrid` function to generate matrices  $X$  and  $Y$ . Create a third matrix,  $Z$ , and plot its contours.

```
x = linspace(-2*pi,2*pi);
y = linspace(0,4*pi);
[X,Y] = meshgrid(x,y);
Z = sin(X)+cos(Y);
```

```
figure
contour(X,Y,Z)
```

## contour

---

### Specify Number of Contour Lines

Store the data from the `peaks` function in matrices `X`, `Y`, and `Z`. Plot 20 contours of the data in `Z`.

```
[X,Y,Z] = peaks;  
figure  
contour(X,Y,Z,20)
```

### Display Contour Labels

Set up matrices X, Y, and Z. Create a contour plot and display the contour labels by setting the ShowText property to on.

```
x = -2:0.2:2;  
y = -2:0.2:3;  
[X,Y] = meshgrid(x,y);  
Z = X.*exp(-X.^2-Y.^2);
```

# contour

```
figure  
contour(X,Y,Z,'ShowText','on')
```

## Display Single Contour Line

Create a contour plot of the peaks function and display only one contour level at  $Z = 1$ .

```
x = -3:0.125:3;  
y = -3:0.125:3;
```

```
[X,Y] = meshgrid(x,y);  
Z = peaks(X,Y);  
v = [1,1];
```

```
figure  
contour(X,Y,Z,v);
```

# contour

---

## Tips

- The `contour` function cannot determine if there are discontinuities in the input data. You can add NaNs to the data to prevent drawing the contour lines in those regions.

## See Also

`clabel` | `contourf` | `contour3` | `contourc` | `quiver` | `contourgroup`

## How To

- “”
- “”

**Purpose**

3-D contour plot

**Syntax**

```
contour3(Z)
contour3(Z,n)
contour3(Z,v)
contour3(X,Y,Z)
contour3(X,Y,Z,n)
contour3(X,Y,Z,v)
contour3(...,LineStyle)
contour3(axes_handle,...)
[C,h] = contour3(...)
```

**Description**

`contour3` creates a 3-D contour plot of a surface defined on a rectangular grid.

`contour3(Z)` draws a contour plot of matrix `Z` in a 3-D view. `Z` is interpreted as heights with respect to the  $x$ - $y$  plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The number of contour levels and the values of contour levels are chosen automatically based on the minimum and maximum values of `Z`. The ranges of the  $x$ - and  $y$ -axis are `[1:n]` and `[1:m]`, where `[m,n] = size(Z)`.

`contour3(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels in a 3-D view.

`contour3(Z,v)` draws a contour plot of matrix `Z` with contour lines at the values specified in vector `v`. The number of contour levels is equal to `length(v)`. Specifying the vector `v` sets the `LevelListMode` to manual to allow user control over contour levels. To display a single contour line at a particular value, define `v` as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level `i`, use `contour3(Z,[i i])`.

`contour3(X,Y,Z)`, `contour3(X,Y,Z,n)`, and `contour3(X,Y,Z,v)` draw contour plots of `Z` using `X` and `Y` to determine the  $x$ - and  $y$ -axis limits.

## contour3

---

- If  $X$  and  $Y$  are vectors, then the length of  $X$  must equal the number of columns in  $Z$  and the length of  $Y$  must equal the number of rows in  $Z$ .
- If  $X$  and  $Y$  are matrices, then their sizes must equal the size of  $Z$ .

If  $X$  or  $Y$  is irregularly spaced, then `contour3` calculates contours using a regularly spaced contour grid, and then transforms the data to  $X$  or  $Y$ .

`contour3(...,LineStyle)` draws the contour lines using the line type and color specified by `LineStyle`. `contour3` ignores marker symbols.

`contour3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`[C,h] = contour3(...)` returns a contour matrix,  $C$ , that contains the data that defines the contour lines, and a handle,  $h$ , to an array of handles to graphics objects. The `clabel` function uses contour matrix  $C$  to label the contour lines. The graphic objects that `contour3` creates are patch objects, or if you specify a `LineStyle` argument, line objects.

### Tips

If you do not specify `LineStyle`, the functions `colormap` and `caxis` control the color.

Label the contour lines using `clabel`.

`contour3(...)` works the same as `contour(...)` with these exceptions:

- The contours are drawn at their corresponding  $Z$  level.
- Multiple patch or line objects are created instead of a `contourgroup`.
- Calling `contour3` with trailing property-value pairs is not allowed.

### Examples

#### Create 3-D Contour Plot

Set up matrices  $X$  and  $Y$  using the `meshgrid` function. Plot 30 contours of matrix  $Z$ .

```
x = -2:0.25:2;  
[X,Y] = meshgrid(x);  
Z = X.*exp(-X.^2-Y.^2);
```

```
contour3(X,Y,Z,30)
```

**See Also**

[contour](#) | [contourc](#) | [contourf](#) | [meshc](#) | [meshgrid](#) | [surfc](#) | [contourgroup](#) properties

# contourc

---

**Purpose** Low-level contour plot computation

**Syntax**

```
C = contourc(Z)
C = contourc(Z,n)
C = contourc(Z,v)
C = contourc(x,y,Z)
C = contourc(x,y,Z,n)
C = contourc(x,y,Z,v)
```

**Description** contourc calculates the contour matrix C used by contour, contour3, and contourf. The values in Z determine the heights of the contour lines with respect to a plane. The contour calculations use a regularly spaced grid determined by the dimensions of Z.

C = contourc(Z) computes the contour matrix from data in matrix Z, where Z must be at least a 2-by-2 matrix. The contours are isolines in the units of Z. The number of contour lines and the corresponding values of the contour lines are chosen automatically.

C = contourc(Z,n) computes contours of matrix Z with n contour levels.

C = contourc(Z,v) computes contours of matrix Z with contour lines at the values specified in vector v. The length of v determines the number of contour levels. To compute a single contour of level i, use contourc(Z,[i i]).

C = contourc(x,y,Z), C = contourc(x,y,Z,n), and C = contourc(x,y,Z,v) compute contours of Z using vectors x and y to determine the x- and y-axis limits. x and y must be monotonically increasing.

**Tips** C is a two-row matrix specifying all the contour lines. Each contour line defined in matrix C begins with a column that contains the value of the contour (specified by v and used by clabel), and the number of (x,y) vertices in the contour line. The remaining columns contain the data for the (x,y) pairs.

```
C = [value1 xdata(1) xdata(2) ... xdata(dim1) value2 xdata(1) xdata(2) ..
```

```
dim1 ydata(1) ydata(2) ... ydata(dim1) dim2 ydata(1) ydata(2) ... y
```

Specifying irregularly spaced *x* and *y* vectors is not the same as contouring irregularly spaced data. If *x* or *y* is irregularly spaced, `contourc` calculates contours using a regularly spaced contour grid, then transforms the data to *x* or *y*.

- “The Contouring Algorithm”

# contourf

---

## Purpose

Filled 2-D contour plot

## Syntax

```
contourf(Z)
contourf(Z,n)
contourf(Z,v)
contourf(X,Y,Z)
contourf(X,Y,Z,n)
contourf(X,Y,Z,v)
contourf(...,LineStyleSpec)
contourf(axes_handle,...)
contour(axes_handle,...)
[C,h] = contourf(...)
```

## Description

A filled contour plot displays isolines calculated from matrix  $Z$  and fills the areas between the isolines using constant colors corresponding to the current figure's colormap.

`contourf(Z)` draws a filled contour plot of matrix  $Z$ , where  $Z$  is interpreted as heights with respect to the  $x$ - $y$  plane.  $Z$  must be at least a 2-by-2 matrix that contains at least two different values. The number of contour lines and the values of the contour lines are chosen automatically based on the minimum and maximum values of  $Z$ . The ranges of the  $x$ - and  $y$ -axis are  $[1:n]$  and  $[1:m]$ , where  $[m,n] = \text{size}(Z)$ .

`contourf(Z,n)` draws a filled contour plot of matrix  $Z$  with  $n$  contour levels.

`contourf(Z,v)` draws a filled contour plot of matrix  $Z$  with contour lines at the data values specified in the monotonically increasing vector  $v$ . Specifying the vector  $v$  sets the `LevelListMode` to manual to allow user control over contour levels. To display a single contour line at a particular value, define  $v$  as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level  $i$ , use `contourf(Z,[i i])`.

`contourf(X,Y,Z)`, `contourf(X,Y,Z,n)`, and `contourf(X,Y,Z,v)` draw filled contour plots of  $Z$  using  $X$  and  $Y$  to determine the  $x$ - and  $y$ -axis limits.

- If  $X$  and  $Y$  are vectors, then the length of  $X$  must equal the number of columns in  $Z$  and the length of  $Y$  must equal the number of rows in  $Z$ .
- If  $X$  and  $Y$  are matrices, then their sizes must equal the size of  $Z$ .

If  $X$  or  $Y$  is irregularly spaced, then `contourf` calculates contours using a regularly spaced contour grid, and then transforms the data to  $X$  or  $Y$ .

`contourf(...,LineStyle)` draws the contour lines using the line type and color specified by `LineStyle`. `contourf` ignores marker symbols.

`contourf(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`contour(axes_handle,...)` plots into axes `axes_handle` instead of `gca`.

`[C,h] = contourf(...)` returns a contour matrix, `C`, that contains the data that defines the contour lines, and a handle, `h`, to a `Contourgroup` object containing the filled contours. The `clabel` function uses contour matrix `C` to label the contour lines. `ContourMatrix` is also a read-only `Contourgroup` property that you can obtain from the returned handle.

## Tips

Label the contour lines using `clabel`.

NaNs in the  $Z$ -data leave white holes with black borders in the contour plot.

## Examples

### Create Filled Contour Plot

Use the `peaks` function to define  $z$  as a 20-by-20 matrix. Create a filled contour plot of  $z$  with 10 contour lines.

```
Z = peaks(20);  
contourf(Z,10);
```

# contourf

---

[properties](#)

## How To

- [""](#)

**Purpose** Define contourgroup properties

**Modifying Properties** You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for contourgroup objects. See “Plot Objects” for more information on contourgroup objects.

**Contourgroup Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation  
hg.Annotation object (read-only)

*Control the display of contourgroup objects in legends.* Specifies whether this contourgroup object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the contourgroup object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the contourgroup object in a legend as one entry, but not its children objects
off	Do not include the contourgroup or its children in a legend (default)
children	Include only the children of the contourgroup as separate entries in the legend

# Contourgroup Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

# Contourgroup Properties

---

## Children

array of graphics object handles

*Children of the contourgroup object.* An array containing the handles of all line objects parented to the contourgroup object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## ContourMatrix

2-by-n matrix (read-only)

*Two-row matrix specifying all contour lines.* Each contour line defined in the `ContourMatrix` begins with a column that contains the value of the contour (specified by the `LevelList` property and is used by `clabel`), and the number of (x,y) vertices in the contour line. The remaining columns contain the data for the (x,y) pairs.

For example:

```
C = [value1 xdata(1) xdata(2)...value2 xdata(1) xdata(2)...;  
     dim1 ydata(1) ydata(2)... dim2 ydata(1) ydata(2)...]
```

That is:

```
C = [C(1) C(2)...C(I)...C(N)]
```

where N is the number of contour levels, and:

```
C(i) = [ level(i) x(1) x(2)...x( numel(i));  
        numel(i) y(1) y(2)...y( numel(i))];
```

For further information, see `contour` and “The Contouring Algorithm”.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where @*CallbackFcn* is a function handle that references the callback function and *graphicfcn* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

# Contourgroup Properties

---

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the contourgroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object’s color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

# Contourgroup Properties

---

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### Fill

`{off} | on`

*Color spaces between contour lines.*

- `on` — Default when using `contourf` or `ezcontourf`.
- `off` — Default when using `contour` or `ezcontour`.

By default, `contour` draws only the contour lines of the surface. If you set `Fill` to `on`, `contour` colors the regions in between the contour lines according to the Z-value of the region and changes the contour lines to black.

### HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

# Contourgroup Properties

---

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

`{on} | off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the contour plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

`on | {off}`

*Select the object by clicking lines or area of extent.* Select plot objects by:

- Clicking contour lines(default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the contour lines (excluding the baseline) to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the contour lines).

## Interruptible

`off | {on}`

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Contourgroup Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LabelSpacing

distance in points (default = 144)

*Spacing between labels on each contour line.* When you display contour line labels using either the `ShowText` property or the `clabel` command, the labels are spaced 144 points (2 inches) apart on each line. You can specify the spacing by setting the `LabelSpacing` property to a value in points. If the length of an individual contour line is less than the specified value, MATLAB displays only one contour label on that line.

## LevelList

vector of `ZData`-values

*Values at which contour lines are drawn.* When the `LevelListMode` property is `auto`, the contour function automatically chooses contour values that span the range of values in `ZData` (the input argument `Z`). You can set this property to the values at which you want contour lines drawn.

To specify the contour interval (space between contour lines) use the `LevelStep` property.

## LevelListMode

{`auto`} | `manual`

*User-specified or autogenerated LevelList values.* By default, the contour function automatically generates the values at which contours are drawn. If you set this property to `manual`, contour does not change the values in `LevelList` as you change the values of `ZData`.

`LevelStep`  
scalar

*Spacing of contour lines.* The contour function draws contour lines at regular intervals determined by the value of `LevelStep`. When the `LevelStepMode` property is `auto`, contour determines the contour interval automatically based on the `ZData`.

`LevelStepMode`  
{`auto`} | `manual`

*User-specified or autogenerated LevelStep values.* By default, the contour function automatically determines a value for the `LevelStep` property. If you set this property to `manual`, contour does not change the value of `LevelStep` as you change the values of `ZData`.

`LineColor`  
{`auto`} | `ColorSpec` | `none`

*Color of the contour lines.* This property determines how MATLAB colors the contour lines.

- `auto` — Each contour line is a single color determined by its contour value, the figure colormap, and the color axis (`caxis`).
- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (black). See `ColorSpec` for more information on specifying color.
- `none` — No contour lines are drawn.

# Contourgroup Properties

---

## LineStyle

{-} | -- | : | -. | none

*Line style of contourgroup object.*

### Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

## Parent

handle of parent axes, hggroup, or hgtransform

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You

can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

**SelectionHighlight**  
{on} | off

*Object highlighted when selected.*

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

**ShowText**  
on | {off}

Display labels on contour lines. When you set this property to `on`, MATLAB displays text labels on each contour line indicating the contour value. See also `LevelList`, `clabel`, and the example “Display Contour Labels” on page 1-1069.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object’s handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

# Contourgroup Properties

---

```
set(findobj('Tag','area1'),'FaceColor','red')
```

**TextList**  
vector

*Contour values to label.* This property contains the contour values where text labels are placed. By default, these values are the same as those contained in the `LevelList` property, which define where the contour lines are drawn. Note that there must be an equivalent contour line to display a text label.

For example, the following statements create and label a contour plot:

```
[c,h]=contour(peaks);  
clabel(c,h)
```

You can get the `LevelList` property to see the contour line values:

```
get(h,'LevelList')
```

Suppose you want to view the contour value 4.375 instead of the value of 4 that the contour function used. To do this, you need to set both the `LevelList` and `TextList` properties:

```
set(h,'LevelList',[-6 -4 -2 0 2 4.375 6 8],...  
    'TextList',[-6 -4 -2 0 2 4.375 6 8])
```

**TextListMode**  
{auto} | manual

*User-specified or auto TextList values.* When this property is `auto`, MATLAB sets the `TextList` property equal to the values of the `LevelList` property (i.e., a text label for each contour line). When this property is `manual`, MATLAB does not set the values of the `TextList` property. Note that specifying values for the `TextList` property causes the `TextListMode` property to be set to `manual`.

TextStep  
scalar

*Determines which contour line have numeric labels.* The contour function labels contour lines at regular intervals which are determined by the value of the TextStep property. When the TextStepMode property is auto, contour labels every contour line when the ShowText property is on.

TextStepMode  
{auto} | manual

*User-specified or autogenerated TextStep values.* By default, the contour function automatically determines a value for the TextStep property. If you set this property to manual, contour does not change the value of TextStep as you change the values of ZData.

Type  
string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For contourgroup objects, Type is 'hggroup'. This statement finds all the hggroup objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

UIContextMenu  
handle of uicontextmenu object

*Associate context menu with object.* Handle of a uicontextmenu object created in the object's parent figure. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

# Contourgroup Properties

---

UserData  
array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

Visible  
{on} | off

*Visibility of object and its children.*

- **on** — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

XData  
vector | matrix

*x-axis values for graph.* The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped.

XDataMode  
{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after having specified `XData`, MATLAB resets the *x*-axis ticks to the column indices of the `ZData`, overwriting any previous values for `XData`.

## `XDataSource`

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## `YData`

scalar | vector | matrix

*Y-axis limits.* This property determines the *y*-axis limits used in the contour plot. If you do not specify a `Y` argument, the `contour` function calculates *y*-axis limits based on the size of the input argument `Z`.

`YData` can be either a matrix equal in size to `ZData` or a vector equal in length to the number of columns in `ZData`.

# Contourgroup Properties

---

Use `YData` to define meaningful coordinates for the underlying surface whose topography is being mapped.

## `YDataMode`

`{auto} | manual`

*Use automatic or user-specified y-axis values.* In `auto` mode (the default) the `contour` function automatically determines the *y*-axis limits. If you set this property to `manual`, specify a value for `YData`, or specify a *Y* argument, then `contour` sets this property to `manual` and does not change the axis limits.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the *y*-axis ticks to the row indices of the `ZData`, overwriting any previous values for `YData`.

## `YDataSource`

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

matrix

*Contour data.* This property contains the data from which the contour lines are generated (specified as the input argument Z). ZData must be at least a 2-by-2 matrix. The number of contour levels and the values of the contour levels are chosen automatically based on the minimum and maximum values of ZData. The limits of the  $x$ - and  $y$ -axis are  $[1:n]$  and  $[1:m]$ , where  $[m,n] = \text{size}(ZData)$ .

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the ZData. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's ZDataSource does not change the object's ZData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

# Contourgroup Properties

---

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## How To

- “Core Graphics Objects”
- “Setting Default Property Values”
- “The Property Editor”

## Purpose

Draw contours in volume slice planes

## Syntax

```
contourslice(X,Y,Z,V,Sx,Sy,Sz)
contourslice(X,Y,Z,V,Xi,Yi,Zi)
contourslice(V,Sx,Sy,Sz)
contourslice(V,Xi,Yi,Zi)
contourslice(...,n)
contourslice(...,cvals)
contourslice(...,[cv cv])
contourslice(...,'method')
contourslice(axes_handle,...)
h = contourslice(...)
```

## Description

`contourslice(X,Y,Z,V,Sx,Sy,Sz)` draws contours in the  $x$ -,  $y$ -, and  $z$ -axis aligned planes at the points in the vectors  $Sx$ ,  $Sy$ ,  $Sz$ . The arrays  $X$ ,  $Y$ , and  $Z$  define the coordinates for the volume  $V$  and must be monotonic and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). The color at each contour is determined by the volume  $V$ , which must be an  $m$ -by- $n$ -by- $p$  volume array.

`contourslice(X,Y,Z,V,Xi,Yi,Zi)` draws contours through the volume  $V$  along the surface defined by the 2-D arrays  $Xi$ ,  $Yi$ ,  $Zi$ . The surface should lie within the bounds of the volume.

`contourslice(V,Sx,Sy,Sz)` and `contourslice(V,Xi,Yi,Zi)` (omitting the  $X$ ,  $Y$ , and  $Z$  arguments) assume  $[X,Y,Z] = \text{meshgrid}(1:n,1:m,1:p)$ , where  $[m,n,p] = \text{size}(v)$ .

`contourslice(...,n)` draws  $n$  contour lines per plane, overriding the automatic value.

`contourslice(...,cvals)` draws `length(cval)` contour lines per plane at the values specified in vector `cvals`.

`contourslice(...,[cv cv])` computes a single contour per plane at the level `cv`.

`contourslice(..., 'method')` specifies the interpolation method to use. *method* can be `linear`, `cubic`, or `nearest`. `nearest` is the default except when the contours are being drawn along the surface defined by `Xi`, `Yi`, `Zi`, in which case `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`contourslice(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = contourslice(...)` returns a vector of handles to patch objects that are used to implement the contour lines.

## Examples

### Contour Slices of Fluid Flow

Store the matrices `X`, `Y`, `Z`, and `V` from the flow data set.

```
[X,Y,Z,V] = flow;
```

Create nine contour plots in the `y-z` plane, no plots in the `x-z` plane, and one plot in the `x-y` plane by specifying `Sx` as a vector of nine elements, `Sy` as an empty vector, and `Sz` as a scalar.

```
Sx = 1:9;  
Sy = [];  
Sz = 0;
```

Draw 10 contour lines between -8 and 2 by specifying `cvals` as a 10-element vector of linearly spaced values between -8 and 2.

```
cvals = linspace(-8,2,10);
```

Create the contour slice plots and set the axis limits. Set the data aspect ratio, change the camera position, and display the black box outline.

```
figure  
contourslice(X,Y,Z,V,Sx,Sy,Sz,cvals);
```

```
axis([0,10,-3,3,-3,3]);  
daspect([1,1,1]);
```

```
campos([0, -20, 7]);  
box on
```

### Contour Slices Along Spherical Surface

Set up matrices X, Y, and Z using the meshgrid function.

```
x = -2:0.2:2;  
y = -2:0.25:2;  
z = -2:0.16:2;
```

## contourslice

---

```
[X,Y,Z] = meshgrid(x,y,z);
```

Use X, Y, and Z to define V as a matrix of volume data.

```
V = X.*exp(-X.^2-Y.^2-Z.^2);
```

Return matrices Xi, Yi, and Zi from the sphere function.

```
[Xi,Yi,Zi] = sphere;
```

Draw contours through the volume V along the surface defined by Xi, Yi, and Zi. Change the plot view to a 3-D view.

```
contourslice(X,Y,Z,V,Xi,Yi,Zi)  
view(3)
```

## Purpose

Summary of classes in MATLAB Constraints Interface

## Description

Constraints specify business rules against which to qualify a calculated value. Use constraints in conjunction with the `matlab.unittest.qualifications` qualification methods `assertThat`, `assumeThat`, `fatalAssertThat`, or `verifyThat`. Constraints determine whether or not a calculated (actual) value satisfies the constraint. Constraints also provide diagnostics. The `matlab.unittest.constraints` package consists of the following classes.

- “Constraint Implementations” on page 1-1108
- “Actual Value Proxies” on page 1-1111
- “Tolerances” on page 1-1111
- “Comparators” on page 1-1111

## Constraint Implementations

### Fundamental Constraint-Related Interfaces

`matlab.unittest.constraints.BooleanConstraint` Interface class for boolean combinations of constraints

`matlab.unittest.constraints.Constraint` Fundamental interface class for comparisons

### General Purpose

`matlab.unittest.constraints.EventuallySatisfies` Interface for value to asynchronously satisfy constraint

`matlab.unittest.constraints.HasField` Constraint specifying structure containing particular field

`matlab.unittest.constraints.IsEqual` General constraint to compare for equality

`matlab.unittest.constraints.IsFalse` Constraint specifying false value

matlab.unittest.constraints.IsSameHandle Constraint specifying handle instance same as another

matlab.unittest.constraints.IsTrue Constraint specifying true value

matlab.unittest.constraints.ReturnsConstraint Constraint specifying function handle that returns true

## Errors and Warnings

matlab.unittest.constraints.IssuesNoWarnings Constraint specifying function that issues no warnings

matlab.unittest.constraints.IssuesWarnings Constraint specifying function that issues expected warning profile

matlab.unittest.constraints.ThrowsConstraint Constraint specifying function handle that throws MException

## Inequalities

matlab.unittest.constraints.IsGreaterThan Constraint specifying value greater than another value

matlab.unittest.constraints.IsGreaterThanOrEqualTo Constraint specifying value greater than or equal to another value

matlab.unittest.constraints.IsLessThan Constraint specifying value less than another value

matlab.unittest.constraints.IsLessThanOrEqualTo Constraint specifying value less than or equal to another value

## Array Size

matlab.unittest.constraints.HasElementCount Constraint specifying expected number of elements

matlab.unittest.constraints.HasLength Constraint specifying expected length of array

# matlab.unittest.constraints

---

matlab.unittest.constraints.HasSizeConstraint specifying expected size of array

matlab.unittest.constraints.IsEmptyConstraint specifying empty value

## Type

matlab.unittest.constraints.IsInstanceOfConstraint specifying inclusion in given class hierarchy

matlab.unittest.constraints.IsOfClassConstraint specifying class type

## Strings

matlab.unittest.constraints.ContainsSubstringConstraint specifying string containing substring

matlab.unittest.constraints.EndsWithSubstringConstraint specifying string ending with substring

matlab.unittest.constraints.IsSubstringOfConstraint specifying substring of another string

matlab.unittest.constraints.MatchesConstraint specifying string matches given regular expression

matlab.unittest.constraints.StartsWithSubstringConstraint specifying string starting with substring

## Finiteness

matlab.unittest.constraints.HasInfConstraint specifying array containing any infinite value

matlab.unittest.constraints.HasNaNConstraint specifying array containing NaN value

matlab.unittest.constraints.IsFiniteConstraint specifying a finite value

## Numeric Attributes

matlab.unittest.constraints.IsReal Constraint specifying real valued array

matlab.unittest.constraints.IsSparse Constraint specifying sparse array

## Actual Value Proxies

matlab.unittest.constraints.AnyCellOf Test if any element of cell array meets constraint

matlab.unittest.constraints.AnyElementOf Test if any element of array meets constraint

matlab.unittest.constraints.EveryCellOf Test if all elements of cell array meets constraint

matlab.unittest.constraints.EveryElementOf Test if all elements of array meets constraint

## Tolerances

matlab.unittest.constraints.Absolute Absolute numeric tolerance

matlab.unittest.constraints.Relative Relative numeric tolerance

matlab.unittest.constraints.Tolerance Abstract interface class for tolerances

## Comparators

matlab.unittest.constraints.CellComparator Comparator for cell arrays

matlab.unittest.constraints.LogicalComparator Comparator for two logical values

matlab.unittest.constraints.NumericComparator Comparator for numeric data types

# matlab.unittest.constraints

---

matlab.unittest.constraints.ObjectComparator for MATLAB or Java objects

matlab.unittest.constraints.StringComparator for two strings

matlab.unittest.constraints.StructComparator for MATLAB structure arrays

<b>Superclasses</b>	Tolerance
<b>Purpose</b>	Absolute numeric tolerance
<b>Description</b>	This numeric Tolerance assesses the magnitude of the difference between actual and expected values. For the tolerance to be satisfied, $\text{abs}(\text{expVal} - \text{actVal}) \leq \text{absTol}$ must be true.
<b>Construction</b>	<p><code>AbsoluteTolerance(tolVals)</code> creates an absolute tolerance object which assesses the magnitude of the difference between actual and expected values.</p> <p>The data types of the inputs to the <code>AbsoluteTolerance</code> constructor determine the data types to which the tolerance is applied. For example, <code>AbsoluteTolerance(10*eps)</code> constructs an <code>AbsoluteTolerance</code> for comparing double-precision numeric arrays while <code>AbsoluteTolerance(int8(2))</code> constructs an <code>AbsoluteTolerance</code> for comparing numeric arrays of type <code>int8</code>. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.</p> <p>Different tolerance values can be specified for different data types by passing multiple tolerance values to the constructor. For example, <code>AbsoluteTolerance(10*eps, 10*eps('single'), int8(1))</code> constructs an <code>AbsoluteTolerance</code> that would apply the following absolute tolerances.</p> <ul style="list-style-type: none"><li>• <code>10*eps</code> applies an absolute tolerance of <code>10*eps</code> for double-precision numeric arrays.</li><li>• <code>10*eps('single')</code> applies an absolute tolerance of <code>10*eps</code> for single-precision numeric arrays.</li><li>• <code>int8(1)</code> applies an absolute tolerance of 1 for numeric arrays of type <code>int8</code>.</li></ul>

# matlab.unittest.constraints.AbsoluteTolerance

---

More than one tolerance can be specified for a particular data type by combining tolerances with the & and | operators. In order to combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

## Input Arguments

### tolVals

Numeric tolerances, specified as a cell array of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array may be a scalar or array of size equal to the actual and expected values.

## Properties

### Values

Numeric tolerances, specified by the tolVals input argument.

## Methods

and	Form logical element-wise conjunction of tolerances
or	Form logical element-wise disjunction of tolerances

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test with Absolute Tolerance

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Simple use in IsEqualTo constraint
testCase.assertThat(4.1, IsEqualTo(4.5, ...
```

```
'Within', AbsoluteTolerance(0.5)));  
  
% Specify different tolerances for different data types  
act = {'abc', 123, single(123), int8([1, 2, 3])};  
exp = {'abc', 122, single(120), int8([2, 4, 6])};  
testCase.verifyThat(act, IsEqualTo(exp, 'Within', ...  
    RelativeTolerance(2, single(1))));
```

## See Also

[matlab.unittest.constraints.RelativeTolerance](#) |  
[matlab.unittest.constraints.IsEqualTo](#) |

## Concepts

# matlab.unittest.constraints.AbsoluteTolerance.and

---

**Purpose** Form logical element-wise conjunction of tolerances

**Syntax** `outTo1Obj = and(to1Obj1,to1Obj2)`

**Description** `outTo1Obj = and(to1Obj1,to1Obj2)` forms the logical element-wise conjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by both `to1Obj1` and `to1Obj2`. A qualification failure occurs when either `to1Obj1` or `to1Obj2` is not satisfied for one or more elements of the comparison values.

Typically, the `and` method is not called directly, but the `and` operator, `&`, is used to denote the conjunction of any two tolerance objects.

**Input Arguments**

**to1Obj**  
Tolerance instance

## Examples Form Logical and of Tolerances

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 10]) & RelativeTolerance([0.02, 0.1])));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
```

# matlab.unittest.constraints.AbsoluteTolerance.and

---

```
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...  
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
```

**See Also** [or](#) |

**Purpose** Form logical element-wise disjunction of tolerances

**Syntax** `outTo1Obj = or(tolObj1, tolObj2)`

**Description** `outTo1Obj = or(tolObj1, tolObj2)` forms the logical element-wise disjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by either `tolObj1` or `tolObj2`. A qualification failure occurs when both `tolObj1` and `tolObj2` are not satisfied for one or more elements of the comparison values.

Forming the logical disjunction of tolerances is particularly useful when relative tolerance is used in general, but absolute tolerance is used when values are small.

Typically, the `or` method is not called directly, but the `or` operator, `|`, is used to denote the disjunction of any two tolerance objects.

**Input Arguments**

**tolObj**  
Tolerance instance

**Examples** **Form Logical or of Tolerances**

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Simple passing qualification
testCase.verifyThat(105, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.1)));

% The following qualification passes because the or
% operation is performed element-wise between the
```

```
% actual and expected values being compared:
testCase.verifyThat([8, 104], IsEqualTo([10, 100], 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.05)));
% Note that the following would fail:
testCase.verifyThat([8, 104], ...
    IsEqualTo([10, 100], 'Within', AbsoluteTolerance(3)) | ...
    IsEqualTo([10, 100], 'Within', RelativeTolerance(0.05)));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(0.5) | RelativeTolerance(0)));
testCase.verifyThat([101, 101], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 0.5]) | RelativeTolerance([0.02, 0.001])));
```

**See Also** and |

# matlab.unittest.constraints.AnyCellOf

---

**Purpose** Test if any element of cell array meets constraint

**Description** The AnyCellOf class creates a proxy of the actual value to the framework. It allows a test writer to apply a constraint against each element of a cell array, and ensure that a passing result occurs if there is at least one element of the cell array that satisfies the constraint.

This class is intended to be used through `matlab.unittest` qualifications as is shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The constraint is analyzed on an element by element basis.

**Construction** `AnyCellOf(actVal)` creates a proxy instance which tests if any element of a provided cell array, `actVal`, meets a constraint. The test passes if at least one element individually satisfies the constraint.

## Input Arguments

### `actVal`

Actual value to test against constraint

**Properties** **ActualValue**

Actual value to test against constraint. This property is set through the constructor via the `actVal` input argument.

**Copy Semantics** Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

**Examples** **Instantiate AnyCellOf Object**

```
import matlab.unittest.constraints.AnyCellOf;  
import matlab.unittest.constraints.IsFinite;  
import matlab.unittest.constraints.IsLessThan;
```

```
% Create a TestCase for interactive use  
testCase = matlab.unittest.TestCase;
```

```
% Passing verification
testCase.verifyThat(AnyCellOf({NaN, Inf, 5}), IsFinite);

% Failing assertion
testCase.verifyThat(AnyCellOf({1, 5}), IsLessThan(0));
```

## See Also

matlab.unittest.qualificationsEveryElementOf | AnyElementOf |  
EveryCellOf |

## Concepts

# matlab.unittest.constraints.AnyElementOf

---

**Purpose** Test if any element of array meets constraint

**Description** The AnyElementOf class creates a proxy of the actual value to the framework. It allows a test writer to apply a constraint against each element of an array, and ensure that a passing result occurs if there is at least one element of the array that satisfies the constraint.

This class is intended to be used through `matlab.unittest` qualifications as is shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The constraint is analyzed on an element by element basis.

**Construction** `AnyElementOf(actVal)` creates a proxy instance which tests if any element of a provided array, `actVal`, meets a constraint. The test passes if at least one element individually satisfies the constraint.

## Tips

- AnyElementOf checks whether any element in the provided array satisfies an associated constraint. However, there are some constraints, such as `HasNaN` and `HasInf`, which validate whether any element in that array satisfies the constraint without requiring the dereferencing operation outside of the constraint itself. In these situations, use of AnyElementOf is unnecessary and impedes qualification performance.

## Input Arguments

### `actVal`

Actual value to test against constraint

**Properties** **ActualValue**

Actual value to test against constraint. This property is set through the constructor via the `actVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate AnyElementOf Object

```
import matlab.unittest.constraints.AnyElementOf;
import matlab.unittest.constraints.IsFinite;
import matlab.unittest.constraints.IsLessThan;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing verification
testCase.verifyThat(AnyElementOf([NaN Inf 5]), IsFinite);

% Failing assertion
testCase.verifyThat(AnyElementOf([1 5]), IsLessThan(0));
```

## Concepts

# matlab.unittest.constraints.BooleanConstraint

---

**Superclasses**    Constraint

**Purpose**            Interface class for boolean combinations of constraints

**Description**      The BooleanConstraint interface class provides an interface for boolean combinations of Constraints. Any constraint which derives from BooleanConstraint can be combined and negated using the and (&), or (|), and not (~) operators of the MATLAB language.

Classes deriving from the BooleanConstraint interface class must implement everything required by the standard Constraint interface. When a given constraint is negated, the diagnostics must be written in a different form than the form presented upon a standard (non-negated) failure. Therefore, classes deriving from the BooleanConstraint class must implement a method to provide a Diagnostic object for the negated case in addition to the non-negated case.

In exchange for meeting these requirements, all BooleanConstraint implementations inherit the appropriate MATLAB overloads for and, or, and not so that they can be combined with other BooleanConstraints objects or negated.

## Methods

and	Form logical conjunction of constraints
getNegativeDiagnosticFor	Produce negated diagnostic for value
not	Form logical negation of constraint
or	Form logical disjunction of constraints

**Copy Semantics**      Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create Boolean Constraint

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% BooleanConstraint Usage (see definition of HasSameSizeAs below)
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
import matlab.unittest.constraints.HasLength;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing verification
testCase.verifyThat([1 2], HasLength(2) | ~HasSameSizeAs(zeros(1, 2)))

% Failing verification
testCase.verifyThat([1 2], HasLength(2) & ~HasSameSizeAs(zeros(1, 2)))

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% BooleanConstraint definition
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
classdef HasSameSizeAs < matlab.unittest.constraints.BooleanConstraint
    % HasSameSizeHas - an example boolean constraint
    %
    % Simple example to demonstrate how to create a custom
    % constraint. This constraint determines whether a
    % given value is the same size as some expected value.
    %
    % It is suggested to make BooleanConstraint implementations immutable
    % (unchangeable) after construction, which is why the example
    % property is private.

    properties(Access=private)

        % ValueWithExpectedSize - an expected value with which to compare
        ValueWithExpectedSize
    end %properties
end
```

# matlab.unittest.constraints.BooleanConstraint

---

```
% Implement the Abstract protected method required by BooleanConstraint
methods(Access=protected)

function diag = getNegativeDiagnosticFor(constraint, actual)
    % getNegativeDiagnosticFor - produce a diagnostic when the constraint
    %
    % This method is called by the testing framework when the constraint
    % has been met but should not have been met because it was negated
    % by a boolean expression. It should produce a Diagnostic result that
    % describes the failure in the correct terms which express the
    % requirement that the constraint actually should not have been met

    import matlab.unittest.diagnostics.StringDiagnostic;

    if constraint.satisfiedBy(actual)
        % Create the negative diagnostic. This will show information about
        % the constraint class name and display the raw actual and expected
        % Using the DiagnosticSense.NegativeDiagnostic enumeration, this
        % produces language more appropriate for the negated case
        diag = StringDiagnostic(sprintf(...
            'Negated HasSameSizeAs failed.\nSize [%s] of Actual Value %s\n',
            int2str(size(actual))));
    else
        % Produce a passing diagnostic, with language appropriate for the
        % passing case
        diag = StringDiagnostic('Negated HasSameSizeAs passed. ');
    end %if

end %function

end

methods

function constraint = HasSameSizeAs(value)
    % Constructor - construct an HasSameSizeAs constraint
    %
    % The HasSameSizeAs constructor takes the value to compare
```

# matlab.unittest.constraints.BooleanConstraint

---

```
        % and stores this value in the ValueWithExpectedSize property
        constraint.ValueWithExpectedSize = value;
    end %function

function bool = satisfiedBy(constraint, actual)
    % satisfiedBy - Determine whether a value is the same size as
    %
    % The satisfiedBy method should be a fast determination of whether
    % the constraint was met by the actual value provided. The method
    % be as fast as possible, optimized for the passing case.

    bool = isequal(size(actual), size(constraint.ValueWithExpectedSize));
end %function

function diag = getDiagnosticFor(constraint, actual)
    % getDiagnosticFor - produce a diagnostic when the constraint is not
    %
    % This method can be called by the testing framework when a constraint
    % has not been met. Unlike the satisfiedBy method, performance is not the
    % primary goal. Rather, a thorough analysis should be performed to
    % determine the reason the constraint was not satisfied. Using the
    % information from this analysis, this method is required to produce a
    % Diagnostic for the framework to present to the user.

    import matlab.unittest.diagnostics.StringDiagnostic;

    if constraint.satisfiedBy(actual)
        % Create a passing diagnostic
        diag = StringDiagnostic('HasSameSizeAs passed.');
```

# matlab.unittest.constraints.BooleanConstraint

---

## See Also

Diagnostic | [matlab.unittest.constraints](#)

## Concepts

# matlab.unittest.constraints.BooleanConstraint.and

## Purpose

Form logical conjunction of constraints

## Syntax

```
outConstObj = and(constObj1, constObj2)
```

## Description

`outConstObj = and(constObj1, constObj2)` forms the logical conjunction of combinable constraints. The `and` method returns a constraint, `outConstObj`, that is the boolean conjunction of `constObj1` and `constObj2`. If `constObj1` and `constObj2` are not satisfied by the actual value provided, the comparison results in a qualification failure.

Typically, the `and` method is not called directly, but the `and` operator, `&`, is used to denote the conjunction of any two combinable constraints.

## Input Arguments

### constObj

BooleanConstraint instance

## Examples

### Implement and method

```
import matlab.unittest.constraints.ContainsSubstring;
import matlab.unittest.constraints.HasElementCount;
import matlab.unittest.constraints.HasSize;
import matlab.unittest.constraints.IsEmpty;
import matlab.unittest.constraints.IsInstanceOf;
import matlab.unittest.constraints.IsGreaterThan;
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
import matlab.unittest.constraints.IsOfClass;
import matlab.unittest.constraints.IsReal;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing qualifications
testCase.verifyThat(3, IsReal & IsGreaterThanOrEqualTo(3));
testCase.verifyThat('Some char', IsOfClass(?char) & ~IsEmpty);
testCase.verifyThat([1 2 3; 4 5 6], HasLength(3) & HasElementCount(6));
```

# matlab.unittest.constraints.BooleanConstraint.and

---

```
% Failing qualifications
testCase.verifyThat(3+i, IsGreaterThan(4), & IsReal);
testCase.verifyThat({1, 2}, IsInstanceOf(?cell) & HasSize([1 2]));
testCase.verifyThat('', ContainsSubstring('string') & IsEmpty);
```

## See Also

or | not | |

# matlab.unittest.constraints.BooleanConstraint.getNegative

**Purpose** Produce negated diagnostic for value

**Syntax** `diag = getNegativeDiagnosticFor(constObj, actVal)`

**Description** `diag = getNegativeDiagnosticFor(constObj, actVal)` produces a negated diagnostic for a value. The `getNegativeDiagnosticFor` method analyzes the provided value, `actVal`, against the constraint, `constObj`, and produces a `matlab.unittest.diagnostics.Diagnostic` object, `diag`, which corresponds to the negation of the constraint, `constObj`. This method is a protected method.

The diagnostics that this method produces are expressed in the negative sense of the constraint. For example, a hypothetical `IsTasty` constraint, when negated, should express that the actual value was "tasty", when it should not have been, and it should describe the details on why it was found to be tasty.

Like the `getDiagnosticFor` method of `Constraint`, the `getNegativeDiagnosticFor` is only called upon failures, and thus can afford a more detailed analysis than the `satisfiedBy` method.

## Input Arguments

### **constObj**

BooleanConstraint instance

### **actVal**

Value for comparison

## Examples

### **Implement getNegativeDiagnosticFor method**

```
function diag = getNegativeDiagnosticFor(constraint, actual)
% getNegativeDiagnosticFor - produce a diagnostic when the constraint
%
% This method is called by the testing framework when the constraint
% been met but should not have been met because it was negated in a
% boolean expression. It should produce a Diagnostic result that
% describes the failure in the correct terms which express the
% requirement that the constraint actually should not have been met
```

# matlab.unittest.constraints.BooleanConstraint.getNegativeDiagnostic

```
import matlab.unittest.diagnostics.StringDiagnostic;

if constraint.satisfiedBy(actual)
    % Create the negative diagnostic. This will show information such as
    % constraint class name and display the raw actual and expected values.
    % Using the DiagnosticSense.NegativeDiagnostic enumeration also
    % produces language more appropriate for the negated case.
    diag = StringDiagnostic(sprintf(...
        'Negated HasSameSizeAs failed.\nSize [%s] of Actual Value and Expected Value is %s.\n',
        int2str(size(actual))));
else
    % Produce a passing diagnostic, with language appropriate for the negated case.
    diag = StringDiagnostic('Negated HasSameSizeAs passed. ');
end %if

end %function
```

## See Also

[getDiagnosticFor](#) | [satisfiedBy](#) | [Diagnostic](#) | [not](#) |

**Purpose** Form logical negation of constraint

**Syntax** `negConstObj = not(constObj)`

**Description** `negConstObj = not(constObj)` forms the logical negation of a negatable constraint. The `not` method returns a constraint, `negConstObj`, that is the boolean complement of the constraint object, `constObj`. This is a means to specify that the constraint should not be satisfied by the actual value provided, and that a qualification failure should be produced when the constraint is satisfied.

Typically, the `not` method is not called directly, but the tilde operator, `~`, is used to denote the negation of any given negatable constraint. Upon encountering a failure, the `getNegativeDiagnosticFor` method provides the resulting constraint diagnostics.

**Input Arguments**

**constObj**  
BooleanConstraint instance

**Examples** **Implement not method**

```
import matlab.unittest.constraints.HasNaN;
import matlab.unittest.constraints.IsEmpty;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.IsInstanceOf;
import matlab.unittest.constraints.IsReal;
import matlab.unittest.constraints.IsOfClass;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

**Purpose** Form logical disjunction of constraints

**Syntax** `outConstObj = or(constObj1, constObj2)`

**Description** `outConstObj = or(constObj1, constObj2)` forms the logical disjunction of combinable constraints. The `or` method returns a constraint, `outConstObj`, that is the boolean disjunction of `constObj1` and `constObj2`. The comparison only results in a qualification failure if both `constObj1` and `constObj2` are not satisfied by the provided actual value.

Typically, the `or` method is not called directly, but the `or` operator, `|`, is used to denote the disjunction of any two combinable constraints.

**Input Arguments**

<b>constObj</b>	BooleanConstraint instance
-----------------	----------------------------

**Examples** **Implement or method**

```
import matlab.unittest.constraints.HasInf;
import matlab.unittest.constraints.HasNaN;
import matlab.unittest.constraints.EndsWithSubstring;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.IsGreaterThan;
import matlab.unittest.constraints.IsLessThan;
import matlab.unittest.constraints.IsOfClass;
import matlab.unittest.constraints.IsReal;
import matlab.unittest.constraints.StartsWithSubstring;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing qualifications
testCase.verifyThat([3 NaN 5], HasNaN | HasInf);
testCase.verifyThat(5, IsEqualTo(5) | IsLessThan(0));
testCase.verifyThat(-3, IsEqualTo(5) | IsLessThan(0));
```

## matlab.unittest.constraints.BooleanConstraint.or

---

```
% Failing qualifications
testCase.verifyThat(3+i, IsGreaterThan(4), | IsReal);
testCase.verifyThat(true, IsOfClass(?char) | IsOfClass(?cell));
testCase.verifyThat('Some long string', StartsWithSubstring('long') | End
```

**Purpose** Comparator for cell arrays

**Description** The CellComparator compares cell arrays.

**Construction** CellComparator creates a comparator for cell arrays.

CellComparator(compObj) indicates a comparator, compObj, that defines the comparator used to compare values contained in the cell array. By default, a cell comparator only supports empty cell arrays.

CellComparator( \_\_\_,Name,Value) provides a comparator with additional options specified by one or more Name,Value pair arguments. Name must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Input Arguments

### **compObj**

Comparator object

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### **'IgnoringCase'**

Indicator whether the comparator is insensitive to case, specified as false or true (logical 0 or 1). When it is false, the comparator is sensitive to case. The comparator only utilizes this name-value pair if the contents being compared are strings.

**Default:** false

### **'IgnoringWhitespace'**

# matlab.unittest.constraints.CellComparator

---

Indicator whether the comparator is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace. Whitespace characters are space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator only utilizes this name-value pair if the contents being compared are strings.

**Default:** `false`

## **'Recursively'**

Indicator of whether comparator operates recursively, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the cell comparator supports are fully supported in recursion. For example:

```
comp1 = CellComparator(StringComparator)
comp1 = CellComparator(StringComparator, 'Recursively', true)
```

Both `comp1` and `comp2` support a cell arrays of strings. However, only `comp2` supports cell arrays that recursively contain either cell arrays or strings as their elements.

**Default:** `false`

## **'Within'**

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. The comparator only utilizes this name-value pair if the contents being compared are a numeric type.

**Default:** (empty)

## Properties

### IgnoreCase

Indicator whether the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'.

### IgnoreWhitespace

Indicator whether the comparator is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'.

### Recursive

Indicator of whether comparator operates recursively, specified in the name-value pair argument, 'Recursively'.

### Tolerance

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'.

## Concepts

# matlab.unittest.constraints.Constraint

---

**Purpose** Fundamental interface class for comparisons

**Description** The Constraint interface class is the means by which `matlab.unittest.constraints` encode comparison logic and the corresponding diagnostic information. Every comparison that can conditionally produce a failure inherits from the Constraint interface class.

Classes deriving from the Constraint interface class must provide a means to determine whether a given value satisfies the constraint. This is done via the `satisfiedBy` method, which includes the definition of the underlying comparison logic. Classes deriving from the Constraint class also must provide a diagnostic for any given actual value which is utilized by the testing framework when a qualification failure is encountered. This is done via the `getDiagnosticFor` method.

In exchange for meeting these requirements, all Constraint implementations are easily plugged into all qualification types by using the `verifyThat`, `assertThat`, `assumeThat`, or `fatalAssertThat` methods. The qualifications utilize the comparison and diagnostic knowledge contained within the constraints. Also, the constraints can be used in situations where a test failure is not wanted, but the comparison logic needs to be reused. For example, a constraint implementation may want to use the logic defined inside of another constraint. Since the constraint can interact with the other constraint directly, it can use the logic without the potential of causing a qualification failure.

## Methods

<code>getDiagnosticFor</code>	Produce diagnostic for compared value
<code>satisfiedBy</code>	Determine whether value satisfies constraint

**Copy Semantics** Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create Constraint

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Constraint Usage (see definition of HasSameSizeAs below)
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing verification
testCase.verifyThat([1 2], HasSameSizeAs(zeros(1, 2)));

% Failing verification
testCase.verifyThat(1, HasSameSizeAs(zeros(1, 2)));

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Constraint definition
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
classdef HasSameSizeAs < matlab.unittest.constraints.Constraint
    % HasSameSizeHas - an example constraint
    %
    % Simple example to demonstrate how to create a custom constraint
    % constraint determines whether a given value is the same size as
    % expected value.
    %
    % It is suggested to make Constraint implementations immutable
    % (unchangeable) after construction, which is why the example pr
    % has SetAccess=immutable.

    properties(SetAccess=immutable)

        % ValueWithExpectedSize - an expected value with which to compare
        ValueWithExpectedSize
    end %properties

    methods

        function constraint = HasSameSizeAs(value)
```

# matlab.unittest.constraints.Constraint

---

```
% Constructor - construct a HasSameSizeAs constraint
%
% The HasSameSizeAs constructor takes the value to compare
% and stores this value in the ValueWithExpectedSize property

constraint.ValueWithExpectedSize = value;
end %function

function bool = satisfiedBy(constraint, actual)
% satisfiedBy - Determine whether a value is the same size as
%
% The satisfiedBy method should be a fast determination of
% the constraint was met by the actual value provided. This
% be as fast as possible, optimized for the passing case.

bool = isequal(size(actual), size(constraint.ValueWithExpectedSize));
end %function

function diag = getDiagnosticFor(constraint, actual)
% getDiagnosticFor - produce a diagnostic when the constraint
%
% This method can be called by the testing framework when the
% constraint has not been met. Unlike the satisfiedBy method, performance is the
% primary goal. Rather, a thorough analysis should be performed to
% determine the reason the constraint was not satisfied. Use the
% information from this analysis, this method is required to return a
% Diagnostic for the framework to present to the user.

import matlab.unittest.diagnostics.StringDiagnostic;

if constraint.satisfiedBy(actual)
% Create a passing diagnostic
diag = StringDiagnostic('HasSameSizeAs passed.');
```

```
        end %function
    end %methods
end %classdef
```

## Concepts

# matlab.unittest.constraints.Constraint.getDiagnosticFor

---

**Purpose** Produce diagnostic for compared value

**Syntax** `diag = getDiagnosticFor(constObj,actVal)`

**Description** `diag = getDiagnosticFor(constObj,actVal)` produces a diagnostic, `diag`, for a compared value, `actVal`. When creating a custom constraint, the class author must implement the `getDiagnosticFor` method so that it analyzes the value, `actVal`, against the constraint, `constObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, the testing framework calls this method when it encounters a qualification failure. Therefore, the constraint author can afford to undertake a more detailed analysis in the `getDiagnosticFor` method than the `satisfiedBy` method.

**Input Arguments**

**actVal**  
Value for comparison

**constObj**  
Constraint instance

**Output Arguments**

**diag**  
Diagnostic instance

**Examples** See example for `matlab.unittest.constraints.Constraint`.

**See Also** `satisfiedBy` | `Diagnostic` | `ConstraintDiagnostic` |

# matlab.unittest.constraints.Constraint.satisfiedBy

---

**Purpose** Determine whether value satisfies constraint

**Syntax** `TF = satisfiedBy(constObj, actVal)`

**Description** `TF = satisfiedBy(constObj, actVal)` determines whether a value, `actVal`, satisfies a constraint, `constObj`. The `satisfiedBy` method is used to determine qualification success or failure. It returns `true` or `false` (logical 0 or 1). When creating a custom constraint, a class author must place comparison logic in this method.

Since the most common usage is for the passing case, the constraint author should optimize for speed in that case. It is only in the failing case that more expensive detailed analysis is helpful.

## Input Arguments

### **actVal**

Value to evaluate against the constraint

### **constObj**

Constraint instance

**Examples** See example for `matlab.unittest.constraints.Constraint`.

**See Also** `getDiagnosticFor` |

# matlab.unittest.constraints.ContainsSubstring

---

**Superclasses** BooleanConstraint

**Purpose** Constraint specifying string containing substring

**Description** The ContainsSubstring class creates a constraint that is only satisfied if the actual value is a string that contains an expected string.

**Construction** ContainsSubstring(substring) creates a constraint that specifies a string containing a substring, `substring`. The constraint is only satisfied if the actual value contains an expected string.

ContainsSubstring(substring,Name,Value) provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **substring**

Text that must be contained within the actual value, specified as a string. `substring` can include newline characters.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **IgnoringCase**

Indicator whether the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## IgnoringWhitespace

Indicator whether the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## Properties

### IgnoreCase

Indicator whether the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoreCase'`. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator whether the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### Substring

String that must be included in the actual value, specified in the input argument, `substring`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate ContainsSubstring Object

```
import matlab.unittest.constraints.ContainsSubstring;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios %%%%%%%%%%%
testCase.verifyThat('SomeLongString', ContainsSubstring('Long'));
testCase.verifyThat('SomeLongString', ...
    ContainsSubstring('lonG', 'IgnoreCase', true));
```

# matlab.unittest.constraints.ContainsSubstring

---

```
testCase.verifyThat('SomeLongString',...
    ContainsSubstring('Some Long String', 'IgnoringWhitespace', true));

% Failing scenarios %%%%%%%%%%%%%%%
testCase.verifyThat('SomeLongString', ContainsSubstring('lonG'));
testCase.verifyThat('SomeLongString', ContainsSubstring('OtherString'));
testCase.verifyThat('SomeLongString',...
    ContainsSubstring('SomeLongStringThatIsLonger'));
```

## Concepts

**Superclasses** BooleanConstraint

**Purpose** Constraint specifying string ending with substring

**Description** The EndsWithSubstring class creates a constraint that is only satisfied if the actual value is a string that ends with an expected string.

**Construction** EndsWithSubstring(suffix) creates a constraint specifying a string ending with a substring. The constraint is only satisfied if the actual value ends with an expected string, suffix.

EndsWithSubstring(suffix,Name,Value) provides a constraint with additional options specified by one or more Name,Value pair arguments. Name must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Input Arguments

### suffix

Text which must occur at the end of the actual value, specified as a string. suffix can include newline characters.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### IgnoringCase

Indicator whether the constraint is insensitive to case, specified as false or true (logical 0 or 1)

**Default:** false

# matlab.unittest.constraints.EndsWithSubstring

---

## IgnoringWhitespace

Indicator whether the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## Properties

### IgnoreCase

Indicator whether the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoreCase'`. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator whether the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### Suffix

Text which must occur at the end of the actual value, specified in the input argument, `suffix`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate EndsWithSubstring Object

```
import matlab.unittest.constraints.EndsWithSubstring;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat('SomeLongString', EndsWithSubstring('String'));
testCase.verifyThat('SomeLongString', EndsWithSubstring('STRING',...
```

# matlab.unittest.constraints.EndsWithSubstring

---

```
        'IgnoringCase', true));
testCase.verifyThat('Some Long String', EndsWithSubstring('LongString',
    'IgnoringWhitespace', true));

% Failing scenarios
%%%%%%%%%%%%%%
testCase.verifyThat('SomeLongString', EndsWithSubstring('STRING'));
testCase.verifyThat('SomeLongString', EndsWithSubstring('OtherString'));
testCase.verifyThat('SomeLongString', EndsWithSubstring('Long'));
```

## See Also

## Concepts

# matlab.unittest.constraints.Eventually

---

**Superclasses**    Constraint

**Purpose**            Poll for value to asynchronously satisfy constraint

**Description**      The Eventually class creates a constraint that is not satisfied by any value that is not a function handle or is a function handle that never returns a value that satisfies a provided constraint within a given timeout period. The drawnow function is invoked while the Eventually constraint waits for the constraint provided to be satisfied.

**Construction**     `outConstObj = Eventually(constObj)` creates a constraint, `outConstObj`, that polls for an actual value function handle to satisfy the constraint specified in the `constObj` constraint. It is not satisfied if evaluation of the function handle does not produce a value that satisfies the constraint within 20 seconds.

`outConstObj = Eventually(constObj, 'WithTimeoutOf', timeOutVal)` creates a constraint that polls for the constraint to be specified within the timer period specified in `timeOutVal`.

## **Input Arguments**

### **constObj**

Constraint instance

### **timeOutVal**

Maximum time to wait for passing behavior, specified in seconds

**Default:** 20 seconds

**Properties**        **TimeOut**

Maximum time to wait for passing behavior, specified by the `timeOutVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate Eventually Object

```
% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Simple passing example
tic;
testCase.verifyThat(@toc, Eventually(IsGreaterThan(10)));

% Simple failing example
tic;
testCase.verifyThat(@toc, Eventually(IsLessThan(0)));

% Passing example with timeout
tic;
testCase.verifyThat(@toc, Eventually(IsGreaterThan(50), ...
    'WithTimeoutOf', 75), 'test diagnostic');

% Failing example with timeout
tic;
testCase.verifyThat(@toc, Eventually(IsGreaterThan(50), ...
    'WithTimeoutOf', 25));
```

[drawnowmatlab.unittest.constraints.Constraint](#) |

## Concepts

# matlab.unittest.constraints.EveryCellOf

---

**Purpose** Test if all elements of cell array meets constraint

**Description** The `EveryCellOf` class creates a proxy of the actual value to the framework. It allows a test writer to apply a constraint against each element of a cell array, and ensure that a passing result occurs if every element of the cell array satisfies the constraint.

This class is intended to be used through `matlab.unittest` qualifications as is shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The constraint is analyzed on an element by element basis.

**Construction** `EveryCellOf(actVal)` creates a proxy instance which tests if every element of a provided cell array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

## Tips

- `EveryCellOf` checks whether every element in the provided cell array satisfies an associated constraint. However, there are some constraints, a prominent one being `IsEqualTo`, which validate all elements in cell arrays without requiring the dereferencing operation outside of the constraint itself. In these situations, use of `EveryCellOf` is unnecessary and impedes qualification performance.

## Input Arguments

### `actVal`

Actual value to test against constraint

**Properties** **ActualValue**

Actual value to test against constraint. This property is set through the constructor via the `actVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Instantiate EveryCellOf Object

```
import matlab.unittest.constraints.EveryCellOf;
import matlab.unittest.constraints.HasNaN;
import matlab.unittest.constraints.ContainsSubstring;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing verification
testCase.verifyThat(EveryCellOf({'abc', 'abc123'}), ContainsSubstring);

% Failing assertion
testCase.verifyThat(EveryCellOf({NaN Inf 5}), HasNaN);
```

## See Also

## Concepts

# matlab.unittest.constraints.EveryElementOf

---

**Purpose** Test if all elements of array meets constraint

**Description** The EveryElementOf class creates a proxy of the actual value to the framework. It allows a test writer to apply a constraint against each element of an array, and ensure that a passing result occurs if every element of the array that satisfies the constraint.

This class is intended to be used through `matlab.unittest` qualifications as is shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The constraint is analyzed on an element by element basis.

**Construction** `EveryElementOf(actVal)` creates a proxy instance which tests if every element of a provided array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

## Tips

- EveryElementOf checks whether every element in the provided array satisfies an associated constraint. However, there are some constraints, such as `IsEqualTo` and `IsGreaterThan`, `IsLessThan`, which validate all elements in the array satisfies the constraint without requiring the dereferencing operation outside of the constraint itself. In these situations, use of `EveryElementOf` is unnecessary and impedes qualification performance.

## Input Arguments

### `actVal`

Actual value to test against constraint

**Properties** **ActualValue**

Actual value to test against constraint. This property is set through the constructor via the `actVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate EveryElementOf Object

```
import matlab.unittest.constraints.EveryElementOf;
import matlab.unittest.constraints.HasNaN;
import matlab.unittest.constraints.IsGreaterThan;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing verification
testCase.verifyThat(EveryElementOf([1 5]), IsGreaterThan(0));

% Failing assertion
testCase.verifyThat(EveryElementOf([NaN Inf 5]), HasNaN);
```

## Concepts

# matlab.unittest.constraints.HasSize

---

**Superclasses** BooleanConstraint

**Purpose** Constraint specifying expected size of array

**Description** The HasSize class creates a constraint that is satisfied if the actual value array has the specified size.

**Construction** HasSize(sizeVal) provides a constraint specifying an expected size of an array. The constraint is satisfied if the actual value array size is equal to the size specified by sizeVal.

## Input Arguments

### sizeVal

Size a value must have to satisfy the constraint.

## Properties

### Count

Size a value must have to satisfy the constraint. This property is set through the constructor via the sizeVal input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate HasSize Object

```
import matlab.unittest.constraints.HasSize;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(ones(2, 5, 3), HasSize([2 5 3]));
testCase.verifyThat({'SomeString', 'SomeOtherString'}, HasSize([1 2]));
testCase.verifyThat([1 2 3; 4 5 6], HasSize([2 3]));
```

```
% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat([2 3], HasSize([3 2]));
testCase.verifyThat([1 2 3; 4 5 6], HasSize(6));
testCase.verifyThat(eye(2), HasSize([4 1]));
```

## Concepts

# matlab.unittest.constraints.IsFinite

---

<b>Superclasses</b>	BooleanConstraint
<b>Purpose</b>	Constraint specifying a finite value
<b>Description</b>	The IsFinite class creates a constraint that is able to determine whether all values of an actual value array are finite. It is not satisfied if the actual value array contains any non-finite value.
<b>Construction</b>	IsFinite provides a constraint specifying an array containing only finite values. This constraint is only satisfied if the actual value array contains no value that is infinite or NaN.
<b>Copy Semantics</b>	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
<b>Examples</b>	<b>Instantiate IsFinite Object</b>

```
import matlab.unittest.constraints.IsFinite;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(5, IsFinite);
testCase.verifyThat([0 5 1], IsFinite);

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(NaN, IsFinite);
testCase.verifyThat(Inf, IsFinite);
testCase.verifyThat(-Inf, IsFinite);
testCase.verifyThat([5 6 NaN 8], IsFinite);
testCase.verifyThat([5 6 7 Inf], IsFinite);
testCase.verifyThat(5+NaN*i, IsFinite);
```

**Concepts**

# matlab.unittest.constraints.IsGreaterThan

---

**Superclasses** Constraint

**Purpose** Constraint specifying value greater than another value

**Description** The IsGreaterThan class creates a constraint that is satisfied if an actual value is greater than a specified floor value, `floorVal`. The actual value is determined to be greater than `floorVal` if and only if the result of the expression `actual > floorVal` is non-empty and all values are true.

**Construction** `IsGreaterThan(floorVal)` provides a constraint specifying a value greater than another value. The constraint is satisfied if the actual value array is greater than the specified floor value, `floorVal`.

## Input Arguments

### **floorVal**

Largest value which fails the constraint.

**Properties** **FloorValue**

Largest value which fails the constraint. This property is set through the constructor via the `floorVal` input argument.

## Methods

`and` Form logical conjunction of constraints

`or` Form logical disjunction of constraints

**Copy Semantics** Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate IsGreaterThan Object

```
import matlab.unittest.constraints.IsGreaterThan;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%
testCase.verifyThat(3, IsGreaterThan(2));
testCase.verifyThat([5 6 7], IsGreaterThan(2));
testCase.verifyThat(5, IsGreaterThan([1 2 3]));
testCase.verifyThat([5 -3 2], IsGreaterThan([4 -9 0]));

% Failing scenarios
%%%%%%%%%%%%%%
testCase.verifyThat(5, IsGreaterThan(9));
testCase.verifyThat([1 2 3; 4 5 6], IsGreaterThan(4));
testCase.verifyThat(eye(2), IsGreaterThan(eye(2)));
```

## Concepts

# matlab.unittest.constraints.IsEqualTo

---

**Superclasses** BooleanConstraint

**Purpose** General constraint to compare for equality

**Description** The IsEqualTo class creates a constraint that compares data for equality. The type of comparison used is governed by the type of the expected value. The first check performed is to check whether the expected value is an object. This check is performed first because in this case it is possible for the object to have overridden methods that are used in subsequent checks (e.g. `islogical`). The following list categorizes and describes the various tests.

Data Type	Equality Comparison Method
MATLAB & Java Objects	If the expected value is a MATLAB or Java object, the IsEqualTo constraint calls the <code>isequal</code> method on the expected value object. If <code>isequal</code> returns <code>false</code> and a supported tolerance has been specified, the actual and expected values are checked for equivalent class, size, and sparsity. If these checks fail, the constraint is not satisfied. If these checks pass, the tolerance is used for comparison.
Logicals	If the expected value is a <code>logical</code> , the actual and expected values are checked for equivalent sparsity. If the sparsity matches, the values are compared using the <code>isequal</code> method. Otherwise, the constraint is not satisfied.
Numerics	If the expected value is <code>numeric</code> , the actual and expected values are checked for equivalent class, size, and sparsity. If all these checks match, <code>isequaln</code> is used. If <code>isequaln</code> returns <code>true</code> , the constraint is satisfied. If the complexity does not match or <code>isequaln</code> returns <code>false</code> , and a supported tolerance has been supplied, it is used to perform the comparison. Otherwise, the constraint is not satisfied.

Data Type	Equality Comparison Method
Strings	If the expected value is a string, the <code>strcmp</code> function is used to check the actual and expected values for equality unless the <code>IgnoreCase</code> property is true, in which case the strings are compared using <code>strcmpi</code> . If the <code>IgnoreWhitespace</code> is true, all whitespace characters are removed from the actual and expected strings before passing them to <code>strcmp</code> or <code>strcmpi</code> .
Structures	If the expected value is a struct, the field count of the actual and expected values is compared. If not equal, the constraint is not satisfied. Otherwise, each field of the expected value struct must exist on the actual value struct. If any field names are different, the constraint is not satisfied. The fields are then recursively compared in a depth first examination. The recursion continues until a fundamental data type is encountered (i.e. logical, numeric, string, or object), and the values are compared as described above.
Cell Arrays	If the expected value is a cell array, the actual and expected values are checked for size equality. If they are not equal in size, the constraint is not satisfied. Otherwise, each element of the array is recursively compared in a manner identical to fields in a structure, described above.

## Construction

`IsEqualTo(expVal)` provides a general constraint to compare for equality.

`IsEqualTo(expVal,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes ( `'` ). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

# matlab.unittest.constraints.IsEqualTo

---

## Input Arguments

### **expVal**

The expected value that will be compared to the actual value.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### **IgnoringCase**

Indicator whether the constraint is insensitive to case, specified as **false** or **true** (logical 0 or 1)

**Default:** **false**

### **IgnoringWhitespace**

Indicator whether the constraint is insensitive to whitespace, specified as **false** or **true** (logical 0 or 1)

**Default:** **false**

### **Using**

Particular comparator to use for constraint construction, specified as a `matlab.unittest.constraints.Comparator` object

**Default:** (empty)

### **Within**

Tolerance to use in constraint construction, specified as a `matlab.unittest.constraints.Tolerance` object

**Default:** (empty)

## Properties

### Comparator

Specific comparator used in construction of the constraint, specified as a `matlab.unittest.constraints.Comparator` object in the name-value pair argument, 'Using'.

### Expected

The expected value that will be compared to the actual value specified in the `expVal` input argument.

### IgnoreCase

Indicator whether the constraint is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator whether the constraint is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'. This property applies at all levels of recursion, such as nested structures.

### Tolerance

Specific tolerance used in construction of the constraint, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'. This property applies at all levels of recursion, such as nested structures.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate IsEqualTo Object

```
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.AbsoluteTolerance;
```

# matlab.unittest.constraints.IsEqualTo

---

```
% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

%%% Simple equality check %%%
testCase.verifyThat(5, IsEqualTo(5));

%%% Comparison using tolerance %%%
testCase.verifyThat(5, IsEqualTo(4.95, 'Within', AbsoluteTolerance(0.1)));

%%% Comparison ignoring case %%%
testCase.verifyThat('aBc', IsEqualTo('ABC', 'IgnoringCase', true));

%%% Comparison ignoring whitespace %%%
testCase.verifyThat('a bc', IsEqualTo('ab c', 'IgnoringWhitespace', true));
```

## Concepts

**Superclasses** BooleanConstraint

**Purpose** Constraint specifying inclusion in given class hierarchy

**Description** The IsInstanceOf class creates a constraint that is satisfied if the actual value derives from or is an instance of a specified class.

**Construction** IsInstanceOf(class) provides a constraint specifying inclusion in a given class hierarchy. The constraint is satisfied if the actual value instance passes the “isa” relationship with class .

### Input Arguments

#### class

Class name a value must either derive from or be to satisfy the constraint, specified as a fully qualified class name string or a meta.class instance.

### Properties

#### Class

Class name a value must either derive from or be to satisfy the constraint. This property is set through the constructor via the class input argument.

### Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### Examples

#### Instantiate IsInstanceOf Object

```
import matlab.unittest.constraints.IsInstanceOf;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%
```

# matlab.unittest.constraints.IsInstanceOf

---

```
testCase.verifyThat(5, IsInstanceOf('double'));
testCase.verifyThat(@sin, IsInstanceOf(?function_handle));

classdef DerivedExample < BaseExample
end
testCase.verifyThat(DerivedExample, IsInstanceOf(?BaseExample));

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(5, IsInstanceOf('char'));
testCase.verifyThat('sin', IsInstanceOf(?function_handle));
```

## Concepts

**Superclasses** Constraint

**Purpose** Constraint specifying value less than another value

**Description** The `IsLessThan` class creates a constraint that is satisfied if an actual value is less than a specified ceiling value, `ceilVal`. The actual value is determined to be less than `ceilVal` if and only if the result of the expression `actual < ceilVal` is non-empty and all values are true.

**Construction** `IsLessThan(ceilVal)` provides a constraint specifying a value less than another value. The constraint is satisfied if the actual value array is less than the specified ceiling value, `ceilVal`.

## Input Arguments

### `ceilVal`

Smallest value which fails the constraint.

**Properties** **CeilingValue**

Smallest value which fails the constraint. This property is set through the constructor via the `ceilVal` input argument.

## Methods

<code>and</code>	Form logical conjunction of constraints
<code>or</code>	Form logical disjunction of constraints

**Copy Semantics** Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

**Examples** **Instantiate IsLessThan Object**

```
import matlab.unittest.constraints.IsLessThan;
```

# matlab.unittest.constraints.IsLessThan

---

```
% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(2, IsLessThan(3));
testCase.verifyThat([5 6 7], IsLessThan(9));
testCase.verifyThat([5 -3 2], IsLessThan([7 -1 8]));

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(9, IsLessThan(5));
testCase.verifyThat([1 2 3; 4 5 6], IsLessThan(4));
testCase.verifyThat(eye(2), IsLessThan(eye(2)));
```

**Concepts**

**Superclasses** BooleanConstraint

**Purpose** Constraint specifying substring of another string

**Description** The IsSubstringOf class creates a constraint that is only satisfied if the actual value is a string that is found within an expected string.

**Construction** IsSubstringOf(superstring) creates a constraint specifying a substring of another string. The constraint is only satisfied if the actual value is contained within an expected string, superstring.

IsSubstringOf(superstring,Name,Value) provides a constraint with additional options specified by one or more Name,Value pair arguments. Name must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Input Arguments

### superstring

Text which must contain the actual value, specified as a string. superstring can include newline characters.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### IgnoringCase

Indicator whether the constraint is insensitive to case, specified as false or true (logical 0 or 1)

**Default:** false

# matlab.unittest.constraints.IsSubstringOf

---

## IgnoringWhitespace

Indicator whether the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## Properties

### IgnoreCase

Indicator whether the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoreCase'`. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator whether the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### Superstring

String that must include the actual value, specified in the input argument, `superstring`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate IsSubstringOf Object

```
import matlab.unittest.constraints.IsSubstringOf;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat('Long', IsSubstringOf('SomeLongString'));
testCase.verifyThat('long', IsSubstringOf('SomeLongString',...
```

```
        'IgnoringCase', true));
testCase.verifyThat('LongString', IsSubstringOf('Some Long String', ..
        'IgnoringWhitespace', true));

% Failing scenarios
%%%%%%%%%%%%%%
testCase.verifyThat('lonG', IsSubstringOf('SomeLongString'));
testCase.verifyThat('OtherString', IsSubstringOf('SomeLongString'));
testCase.verifyThat('SomeLongStringThatIsLonger', ...
        IsSubstringOf('SomeLongString'));
```

## Concepts

# matlab.unittest.constraints.IssuesNoWarnings

---

**Superclasses**    Constraint

**Purpose**            Constraint specifying function that issues no warnings

**Description**      The IssuesNoWarnings class creates a constraint that specifies a function that issues no warnings. The constraint is not satisfied when the value is not a function handle or when it is a function handle that issues at least one warning.

**Construction**     `outConstObj = IssuesNoWarnings` provides a constraint, `outConstObj`, specifying a function that issues no warnings when invoked, and is satisfied if no warnings are issued upon function invocation.

`outConstObj = IssuesNoWarnings('WhenNargoutIs', numOutputs)` creates a constraint that is able to determine whether an actual value is a function handle that issues no warnings when invoked with a particular number of output arguments, `numOutputs`.

## **Input Arguments**

### **numOutputs**

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

**Default:** 0

## **Properties**

### **FunctionOutputs**

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and is set when the function handle is invoked. The number of outputs is determined by the `Nargout` property.

### **Nargout**

Number of output arguments the instance uses when executing functions. This property is set through the constructor via the `numOutputs` input argument.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate IssuesNoWarnings Constraint

```
import matlab.unittest.constraints.IssuesNoWarnings;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%

% Simple case
testCase.verifyThat(@true, IssuesNoWarnings);
testCase.verifyThat(@( ) size([]), IssuesNoWarnings('WhenNargoutIs', 2));

% Access the outputs returned by the function handle
issuesNoWarningsConstraint = IssuesNoWarnings('WhenNargoutIs', 2);
testCase.verifyThat(@( ) size([]), issuesNoWarningsConstraint);
[actualOut1, actualOut2] = issuesNoWarningsConstraint.FunctionOutputs;

% Failing scenarios
%%%%%%%%%%%%%%

% is not a function handle
testCase.verifyThat(5, IssuesNoWarnings);

% Issues a warning
testCase.verifyThat(@( ) warning('some:id', 'Message'), IssuesNoWarnings);
```

## Concepts

<b>Superclasses</b>	Constraint
<b>Purpose</b>	Constraint specifying function that issues expected warning profile
<b>Description</b>	<p>The IssuesWarnings class creates a constraint that issues an expected warning profile. The constraint is not satisfied for any value that is not a function handle that issues a specific set of warnings. The warnings are specified and compared using warning identifiers.</p> <p>By default, the constraint only confirms that the set of warnings specified are issued. It ignores the number of times they are issued, in what order they are issued, and whether or not any unspecified warnings are issued. However, parameters can be set to respect the order, the count, and the warning set. Alternatively, you can specify the exact warning profile for comparison.</p>

**Construction**

`outConstObj = IssuesWarnings(warnArr)` provides a constraint, `outConstObj`, specifying a function that issues expected warnings, `warnArr`.

`outConstObj = IssuesWarnings(expVal,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **warnArr**

Warning identifiers expected to be produced upon invocation of the function handle, specified as a cell array of warning identifiers. If `warnArr` is empty, the constructor throws an `MException`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **Exactly**

Indicator whether the value is a function handle must issue a warning profile that is an exact match, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance relies on specification of other parameters and default instance behavior in order to determine the strictness of its comparison. When set to `true`, the instance requires the warning profile to be exactly the same as the specified warning profile.

**Default:** `false`

## **RespectingCount**

Indicator whether to respect element counts, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance is insensitive to the number of occurrences of members and their frequency is ignored. When set to `true`, the instance is sensitive to the total number of set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if the number of times that a particular warning issues differs from the number of times that warning is specified in `warnArr`.

**Default:** `false`

## **RespectingOrder**

Indicator whether to respect the order of elements, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance is insensitive to the order of the set members. When set to `true`, the instance is sensitive to the order of the set members. This means that this instance is not satisfied if the order of the issued warnings differs from the order the warnings are specified in `warnArr`.

The order of a given set of warnings is determined by trimming the warning profiles to a profile with no repeated adjacent warnings. For example, the warning profile {id:A, id:A, id:B, id:C, id:C, id:C, id:A, id:A, id:A} is trimmed to {id:A, id:B, id:C, id:A}.

When this constraint respects order, the order of the warnings that are both issued and expected must match the order of the expected warning profile. Warnings issued that are not listed in warnArr are ignored when determining order.

**Default:** false

## **RespectingSet**

Indicator whether to respect set elements, specified as false or true (logical 0 or 1). When this value is false, the instance ignores additional set members. When set to true, the instance is sensitive to additional set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if any extra, unspecified warnings are issued.

**Default:** false

## **WhenNargoutIs**

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

**Default:** 0

## **Properties**

### **Exact**

Indicator of whether the constraint performs exact comparisons, specified through the constructor via the name-value pair argument, 'Exactly'.

## **ExpectedWarnings**

Expected warning identifiers. This property is read only and can only be set through the constructor via the `warnArr` input argument.

## **FunctionOutputs**

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and is set when the function handle is invoked. The number of outputs is determined by the `Nargout` property.

## **Nargout**

Number of output arguments the instance uses when executing functions. This property is set through the constructor via the name-value pair argument, `'WhenNargoutIs'`.

## **RespectCount**

Indicator of whether the constraint respects the element counts, specified through the constructor via the name-value pair argument, `'RespectingCount'`.

## **RespectOrder**

Indicator of whether the constraint respects the order of elements, specified through the constructor via the name-value pair argument, `'RespectingOrder'`.

## **RespectSet**

Indicator of whether the constraint respects set elements, specified through the constructor via the name-value pair argument, `'RespectingSet'`.

## **Copy Semantics**

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate IssuesWarnings Constraint

```
import matlab.unittest.constraints.IssuesWarnings;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Helper anonymous function to aid in examples
issueWarnings = @(idCell) cellfun(@(id) warning(id,'Message'), idCell);

% Create some ids for the examples
firstID = 'first:id';
secondID = 'second:id';
thirdID = 'third:id';

% Passing scenarios
%%%%%%%%%%%%%%

% Simple case
testCase.verifyThat(@() issueWarnings({firstID}), IssuesWarnings({firstID}));

% Specifying number of outputs to use when invoking the function
testCase.verifyThat(@() issueWarnings({firstID}), ...
    IssuesWarnings({firstID}, 'WhenNargoutIs', 0));

% Ignores count, warning set, and order
testCase.verifyThat(@() issueWarnings({firstID, thirdID, secondID}, firstID, secondID, thirdID),
    IssuesWarnings({firstID, secondID}));

% Respects warning set
testCase.verifyThat(@() issueWarnings({firstID, thirdID, secondID}, firstID, secondID, thirdID),
    IssuesWarnings({firstID, secondID, thirdID}, 'RespectingSet', true));

% Respects warning count
testCase.verifyThat(@() issueWarnings({secondID, firstID, thirdID}, secondID, firstID, thirdID),
    IssuesWarnings({firstID, secondID, secondID}, 'RespectingCount', true));
```

# matlab.unittest.constraints.IssuesWarnings

---

```
% Respects warning order
testCase.verifyThat(@() issueWarnings({firstID, secondID, secondID, thirdID},
    IssuesWarnings({firstID, secondID}, 'RespectingOrder', true));

% Requires an exact match to the expected warning profile
testCase.verifyThat(@() issueWarnings({firstID, secondID, secondID, thirdID},
    IssuesWarnings({firstID, secondID, secondID, thirdID}, ...
    'Exactly', true));

% Access the outputs returned by the function handle
issuesWarningsConstraint = IssuesWarnings({'first:id'}, 'WhenNargoutIs',
testCase.verifyThat(@warnWithOutput, issuesWarningsConstraint); %warnWithOutput
[actualOut1, actualOut2] = issuesWarningsConstraint.FunctionOutputs{:};
function varargout = warnWithOutput()
warning('first:id', 'Message');
varargout = {123, 'abc'};
end

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% is not a function handle
testCase.verifyThat(5, IssuesWarnings({firstID}));

% does not issue any warning
testCase.verifyThat(@why, IssuesWarnings({firstID}));

% wrong id
testCase.verifyThat(@() issueWarnings({firstID}), IssuesWarnings({secondID}));

% Ignores count, warning set, and order, but missing an ID
testCase.verifyThat(@() issueWarnings({firstID, thirdID, secondID, firstID},
    IssuesWarnings({firstID}));

% Respects warning set
testCase.verifyThat(@() issueWarnings({firstID, secondID}), ...
    IssuesWarnings({firstID}, 'RespectingSet', true));
```

# matlab.unittest.constraints.IssuesWarnings

---

```
% Respects warning count
testCase.verifyThat(@() issueWarnings({firstID, firstID}), ...
    IssuesWarnings({firstID}, 'RespectingCount', true));

% Respects warning order
testCase.verifyThat(@() issueWarnings({firstID, secondID}), ...
    IssuesWarnings({secondID, firstID}, 'RespectingOrder', true));

% Requires an exact match to the expected warning profile
testCase.verifyThat(@() issueWarnings({firstID, firstID, secondID, firstID}), ...
    IssuesWarnings({firstID, secondID, firstID, firstID }, ...
    'Exactly', true));
```

# matlab.unittest.constraints.IsTrue

---

<b>Superclasses</b>	Constraint
<b>Purpose</b>	Constraint specifying true value
<b>Description</b>	The IsTrue class creates a constraint that is able to determine whether an actual value is true, and is not satisfied by any other value.
<b>Construction</b>	IsTrue provides a constraint specifying a true value. This constraint is only satisfied by a scalar logical with a value of true.
<b>Copy Semantics</b>	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
<b>Tips</b>	<ul style="list-style-type: none"><li>• For test execution speed, use <code>verifyTrue</code>, <code>assertTrue</code>, <code>assumeTrue</code>, or <code>fatalAssertTrue</code> instead of <code>IsTrue</code>.</li><li>• To display custom comparisons in the form of a function handle, use <code>ReturnsTrue</code> instead of <code>IsTrue</code>.</li></ul>

## Examples

### Instantiate IsTrue Object

```
import matlab.unittest.constraints.IsTrue;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(true, IsTrue);

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(false, IsTrue);
testCase.verifyThat(1, IsTrue);
testCase.verifyThat([true true true], IsTrue);
```

- Concepts**

<b>Superclasses</b>	BooleanConstraint
<b>Purpose</b>	Constraint specifying string matches given regular expression
<b>Description</b>	The Matches class creates a constraint that is only satisfied if the actual value is a string that matches the given regular expression.
<b>Construction</b>	<p>Matches(expr) creates a constraint specifying string matches given regular expression. The constraint is only satisfied if the actual value matches the given regular expression, expr.</p> <p>Matches(expr, 'IgnoringCase', caseInsensitive) creates a constraint indicating whether to ignore case difference.</p>
	<b>Input Arguments</b>
	<b>expr</b> Regular expression which the actual value must match, specified as a string. expr can include newline characters.
	<b>caseInsensitive</b> Indicator whether the constraint is insensitive to case, specified as false or true (logical 0 or 1)  <b>Default:</b> false
<b>Properties</b>	<b>Expression</b> Regular expression which the actual value must match, specified in the input argument, expr.
	<b>IgnoreCase</b> Indicator whether the constraint is insensitive to case, specified in the input argument, ignoreCase. This property applies at all levels of recursion, such as nested structures.

# matlab.unittest.constraints.Matches

---

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate Matches Object

```
import matlab.unittest.constraints.Matches;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%
testCase.verifyThat('SomeString', Matches('Some[Ss]?tring'));
testCase.verifyThat('Somestring', Matches('Some[Ss]?tring'));
testCase.verifyThat('Sometring', Matches('Some[Ss]?tring'));
testCase.verifyThat('SomeString', Matches('some*', 'IgnoringCase', true));

% Failing scenarios
%%%%%%%%%%
testCase.verifyThat('SomeSstring', Matches('Some[Ss]?tring'));
```

# matlab.unittest.constraints.NumericComparator

---

<b>Purpose</b>	Comparator for numeric data types
<b>Description</b>	The NumericComparator compares numeric data types. The comparator is satisfied if inputs are of the same class with equivalent size, complexity, and sparsity and the built-in <code>isequaln</code> function returns <code>true</code> .
<b>Construction</b>	<p>NumericComparator creates a comparator for numeric data types.</p> <p><code>NumericComparator('Within',tolObj)</code> creates a comparator using a specified tolerance. In this case, NumericComparator first checks for equivalent class, size, and sparsity of the actual and expected values. If these checks fail, the comparator is not satisfied. If these checks pass and the <code>isequaln</code> or complexity check fails, NumericComparator delegates comparison to the supplied tolerance, <code>tolObj</code>.</p>
<b>Input Arguments</b>	<p><b>tolObj</b></p> <p>matlab.unittest.constraints.Tolerance instance</p>
<b>Properties</b>	<p><b>Tolerance</b></p> <p>Specific tolerance used in construction of the comparator, specified as a Tolerance object in the <code>tolObj</code> input argument.</p>
<b>Copy Semantics</b>	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
<b>See Also</b>	matlab.unittest.constraints.IsEqualTo   matlab.unittest.constraints.Tolerance   <code>isequaln</code>
<b>Concepts</b>	

# matlab.unittest.constraints.ObjectComparator

---

<b>Purpose</b>	Comparator for MATLAB or Java objects
<b>Description</b>	The ObjectComparator compares MATLAB or Java objects. The comparator is satisfied if inputs the built-in <code>isequal</code> function returns true.
<b>Construction</b>	<p>ObjectComparator creates a comparator for MATLAB or Java objects.</p> <p>ObjectComparator('Within', tolObj) creates a comparator using a specified tolerance. In this case, ObjectComparator first checks that a call to <code>isequal</code> returns true. If the check fails,</p> <p>the ObjectComparator then checks for equivalent class, size, and sparsity of the actual and expected values. If these checks pass, ObjectComparator delegates comparison to the supplied tolerance, tolObj. This value of this tolerance must be of the same class as the actual and expected values.</p>
<b>Input Arguments</b>	<p><b>tolObj</b></p> <p>Tolerance instance</p>
<b>Properties</b>	<p><b>Tolerance</b></p> <p>Specific tolerance used in construction of the comparator, specified as a matlab.unittest.constraints.Tolerance object in the tolObj input argument.</p>
<b>Copy Semantics</b>	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
<b>See Also</b>	matlab.unittest.constraints.IsEqualTo   matlab.unittest.constraints.Tolerance   isequal
<b>Concepts</b>	

<b>Superclasses</b>	Tolerance
<b>Purpose</b>	Relative numeric tolerance
<b>Description</b>	This numeric Tolerance assesses the magnitude of the difference between actual and expected values, relative to the expected value. For the tolerance to be satisfied, <code>abs(expVal - actVal) &lt;= relTol.*abs(expVal)</code> must be true.
<b>Construction</b>	<p><code>RelativeTolerance(tolVals)</code> creates a relative tolerance object which assesses the magnitude of the difference between actual and expected values, relative to the expected value.</p> <p>The data types of the inputs to the <code>RelativeTolerance</code> constructor determine the data types to which the tolerance is applied. For example, <code>RelativeTolerance(10*eps)</code> constructs a <code>RelativeTolerance</code> for comparing double-precision numeric arrays while <code>RelativeTolerance(int8(2))</code> constructs a <code>RelativeTolerance</code> for comparing numeric arrays of type <code>int8</code>. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.</p> <p>Different tolerance values can be specified for different data types by passing multiple tolerance values to the constructor. For example, <code>RelativeTolerance(10*eps, 10*eps('single'), int8(1))</code> constructs an <code>RelativeTolerance</code> that would apply the following absolute tolerances.</p> <ul style="list-style-type: none"><li>• <code>10*eps</code> applies a relative tolerance of <code>10*eps</code> for double-precision numeric arrays.</li><li>• <code>10*eps('single')</code> applies a relative tolerance of <code>10*eps</code> for single-precision numeric arrays.</li><li>• <code>int8(1)</code> applies a relative tolerance of 1 for numeric arrays of type <code>int8</code>.</li></ul>

# matlab.unittest.constraints.RelativeTolerance

---

More than one tolerance can be specified for a particular data type by combining tolerances with the & and | operators. In order to combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

## Input Arguments

### tolVals

Numeric tolerances, specified as a cell array of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array may be a scalar or array of size equal to the actual and expected values.

## Properties

### Values

Numeric tolerances, specified by the tolVals input argument.

## Methods

and	Form logical element-wise conjunction of tolerances
or	Form logical element-wise disjunction of tolerances

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test with Relative Tolerance

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;
```

```
% Simple use in IsEqualTo constraint
testCase.verifyThat(4.1, IsEqualTo(4.5, ...
    'Within', RelativeTolerance(0.1)));

% Specify different tolerances for different data types
act = {'abc', 123, single(123), int8([1, 2, 3])};
exp = {'abc', 122, single(120), int8([2, 4, 6])};
testCase.verifyThat(act, IsEqualTo(exp, 'Within', ...
    RelativeTolerance(2, single(1))));
```

## See Also

[matlab.unittest.constraints.AbsoluteTolerance](#) |  
[matlab.unittest.constraints.IsEqualTo](#) |

## Concepts

# matlab.unittest.constraints.RelativeTolerance.and

---

**Purpose** Form logical element-wise conjunction of tolerances

**Syntax** `outTo1Obj = and(to1Obj1,to1Obj2)`

**Description** `outTo1Obj = and(to1Obj1,to1Obj2)` forms the logical element-wise conjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by both `to1Obj1` and `to1Obj2`. A qualification failure occurs when either `to1Obj1` or `to1Obj2` is not satisfied for one or more elements of the comparison values.

Typically, the `and` method is not called directly, but the `and` operator, `&`, is used to denote the conjunction of any two tolerance objects.

**Input Arguments**

**to1Obj**  
Tolerance instance

## Examples Form Logical and of Tolerances

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 10]) & RelativeTolerance([0.02, 0.1])));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
```

# matlab.unittest.constraints.RelativeTolerance.and

---

```
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...  
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
```

**See Also** [or](#) |

# matlab.unittest.constraints.RelativeTolerance.or

---

**Purpose** Form logical element-wise disjunction of tolerances

**Syntax** `outTo1Obj = or(to1Obj1,to1Obj2)`

**Description** `outTo1Obj = or(to1Obj1,to1Obj2)` forms the logical element-wise disjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by either `to1Obj1` or `to1Obj2`. A qualification failure occurs when both `to1Obj1` and `to1Obj2` are not satisfied for one or more elements of the comparison values.

Forming the logical disjunction of tolerances is particularly useful when relative tolerance is used in general, but absolute tolerance is used when values are small.

Typically, the `or` method is not called directly, but the `or` operator, `|`, is used to denote the disjunction of any two tolerance objects.

## Input Arguments

**to1Obj**  
Tolerance instance

## Examples

### Form Logical or of Tolerances

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Simple passing qualification
testCase.verifyThat(105, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.1)));

% The following qualification passes because the or
% operation is performed element-wise between the
```

```
% actual and expected values being compared:
testCase.verifyThat([8, 104], IsEqualTo([10, 100], 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.05)));
% Note that the following would fail:
testCase.verifyThat([8, 104], ...
    IsEqualTo([10, 100], 'Within', AbsoluteTolerance(3)) | ...
    IsEqualTo([10, 100], 'Within', RelativeTolerance(0.05)));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(0.5) | RelativeTolerance(0)));
testCase.verifyThat([101, 101], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 0.5]) | RelativeTolerance([0.02, 0.001])));
```

**See Also** and |

# matlab.unittest.constraints>ReturnsTrue

---

**Superclasses** BooleanConstraint

**Purpose** Constraint specifying function handle that returns true

**Description** The ReturnsTrue class creates a constraint that is not satisfied by any value that is not a function handle that returns a scalar logical with a value of true.

When negated using the tilde operator, ~, this constraint does not only pass when the function handle returns false. It also passes if the function handle returns any non-scalar value (such as [true true]) or any non-logical (such as integer valued1).

**Construction** ReturnsTrue provides a constraint specifying that a function handle that returns true.

**Copy Semantics** Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

**Tips**

- Use ReturnsTrue instead of IsTrue in order to display the custom comparison, in the form of a function handle string, upon failure.

**Examples** **Instantiate ReturnsTrue Object**

```
import matlab.unittest.constraints>ReturnsTrue;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Note these are for example only, there exist fully featured
% Constraints to better handle these particular comparisons
testCase.verifyThat(@true, ReturnsTrue);
testCase.verifyThat(@() isequal(1,1), ReturnsTrue);
testCase.verifyThat(@() ~strcmp('a','b'), ReturnsTrue);
```

```
% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat(@false, ReturnsTrue);
testCase.verifyThat(@() strcmp('a',{ 'a', 'a' }), ReturnsTrue);
testCase.verifyThat(@() exist('exist'), ReturnsTrue);
```

## Concepts

# matlab.unittest.constraints.StartsWithSubstring

---

**Superclasses** BooleanConstraint

**Purpose** Constraint specifying string starting with substring

**Description** The StartsWithSubstring class creates a constraint that is only satisfied if the actual value is a string that starts with an expected string.

**Construction** StartsWithSubstring(prefix) creates a constraint specifying a string starting with a substring. The constraint is only satisfied if the actual value starts with an expected string, prefix.

StartsWithSubstring(prefix,Name,Value) provides a constraint with additional options specified by one or more Name,Value pair arguments. Name must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Input Arguments

### prefix

Text which must occur at the start of the actual value, specified as a string. prefix can include newline characters.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### IgnoringCase

Indicator whether the constraint is insensitive to case, specified as false or true (logical 0 or 1)

**Default:** false

## IgnoringWhitespace

Indicator whether the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## Properties

### IgnoreCase

Indicator whether the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoreCase'`. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator whether the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### Prefix

Text which must occur at the start of the actual value, specified in the input argument, `prefix`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate EndsWithSubstring Object

```
import matlab.unittest.constraints.StartsWithSubstring;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%%%%%
testCase.verifyThat('SomeLongString', StartsWithSubstring('Some'));
testCase.verifyThat('SomeLongString', ...
```

# matlab.unittest.constraints.StartsWithSubstring

---

```
        StartsWithSubstring('sOME', 'IgnoringCase', true));
testCase.verifyThat('Some Long String', ...
    StartsWithSubstring('SomeLong', 'IgnoringWhitespace', true));

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
testCase.verifyThat('SomeLongString', StartsWithSubstring('sOME'));
testCase.verifyThat('SomeLongString', StartsWithSubstring('OtherString'));
testCase.verifyThat('SomeLongString', StartsWithSubstring('Long'));
```

## Concepts

**Purpose** Comparator for two strings

**Description** The StringComparator compares two strings. The comparator is satisfied if the two strings are equal.

**Construction** StringComparator creates a comparator for two strings.

StringComparator(,Name,Value) provides a comparator with additional options specified by one or more Name,Value pair arguments. Name must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Input Arguments

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### **'IgnoringCase'**

Indicator whether the comparator is insensitive to case, specified as false or true (logical 0 or 1). When it is false, the comparator is sensitive to case.

**Default:** false

### **'IgnoringWhitespace'**

Indicator whether the comparator is insensitive to whitespace, specified as false or true (logical 0 or 1). When it is false, the comparator is sensitive to whitespace. Whitespace characters are space, form feed, new line, carriage return, horizontal tab, and vertical tab.

**Default:** false

# matlab.unittest.constraints.StringComparator

---

## Properties

### IgnoreCase

Indicator whether the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'.

### IgnoreWhitespace

Indicator whether the comparator is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'.

**Default:** false

## **'IgnoringWhitespace'**

Indicator whether the comparator is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace. Whitespace characters are space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator only utilizes this name-value pair if the contents being compared are strings.

**Default:** false

## **'Recursively'**

Indicator of whether comparator operates recursively, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the `StructComparator` supports are fully supported in recursion. For example:

```
comp1 = StructComparator(NumericComparator);  
comp2 = StructComparator(NumericComparator, 'Recursively', true);
```

Both `comp1` and `comp2` support structures that contain numeric values as their fields. However, only `comp2` supports a structures that recursively contain either structures or numeric values as their fields.

**Default:** false

## **'Within'**

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. This name-value pair is applicable to contents that are a numeric type.

**Default:** (empty)

## Properties

### IgnoreCase

Indicator whether the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'.

### IgnoreWhitespace

Indicator whether the comparator is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'.

### Recursive

Indicator of whether comparator operates recursively, specified in the name-value pair argument, 'Recursively'.

### Tolerance

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Concepts

# matlab.unittest.constraints.Throws

---

**Superclasses**    Constraint

**Purpose**            Constraint specifying function handle that throws MException

**Description**      The Throws class creates a constraint that is not satisfied by any value that is not a function handle that throws a specific exception.

If an MException is thrown by the function handle and the ExpectedException property is an error identifier, a qualification failure occurs if the actual MException thrown has a different identifier. Alternately, if the ExpectedException property is a meta.class, the constraint is not satisfied if the actual MException thrown does not derive from the ExpectedException.

**Construction**      outConstObj = Throws(excep) provides a constraint, outConstObj, specifying a function handle that throws a particular MException, excep.

outConstObj = Throws(excep, 'WhenNargoutIs', numOutputs) creates a constraint specifying that a constraint throws a certain MException when invoked with a particular number of output arguments, numOutputs.

## Input Arguments

### excep

Error identifier or meta.class representing the specific type of exception that is expected to be thrown. The Throws constructor throws an MException if excep is a meta.class but does not derive from MException.

### numOutputs

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

**Default:** 0

## Properties

### ExpectedException

Expected MException identifier or class. This property is read only and can only be set through the constructor via the `except` input argument.

### Nargout

Number of output arguments the instance uses when executing functions. This property is set through the constructor via the `numOutputs` input argument.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Instantiate Throws Constraint

```
import matlab.unittest.constraints.Throws;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%%%%%%%%%

% By identifier
testCase.verifyThat(@() error('SOME:error:id','Error!'), Throws('SOME:'));

% By class
testCase.verifyThat(@() error('SOME:error:id','Error!'), Throws(?MException));

% With a certain number of outputs
testCase.verifyThat(@() disp('hi'), Throws('MATLAB:maxlhs','WhenNargout'));

% Failing scenarios
%%%%%%%%%%
% is not a function handle
testCase.verifyThat(5, Throws('some:id'));
```

# matlab.unittest.constraints.Throws

---

```
% does not throw any exception
testCase.verifyThat(@why, Throws(?MException));

% wrong id
testCase.verifyThat(@() error('SOME:id'), Throws('OTHER:id'));

% wrong type
testCase.verifyThat(@testCase.fatalAssertFail, ...
    Throws(?matlab.unittest.qualifications.AssumptionFailedException));
```

## Concepts

- “Message Identifiers”

## Purpose

Abstract interface class for tolerances

## Description

Tolerances define a notion of fuzzy equality for a set of data types and can be plugged in to the IsEqualTo constraint through the `'Within'` name-value pair argument.

Classes which derive from the Tolerance interface class must provide a tolerance definition. This is done via the `satisfiedBy` method. Classes which derive from the Tolerance class also must provide a diagnostic for two compared values which is utilized by the testing framework when the compared values are outside of the allowable tolerance. This is done via the `getDiagnosticFor` method. Finally, classes which derive from the Tolerance class must provide a means to determine which data types are supported by the tolerance. This is done via the `supports` method.

## Methods

<code>getDiagnosticFor</code>	Produce diagnostic for two values specified to be within tolerance
<code>satisfiedBy</code>	Determine whether two values are within tolerance
<code>supports</code>	Determine whether tolerance supports specified data type

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Concepts

# matlab.unittest.constraints.Tolerance.getDiagnosticFor

---

**Purpose** Produce diagnostic for two values specified to be within tolerance

**Syntax** `diag = getDiagnosticFor(tolObj,actVal,expVal)`

**Description** `diag = getDiagnosticFor(tolObj,actVal,expVal)` produces a diagnostic, `diag`, for a value, `actVal`, evaluated against another value, `expVal`, within the tolerance defined by `tolObj`. When creating a custom tolerance, the class author must implement the `getDiagnosticFor` method so that it analyzes the two values, `actVal` and `expVal`, against the tolerance, `tolObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, this diagnostic is used when the `getDiagnosticFor` method of `IsEqualTo` is invoked, and the result is incorporated into the diagnostic output of the `IsEqualTo` constraint.

## Input Arguments

### **actVal**

Value to determine if is within tolerance of `expVal`

### **tolObj**

Tolerance instance

### **expVal**

Expected value

## See Also

`supports` | `satisfiedBy` | `Diagnostic` | `ConstraintDiagnostic` |

**Purpose** Determine whether two values are within tolerance

**Syntax** `TF = satisfiedBy(tolObj,actVal,expVal)`

**Description** `TF = satisfiedBy(tolObj,actVal,expVal)` determines whether two values, `actVal` and `expVal`, are within the tolerance defined by `tolObj`. The `satisfiedBy` method is used to determine whether the tolerance is met. It returns `true` or `false` (logical 0 or 1). When creating a custom tolerance, a class author uses this method to contain the tolerance definition.

**Input Arguments**

**actVal**

Value to determine if is within tolerance of `expVal`

**tolObj**

Tolerance instance

**expVal**

Expected value

**See Also** `getDiagnosticFor` | `supports` |

# matlab.unittest.constraints.Tolerance.supports

---

<b>Purpose</b>	Determine whether tolerance supports specified data type
<b>Syntax</b>	<code>TF = supports(tolObj,typeVal)</code>
<b>Description</b>	<p><code>TF = supports(tolObj,typeVal)</code> determines whether the tolerance supports a specific data type. It returns <code>true</code> or <code>false</code> (logical 0 or 1).</p> <p>The <code>supports</code> method provides the ability for a tolerance author to specify support for data types. Generally, the method operates by examining the type of <code>typeVal</code> to determine whether it is supported.</p>
<b>Input Arguments</b>	<p><b>tolObj</b> Tolerance instance</p> <p><b>typeVal</b> Value used to determine tolerance support</p>
<b>See Also</b>	<code>getDiagnosticFor</code>   <code>satisfiedBy</code>

**Purpose** Grayscale colormap for contrast enhancement

**Syntax**  
`cmap = contrast(X)`  
`cmap = contrast(X,m)`

**Description** The `contrast` function enhances the contrast of an image. It creates a new gray colormap, `cmap`, that has an approximately equal intensity distribution. All three elements in each row are identical.

`cmap = contrast(X)` returns a gray colormap that is the same length as the current colormap. If there are NaN or Inf elements in `X` the length of the colormap increases.

`cmap = contrast(X,m)` returns an `m`-by-3 gray colormap.

**Examples** Add contrast to the clown image defined by `X`.

```
load clown;  
cmap = contrast(X);  
image(X);  
colormap(cmap);
```

**See Also** `brighten` | `colormap` | `image`

# conv

---

**Purpose** Convolution and polynomial multiplication

**Syntax**  
`w = conv(u,v)`  
`w = conv(..., 'shape')`

**Description** `w = conv(u,v)` convolves vectors `u` and `v`. Algebraically, convolution is the same operation as multiplying the polynomials whose coefficients are the elements of `u` and `v`.

`w = conv(..., 'shape')` returns a subsection of the convolution, as specified by the `shape` parameter:

<code>full</code>	Returns the full convolution (default).
<code>same</code>	Returns the central part of the convolution of the same size as <code>u</code> .
<code>valid</code>	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, <code>length(w)</code> is <code>max(length(u)-max(0,length(v)-1),0)</code> .

**Definitions** Let  $m = \text{length}(u)$  and  $n = \text{length}(v)$ . Then  $w$  is the vector of length  $m+n-1$  whose  $k$ th element is

$$w(k) = \sum_j u(j)v(k-j+1)$$

The sum is over all the values of  $j$  which lead to legal subscripts for  $u(j)$  and  $v(k+1-j)$ , specifically  $j = \max(1, k+1-n) : \min(k, m)$ . When  $m = n$ , this gives

`w(1) = u(1)*v(1)`  
`w(2) = u(1)*v(2)+u(2)*v(1)`  
`w(3) = u(1)*v(3)+u(2)*v(2)+u(3)*v(1)`  
...  
`w(n) = u(1)*v(n)+u(2)*v(n-1)+ ... +u(n)*v(1)`  
...

$$w(2*n-1) = u(n)*v(n)$$

**See Also**

`conv2` | `convn` | `deconv` | `filter` | `convmtx` | `xcorr`

# conv2

---

**Purpose** 2-D convolution

**Syntax**  
`C = conv2(A,B)`  
`C = conv2(h1,h2,A)`  
`C = conv2(...,shape)`

**Description** `C = conv2(A,B)` computes the two-dimensional convolution of matrices *A* and *B*. If one of these matrices describes a two-dimensional finite impulse response (FIR) filter, the other matrix is filtered in two dimensions. The size of *C* is determined as follows: if  $[ma,na] = \text{size}(A)$ ,  $[mb,nb] = \text{size}(B)$ , and  $[mc,nc] = \text{size}(C)$ , then  $mc = \max([ma+mb-1, ma, mb])$  and  $nc = \max([na+nb-1, na, nb])$ .

`C = conv2(h1,h2,A)` first convolves *A* with the vector *h1* along the rows and then with the vector *h2* along the columns. The size of *C* is determined as follows: if  $n1 = \text{length}(h1)$  and  $n2 = \text{length}(h2)$ , then  $mc = \max([ma+n1-1, ma, n1])$  and  $nc = \max([na+n2-1, na, n2])$ .

`C = conv2(...,shape)` returns a subsection of the two-dimensional convolution, as specified by the *shape* parameter:

'full'	Returns the full two-dimensional convolution (default).
'same'	Returns the central part of the convolution of the same size as <i>A</i> .
'valid'	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, $\text{size}(C) = \max([ma - \max(0, mb - 1), na - \max(0, nb - 1)], 0)$ .

---

**Note** All numeric inputs to `conv2` must be of type `double` or `single`.

---

**Algorithms** `conv2` uses a straightforward formal implementation of the two-dimensional convolution equation in spatial form. If *a* and *b* are

functions of two discrete variables,  $n_1$  and  $n_2$ , then the formula for the two-dimensional convolution of  $a$  and  $b$  is

$$c(n_1, n_2) = \sum_{k_1=-\infty}^{\infty} \sum_{k_2=-\infty}^{\infty} a(k_1, k_2) b(n_1 - k_1, n_2 - k_2)$$

In practice however, `conv2` computes the convolution for finite intervals.

Note that matrix indices in MATLAB software always start at 1 rather than 0. Therefore, matrix elements  $A(1, 1)$ ,  $B(1, 1)$ , and  $C(1, 1)$  correspond to mathematical quantities  $a(0, 0)$ ,  $b(0, 0)$ , and  $c(0, 0)$ .

## Examples

### Example 1

For the 'same' case, `conv2` returns the central part of the convolution. If there are an odd number of rows or columns, the "center" leaves one more at the beginning than the end.

This example first computes the convolution of  $A$  using the default ('full') shape, then computes the convolution using the 'same' shape. Note that the array returned using 'same' corresponds to the red highlighted elements of the array returned using the default shape.

```
A = rand(3);
B = rand(4);
C = conv2(A,B) % C is 6-by-6
```

```
C =
    0.1838    0.2374    0.9727    1.2644    0.7890    0.3750
    0.6929    1.2019    1.5499    2.1733    1.3325    0.3096
    0.5627    1.5150    2.3576    3.1553    2.5373    1.0602
    0.9986    2.3811    3.4302    3.5128    2.4489    0.8462
    0.3089    1.1419    1.8229    2.1561    1.6364    0.6841
    0.3287    0.9347    1.6464    1.7928    1.2422    0.5423
```

```
Cs = conv2(A,B,'same') % Cs is the same size as A: 3-by-3
Cs =
    2.3576    3.1553    2.5373
```

```
3.4302  3.5128  2.4489
1.8229  2.1561  1.6364
```

## Example 2

In image processing, the Sobel edge finding operation is a two-dimensional convolution of an input array with the special matrix

```
s = [1 2 1; 0 0 0; -1 -2 -1];
```

These commands extract the horizontal edges from a raised pedestal.

```
A = zeros(10);
A(3:7,3:7) = ones(5);
H = conv2(A,s);
mesh(H)
```

Transposing the filter `s` extracts the vertical edges of `A`.

```
V = conv2(A,s');  
figure, mesh(V)
```

This figure combines both horizontal and vertical edges.

```
figure  
mesh(sqrt(H.^2 + V.^2))
```

## See Also

[conv](#) | [convn](#) | [filter2](#) | [xcorr2](#)

**Purpose** Convex hull

---

**Note** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `convhull`.

---

**Syntax**

```
K = convhull(X,Y)
K = convhull(X,Y,Z)
K = convhull(X)
K = convhull(...,'simplify', logicalvar)
[K,V] = convhull(...)
```

**Definitions** `convhull` returns the convex hull of a set of points in 2-D or 3-D space.

**Description** `K = convhull(X,Y)` returns the 2-D convex hull of the points (X,Y), where X and Y are column vectors. The convex hull K is expressed in terms of a vector of point indices arranged in a counterclockwise cycle around the hull.

`K = convhull(X,Y,Z)` returns the 3-D convex hull of the points (X,Y,Z), where X, Y, and Z are column vectors. K is a triangulation representing the boundary of the convex hull. K is of size `mtri-by-3`, where `mtri` is the number of triangular facets. That is, each row of K is a triangle defined in terms of the point indices.

`K = convhull(X)` returns the 2-D or 3-D convex hull of the points X. This variant supports the definition of points in matrix format. X is of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . The output facets are equivalent to those generated by the 2-input or 3-input calling syntax.

`K = convhull(...,'simplify', logicalvar)` provides the option of removing vertices that do not contribute to the area/volume of the convex hull, the default is false. Setting 'simplify' to true returns the topology in a more concise form.

# convhull

`[K,V] = convhull(...)` returns the convex hull `K` and the corresponding area/volume `V` bounded by `K`.

**Visualization** Use `plot` to plot the output of `convhull` in 2-D. Use `trisurf` or `trimesh` to plot the output of `convhull` in 3-D.

## Examples **Example 1**

```
xx = -1:.05:1; yy = abs(sqrt(xx));  
[x,y] = pol2cart(xx,yy);  
k = convhull(x,y);  
plot(x(k),y(k),'r-',x,y,'b+')
```

<b>Purpose</b>	N-D convex hull
<b>Syntax</b>	<pre>K = convhulln(X) K = convhulln(X, options) [K, v] = convhulln(...)</pre>
<b>Description</b>	<p><code>K = convhulln(X)</code> returns the indices <code>K</code> of the points in <code>X</code> that comprise the facets of the convex hull of <code>X</code>. <code>X</code> is an <code>m</code>-by-<code>n</code> array representing <code>m</code> points in <code>N</code>-dimensional space. If the convex hull has <code>p</code> facets then <code>K</code> is <code>p</code>-by-<code>n</code>.</p> <p><code>convhulln</code> uses <code>Qhull</code>.</p> <p><code>K = convhulln(X, options)</code> specifies a cell array of strings <code>options</code> to be used as options in <code>Qhull</code>. The default options are:</p> <ul style="list-style-type: none"><li>• <code>{'Qt'}</code> for 2-, 3-, and 4-dimensional input</li><li>• <code>{'Qt', 'Qx'}</code> for 5-dimensional input and higher.</li></ul> <p>If <code>options</code> is <code>[]</code>, the default options are used. If <code>options</code> is <code>{''}</code>, no options are used, not even the default. For more information on <code>Qhull</code> and its options, see <a href="http://www.qhull.org/">http://www.qhull.org/</a>.</p> <p><code>[K, v] = convhulln(...)</code> also returns the volume <code>v</code> of the convex hull.</p>
<b>Visualization</b>	<p>Plotting the output of <code>convhulln</code> depends on the value of <code>n</code>:</p> <ul style="list-style-type: none"><li>• For <code>n = 2</code>, use <code>plot</code> as you would for <code>convhull</code>.</li><li>• For <code>n = 3</code>, you can use <code>trisurf</code> to plot the output. The calling sequence is</li></ul> <pre>K = convhulln(X); trisurf(K,X(:,1),X(:,2),X(:,3))</pre> <ul style="list-style-type: none"><li>• You cannot plot <code>convhulln</code> output for <code>n &gt; 3</code>.</li></ul>
<b>Examples</b>	The following example illustrates the options input for <code>convhulln</code> . The following commands

# convhulln

---

```
X = [0 0; 0 1e-10; 0 0; 1 1];  
K = convhulln(X)
```

return a warning.

```
Warning: qhull precision warning:  
The initial hull is narrow  
(cosine of min. angle is 0.9999999999999998).  
A coplanar point may lead to a wide facet.  
Options 'QbB' (scale to unit box) or 'Qbb'  
(scale last coordinate) may remove this warning.  
Use 'Pp' to skip this warning.
```

To suppress the warning, use the option 'Pp'. The following command passes the option 'Pp', along with the default 'Qt', to convhulln.

```
K = convhulln(X,{'Qt','Pp'})
```

```
K =
```

```
   1   4  
   1   2  
   4   2
```

## Algorithms

convhulln is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>. For copyright information, see <http://www.qhull.org/COPYING.txt>.

# matlab.mixin.CustomDisplay

---

**Purpose** Display customization interface class

**Description** This class provides an interface for customizing the MATLAB display of objects. Derive your class from `matlab.mixin.CustomDisplay` to add the custom display functionality to your class.

`matlab.mixin.CustomDisplay` implements three public sealed methods. `disp` and `display` provide a simple object display. The `details` method provides a standard formal display of object information.

For customizing object display, `matlab.mixin.CustomDisplay` defines a number of protected methods that you can override in your subclass. By overriding specific methods, you can customize specific aspects of the object display.

## Methods

<code>convertDimensionsToString</code>	Return array dimensions as string
<code>details</code>	Fully detailed formal object display
<code>disp</code>	Simple informal object display
<code>display</code>	Print variable name and display object
<code>displayEmptyObject</code>	Display for empty object arrays
<code>displayNonScalarObject</code>	Display format for non-scalar objects
<code>displayPropertyGroups</code>	Display titles and property groups as defined
<code>displayScalarHandleToDeletedObject</code>	Display format for deleted scalar handles
<code>displayScalarObject</code>	Display format for scalar objects
<code>getClassNameForHeader</code>	Return class name for display

<code>getDeletedHandleText</code>	Returns text for handle to deleted object display
<code>getDetailedFooter</code>	Returns default detailed footer for object display
<code>getDetailedHeader</code>	Returns default detailed header for object display
<code>getFooter</code>	Build and return display footer text
<code>getHandleText</code>	Return string 'handle' with link to documentation
<code>getHeader</code>	Build and return display header text
<code>getPropertyGroups</code>	Construct array of property groups
<code>getSimpleHeader</code>	Return simple header for object display

## Attributes

Abstract	This class defines an interface that subclasses inherit. You cannot instantiate this class.
HandleCompatible	You can use this class to derive both handle and value classes.

**See Also** [matlab.mixin.util.PropertyGroup](#) |

## Related Examples

- “Custom Display Interface”

# matlab.mixin.CustomDisplay.convertDimensionsToString

**Purpose** Return array dimensions as string

**Syntax**

```
dimstr =  
matlab.mixin.CustomDisplay.convertDimensionsToString(  
    obj)
```

**Description** `dimstr = matlab.mixin.CustomDisplay.convertDimensionsToString(obj)` converts a size vector into a properly formatted string of dimensions for the nonscalar header.

**Input Arguments**

**obj**  
MATLAB object

**Output Arguments**

**dimstr**  
String representing the object's dimensions as determined by calling `size`.

**Attributes**

Static	true
Access	Protected
Sealed	true
Hidden	true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

**See Also** [matlab.mixin.CustomDisplay.getHeader](#) |

**Related Examples**

- “Custom Display Interface”

**Purpose** Fully detailed formal object display

**Syntax** `details(obj)`

**Description** `details(obj)` displays the detailed state of `obj`. The detailed display is not affected by customizations made to classes derived from `matlab.mixin.CustomDisplay`.

## Attributes

Access = public	You can call <code>details</code> on any object that is a class derived from <code>matlab.mixin.CustomDisplay</code> .
Sealed	You cannot override the <code>details</code> method in your subclass of <code>matlab.mixin.CustomDisplay</code> .

## Input Arguments

**obj**

Instance of a class derived from `matlab.mixin.CustomDisplay`.

**Default:** none

## Examples

Suppose `EmployeeInfo` is a subclass of `matlab.mixin.CustomDisplay`

```
details(e1)
```

`EmployeeInfo` handle with properties:

```
Name: 'Bill Tork'  
JobTitle: 'Software Engineer'  
Department: 'Product Development'  
Salary: 1000  
Password: 'bill123'
```

[Methods, Events, Superclasses](#)

# matlab.mixin.CustomDisplay.details

---

## See Also

disp | display |

## Related Examples

- “Custom Display Interface”

**Purpose** Simple informal object display

**Syntax** `disp(obj)`

**Description** `disp(obj)` displays the contents of `obj` in one of four simple formats, based on the state of `obj`.

- Handle to deleted object
- Empty object array
- Scalar
- Nonscalar

To customize a display format, override one or more of the four handler methods.

## Input Arguments

**obj**

Object of a class derived from `matlab.mixin.CustomDisplay`

## Attributes

Access	public
Sealed	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

# matlab.mixin.CustomDisplay.display

---

**Purpose** Print variable name and display object

**Syntax** `display(obj)`

**Description** `display(obj)` prints the name of input argument `obj` as it appears in the workspace of the caller. If there is no assignment to a variable, `display` uses, `ans`. `display` then calls the `disp` method to print the object.

**Input Arguments**

**obj**  
Object array of a class derived from `matlab.mixin.CustomDisplay`

## Attributes

Access	public
Sealed	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

**See Also** `disp` | `details` |

**Related Examples**

- “Custom Display Interface”

# matlab.mixin.CustomDisplay.displayEmptyObject

---

**Purpose** Display for empty object arrays

**Syntax** `displayEmptyObject(obj)`

**Description** `displayEmptyObject(obj)` is called by `disp` when the object, `obj`, is empty. An object array is empty if one or more of its dimensions are zero. An empty object array is never scalar.

The default display of an empty object consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayEmptyObject` shows only those properties with `public GetAccess` and `Hidden` set to `false`.

Override this method to customize the appearance of an empty object array.

**Input Arguments**

**obj**  
Object of a class derived from `matlab.mixin.CustomDisplay`

**Attributes**

Access protected

`matlab.mixin.CustomDisplay.displayScalarHandleToDeletedObject` |

**Related Examples**

- “Custom Display Interface”

# matlab.mixin.CustomDisplay.displayNonScalarObject

---

**Purpose** Display format for non-scalar objects

**Syntax** `displayNonScalarObject(obj)`

**Description** `displayNonScalarObject(obj)` is called by the `disp` method when the object, `obj`, is nonscalar (`prod(size(obj)) > 1`)

The default display of a nonscalar object array consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayNonScalarObject` shows only those properties with public `GetAccess` and `Hidden` set to `false`.

Override this method to customize the display a nonscalar object array.

**Input Arguments**

**obj**  
Object array of a class derived from `matlab.mixin.CustomDisplay`

**Attributes**

Access protected

# matlab.mixin.CustomDisplay.displayScalarHandleToDeletedOb

**Purpose** Display format for deleted scalar handles

**Syntax** `displayScalarHandleToDeletedObject(obj)`

**Description** `displayScalarHandleToDeletedObject(obj)` is called by the `disp` method when `obj` is:

- An instance of a handle class
- Scalar
- A handle to a deleted object

That is, the following expression is true.

```
isa(obj, 'handle') && isscalar(obj) && ~isvalid(obj)
```

Override this method to customize the appearance of your object's display when it is deleted.

**Input Arguments** **obj**  
Object of a class derived from `matlab.mixin.CustomDisplay`

**Attributes**

<b>Purpose</b>	Construct array of property groups
<b>Syntax</b>	<code>groups = getPropertyGroups(obj)</code>
<b>Description</b>	<p><code>groups = getPropertyGroups(obj)</code> returns an array of <code>matlab.mixin.util.PropertyGroup</code> objects. MATLAB displays property groups separated by blank spaces.</p> <p>Each default display state handler method calls this method once. The default implementation returns the properties in one group. These properties must have public <code>GetAccess</code> and not be defined as <code>Hidden</code>. If the object is scalar, MATLAB includes dynamic properties.</p> <p>Override this method to construct one or more customized groups of properties to display.</p> <p>Each group object array has the following fields:</p> <ul style="list-style-type: none"><li>• <b>Title</b> — String used as the header for the property group or an empty string if no title is used.</li><li>• <b>PropertyList</b> — The property list can be either:<ul style="list-style-type: none"><li>▪ A 1-by-1 struct of property name-property value pairs</li><li>▪ A cell array of string property names.</li></ul></li></ul> <p>Use the struct of name-value pairs if the object is scalar and you want to assign custom property values. Otherwise, use a cell array of string property names. If the object is scalar MATLAB adds the property values retrieved from the object.</p>
<b>Input Arguments</b>	<p><b>obj</b></p> <p>Object array of a class derived from <code>matlab.mixin.CustomDisplay</code></p>
<b>Output Arguments</b>	<p><b>groups</b></p> <p>1xN array of <code>matlab.mixin.util.PropertyGroup</code> objects, where N is the number of groups</p>

# matlab.mixin.CustomDisplay.getPropertyGroups

---

## Examples

### Custom Property Group

Customize the values returned by some properties.

Write a `getPropertyGroups` method.

```
methods (Access = protected)
    function propgrp = getPropertyGroups(obj)
        if ~isscalar(obj)
            propgrp = getPropertyGroups@matlab.mixin.CustomDisplay(obj);
        else
            pd(1:length(obj.Password)) = '*';
            propList = struct('Department',obj.Department,...
                'JobTitle',obj.JobTitle,...
                'Name',obj.Name,...
                'Salary','Not available',...
                'Password',pd);
            propgrp = matlab.mixin.util.PropertyGroup(propList);
        end
    end
end
```

Add function to class definition.

**Related Examples**

- “Custom Display Interface”

# matlab.mixin.Copyable

---

**Purpose** Superclass providing copy functionality for handle objects

**Description** The `matlab.mixin.Copyable` class is an abstract handle class that provides a `copy` method for copying handle objects. The `copy` method makes a shallow copy of the object (that is, it shallow copies all non-dependent properties from the source to the destination object). In making a shallow copy, MATLAB does not call `copy` recursively on any handles contained in property values.

Subclass `matlab.mixin.Copyable` when you want to define handles classes that inherit a `copy` method. The `copy` method:

- Copies data without calling class constructors or property set functions and therefore produces no side effects.
- Enables subclasses to customize the copy behavior

## Customizing Subclass Copy Behavior

The `copy` method provides the public, non-overrideable interface to copy behavior. `copy` takes an array of objects as input and returns an array of the same shape and dimensions.

`copyElement` is a protected method that the `copy` method uses to perform the copy operation on each object in the input array. `copyElement` is not `Sealed` so you can override it in your subclass to customize the behavior of the inherited `copy` method.

## Implementing a Selective Deep Copy

This example overrides the `copyElement` method in a subclass of `matlab.mixin.Copyable` to implement a deep copy of a specific class of handle objects.

Consider the following classes:

- `ContainsHandles` — subclass of `matlab.mixin.Copyable` that contains handle objects in two properties
- `DeepCp` — subclass of `matlab.mixin.Copyable`
- `ShallowCp` — subclass of `handle`

Here are the simplified class definitions:

```
classdef ContainsHandles < matlab.mixin.Copyable
    properties
        Prop1
        Prop2
        DeepObj    % Contains a DeepCp object
        ShallowObj % Contains a ShallowCp object
    end
    methods
        function obj = ContainsHandles(val1, val2, deepobj, shallowobj)
            if nargin > 0
                obj.Prop1 = val1;
                obj.Prop2 = val2;
                obj.DeepObj = deepobj;
                obj.ShallowObj = shallowobj;
            end
        end
    end
    methods(Access = protected)
        % Override copyElement method:
        function cpObj = copyElement(obj)
            % Make a shallow copy of all four properties
            cpObj = copyElement@matlab.mixin.Copyable(obj);
            % Make a deep copy of the DeepCp object
            cpObj.DeepObj = copy(obj.DeepObj);
        end
    end
end
```

The DeepCp class derives from matlab.mixin.Copyable:

```
classdef DeepCp < matlab.mixin.Copyable
    properties
        DpProp
    end
    methods
        function obj = DeepCp(val)
```

# matlab.mixin.Copyable

---

```
        ...
    end
end
end
```

The handle class `ShallowCp` does not derive from `matlab.mixin.Copyable` and, therefore, has no copy method:

```
classdef ShallowCp < handle
    properties
        ShProp
    end
    methods
        function obj = ShallowCp(val)
            ...
        end
    end
end
```

Create a `ContainsHandles` object, which contains the two handle objects in its `DpProp` and `ShProp` properties:

```
>> sc = ShallowCp(7);
>> dc = DeepCp(7);
>> a = ContainsHandles(4,5,dc,sc);
>> a.DeepObj
ans =
```

DeepCp with properties:

```
    DpProp: 7
>> a.ShallowObj.ShProp
ans =
```

ShallowCp with properties:

```
    ShProp: 7
```

Make a copy of the ContainsHandles object:

```
>> b = copy(a);
```

The returned copy `b` contains a shallow copy of object `sc`, and a deep copy of object `dc`. That is, the `dc` object passed to `ContainsHandles` constructor is now a new, independent objects as a result of the copy operation. You can now change the `dc` object without affecting the copy. This is not the case for the shallow copied object, `sc`:

```
% Change the property values of the handle objects:
```

```
>> sc.ShProp = 5;
```

```
>> dc.DpProp = 5;
```

```
% Note that the deep copied object is not affected:
```

```
>> b.DeepObj
```

```
ans =
```

```
DeepCp with properties:
```

```
DpProp: 7
```

```
% The shallow copied object is still referencing the same data:
```

```
>> b.ShallowObj
```

```
ans =
```

```
ShallowCp with properties:
```

```
ShProp: 5
```

## Overriding Copy Behavior in Hierarchies

The `copyElement` method in a superclass cannot access the private data in a subclass.

If you override `copyElement` in a subclass of `matlab.mixin.Copyable`, and then use this subclass as a superclass, you need to override `copyElement` in all subclasses that contain private properties. The

# matlab.mixin.Copyable

---

override of copyElement in subclasses should call the copyElement in the respective superclass, as in the previous example.

The following simplified code demonstrates this approach:

```
classdef SuperClass < matlab.mixin.Copyable
    properties(Access = private)
        super_prop
    end
    methods
        ...

        function cpObj = copyElement(obj)
            ...
            cpObj = copyElement@matlab.mixin.Copyable(obj);
            ...
        end
    end
end

classdef SubClass1 < SuperClass
    properties(Access=private)
        sub_prop1
    end
    methods
        function cpObj = copyElement(obj)
            % Copy super_prop
            cpObj = copyElement@SuperClass(obj);
            % Copy sub_prop1 in subclass
            % Assignment can introduce side effects
            cpObj.sub_prop1 = obj.sub_prop1;
        end
    end
end
```

The override of `copyElement` in `SubClass1` copies the private subclass property because the superclass cannot access private data in the subclass.

---

**Note** The assignment of `sub_prop1` in the override of `copyElement` in `SubClass1` calls the property set method, if one exists, possibly introducing side effects to the copy operation.

---

### Copy Behaviors for Specific Inputs

Given a call to the `matlab.mixin.Copyable` `copy` method of the form:

```
B = copy(A);
```

Under the following conditions, produces the described results:

- A has dynamic properties — `copy` does not copy dynamic properties. You can implement dynamic-property copying in the subclass if needed.
- A has no non-Dependent properties — `copy` creates a new object with no property values without calling the class constructor to avoid introducing side effects.
- A contains deleted handles — `copy` creates deleted handles of the same class in the output array.
- A has attached listeners — `copy` does not copy listeners.
- A contains objects of enumeration classes — Enumeration classes cannot subclass `matlab.mixin.Copyable`.
- A `delete` method calls `copy` — `copy` creates a legitimate copy, obeying all the behaviors that apply in any other usage.

# matlab.mixin.Copyable

---

---

**Note** You cannot derive an enumeration class from `matlab.mixin.Copyable` because the number of instances you can create are limited to the ones defined inside the enumeration block. See “Working with Enumerations” for more information about enumeration classes.

---

## Methods

`copy` Copy array of handle objects

## Definitions

### Deep Copy

Copy each property value and assign it to the new (copied) property. Recursively copy property values that reference handle objects to copy all of the underlying data.

### Shallow Copy

Copy each property value and assign it to the new (copied) property. If a property value is a handle, copy the handle but not the underlying data.

## Attributes

# matlab.mixin.Copyable.copy

---

## Attributes

Sealed true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.Copyable` | `handle` | `copyElement`

**Purpose**

Copy file or folder

**Syntax**

```
copyfile('source','destination')
copyfile('source','destination','f')
[status] = copyfile(___)
[status, message] = copyfile(___)
[status,message,messageid] = copyfile(___)
```

**Description**

`copyfile('source','destination')` copies the file or folder named `source` to the file or folder `destination`. The values for `source` and `destination` are 1 x n strings. Use full path names or path names relative to the current folder. To copy multiple files or folders, use one or more wildcard characters (\*) after the last file separator in `source`. You cannot use a wildcard character in `destination`.

`copyfile('source','destination','f')` copies `source` to `destination`, even when `destination` is not writable. The state of the read-write attribute for `destination` does not change. You can use `f` with any syntax for `copyfile`.

`[status] = copyfile(___)` reports the outcome as a logical scalar, `status`. The value is 1 for success and 0 for failure.

`[status, message] = copyfile(___)` returns any warning or error message as a string to `message`. When `copyfile` succeeds, `message` is an empty string.

`[status,message,messageid] = copyfile(___)` returns any warning or error identifier as a string to `messageId`. When `copyfile` succeeds, `messageId` is an empty string.

**Tips**

- The timestamp for `destination` is the same as the timestamp for `source`.
- When `source` is a folder, `destination` must be a folder.
  - When `source` is a folder and `destination` does not exist, `copyfile` creates `destination` and copies the contents of `source` into `destination`.

- When source is a folder and destination is an existing folder, copyfile copies the contents of source into destination.
- When source is multiple files and destination does not exist, copyfile creates destination.

## Examples

### Copy File to Another Folder

Copy myFun.m from the current folder to d:/work/Projects/.

```
copyfile('myFun.m', 'd:/work/Projects/')
```

### Copy File to Its Current Folder

Copy myFun.m in the current folder, assigning it the name myFun2.m.

```
copyfile('myFun.m', 'myFun2.m')
```

### Copy Files and Folders to a New Folder Using Wildcards

Copy files and subfolders whose names begin with my, from the Projects subfolder within the current folder to the folder newProjects, which is at the same level as the current folder:

```
copyfile('Projects/my*', '../newProjects/')
```

### Copy Files to a New, Nonexistent Folder

Copy the contents of the Projects subfolder within the current folder to the I:/work/newProjects folder, where newProjects does not exist.

```
copyfile('Projects', 'I:/work/newProjects')
```

### Copy File that Overwrites a Read-Only File

Copy the contents of myFun.m from the current folder to d:/work/restricted/myFun2.m, where myFun2.m is read-only.

```
[status,message,messageId]=copyfile('myFun.m', ...  
'd:/work/restricted/myFun2.m', 'f')
```

```
status =  
    1
```

```
message =  
    ''  
  
messageId =  
    ''
```

The status of 1 and empty `message` and `messageId` strings confirm the copy was successful.

## How To

- “Path Names in MATLAB”
- “Creating, Opening, Changing, and Deleting Files and Folders”

# copyobj

---

**Purpose** Copy graphics objects and their descendants

**Syntax** `new_handle = copyobj(h,p)`

**Description** `copyobj` creates copies of graphics objects. The copies are identical to the original objects except the copies have different values for their Parent property and a new handle. The new parent must be appropriate for the copied object (e.g., you can copy a line object only to another axes object).

`new_handle = copyobj(h,p)` copies one or more graphics objects identified by `h` and returns the handle of the new object or a vector of handles to new objects. The new graphics objects are children of the graphics objects specified by `p`.

**Tips** `h` and `p` can be scalars or vectors. When both are vectors, they must be the same length, and the output argument, `new_handle`, is a vector of the same length. In this case, `new_handle(i)` is a copy of `h(i)` with its Parent property set to `p(i)`.

When `h` is a scalar and `p` is a vector, `h` is copied once to each of the parents in `p`. Each `new_handle(i)` is a copy of `h` with its Parent property set to `p(i)`, and `length(new_handle)` equals `length(p)`.

When `h` is a vector and `p` is a scalar, each `new_handle(i)` is a copy of `h(i)` with its Parent property set to `p`. The length of `new_handle` equals `length(h)`.

When programming a GUI, do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

**Examples** Copy a surface to a new axes within a different figure.

```
h = surf(peaks);  
colormap hot  
figure % Create a new figure
```

```
axes      % Create an axes object in the figure
new_handle = copyobj(h,gca);
colormap hot
view(3)
grid on
```

Note that while the surface is copied, the `colormap` (figure property), `view`, and `grid` (axes properties) are not copied.

`findobj` | `gcf` | `gca` | `gco` | `get` | `set`

# corrcoef

---

**Purpose** Correlation coefficients

**Syntax**

```
R = corrcoef(X)
R = corrcoef(x,y)
[R,P]=corrcoef(...)
[R,P,RLO,RUP]=corrcoef(...)
[...]=corrcoef(...,'param1',val1,'param2',val2,...)
```

**Description** `R = corrcoef(X)` returns a matrix `R` of correlation coefficients calculated from an input matrix `X` whose rows are observations and whose columns are variables. The matrix `R = corrcoef(X)` is related to the covariance matrix `C = cov(X)` by

$$R(i,j) = \frac{C(i,j)}{\sqrt{C(i,i)C(j,j)}}.$$

`corrcoef(X)` is the zeroth lag of the normalized covariance function, that is, the zeroth lag of `xcov(x, 'coeff')` packed into a square array.

`R = corrcoef(x,y)` where `x` and `y` are column vectors is the same as `corrcoef([x y])`. If `x` and `y` are not column vectors, `corrcoef` converts them to column vectors. For example, in this case `R=corrcoef(x,y)` is equivalent to `R=corrcoef([x(:) y(:)])`.

`[R,P]=corrcoef(...)` also returns `P`, a matrix of p-values for testing the hypothesis of no correlation. Each p-value is the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero. If `P(i,j)` is small, say less than 0.05, then the correlation `R(i,j)` is significant.

`[R,P,RLO,RUP]=corrcoef(...)` also returns matrices `RLO` and `RUP`, of the same size as `R`, containing lower and upper bounds for a 95% confidence interval for each coefficient.

`[...]=corrcoef(...,'param1',val1,'param2',val2,...)` specifies additional parameters and their values. Valid parameters are the following.

'alpha'	A number between 0 and 1 to specify a confidence level of $100*(1 - \alpha)\%$ . Default is 0.05 for 95% confidence intervals.
'rows'	Either 'all' (default) to use all rows, 'complete' to use rows with no NaN values, or 'pairwise' to compute $R(i, j)$ using rows with no NaN values in either column $i$ or $j$ .

The p-value is computed by transforming the correlation to create a  $t$  statistic having  $n-2$  degrees of freedom, where  $n$  is the number of rows of  $X$ . The confidence bounds are based on an asymptotic normal distribution of  $0.5*\log((1+R)/(1-R))$ , with an approximate variance equal to  $1/(n-3)$ . These bounds are accurate for large samples when  $X$  has a multivariate normal distribution. The 'pairwise' option can produce an  $R$  matrix that is not positive definite.

## Examples

Generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4);      % Uncorrelated data
x(:,4) = sum(x,2);    % Introduce correlation.
[r,p] = corrcoef(x)  % Compute sample correlation and p-values.
[i,j] = find(p<0.05); % Find significant correlations.
[i,j]                % Display their (row,col) indices.
```

```
r =
    1.0000    -0.3566     0.1929     0.3457
   -0.3566     1.0000    -0.1429     0.4461
    0.1929    -0.1429     1.0000     0.5183
    0.3457     0.4461     0.5183     1.0000
```

```
p =
    1.0000    0.0531    0.3072    0.0613
    0.0531    1.0000    0.4511    0.0135
    0.3072    0.4511    1.0000    0.0033
    0.0613    0.0135    0.0033    1.0000
```

# corrcoef

---

```
ans =  
    4    2  
    4    3  
    2    4  
    3    4
```

**Purpose** Cosine of argument in radians

**Syntax**  $Y = \cos(X)$

**Description**  $Y = \cos(X)$  returns the cosine for each element of  $X$ . The `cos` function operates element-wise on arrays. All angles are in radians.

**Examples** Graph the cosine function over the domain  $-\pi \leq x \leq \pi$ :

```
x = -pi:0.01:pi;  
plot(x,cos(x)), grid on
```

**Definitions** **Cosine**

The cosine of an angle is

$$\cos(x) = \frac{e^{ix} + e^{-ix}}{2}.$$

**Cosine of Complex Angle**

For complex values, cosine is

$$\cos(x + iy) = \cos(x)\cosh(y) - i\sin(x)\sinh(y).$$

**Purpose** Hyperbolic cosine

**Syntax**  $Y = \cosh(X)$

**Description** The cosh function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \cosh(X)$  returns the hyperbolic cosine for each element of  $X$ .

**Examples** Graph the hyperbolic cosine function over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;  
plot(x,cosh(x)), grid on
```

## Hyperbolic Cosine

The hyperbolic cosine of  $z$  is

$$\cosh(z) = \frac{e^z + e^{-z}}{2}.$$

# cosh

---

`acosh` | `cos` | `sinh` | `tanh`

**Purpose** Cotangent of argument in radians

**Syntax**  $Y = \cot(X)$

**Description** The cot function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \cot(X)$  returns the cotangent for each element of  $X$ .

**Examples** Graph the cotangent the domains  $-\pi < x < 0$  and  $0 < x < \pi$ .

```
x1 = -pi+0.01:0.01:-0.01;  
x2 = 0.01:0.01:pi-0.01;  
plot(x1,cot(x1),x2,cot(x2)), grid on
```

### Cotangent

The cotangent of  $z$  is

# cot

---

$$\cot(z) = \frac{1}{\tan(z)}.$$

## See Also

[cotd](#) | [coth](#) | [acot](#) | [acotd](#) | [acoth](#)

<b>Purpose</b>	Cotangent of argument in degrees
<b>Syntax</b>	$Y = \text{cotd}(X)$
<b>Description</b>	$Y = \text{cotd}(X)$ returns the cotangent of the elements of $X$ , which are expressed in degrees.
<b>Input Arguments</b>	<p><b>X - Angle in degrees</b>  scalar value   vector   matrix   N-D array</p> <p>Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The <code>cotd</code> operation is element-wise when <math>X</math> is nonscalar.</p> <p><b>Data Types</b>  single   double</p> <p><b>Complex Number Support:</b> Yes</p>
<b>Output Arguments</b>	<p><b>Y - Cotangent of angle</b>  scalar value   vector   matrix   N-D array</p> <p>Cotangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as <math>X</math>.</p>
<b>Examples</b>	<p><b>Cotangent of angles approaching 90 and 180 degrees</b></p> <p>Create a vector of input angles consisting of <math>90^\circ</math> and the next smaller and larger double precision numbers. Then compute the cotangent.</p> <pre>x1 = [90-eps(90) 90 90+eps(90)]; y1 = cotd(x1)</pre> <p>y1 =</p> <pre>1.0e-15 * 0.2480      0      -0.2480</pre>

`cotd` returns zero when the input angle is exactly 90°. Evaluation at the next smaller double-precision angle returns a slightly positive result. Likewise, the cotangent is slightly negative when the input angle is the next double-precision number larger than 90.

The behavior is similar for input angles near 180°.

```
x2 = [180-eps(180) 180 180+eps(180)];  
y2 = cotd(x2)
```

```
y2 =
```

```
1.0e+15 *  
-2.0159      Inf      2.0159
```

## **Cotangent of complex angle, specified in degrees**

```
x = 35+5i;  
y = cotd(x)
```

```
y =
```

```
1.3958 - 0.2606i
```

## **See Also**

<b>Purpose</b>	Count occurrences of categorical array elements by category
<b>Syntax</b>	<pre>B = countcats(A) B = countcats(A,dim)</pre>
<b>Description</b>	<p><code>B = countcats(A)</code> returns the number of elements in each category of the categorical array, <code>A</code>.</p> <ul style="list-style-type: none"><li>• If <code>A</code> is a vector, then <code>countcats</code> returns the number of elements in each category.</li><li>• If <code>A</code> is a matrix, then <code>countcats</code> treats the columns of <code>A</code> as vectors and returns the category counts for each column of <code>A</code>.</li><li>• If <code>A</code> is a multidimensional array, then <code>countcats</code> acts along the first array dimension whose size does not equal 1.</li></ul> <p><code>B = countcats(A,dim)</code> returns the category counts along dimension <code>dim</code>.</p> <p>For example, you can return the category counts of each row in a categorical array using <code>countcats(A,2)</code>.</p>
<b>Input Arguments</b>	<p><b>A - Categorical array</b> vector   matrix   multidimensional array</p> <p>Categorical array, specified as a vector, matrix, or multidimensional array.</p> <p><b>dim - Dimension to operate along</b> positive integer scalar</p> <p>Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.</p> <p>Consider a two-dimensional categorical array, <code>A</code>.</p> <p>If <code>dim = 1</code>, then <code>countcats(A,1)</code> returns the category counts for each column of <code>A</code>.</p>

# countcats

If `dim = 2`, then `countcats(A, 2)` returns the category counts of each row of A.

If `dim` is greater than `ndims(A)`, then `countcats(A)` returns an array the same size as A for each category. `countcats` returns 1 for elements in the corresponding category and 0 otherwise.

## Examples

### Category Counts of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```
plane    car    train    car    plane
```

A has three categories, car, plane, and train.

Find the number of elements in each category of A.

```
B = countcats(A)
```

```
B =
```

```
     2     2     1
```

The first element in B corresponds to the first category of A, which is `car`. The second element in B corresponds to the second category of A, which is `plane`. The third element of B corresponds to the third category of A, which is `train`.

Since A is a row vector, `countcats` returns a row vector.

### Category Counts of Each Column in Array

Create a 3-by-2 categorical array, A, from a numeric array.

```
valueset = 1:3;
```

```
catnames = {'red' 'green' 'blue'};
```

```
A = categorical([1 3; 2 1; 3 1],valueset,catnames)
```

```
A =
```

```
     red     blue
     green    red
     blue     red
```

A has three categories, `red`, `green`, and `blue`.

Find the category counts of each column in A.

```
B = countcats(A)
```

```
B =
```

```
     1     2
     1     0
```

```
1 1
```

The first row of B corresponds to the first category of A. The value, **red**, occurs once in the first column of A and twice in the second column.

The second row of B corresponds to the second category of A. The value, **green**, occurs once in the first column of A, and it does not occur in the second column.

The third row of B corresponds to the third category of A. The value, **blue**, occurs once in the first column of A and once in the second column.

## Category Counts of Each Row in Array

Create a 3-by-2 categorical array, A, from a numeric array.

```
valueset = 1:3;  
catnames = {'red' 'green' 'blue'};  
  
A = categorical([1 3; 2 1; 3 1],valueset,catnames)
```

A =

```
    red    blue  
    green  red  
    blue   red
```

A has three categories, red, green, and blue.

Find the category counts of A along the second dimension.

```
B = countcats(A,2)
```

B =

```
1 0 1  
1 1 0  
1 0 1
```

The first column of **B** corresponds to the first category of **A**. The value, **red**, occurs once in the first row of **A**, once in the second row, and once in the third row.

The second column of **B** corresponds to the second category of **A**. The value, **green**, occurs in only one element. It occurs in the second row of **A**.

The third column of **B** corresponds to the third category of **A**. The value, **blue**, occurs once in the first row of **A** and once in the third row.

### **Category Counts of Array Containing Undefined Elements**

Create a 6-by-1 categorical array, **A**, from a numeric array.

```
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical([1;3;2;1;3;1],valueset,catnames)
```

```
A =

    red
    blue
    green
    red
    blue
    red
```

Remove the **blue** category.

```
A = removecats(A,'blue')
```

```
A =

    red
<undefined>
    green
    red
<undefined>
```

# countcats

---

```
red
```

A has two categories, red and green. Elements of A that were from the blue category are now undefined.

Find the number of elements in each category of A.

```
B = countcats(A)
```

```
B =
```

```
    3  
    1
```

The first element in B corresponds to the first category of A. The value, red, occurs three times in A.

The second element in B corresponds to the second category of A. The value, green, occurs once in A.

countcats does not return any information on undefined elements.

Use the summary function to view the number of undefined elements in addition to the number of elements in each category of A.

```
summary(A)
```

```
red           3  
green        1  
<undefined>  2
```

## Tips

- To find the number of undefined elements in a categorical array, A, you must use `summary` or `isundefined`.

## See Also

`iscategory` | `ismember` | `summary` | `isundefined` | `categories`

**Purpose**

Covariance matrix

**Syntax**

```
C = cov(x)
C = cov(x,y)
C = cov(x,1)
C = cov(x,y,1)
```

**Description**

`C = cov(x)`, if `x` is a vector, returns the variance of `x`. For matrix input `X`, where each row is an observation, and each column is a variable, `cov(X)` is the covariance matrix. `diag(cov(X))` is a vector of variances for each column, and `sqrt(diag(cov(X)))` is a vector of standard deviations. `cov(X,Y)`, where `X` and `Y` are matrices with the same number of elements, is equivalent to `cov([X(:) Y(:)])`.

`C = cov(x)` or `C = cov(x,y)` normalizes by  $N - 1$ , if  $N > 1$ , where  $N$  is the number of observations. This makes `cov(X)` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For  $N = 1$ , `cov` normalizes by  $N$ .

`C = cov(x,1)` or `C = cov(x,y,1)` normalizes by  $N$  and produces the second moment matrix of the observations about their mean. `cov(X,Y,0)` is the same as `cov(X,Y)` and `cov(X,0)` is the same as `cov(X)`.

**Tips**

`cov` removes the mean from each column before calculating the result.

The *covariance* between two random variables is:

$$\text{cov}(x_1, x_2) = E[(x_1 - \mu_1)(x_2 - \mu_2)]$$

where  $E$  is the mathematical expectation and  $\mu_i = E x_i$ .

**Examples**

Consider `A = [-1 1 2 ; -2 3 1 ; 4 0 3]`. To obtain a vector of variances for each column of `A`:

```
v = diag(cov(A))'
v =
    10.3333    2.3333    1.0000
```

Compare vector  $v$  with covariance matrix  $C$  of  $A$ :

$C = \text{cov}(A)$

$C =$

10.3333	-4.1667	3.0000
-4.1667	2.3333	-1.5000
3.0000	-1.5000	1.0000

The diagonal elements  $C(i, i)$  represent the variances for the columns of  $A$ . The off-diagonal elements  $C(i, j)$  represent the covariances of columns  $i$  and  $j$ .

**See Also**

[corrcoef](#) | [mean](#) | [median](#) | [std](#) | [var](#) | [xcorr](#) | [xcov](#)

**Purpose**

Sort complex numbers into complex conjugate pairs

**Syntax**

```
B = cplxpair(A)
B = cplxpair(A,tol)
B = cplxpair(A,[],dim)
B = cplxpair(A,tol,dim)
```

**Description**

`B = cplxpair(A)` sorts the elements along different dimensions of a complex array, grouping together complex conjugate pairs.

The conjugate pairs are ordered by increasing real part. Within a pair, the element with negative imaginary part comes first. The purely real values are returned following all the complex pairs. The complex conjugate pairs are forced to be exact complex conjugates. A default tolerance of  $100 \times \text{eps}$  relative to  $\text{abs}(A(i))$  determines which numbers are real and which elements are paired complex conjugates.

If `A` is a vector, `cplxpair(A)` returns `A` with complex conjugate pairs grouped together.

If `A` is a matrix, `cplxpair(A)` returns `A` with its columns sorted and complex conjugates paired.

If `A` is a multidimensional array, `cplxpair(A)` treats the values along the first non-singleton dimension as vectors, returning an array of sorted elements.

`B = cplxpair(A,tol)` overrides the default tolerance.

`B = cplxpair(A,[],dim)` sorts `A` along the dimension specified by scalar `dim`.

`B = cplxpair(A,tol,dim)` sorts `A` along the specified dimension and overrides the default tolerance.

**Diagnostics**

If there are an odd number of complex numbers, or if the complex numbers cannot be grouped into complex conjugate pairs within the tolerance, `cplxpair` generates the error message

Complex numbers can't be paired.

# cputime

---

**Purpose** Elapsed CPU time

**Syntax** `cputime`

**Description** `cputime` returns the total CPU time (in seconds) used by your MATLAB application from the time it was started. This number can overflow the internal representation and wrap around.

**Tips** Although it is possible to measure performance using the `cputime` function, it is recommended that you use the `timeit` or `tic` and `toc` functions for this purpose exclusively. See [Using tic and toc Versus the cputime Function in the MATLAB Programming Fundamentals documentation](#) for more information.

**Examples** The following code returns the CPU time used to run `surf(peaks(40))`.

```
t = cputime; surf(peaks(40)); e = cputime-t
```

```
e =  
    0.4667
```

**See Also** `clock` | `etime` | `tic` | `timeit` | `toc`

**Purpose** Create random number streams

**Class** RandStream

**Syntax**

```
[s1,s2,...] = RandStream.create('gentype','NumStreams',n)
s = RandStream.create('gentype')
[ ... ] = RandStream.create('gentype', Name, Value,...)
```

**Description**

[s1,s2,...] = RandStream.create('gentype','NumStreams',n) creates n random number streams that use the uniform pseudorandom number generator algorithm specified by `gentype`. The streams are independent in a pseudorandom sense. The streams are not necessarily independent from streams created at other times. `RandStream.list` returns all possible values for `gentype` or see “Choosing a Random Number Generator” in the MATLAB Mathematics documentation for details on generator algorithms.

---

**Note** Multiple streams are not supported by all generator types. Use either the multiplicative lagged Fibonacci generator (`m1fg6331_64`) or the combined multiple recursive generator (`mrg32k3a`) to create multiple streams.

---

`s = RandStream.create('gentype')` creates a single random stream. The `RandStream` constructor is a more concise alternative when you need to create a single stream.

[ ... ] = `RandStream.create('gentype', Name, Value,...)` allows you to specify optional `Name, Value` pairs to control creation of the stream. The parameters are:

## RandStream.create

---

NumStreams	Total number of streams of this type that will be created across sessions or labs. Default is 1.
StreamIndices	Stream indices that should be created in this call. Default is 1:N, where N is the value given with the 'NumStreams' parameter.
Seed	Nonnegative scalar integer with which to initialize all streams. Default is 0. Seeds must be an integer between 0 and $2^{32} - 1$ or 'shuffle' to create a seed based on the current time.
NormalTransform	Transformation algorithm used by randn(S, ...) to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'.
RandnAlg	RandnAlg has been removed. Use NormalTransform instead.  Transformation algorithm used by randn(S, ...) to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'.
CellOutput	Logical flag indicating whether or not to return the stream objects as elements of a cell array. Default is false.

Typically, you call `RandStream.create` once to create multiple independent streams in a single pass. Alternatively, you can create each stream from separate calls to `RandStream.create`, but you must

specify the appropriate values for `gentype`, `'NumStreams'`, `'Seed'`, and `'StreamIndices'` to ensure their independence:

- Specify the same set of values for `gentype`, `'NumStreams'`, and `'Seed'` in each case.
- Specify a different value for `'StreamIndices'` that is between 1 and the `'NumStreams'` value in each case.

## Examples

Create three independent streams.

```
[s1,s2,s3] = RandStream.create('mrg32k3a','NumStreams',3);  
r1 = rand(s1,100000,1);  
r2 = rand(s2,100000,1);  
r3 = rand(s3,100000,1);  
corrcoef([r1,r2,r3])
```

Create one stream from a set of three independent streams and designate it as the global stream.

```
s2 = RandStream.create('mrg32k3a','NumStreams',3,'StreamIndices',2);  
RandStream.setGlobalStream(s2);
```

`RandStream` | `RandStream.list`

# createClassFromWsd1

---

**Purpose** Create MATLAB class based on WSDL document

**Syntax** `createClassFromWsd1(source)`

**Description** `createClassFromWsd1(source)` creates a MATLAB class, `servicename`, based on a service name defined in `source`. The `source` argument is a string that specifies a URL, full path, or relative path to a Web Services Description Language (WSDL) document located on a server. `createClassFromWsd1` creates a class folder, `@servicename`, in the current folder. The class folder contains a method file for each Web service operation, and the display method (`display.m`) and constructor (`servicename.m`) for the class.

**Examples** Get the methods from the `myWebService` WSDL document, which specifies two methods. The example does not use an actual WSDL document; therefore, you cannot run it. The example only illustrates how to use the function.

Create the class:

```
createClassFromWsd1('path_to_myWebService')
```

MATLAB creates the following in the current folder:

```
@myWebService
@myWebService/method1.m
@myWebService/method2.m
@myWebService/display.m
@myWebService/myWebService.m
```

---

Retrieve a student name, given the WSDL document for `TestScoreWebService`, at `http://examplestandardtests.com/scoreswebservice?WSDL`. The example does not use an actual WSDL document; therefore, you cannot run it. The example only illustrates how to use the function.

```
url = 'http://examplestandardtests.com/scoreswebservice?WSDL';
```

```
createClassFromWsd1(url);  
obj = TestScoreWebService;  
% Show the methods  
methods(obj)  
% Retrieve the first student name  
students = StudentNames(obj);  
students.StudentInfo(1)
```

MATLAB returns

```
StudentNameLast: 'Benjamin'  
StudentNameFirst: 'Ali'
```

---

Display the endpoint and WSDL document location:

```
display('TestScoreWebService')
```

MATLAB returns

```
endpoint: 'http://examplestandardtests.com/scoreswebservice'  
wsdl: 'http://examplestandardtests.com/scoreswebservice?WSDL'
```

# inputParser.createCopy

---

<b>Purpose</b>	Create copy of inputParser object (to be removed)
<b>Compatibility</b>	The createCopy method will be removed in a future release. Use copy instead.
<b>Syntax</b>	<code>pNew = createCopy(p)</code>
<b>Description</b>	<code>pNew = createCopy(p)</code> creates a copy of inputParser object <code>p</code> .
<b>Tips</b>	<ul style="list-style-type: none"><li>Using <code>createCopy</code> is not the same as copying by assignment, such as <code>pNew = p</code>, which creates a new handle to the same object <code>p</code>.</li></ul>
<b>Input Arguments</b>	<p><b>p</b></p> <p>Object of class <code>inputParser</code>.</p>
<b>Output Arguments</b>	<p><b>pNew</b></p> <p><code>inputParser</code> object with the same properties as object <code>p</code>.</p>
<b>Examples</b>	<p><b>Copy Input Parser Scheme</b></p> <p>Create a copy of an existing <code>inputParser</code> object, and add an optional input to the copy.</p> <pre>p = inputParser; default = 0;  addRequired(p, 'first'); addOptional(p, 'second', default);  pNew = createCopy(p); addOptional(pNew, 'third', default);</pre> <p>Object <code>p</code> has two inputs in the scheme, <code>first</code> and <code>second</code>. Object <code>pNew</code> has an additional input, <code>third</code>.</p> <p>Parse each object.</p>

```
input1 = 1; input2 = 2; input3 = 3;

parse(p,input1);
p.Results

ans =
    first: 1
    second: 0

parse(pNew,input1,input2,input3);
pNew.Results

ans =
    first: 1
    second: 2
    third: 3
```

**See Also** [inputParser](#) |

# createSoapMessage

---

**Purpose** Create SOAP message to send to server

**Syntax** `message = createSoapMessage(namespace,method,values,names,types,style)`

**Description** `message = createSoapMessage(namespace,method,values,names,types,style)` creates a SOAP message based on the values you provide for the arguments. `message` is a Java document object model (DOM). To send message to the Web service, use it with `callSoapService`.

Argument	Description
<code>namespace</code>	Location of the Web service in the form of a valid Uniform Resource Identifier (URI).
<code>method</code>	Name of the Web service operation you want to run.
<code>values</code>	Cell array of input you need to provide for the method.
<code>names</code>	Cell array of parameters for method.
<code>types</code>	Cell array defining the XML data types for <code>values</code> . Specifying <code>style</code> is optional; when you do not include the argument, MATLAB uses unspecified.
<code>style</code>	Style for structuring the SOAP message, either ' <b>document</b> ' or ' <b>rpc</b> '. Specifying <code>style</code> is optional; when you do not include the argument, MATLAB uses <b>rpc</b> . Use a style supported by the service you specified in <code>namespace</code> .

## Examples

This example uses `createSoapMessage` in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

---

**Note** The example is not based on an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

---

```
% Create the message:
message = createSoapMessage(...
    'urn:LibraryCatalog',...
    'getAuthor',...
    {'In the Fall'},...
    {'nameToLookUp'},...
    {'{http://www.w3.org/2001/XMLSchema}string'},...
    'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
    'http://test/soap/services/LibraryCatalog',...
    'urn:LibraryCatalog#getAuthor',...
    message)
%
% Extract MATLAB data from the response
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

## How To

- “Access Web Services Using MATLAB SOAP Functions”

# **CROSS**

---

**Purpose** Vector cross product

**Syntax** `C = cross(A,B)`  
`C = cross(A,B,dim)`

**Description** `C = cross(A,B)` returns the cross product of the vectors `A` and `B`. That is,  $C = A \times B$ . `A` and `B` must be 3-element vectors. If `A` and `B` are multidimensional arrays, `CROSS` returns the cross product of `A` and `B` along the first dimension of length 3.

`C = cross(A,B,dim)` where `A` and `B` are multidimensional arrays, returns the cross product of `A` and `B` in dimension `dim`. `A` and `B` must have the same size, and both `size(A,dim)` and `size(B,dim)` must be 3.

**Tips** To perform a dot (scalar) product of two vectors of the same size, use `c = dot(a,b)`.

**Examples** The cross and dot products of two vectors are calculated as shown:

```
a = [1 2 3];  
b = [4 5 6];  
c = cross(a,b)  
  
c =  
    -3     6    -3  
  
d = dot(a,b)  
  
d =  
    32
```

**See Also** `dot`

**Purpose** Cosecant of argument in radians

**Syntax**  $Y = \text{csc}(x)$

**Description** The `csc` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \text{csc}(x)$  returns the cosecant for each element of  $x$ .

**Examples** Graph the cosecant over the domains  $-\pi < x < 0$  and  $0 < x < \pi$ .

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csc(x1),x2,csc(x2)), grid on
```

### Cosecant

The cosecant of  $z$  is

$$\csc(z) = \frac{1}{\sin(z)}.$$

**Purpose** Hyperbolic cosecant

**Syntax**  $Y = \operatorname{csch}(x)$

**Description** The `csch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \operatorname{csch}(x)$  returns the hyperbolic cosecant for each element of  $x$ .

**Examples** Graph the hyperbolic cosecant over the domains  $-\pi < x < 0$  and  $0 < x < \pi$ .

```
x1 = -pi+0.01:0.01:-0.01;  
x2 = 0.01:0.01:pi-0.01;  
plot(x1,csch(x1),x2,csch(x2)), grid on
```

**Definitions** **Hyperbolic Cosecant**

The hyperbolic cosecant of  $z$  is

# csch

---

$$\operatorname{csch}(z) = \frac{1}{\sinh(z)}.$$

**Purpose** Read comma-separated value file

**Syntax**

```
M = csvread(filename)
M = csvread(filename,row,col)
M = csvread(filename,row,col, csvRange)
```

**Description** M = csvread(filename) reads a comma-separated value formatted file, filename. The file can only contain numeric values.

M = csvread(filename, row, col) reads data from the file starting at the specified row and column. The row and column arguments are zero based, so that row = 0 and col = 0 specify the first value in the file.

M = csvread(filename, row, col, csvRange) reads only the range specified by csvRange.

## Input Arguments

### filename - Name of file to read

string

Name of the file to read, specified as a string.

**Example:** 'myFile.dat'

### Data Types

char

### row - Row of first value to read

0 (default) | positive integer

Row of the first value to read, specified as a positive integer. row is zero based, so that row = 0 specifies the first row of data.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### col - Column of first value to read

0 (default) | positive integer

Column of the first value to read, specified as a positive integer. `col` is zero based, so that `col = 0` specifies the first column of data.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## csvRange - Range of data to read

4-element vector | string

Range of the data to read, specified as a 4-element vector or a string.

- If `csvRange` is a 4-element vector, then it must have the form `[R1,C1,R2,C2]`, where `(R1,C1)` is the upper left corner of the data to be read and `(R2,C2)` is the lower right corner. The range is zero based, so that `R1 = 0` specifies the first row of data, and `C1 = 0` specifies the first column of data.
- If `csvRange` is a string, then it should be specified using spreadsheet notation, as in `csvRange = 'A1..B7'`.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | char

## Output Arguments

### M - Numeric data

matrix

Numeric data, returned as a matrix of double values.

## Examples

### Read File Containing Comma-Separated Values

Create a file, `csvlist.dat`, that contains these comma-separated values.

```
02, 04, 06, 08  
03, 06, 09, 12  
05, 10, 15, 20  
07, 14, 21, 28
```

Read the entire file.

```
filename = 'csvlist.dat';
M = csvread(filename)
```

M =

```

     2     4     6     8
     3     6     9    12
     5    10    15    20
     7    14    21    28
```

csvread returns the numeric data in M.

### Read Data Starting at Specific Row and Column

Read data from the file, csvlist.dat, of the previous example, starting at zero-based row 2, column 0.

```
M = csvread('csvlist.dat',2,0)
```

M =

```

     5    10    15    20
     7    14    21    28
```

### Read a Specific Range of Data

Read a specific range of data from the file, csvlist.dat, of the first example.

Read the matrix bounded by zero-based (1,0) and (2,2).

```
M = csvread('csvlist.dat',1,0,[1,0,2,2])
```

M =

```

     3     6     9
     5    10    15
```

# csvread

---

## Algorithms

csvread fills empty delimited fields with zero. When csvread reads data files with lines that end with a nonspace delimiter, such as a semicolon, it returns a matrix, M, that has an additional last column of zeros.

csvread imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type. The table shows valid forms for a complex number.

Form	Example
-<real>-<imag>i j	5.7-3.1i
-<imag>i j	-7j

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

## See Also

csvwrite | dlmread | textscan | importdata | readtable | uiimport

**Purpose** Complex conjugate transpose

**Syntax**  
 $b = a'$   
 $b = \text{ctranspose}(a)$

**Description**  
 $b = a'$  computes the complex conjugate transpose of matrix  $a$  and returns the result in  $b$ .  
 $b = \text{ctranspose}(a)$  is called for the syntax  $a'$  (complex conjugate transpose) when  $a$  is an object.

**See Also** transpose

# csvwrite

---

**Purpose** Write comma-separated value file

**Syntax** `csvwrite(filename,M)`  
`csvwrite(filename,M,row,col)`

**Description** `csvwrite(filename,M)` writes matrix `M` into `filename` as comma-separated values. The `filename` input is a string enclosed in single quotes.

`csvwrite(filename,M,row,col)` writes matrix `M` into `filename` starting at the specified row and column offset. The row and column arguments are zero based, so that `row=0` and `C=0` specify the first value in the file.

**Tips**

- `csvwrite` terminates each line with a line feed character and no carriage return.
- `csvwrite` writes a maximum of five significant digits. If you need greater precision, use `dlmwrite` with a precision argument.
- `csvwrite` does not accept cell arrays for the input matrix `M`. To export a cell array that contains only numeric data, use `cell2mat` to convert the cell array to a numeric matrix before calling `csvwrite`. To export cell arrays with mixed alphabetic and numeric data, where each cell contains a single element, you can create an Excel spreadsheet (if your system has Excel installed) using `xlswrite`. For all other cases, you must use low-level export functions to write your data. For more information, see “Exporting a Cell Array to a Text File” in the MATLAB Data Import and Export documentation.

**Examples** The following example creates a comma-separated value file from the matrix `m`.

```
m = [3 6 9 12 15; 5 10 15 20 25; ...  
     7 14 21 28 35; 11 22 33 44 55];
```

```
csvwrite('csvlist.dat',m)  
type csvlist.dat
```

```
3,6,9,12,15
5,10,15,20,25
7,14,21,28,35
11,22,33,44,55
```

The next example writes the matrix to the file, starting at a column offset of 2.

```
csvwrite('csvlist.dat',m,0,2)
type csvlist.dat
```

```
,,3,6,9,12,15
,,5,10,15,20,25
,,7,14,21,28,35
,,11,22,33,44,55
```

**See Also**

# cumprod

---

**Purpose** Cumulative product

**Syntax**  
B = cumprod(A)  
B = cumprod(A,dim)

**Description** B = cumprod(A) returns an array the same size as the array A containing the cumulative product.

- If A is a vector, then cumprod(A) returns a vector containing the cumulative product of the elements of A.
- If A is a matrix, then cumprod(A) returns a matrix containing the cumulative products for each column of A.
- If A is a multidimensional array, then cumprod(A) acts along the first nonsingleton dimension.

B = cumprod(A,dim) returns the cumulative product along dimension dim. For example, if A is a matrix, then cumprod(A,2) returns the cumulative product of each row.

## Input Arguments

**A - Input array**  
vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

**Data Types**  
double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

### **dim - Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A.

- `cumprod(A,1)` works along the rows of `A` and returns the cumulative product of each column.
- `cumprod(A,2)` works along the columns of `A` and returns the cumulative product of each row.

`cumprod` returns `A` if `dim` is greater than `ndims(A)`.

#### Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **B** - Cumulative product array

`vector` | `matrix` | `multidimensional array`

Cumulative product array, returned as a vector, matrix, or multidimensional array of the same size as the input array `A`.

The class of `B` is the same as the class of `A` except if `A` is `logical`, in which case `B` is `double`.

## Definitions

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If `X` is a 1-by-`n` row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-`n` empty array, then the second dimension is the first nonsingleton dimension of `X`.

- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

## Examples

### Cumulative Product of Vector

Find the cumulative product of the integers from 1 to 5.

```
A = [1:5];  
B = cumprod(A)
```

B =

```
     1     2     6    24   120
```

$B(2)$  is the product of  $A(1)$  and  $A(2)$ , while  $B(5)$  is the product of elements  $A(1)$  through  $A(5)$ .

### Cumulative Product of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

A =

```
     1     4     7  
     2     5     8  
     3     6     9
```

Find the cumulative product of the columns of  $A$ .

```
B = cumprod(A)
```

B =

```
     1     4     7  
     2    20    56  
     6   120   504
```

B(5) is the product of A(4) and A(5), while B(9) is the product of A(7) , A(8), and A(9).

### Cumulative Product of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

```
A =
```

```
     1     3     5
     2     4     6
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)
```

```
B =
```

```
     1     3    15
     2     8    48
```

B(3) is the product of A(1) and A(3), while B(5) is the product of A(1), A(3), and A(5) .

### Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

```
A =
```

```
     1     0     1
     1     1     0
```

Find the cumulative product of the rows of A.

# cumprod

<b>Purpose</b>	Cumulative sum
<b>Syntax</b>	<pre>B = cumsum(A) B = cumsum(A,dim)</pre>
<b>Description</b>	<p><code>B = cumsum(A)</code> returns an array of the same size as the array <code>A</code> containing the cumulative sum.</p> <ul style="list-style-type: none"><li>• If <code>A</code> is a vector, then <code>cumsum(A)</code> returns a vector containing the cumulative sum of the elements of <code>A</code>.</li><li>• If <code>A</code> is a matrix, then <code>cumsum(A)</code> returns a matrix containing the cumulative sums for each column of <code>A</code>.</li><li>• If <code>A</code> is a multidimensional array, then <code>cumsum(A)</code> acts along the first nonsingleton dimension.</li></ul> <p><code>B = cumsum(A,dim)</code> returns the cumulative sum of the elements along dimension <code>dim</code>. For example, if <code>A</code> is a matrix, then <code>cumsum(A,2)</code> returns the cumulative sum of each row.</p>
<b>Input Arguments</b>	<p><b>A - Input array</b> vector   matrix   multidimensional array</p> <p>Input array, specified as a vector, matrix, or multidimensional array.</p> <p><b>Data Types</b> double   single   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical</p> <p><b>Complex Number Support:</b> Yes</p> <p><b>dim - Dimension to operate along</b> positive integer scalar</p> <p>Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.</p> <p>Consider a two-dimensional input array, <code>A</code>:</p>

# cumsum

---

- `cumsum(A,1)` works along the rows of A and returns the cumulative sum of each column.
- `cumsum(A,2)` works along the columns of A and returns the cumulative sum of each row.

`cumsum` returns A if `dim` is greater than `ndims(A)`.

## Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### B - Cumulative sum array

`vector` | `matrix` | `multidimensional array`

Cumulative sum array, returned as a vector, matrix, or multidimensional array of the same size as the input array A.

The class of B is the same as the class of A except if A is `logical`, in which case B is `double`.

## Definitions

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If X is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of X.
- If X is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of X.

- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

## Examples

### Cumulative Sum of Vector

Find the cumulative sum of the integers from 1 to 5.

```
A = [1:5];
B = cumsum(A)
```

B =

```
     1     3     6    10    15
```

$B(2)$  is the sum of  $A(1)$  and  $A(2)$ , while  $B(5)$  is the sum of elements  $A(1)$  through  $A(5)$ .

### Cumulative Sum of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

A =

```
     1     4     7
     2     5     8
     3     6     9
```

Find the cumulative sum of the columns of  $A$ .

```
B = cumsum(A)
```

B =

```
     1     4     7
     3     9    15
     6    15    24
```

B(5) is the sum of A(4) and A(5), while B(9) is the sum of A(7) , A(8), and A(9).

## Cumulative Sum of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

A =

```
     1     3     5
     2     4     6
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

B =

```
     1     4     9
     2     6    12
```

B(3) is the sum of A(1) and A(3), while B(5) is the sum of A(1), A(3), and A(5) .

## Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

A =

```
     1     0     1
     1     1     0
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

```
B =
```

```
     1     1     2
     1     2     2
```

The output is double.

```
class(B)
```

```
ans =
```

```
double
```

# cumtrapz

---

**Purpose** Cumulative trapezoidal numerical integration

**Syntax**  
`Z = cumtrapz(Y)`  
`Z = cumtrapz(X,Y)`  
`Z = cumtrapz( ___,dim)`

**Description** `Z = cumtrapz(Y)` computes an approximation of the cumulative integral of `Y` via the trapezoidal method with unit spacing. To compute the integral with other than unit spacing, multiply `Z` by the spacing increment. Input `Y` can be complex.

For vectors, `cumtrapz(Y)` is a vector containing the cumulative integral of `Y`.

For matrices, `cumtrapz(Y)` is a matrix the same size as `Y` with the cumulative integral over each column.

For multidimensional arrays, `cumtrapz(Y)` works across the first nonsingleton dimension.

`Z = cumtrapz(X,Y)` computes the cumulative integral of `Y` with respect to `X` using trapezoidal integration. `X` and `Y` must be vectors of the same length, or `X` must be a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`. `cumtrapz` operates across this dimension. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `cumtrapz(X,Y)` operates across this dimension.

`Z = cumtrapz( ___,dim)` integrates across the dimension of `Y` specified by scalar `dim`, using any of the input arguments in the previous syntaxes. The length of `X` must be the same as `size(Y,dim)`.

## Examples

### Example 1

```
Y = [0 1 2; 3 4 5];
```

```
cumtrapz(Y,1)  
ans =  
0      0      0
```

```
        1.5000    2.5000    3.5000
cumtrapz(Y,2)
ans =
0     0.5000    2.0000
      0     3.5000    8.0000
```

### **Example 2**

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);

ct = cumtrapz(z,1./z);
ct(end)
ans =
    0.0000 + 3.1411i
```

### **See Also**

[cumsum](#) | [trapz](#)

# curl

---

**Purpose** Compute curl and angular velocity of vector field

**Syntax**

```
[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)
[curlx,curly,curlz,cav] = curl(U,V,W)
[curlz,cav]= curl(X,Y,U,V)
[curlz,cav]= curl(U,V)
[curlx,curly,curlz] = curl(...), [curlx,curly] = curl(...)
cav = curl(...)
```

**Description** [curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W) computes the curl (curlx, curly, curlz) and angular velocity (cav) perpendicular to the flow (in radians per time unit) of a 3-D vector field U, V, W.

The arrays X, Y, and Z, which define the coordinates for U, V, and W, must be monotonic, but do not need to be uniformly spaced. X, Y, and Z must have the same number of elements, as if produced by meshgrid.

[curlx,curly,curlz,cav] = curl(U,V,W) assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where [m,n,p] = size(U).

[curlz,cav]= curl(X,Y,U,V) computes the curl z-component and the angular velocity perpendicular to z (in radians per time unit) of a 2-D vector field U, and V.

The arrays X and Y, which define the coordinates for U and V, must be monotonic, but do not need to be uniformly spaced. X and Y must have the same number of elements, as if produced by meshgrid.

[curlz,cav]= curl(U,V) assumes X and Y are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where [m,n] = size(U).

```
[curlx,curly,curlz] = curl(...), [curlx,curly] = curl(...)  
returns only the curl.
```

```
cav = curl(...) returns only the curl angular velocity.
```

## Examples

This example uses colored slice planes to display the curl angular velocity at specified locations in the vector field.

```
figure  
load wind  
cav = curl(x,y,z,u,v,w);  
h = slice(x,y,z,cav,[90 134],59,0);  
shading interp  
daspect([1 1 1]);  
axis tight  
colormap hot(16)  
camlight  
set([h(1),h(2)],'ambientstrength',.6)
```

# curl

---

This example views the curl angular velocity in one plane of the volume and plots the velocity vectors (quiver) in the same plane.

```
load wind
k = 4;
x = x(:,:,k); y = y(:,:,k); u = u(:,:,k); v = v(:,:,k);
cav = curl(x,y,u,v);
pcolor(x,y,cav); shading interp
hold on;
quiver(x,y,u,v,'y')
hold off
colormap copper
```

## How To

- “Displaying Curl with Stream Ribbons”

**Purpose** Index of current IFD

**Syntax** `dirNum = tiffobj.currentDirectory()`

**Description** `dirNum = tiffobj.currentDirectory()` returns the index of the current image file directory (IFD). Index values are one-based. Use this index value with the `setDirectory` member function.

**Examples**      **Determine Current IFD**

Open a Tiff object and determine which IFD is the current IFD.

```
t = Tiff('example.tif', 'r');  
dnum = t.currentDirectory()
```

```
dnum =
```

```
1
```

Close the Tiff object.

```
t.close();
```

**References** This method corresponds to the `TIFFCurrentDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

**See Also** `Tiff.setDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# customverctrl

---

**Purpose** Allow custom source control system (UNIX platforms)

**Syntax** `customverctrl`

**Description** `customverctrl` function is for customers who want to integrate a source control system that is not supported for use with MATLAB software. When using this function, conform to the structure of one of the supported version control systems, for example, RCS. For examples, see the files `clearcase.m`, `cvs.m`, `pvcs.m`, and `rsc.m` in `matlabroot\toolbox\matlab\verctrl`.

**See Also** `checkin` | `checkout` | `cmopts` | `undocheckout` | `verctrl`

**Purpose**

Generate cylinder

**Syntax**

```
[X,Y,Z] = cylinder
[X,Y,Z] = cylinder(r)
[X,Y,Z] = cylinder(r,n)
cylinder(axes_handle,...)
cylinder(...)
```

**Description**

`cylinder` generates  $x$ -,  $y$ -, and  $z$ -coordinates of a unit cylinder. You can draw the cylindrical object using `surf` or `mesh`, or draw it immediately by not providing output arguments.

`[X,Y,Z] = cylinder` returns the  $x$ -,  $y$ -, and  $z$ -coordinates of a cylinder with a radius equal to 1. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r)` returns the  $x$ -,  $y$ -, and  $z$ -coordinates of a cylinder using  $r$  to define a profile curve. `cylinder` treats each element in  $r$  as a radius at equally spaced heights along the unit height of the cylinder. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r,n)` returns the  $x$ -,  $y$ -, and  $z$ -coordinates of a cylinder based on the profile curve defined by vector  $r$ . The cylinder has  $n$  equally spaced points around its circumference.

`cylinder(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`cylinder(...)`, with no output arguments, plots the cylinder using `surf`.

# cylinder

---

## Tips

`cylinder` treats its first argument as a profile curve. The resulting surface graphics object is generated by rotating the curve about the  $x$ -axis, and then aligning it with the  $z$ -axis.

## Examples

Create a cylinder with randomly colored faces.

```
cylinder
axis square
h = findobj('Type','surface');
set(h,'CData',rand(size(get(h,'CData'))))
```

Generate a cylinder defined by the profile function  $2+\sin(t)$ .

```
t = 0:pi/10:2*pi;
```

```
[X,Y,Z] = cylinder(2+cos(t));  
surf(X,Y,Z)  
axis square
```

## See Also

[sphere](#) | [surf](#)

# daqread

---

**Purpose** Read Data Acquisition Toolbox (.daq) file

**Syntax**

```
data = daqread('filename')
[data, time] = daqread(...)
[data, time, abstime] = daqread(...)
[data, time, abstime, events] = daqread(...)
[data, time, abstime, events, daqinfo] = daqread(...)
data = daqread(..., 'Param1', Val1, ...)
daqinfo = daqread('filename', 'info')
```

**Description** `data = daqread('filename')` reads all the data from the Data Acquisition Toolbox™ (.daq) file specified by `filename`. `daqread` returns `data`, an  $m$ -by- $n$  data matrix, where  $m$  is the number of samples and  $n$  is the number of channels. If `data` includes data from multiple triggers, the data from each trigger is separated by a NaN. If you set the `OutputFormat` property to `tscollection`, `daqread` returns a time series collection object. See below for more information.

`[data, time] = daqread(...)` returns `time/value` pairs. `time` is an  $m$ -by-1 vector, the same length as `data`, that contains the relative time for each sample. Relative time is measured with respect to the first trigger that occurs.

`[data, time, abstime] = daqread(...)` returns the absolute time of the first trigger. `abstime` is returned as a clock vector.

`[data, time, abstime, events] = daqread(...)` returns a log of events. `events` is a structure containing event information. If you specify either the `Samples`, `Time`, or `Triggers` parameters (see below), the events structure contains only the specified events.

`[data, time, abstime, events, daqinfo] = daqread(...)` returns a structure, `daqinfo`, that contains two fields: `ObjInfo` and `HwInfo`. `ObjInfo` is a structure containing property name/property value pairs and `HwInfo` is a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

`data = daqread(..., 'Param1', Val1, ...)` specifies the amount of data returned and the format of the data, using the following parameters.

Parameter	Description
Samples	Specify the sample range.
Time	Specify the relative time range.
Triggers	Specify the trigger range.
Channels	Specify the channel range. Channel names can be specified as a cell array.
DataFormat	Specify the data format as doubles (default) or native.
TimeFormat	Specify the time format as vector (default) or matrix.
OutputFormat	Specify the output format as matrix (the default) or <code>tscollection</code> . When you specify <code>tscollection</code> , <code>daqread</code> only returns data.

The `Samples`, `Time`, and `Triggers` properties are mutually exclusive; that is, either `Samples`, `Triggers` or `Time` can be defined at once.

`daqinfo = daqread('filename', 'info')` returns metadata from the file in the `daqinfo` structure, without incurring the overhead of reading the data from the file as well. The `daqinfo` structure contains two fields:

#### `daqinfo.ObjInfo`

a structure containing parameter/value pairs for the data acquisition object used to create the file, `filename`. Note: The `UserData` property value is not restored.

#### `daqinfo.HwInfo`

a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

## Tips

### More About .daq Files

- The format used by `daqread` to return data, relative time, absolute time, and event information is identical to the format used by the `getdata` function that is part of Data Acquisition Toolbox. For more information, see the Data Acquisition Toolbox documentation.
- If data from multiple triggers is read, then the size of the resulting data array is increased by the number of triggers issued because each trigger is separated by a NaN.
- `ObjInfo.EventLog` always contains the entire event log regardless of the value specified by `Samples`, `Time`, or `Triggers`.
- The `UserData` property value is not restored when you return device object (`ObjInfo`) information.
- When reading a `.daq` file, the `daqread` function does not return property values that were specified as a cell array.
- Data Acquisition Toolbox (`.daq`) files are created by specifying a value for the `LogFileName` property (or accepting the default value), and configuring the `LoggingMode` property to `Disk` or `Disk&Memory`.

### More About Time Series Collection Object Returned

When `OutputFormat` is set to `tscollection`, `daqread` returns a time series collection object. This times series collection object contains an absolute time series object for each channel in the file. The following describes how `daqread` sets some of the properties of the times series collection object and the time series objects.

- The `time` property of the time series collection object is set to the value of the `InitialTriggerTime` property specified in the file.
- The `name` property of each time series object is set to the value of the `Name` property of a channel in the file. If this name cannot be used as a time series object name, `daqread` sets the name to `'Channel'` with the `HwChannel` property of the channel appended.
- The value of the `Units` property of the time series object depends on the value of the `DataFormat` parameter. If the `DataFormat` parameter

is set to 'double', `daqread` sets the `DataInfo` property of each time series object in the collection to the value of the `Units` property of the corresponding channel in the file. If the `DataFormat` parameter is set to 'native', `daqread` sets the `Units` property to 'native'. See the Data Acquisition Toolbox documentation for more information on these properties.

- Each time series object will have `tsdata.event` objects attached corresponding to the log of events associated with the channel.

If `daqread` returns data from multiple triggers, the data from each trigger is separated by a NaN in the time series data. This increases the length of data and time vectors in the time series object by the number of triggers.

## Examples

Use Data Acquisition Toolbox to acquire data. The analog input object, `ai`, acquires one second of data for four channels, and saves the data to the output file `data.daq`.

```
ai = analoginput('nidaq','Dev1');
chans = addchannel(ai,0:3);
set(ai,'SampleRate',1000)
ActualRate = get(ai,'SampleRate');
set(ai,'SamplesPerTrigger', ActualRate)
set(ai,'LoggingMode','Disk&Memory')
set(ai,'LogFileName','data.daq')
start(ai)
```

After the data has been collected and saved to a disk file, you can retrieve the data and other acquisition-related information using `daqread`. To read all the sample-time pairs from `data.daq`:

```
[data,time] = daqread('data.daq');
```

To read samples 500 to 1000 for all channels from `data.daq`:

```
data = daqread('data.daq','Samples',[500 1000]);
```

# daqread

---

To read only samples 1000 to 2000 of channel indices 2, 4 and 7 in native format from the file, `data.daq`:

```
data = daqread('data.daq', 'Samples', [1000 2000],...  
              'Channels', [2 4 7], 'DataFormat', 'native');
```

To read only the data which represents the first and second triggers on all channels from the file, `data.daq`:

```
[data, time] = daqread('data.daq', 'Triggers', [1 2]);
```

To obtain the channel property information from `data.daq`:

```
daqinfo = daqread('data.daq', 'info');  
chaninfo = daqinfo.ObjInfo.Channel;
```

To obtain a list of event types and event data contained by `data.daq`:

```
daqinfo = daqread('data.daq', 'info');  
events = daqinfo.ObjInfo.EventLog;  
event_type = {events.Type};  
event_data = {events.Data};
```

To read all the data from the file `data.daq` and return it as a time series collection object:

```
data = daqread('data.daq', 'OutputFormat', 'tscollection');
```

<b>Purpose</b>	Set or query axes data aspect ratio
<b>Syntax</b>	<pre>daspect daspect([aspect_ratio]) daspect('mode') daspect('auto') daspect('manual') daspect(axes_handle,...)</pre>
<b>Description</b>	<p>The data aspect ratio determines the relative scaling of the data units along the <math>x</math>-, <math>y</math>-, and <math>z</math>-axes.</p> <p><code>daspect</code> with no arguments returns the data aspect ratio of the current axes.</p> <p><code>daspect([aspect_ratio])</code> sets the data aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the <math>x</math>-, <math>y</math>-, and <math>z</math>-axis scaling (e.g., [1 1 3] means one unit in <math>x</math> is equal in length to one unit in <math>y</math> and three units in <math>z</math>).</p> <p><code>daspect('mode')</code> returns the current value of the data aspect ratio mode, which can be either <code>auto</code> (the default) or <code>manual</code>. See <code>TipsRemarks</code>.</p> <p><code>daspect('auto')</code> sets the data aspect ratio mode to <code>auto</code>.</p> <p><code>daspect('manual')</code> sets the data aspect ratio mode to <code>manual</code>.</p> <p><code>daspect(axes_handle,...)</code> performs the set or query on the axes identified by the first argument, <code>axes_handle</code>. When you do not specify an axes handle, <code>daspect</code> operates on the current axes.</p>
<b>Tips</b>	<p><code>daspect</code> sets or queries values of the axes object <code>DataAspectRatio</code> and <code>DataAspectRatioMode</code> properties.</p> <p>When the data aspect ratio mode is <code>auto</code>, the data aspect ratio adjusts so that each axis spans the space available in the figure window. If you are displaying a representation of a real-life object, you should set the data aspect ratio to [1 1 1] to produce the correct proportions.</p>

Setting a value for data aspect ratio or setting the data aspect ratio mode to manual disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the data aspect ratio to a value, including its current value,

```
daspect(daspect)
```

can cause a change in the way the graphs look. See the Remarks section of the axes description for more information.

## Examples

The following surface plot of the function  $z = xe^{(-x^2 - y^2)}$  is useful to illustrate the data aspect ratio. First plot the function over the range  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ ,

```
[x,y] = meshgrid([-2:.2:2]);  
z = x.*exp(-x.^2 - y.^2);  
surf(x,y,z)
```

Querying the data aspect ratio shows how the surface is drawn.

```
daspect
ans =
     4     4     1
```

Setting the data aspect ratio to [1 1 1] produces a surface plot with equal scaling along each axis.

```
daspect([1 1 1])
```

- [ZLim](#)

- “Understanding Axes Aspect Ratio”

<b>Purpose</b>	Enable, disable, and manage interactive data cursor mode
<b>Syntax</b>	<pre>datacursormode on datacursormode off datacursormode datacursormode toggle datacursormode(<i>figure_handle</i>) dcm_obj = datacursormode(<i>figure_handle</i>)</pre>
<b>Description</b>	<p><code>datacursormode on</code> enables data cursor mode on the current figure.</p> <p><code>datacursormode off</code> disables data cursor mode on the current figure.</p> <p><code>datacursormode</code> or <code>datacursormode toggle</code> toggles data cursor mode in the current figure.</p> <p><code>datacursormode(<i>figure_handle</i>)</code> enables or disables data cursor mode on the specified figure.</p> <p><code>dcm_obj = datacursormode(<i>figure_handle</i>)</code> returns the data cursor mode object for the figure. The object enables you to customize the data cursor. For more information on data cursor mode objects, see “Output Arguments” on page 1-1368. You cannot change the state of data cursor mode in a call to <code>datacursormode</code> that returns a mode object.</p> <p>A <i>data cursor</i> is a small black square with a white border that you interactively position on a graph in data cursor mode. When you click a graphic object such as a line on a graph, a <i>data tip</i> appears. Data tips are small text boxes or windows that float within an axes that display data values at data cursor locations. The default style is a text box. Data tips list <i>x</i>-, <i>y</i>- and (where appropriate) <i>z</i>-values for one data point at a time. See “Examples” on page 1-1372 for an illustration of these two styles.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• Most types of graphs and 3-D plots support data cursor mode, but several do not (pareto, for example).</li><li>• Polar plots support data tips, but display Cartesian rather than polar coordinates on them.</li></ul>

# datacursormode

---

- Histograms created with `hist` display specialized data tips that itemize the observation counts, lower and upper limits and center point for histogram bins.
- You place data tips only by clicking data objects on graphs. You cannot place them programmatically (by executing code to position a data cursor).
- When `DisplayStyle` is `datatip`, you can place multiple data tips on a graph. When `DisplayStyle` is `window`, it reports only the most recent data tip.
- `datacursormode off` exits data cursor mode but does not remove displayed data tips. However, if the `DisplayStyle` is `window`, the data tip window goes away.

## Input Arguments

### **figure\_handle**

Optional handle of figure window

**Default:** The current figure

### **state**

`'`, `'toggle'`, `'on'`, or `'off'`

**Default:** `'toggle'`

## Output Arguments

### **dcm\_obj**

Use the object returned by `datacursormode` to control aspects of data cursor behavior. You can use the `set` and `get` commands to set and query object property values. You can customize how data cursor mode presents information by coding callback functions for these objects.

### **Parameter Name/Value Pairs for Data Cursor Mode Objects**

The following parameters apply to objects returned by calls to `datacursormode`, not to the function itself.

## **'DisplayStyle'**

datatip | window

Determines how the data cursor displays.

- datatip displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select.
- window displays data cursor information for the data point you interactively select in a floating window within the figure.

**Default:** datatip

## **'Enable'**

on | off

Specifies whether data cursor mode is currently enabled for the figure.

**Default:** off

## **'Figure'**

handle

Handle of the figure associated with the data cursor mode object.

## **'SnapToDataVertex'**

on | off

Specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position.

**Default:** on

## **'UpdateFcn'**

function handle

Reference to a function that formats the text appearing in the data cursor. You can supply your own function to customize data tip display. Your function must include at least two arguments. The first argument is unused, and can be a variable name or tilde (~). The second argument passes the data cursor event object to your update function. The event object encapsulates the state of the data cursor. The following function definition illustrates the update function:

```
function output_txt = myfunction(~,event_obj)
% ~           Currently not used (empty)
% event_obj  Object containing event data structure
% output_txt Data cursor text (string or cell array of strings)
```

event\_obj is an object that has the following properties.

Target	Handle of the object the data cursor is referencing (the object which you click, for example, a line or a bar from a series)
Position	An array specifying the <i>x</i> , <i>y</i> (and <i>z</i> for 3-D graphs) coordinates of the cursor

You can query these properties within your function. For example,

```
pos = get(event_obj, 'Position');
```

returns the coordinates of the cursor. Another way of accessing that data is to obtain the struct and query its Position field:

```
eventdata = get(event_obj);
pos = eventdata.Position;
```

You can also obtain the position directly from the object:

```
pos = event_obj.Position;
```

You can redefine the data cursor UpdateFcn at run time. For example:

```
set(dcm_obj, 'UpdateFcn', @myupdatefcn)
```

applies the function `myupdatefcn` to the current data tip or tips. When you set an update function in this way, the function must be on the MATLAB path. If instead you select the data cursor mode context menu item **Select text update function**, you can interactively select a function that is not on the path.

*Do not redefine figure window callbacks*, such as `ButtonDownFcn`, `KeyPressFcn`, or `CloseRequestFcn` *while in data cursor mode*. If you attempt to change any *figure* callbacks when you are in an interactive mode, you receive a warning and the attempt fails. MATLAB interactive modes are:

- brush
- datacursormode
- pan
- rotate3d
- zoom

This restriction does not apply to changing the figure `WindowButtonMotionFcn` callback or `uicontrol` callbacks.

## Querying Data Cursor Mode

Use the `getCursorInfo` function to query the data cursor mode object (`dcm_obj` in the update function syntax) to obtain information about the data cursor. For example,

```
info_struct = getCursorInfo(dcm_obj);
```

returns a vector of structures, one for each data cursor on the graph. Each structure has the following fields.

Target	The handle of the graphics object containing the data point
Position	An array specifying the $x$ , $y$ , (and $z$ ) coordinates of the cursor

Line and lineseries objects have an additional field.

# datacursormode

---

DataIndex	A scalar index into the data arrays that correspond to the nearest data point. The value is the same for each array.
-----------	--

See “Output Arguments” on page 1-1368 for more details on data cursor mode objects.

## Examples

This example creates a plot and enables data cursor mode from the command line.

```
surf(peaks)
datacursormode on
% Click mouse on surface to display data cursor
```

Selecting a point on the surface opens a data tip displaying its  $x$ -,  $y$ -, and  $z$ -coordinates.

You change the data tip display style to be a window instead of a text box using the **Tools > Options > Display cursor in window** , or use the context menu **Display Style > Window inside figure** to view the data tip in a floating window that you can move around inside the axes.

You can position multiple text box data tips on the same graph, the window style of data tip displays only one value at a time. For more information on interacting with data cursors, including point selection options and exporting data tips to the workspace, see “Data Cursor — Displaying Data Values Interactively”.

---

This example enables data cursor mode on the current figure and sets data cursor mode options. The following statements

- Create a graph
- Toggle data cursor mode to on
- Obtain the data cursor mode object, specify data tip options, and get the handle of the line the data tip occupies:

```
fig = figure;  
z = peaks;  
plot(z(:,30:35))
```

```
dcm_obj = datacursormode(fig);  
set(dcm_obj, 'DisplayStyle', 'datatip', ...  
    'SnapToDataVertex', 'off', 'Enable', 'on')  
  
disp('Click on a line to display a data tip, then press Return.')  
pause % Wait while the user does this.  
  
c_info = getCursorInfo(dcm_obj);  
set(c_info.Target, 'LineWidth', 2) % Make selected line wider
```

This example shows you how to customize the text that the data cursor displays. For example, you can replace the text displayed in the data tip and data window (x: and y:) with Time: and Amplitude: by creating a simple update function.

Save the following functions in your current directory or any writable directory on the MATLAB path before running them. As they are functions, you cannot highlight them and then evaluate the selection to make them work.

Save this code as `doc_datacursormode.m`:

# datacursormode

---

```
function doc_datacursormode
% Plots graph and sets up a custom data tip update function
fig = figure;
a = -16; t = 0:60;
plot(t,sin(a*t))
dcm_obj = datacursormode(fig);
set(dcm_obj, 'UpdateFcn', @myupdatefcn)
```

Save the following code as myupdatefcn.m on the MATLAB path:

```
function txt = myupdatefcn(empty,event_obj)
% Customizes text of data tips

pos = get(event_obj, 'Position');
txt = {[ 'Time: ', num2str(pos(1)) ], ...
      [ 'Amplitude: ', num2str(pos(2)) ]};
```

To set up and use the update function, type:

```
doc_datacursormode
```

When you place a data tip using this update function, it looks like the one in the following figure.

## Alternatives

Use the Data Cursor tool  to label  $x$ ,  $y$ , and  $z$  values on graphs and surfaces. You can control how data tips display by right-clicking and selecting items from the context menu.

## **How To**

- “Example — Visually Exploring Demographic Statistics”
- “Data Cursors with Histograms”

# datatipinfo

---

**Purpose** Produce short description of input variable

**Syntax** `datatipinfo(var)`

**Description** `datatipinfo(var)` displays a short description of a variable, similar to what is displayed in a datatip in the MATLAB debugger.

**Examples** Get datatip information for a 5-by-5 matrix:

```
A = rand(5);

datatipinfo(A)
A: 5x5 double =
    0.4445    0.3567    0.7458    0.0767    0.4400
    0.7962    0.6575    0.3918    0.8289    0.9746
    0.5641    0.9808    0.0265    0.4838    0.6722
    0.9099    0.9653    0.2508    0.4859    0.4054
    0.2857    0.5198    0.7383    0.9301    0.9604
```

Get datatip information for a 50-by-50 matrix. For this larger matrix, `datatipinfo` displays just the size and data type:

```
A = rand(50);

datatipinfo(A)
A: 50x50 double
```

Also for multidimensional matrices, `datatipinfo` displays just the size and data type:

```
A = rand(5);
A(:,:,2) = A(:,:,1);

datatipinfo(A)
A: 5x5x2 double
```

**See Also** `inputname` | `narginchk` | `nargin` | `varargin` | `inputParser`

**Purpose** Current date string

**Syntax** `str = date`

**Description** `str = date` returns a string containing the date in dd-mm-yyyy format.

**See Also** `clock` | `datestr` | `datetime` | `now`

# datenum

---

**Purpose** Convert date and time to serial date number

**Syntax**

```
DateNumber = datenum(DateString)
DateNumber = datenum(DateString,formatIn)
DateNumber = datenum(DateString,PivotYear)
DateNumber = datenum(DateString,formatIn,PivotYear)

DateNumber = datenum(DateVector)
DateNumber = datenum(Y,M,D)
DateNumber = datenum(Y,M,D,H,MN,S)
```

**Description** `DateNumber = datenum(DateString)` converts date strings to serial date numbers. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`DateNumber = datenum(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateNumber = datenum(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateNumber = datenum(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

`DateNumber = datenum(DateVector)` converts date vectors to serial date numbers, and returns a column vector of `m` date numbers, where `m` is the total number of date vectors in `DateVector`.

`DateNumber = datenum(Y,M,D)` returns the serial date numbers for corresponding elements of the `Y`, `M`, and `D` (year, month, day) arrays. The arrays must be of the same size (or any can be a scalar). You can also specify the input arguments as a date vector, `[Y,M,D]`.

`DateNumber = datenum(Y,M,D,H,MN,S)` additionally returns the serial date numbers for corresponding elements of the `H`, `MN`, and `S` (hour, minute, and second) arrays. The arrays must be of the same size (or any can be a scalar). You can also specify the input arguments as a date vector, `[Y,M,D,H,MN,S]`.

## Input Arguments

### **DateVector - Date vectors**

matrix

Date vectors, specified as an `m`-by-6 or `m`-by-3 matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements, specifying year, month, day, hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, MATLAB adjusts both that date vector element and the previous element. For example, if the minutes element is 70, MATLAB adjusts the hours element by 1 and sets the minutes element to 10. If the minutes element is -15, then MATLAB decreases the hours element by 1 and sets the minutes element to 45. Month values are an exception. MATLAB sets month values less than 1 to 1.

**Example:** `[2003,10,24,12,45,07]`

### **Data Types**

double

### **DateString - Date strings**

string | cell array of strings

Date strings, specified as a single string or a cell array of strings, where each row corresponds to one date string. All of the date strings must have the same format.

**Example:** '24 Oct-2003 12:45:07'

**Example:** {'15-Oct-2010'; '20-Nov-2012'}

If the date string format is known, you should also specify `formatIn`. If you do not specify `formatIn`, `DateString` must be in one of the following formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. MATLAB considers two-character date

string years (e.g., '79') to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (mm), the month value must not be greater than 12.
- However, for the format 'mm/dd/yy', if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, MATLAB considers the date string to be in 'yy/mm/dd' format.

### **formatIn - Format of the input date string**

string

Format of the input date string, specified as a string of symbolic identifiers.

**Example:** 'dddd, mmm dd, yyyy'

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

<b>Symbolic Identifier</b>	<b>Description</b>	<b>Example</b>
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D

<b>Symbolic Identifier</b>	<b>Description</b>	<b>Example</b>
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The formatIn string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-mmm-dd-m' because it has two month identifiers. The one exception to this is that you can combine one instance of dd with one instance of any of the other day identifiers. For example, 'dddd mmm dd yyyy' is a valid input.
- When you use AM or PM, the HH field is also required.
- You only can use QQ alone or with a year specifier.

### **PivotYear - Start year of 100-year date range**

current year minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

**Example:** 2000

### Data Types

double

### **Y,M,D - Year, month, and day arrays**

scalar | vector | matrix | array

Year, month, and day arrays specified as a scalar, vector, matrix or array. These must be the same size, or any one can be a scalar. Y, M, D should be integer values.

If Y, M, D are all scalars or all column vectors, you can specify the input arguments as a date vector, [Y, M, D].

**Example:** 2003, 10, 24

### Data Types

double

### **Y,M,D,H,MN,S - Year, month, day, hour, minute and second arrays**

scalar | vector | matrix | array

Year, month, day, hour, minute and second arrays specified as a scalar, vector, matrix or array. These must be the same size, or any one can be a scalar. `datenum` does not accept milliseconds as a separate input, but as a fractional part of the seconds input, S. Y, M, D, H, MN should be integer values.

If Y, M, D, H, MN, S are all scalars or all column vectors, you can specify the input arguments as a date vector [Y, M, D, H, MN, S].

**Example:** 2003, 10, 24, 12, 45, 07.451

### Data Types

double

## Output Arguments

### **DateNumber - Serial date numbers**

scalar | vector

Serial date numbers, returned as a column vector of length *m*, where *m* is the total number of input date vectors or date strings.

## Examples

### **Convert Date String to Date Number**

```
DateString = '19-May-2001';  
formatIn = 'dd-mmm-yyyy';  
datenum(DateString,formatIn)
```

```
ans =  
    730990
```

`datenum` returns a date number for the date string with the format 'dd-mmm-yyyy'.

### **Convert Multiple Date Strings to Date Numbers**

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};  
formatIn = 'mm/dd/yyyy';  
datenum(DateString,formatIn)
```

```
ans =  
    733301  
    729159  
    734471
```

### **Convert Date String to Date Number Using Pivot Year**

Convert a date string to a serial date number using the default pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy')
```

```
n =
```

```
736858
```

The corresponding date string to this date number is 12-Jun-2017.

Convert the same date string to a serial date number using 1400 as the pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy',1400)
```

```
n =
    517712
```

The corresponding date string to this date number is 12-Jun-1417.

## Convert Date Vector to Date Number

```
datenum([2009,4,2,11,7,18])
```

```
ans =
    7.3387e+05
```

## Convert Year, Month, and Day to Date Number

Convert a date specified by year, month and day values to a serial date number.

```
n = datenum(2001,12,19)
```

```
n =
    731204
```

## Tips

- To create arbitrarily shaped output, use `thedataenum(Y,M,D)` and `datenum(Y,M,D,H,MN,S)` syntaxes. The `datenum(DateVector)` syntax creates only a column vector of date numbers.

```
datenum(2013,[1 3; 2 4],ones(2,2))
```

```
ans =
    735235    735294
```

# datetime

---

735266      735325

## See Also

[datestr](#) | [datevec](#)

## Concepts

- “Represent Dates and Times in MATLAB”
- “Carryover in Date Vectors and Strings”

**Purpose**

Convert date and time to string format

**Syntax**

```
DateString = datestr(DateVector)
```

```
DateString = datestr(DateNumber)
```

```
DateString = datestr( ____, formatOut)
```

```
DateString = datestr(DateStringIn)
```

```
DateString = datestr(DateStringIn, formatOut, PivotYear)
```

```
DateString = datestr( ____, 'local')
```

**Description**

`DateString = datestr(DateVector)` converts date vectors to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date vectors in `DateVector`. `datestr` returns date strings in the default date string format `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second). By default, if `HH:MM:SS = 00:00:00` then the date string returned has the format `dd-mmm-yyyy`.

`DateString = datestr(DateNumber)` converts serial date numbers to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date numbers in `DateNumber`.

`DateString = datestr( ____, formatOut)` specifies the format of the output date strings using `formatOut`. You can use `formatOut` with any of the input arguments in the above syntaxes.

`DateString = datestr(DateStringIn)` converts `DateStringIn` to date strings in the default date string format `dd-mmm-yyyy HH:MM:SS`. All date strings in `DateStringIn` must have the same format.

`DateString = datestr(DateStringIn, formatOut, PivotYear)` converts `DateStringIn` to `DateString`, in the format specified by `formatOut`, and using optional `PivotYear` to interpret date strings that specify the year as two characters.

# datestr

---

`DateString = datestr( ___, 'local' )` returns the date string in the language of the current locale. This is the language you select by means of your computer's operating system. If you leave `local` out of the argument list, `datestr` returns the date string in the default language, which is US English. Use `local` with any of the previous syntaxes. The `local` argument must be last in the argument sequence.

## Input Arguments

### **DateVector - Date vectors**

matrix

Date vectors, specified as an `m`-by-6 matrix, where `m` is the number of full (six-element) date vectors. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, MATLAB adjusts both that date vector element and the previous element. For example, if the minutes element is 70, MATLAB adjusts the hours element by 1 and sets the minutes element to 10. If the minutes element is -15, then MATLAB decreases the hours element by 1 and sets the minutes element to 45. Month values are an exception. MATLAB sets month values less than 1 to 1.

**Example:** `[2003,10,24,12,45,07]`

### **Data Types**

double

### **DateNumber - Serial date numbers**

scalar | vector | matrix | array

Serial date numbers, specified as a scalar, vector, matrix, or array of positive double-precision numbers.

**Example:** `731878`

### **Data Types**

double

### **formatOut - Format of the date string output**

-1 (default) | string | integer

Format of the date string output, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format. If you do not specify `formatOut`, `datestr` returns a date string in the default date string format `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second). By default, if `HH:MM:SS = 00:00:00` then the date string returned has the format `dd-mmm-yyyy`.

The following table shows symbolic identifiers you can use to construct the `formatOut` string. You can include characters such as a hyphen, space, or colon to separate the fields.

<b>Symbolic Identifier</b>	<b>Description</b>	<b>Example</b>
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20
d	Day using capitalized first letter	M, T

Symbolic Identifier	Description	Example
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The formatOut string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-mmm-dd-m' because it has two month identifiers. The one exception to this is that you can combine one instance of dd with one instance of any of the other day identifiers. For example, 'dddd mmm dd yyyy' is a valid input.
- When you use AM or PM, the HH field is also required.
- You only can use QQ alone or with a year specifier.

The following table lists predefined MATLAB date formats.

Numeric Identifier	Date String Format	Example
-1 (default)	'dd-mmm-yyyy HH:MM:SS' or 'dd-mmm-yyyy' if 'HH:MM:SS' = 00:00:00	01-Mar-2000 15:45:17 or 01-Mar-2000
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000

<b>Numeric Identifier</b>	<b>Date String Format</b>	<b>Example</b>
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01

Numeric Identifier	Date String Format	Example
26	'yyyymmdd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000
29	'yyyy-mm-dd' (ISO 8601)	2000-03-01
30	'yyyymmddTHHMMSS' (ISO 8601)	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

## DateStringIn - Date strings to convert

string | cell array

Date strings to convert, specified as a single string or a cell array of strings, where each row corresponds to one date string.

MATLAB considers two-character date string years (for example, '79') to fall within the 100-year range centered around the current year.

All date strings must have the same date format, and they must be in one of the following MATLAB date formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000

Date String Format	Example
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

---

**Note** When converting from one date string format to another, you should first pass the strings to the `datenum` function, so that you can specify the format of the input date strings. This ensures that the format of the input date strings is correctly interpreted. For example, see “Convert Date String from Custom Format” on page 1-1397.

---

### **PivotYear - Start year of 100-year date range**

current year minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

**Example:** 2000

### **Data Types**

double

## **Output Arguments**

### **DateString - Date strings**

string | two-dimensional character array

Date strings, returned as a character array with  $m$  rows, where  $m$  is the total number of input date vectors, serial date numbers, or date strings. The default output date string format is `dd-mmm-yyyy HH:MM:SS`

(day-month-year hour:minute:second) unless the hours, minutes and seconds are all 0 in which case HH:MM:SS is suppressed.

## Tips

- To convert a date string not in a predefined MATLAB date format, first convert the date string to a date number, using either `datenum` or `datevec`.

## Examples

### Convert Date Vector to Date String

```
DateVector = [2009,4,2,11,7,18];
```

```
datestr(DateVector)
```

```
ans =  
    02-Apr-2009 11:07:18
```

`datestr` returns a date string in the default date string format.

### Convert Date and Time to Specific Format

Format the current date in the mm/dd/yy format.

You can specify this format using a string of symbolic identifiers.

```
formatOut = 'mm/dd/yy';  
datestr(now, formatOut)
```

```
ans =  
    09/07/12
```

Alternatively, you can specify this format using a numeric identifier.

```
formatOut = 2;  
datestr(now, formatOut)
```

```
ans =  
    09/07/12
```

You can reformat the date and time, and also show milliseconds.

```
dt = datestr(now, 'mmm dd, yyyy HH:MM:SS.FFF AM')
```

```
dt =  
January 05, 2012  2:44:48.753 PM
```

### **Convert 12-Hour Time String to 24-Hour Equivalent**

Convert the 12-hour time 05:32 p.m. to its 24-hour equivalent.

```
datestr('05:32 PM', 'HH:MM')
```

```
ans =
```

```
17:32
```

Convert the 24-hour time 05:32 to its 12-hour equivalent.

```
datestr('05:32', 'HH:MM PM')
```

```
ans =
```

```
5:32 AM
```

The use of AM or PM in the `formatOut` string does not influence which characters actually become part of the date string; they only determine whether or not to include them in the date string. MATLAB selects AM or PM based on the time entered.

### **Convert Date String from Custom Format**

Call `datenum` inside of `datestr` to specify the format of the input date string.

```
formatOut = 'dd mmm yyyy';  
datestr(datenum('16-04-55', 'dd-mm-yy', 1900), formatOut)
```

```
ans =
```

```
16 Apr 1955
```

## Convert Multiple Date Strings

Convert more than one date string input by passing the multiple date strings in a cell array.

All input date strings must use the same format. For example, the following command passes three dates that all use the mm/dd/yyyy format.

```
datestr(datenum({'09/16/2007';'05/14/1996';'11/29/2010'}, ...  
          'mm/dd/yyyy'))
```

```
ans =  
    16-Sep-2007  
    14-May-1996  
    29-Nov-2010
```

datestr returns a character array of converted date strings in the default date string format.

## Convert Date String with Values Outside Normal Range

Call datenum inside of datestr to return the expected value, because the date below uses a value outside its normal range (month=13).

```
datestr(datenum('13/24/88','mm/dd/yy'))
```

```
ans =  
    24-Jan-1989
```

## Use a Pivot Year

Change the pivot year to change the year range.

Use a pivot year of 1900.

```
DateStringIn = '4/16/55';  
formatOut = 1;  
PivotYear = 1900;  
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =  
    16-Apr-1955
```

For the same date string, use a pivot year of 2000.

```
PivotYear = 2000;  
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =  
    16-Apr-2055
```

### Return Date String in Local Language

Convert a date number to a date string in the language of the current locale.

Use the `local` argument in a French locale.

```
DateNumber = 725935;  
formatOut = 'mmm-dd-yyyy';  
str = datestr(DateNumber,formatOut,'local')
```

```
str =  
    Juillet-17-1987
```

You can make the same call without specifying `'local'`.

```
str = datestr(DateNumber,formatOut)
```

```
str =  
    July-17-1987
```

In this case, the output defaults to the English language.

### Concepts

- “Represent Dates and Times in MATLAB”
- “Troubleshooting: Converting Date Vector Returns Unexpected Output”

# datetick

---

## Purpose

Date formatted tick labels

## Syntax

```
datetick(tickaxis)
datetick(tickaxis,dateFormat)

datetick( __ , 'keeplimits' )
datetick( __ , 'keepticks' )
datetick(axes_handle, __ )
```

## Description

`datetick(tickaxis)` labels the tick lines of the axis specified by `tickaxis` using dates, replacing the default numeric labels. `datetick` selects a label format based on the minimum and maximum limits of the specified axis. The axis data values should be serial date numbers, as returned by the `datenum` function.

`datetick(tickaxis,dateFormat)` formats the labels according to the string `dateFormat`.

`datetick( __ , 'keeplimits' )` changes the tick labels to date-based labels while preserving the axis limits. Append `'keeplimits'` to any of the previous syntaxes.

`datetick( __ , 'keepticks' )` changes the tick labels to date-based labels while preserving their locations. Append `'keepticks'` to any of the previous syntaxes.

`datetick(axes_handle, __ )` labels the tick lines of an axis on the axes specified by `axes_handle`. The `axes_handle` argument can precede any of the input argument combinations in the previous syntaxes.

## Input Arguments

### tickaxis - Axis to label

'x' (default) | 'y' | 'z'

Axis to label with dates, specified as 'x', 'y', or 'z'.

### dateFormat - Format of tick line labels

string | integer

Format of the tick line labels, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format.

The following table shows symbolic identifiers you can use to construct the `dateFormat` string. You can include characters such as a hyphen, space, or colon to separate the fields. For example, to display the day of the month followed by the three-letter abbreviation of the day of the week in parentheses, use `dateFormat = 'dd (ddd)'`.

Symbolic Identifier	Description	Example
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20

<b>Symbolic Identifier</b>	<b>Description</b>	<b>Example</b>
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The following table lists predefined MATLAB date formats.

<b>Numeric Identifier</b>	<b>Date String Format</b>	<b>Example</b>
-1 (default)	'dd-mmm-yyyy HH:MM:SS' or 'dd-mmm-yyyy' if 'HH:MM:SS' = 00:00:00	01-Mar-2000 15:45:17 or 01-Mar-2000
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01

<b>Numeric Identifier</b>	<b>Date String Format</b>	<b>Example</b>
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmyyyy'	Mar2000
29	'yyyy-mm-dd' (ISO 8601)	2000-03-01

<b>Numeric Identifier</b>	<b>Date String Format</b>	<b>Example</b>
30	'yyymmddTHMMSS' (ISO 8601)	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

## Examples

### Label x-Axis Ticks with 2-digit Years

Graph population data for the 20th Century taken from the 1990 US census and label *x*-axis ticks with 2-digit years.

Create time data by decade.

```
t = (1900:10:1990)';
```

Enter total population counts for the USA.

```
p = [75.995 91.972 105.711 123.203 131.669 ...  
150.697 179.323 203.212 226.505 249.633]';
```

Convert years to serial date numbers using the `datenum` function, and then plot the data.

```
figure  
plot(datenum(t,1,1),p)  
grid on
```

Replace *x*-axis ticks with 2-digit years. The numeric identifier 11 corresponds to the predefined MATLAB date format 'yy'.

```
dateFormat = 11;  
datetick('x',dateFormat)
```

### Label x-Axis Ticks with Hours of the Day

Plot traffic count data against date ticks for hours of the day showing AM and PM.

Get traffic count data.

```
load count.dat
```

Create arrays for an arbitrary date, for example, April 18, 1995

```
n = length(count);  
year = 1990 * ones(1,n);  
month = 4 * ones(1,n);
```

# datetick

---

```
day = 18 * ones(1,n);
```

Create arrays for each of 24 hours.

```
hour = 1:n;  
minutes = zeros(1,n);
```

Get the serial date numbers for the date arrays.

```
xdate = datenum(year,month,day,hour,minutes,minutes);
```

Plot the traffic data against the serial date numbers.

```
figure  
plot(xdate,count)
```

Label the tick lines of the graph's *x*-axis with the hours of the day.

```
datetick('x','HHPM')
```

### Label x-Axis and Preserve Axis Limits

Select a starting date.

```
startDate = datenum('02-01-1962');
```

Select an ending date.

```
endDate = datenum('11-15-2012');
```

Create a variable, `xdata`, that corresponds to the number of years between the start and end dates.

```
xData = linspace(startDate,endDate,50);
```

For this example, plot random data.

```
figure  
plot(xData,rand(1,50))
```

Label the *x*-axis with 4-digit years, preserving the *x*-axis limits by using the 'keeplimits' option.

```
datetick('x','yyyy','keeplimits')
```

### Add Month Labels to a Plot and Preserve Number of Ticks

Select a starting date.

```
startDate = datenum('01-01-2009');
```

Select an ending date.

```
endDate = datenum('12-31-2009');
```

# datetick

---

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate, endDate, 12);
```

For this example, plot random data.

```
figure  
plot(xData, rand(1, 12))
```

Set the number of `XTicks` to the number of points in `xData`.

```
set(gca, 'XTick', xData)
```

Label the *x*-axis with month names, preserving the total number of ticks by using the `'keepticks'` option.

```
datetick('x', 'mmm', 'keepticks')
```

### Create Multiple Plots Within One Figure and Label Axis with Month Names

Select a starting date and an ending date.

```
startDate = datenum('01-01-2009');  
endDate = datenum('12-31-2009');
```

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate,endDate,12);
```

For this example, plot random data.

```
figure
s(1)=subplot(2,1,1);
plot(xData,rand(1,12))
s(2) = subplot(2,1,2);
plot(xData,rand(1,12))
```

Set the number of XTicks to the number of points in xData.

```
set(s,'XTick',xData)
```

Label the *x*-axis of each subplot with month names, referring to each subplot using its axes handle. Preserve the total number of ticks by using the 'keepticks' option.

```
for i = 1:2
    datetick(s(i),'x','mmm','keepticks')
end
```

## Algorithms

`datetick` calls the `datestr` function to convert date numbers to date strings.

## Tips

- To change the tick spacing and locations, set the appropriate axes property (i.e., `XTick`, `YTick`, or `ZTick`) before calling `datetick`.
- Calling `datetick` sets the `TickMode` of the specified axis to `'manual'`. This means that after zooming, panning or otherwise changing axis limits, you should call `datetick` again to update the ticks and labels.

# datetick

---

## See Also

[XTick](#) | [YTick](#) | [ZTick](#) | [datenum](#) | [datestr](#)

**Purpose**

Convert date and time to vector of components

**Syntax**

```
DateVector = datevec(DateNumber)
```

```
DateVector = datevec(DateString)
```

```
DateVector = datevec(DateString,formatIn)
```

```
DateVector = datevec(DateString,PivotYear)
```

```
DateVector = datevec(DateString,formatIn,PivotYear)
```

```
[Y, M, D, H, MN, S] = datevec( ___ )
```

**Description**

`DateVector = datevec(DateNumber)` converts one or more date numbers to date vectors. `datevec` returns an `m`-by-6 matrix containing `m` date vectors, where `m` is the total number of date numbers in `DateNumber`.

`DateVector = datevec(DateString)` converts date strings to date vectors. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateVector = datevec(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

[Y, M, D, H, MN, S] = datevec( \_\_\_ ) returns the components of the date vector as individual variables Y, M, D, H, MN, and S (year, month, day, hour, minutes and seconds). datevec returns milliseconds as a fractional part of the seconds (S) output.

## Input Arguments

### DateNumber - Serial date number

scalar | vector | multidimensional array

Serial date number, specified as a scalar, vector, or multidimensional array of positive double-precision numbers.

**Example:** 731878

### Data Types

double

### DateString - Date strings

string | cell array of strings

Date strings, specified as a single string or a cell array of strings, where each row corresponds to one date string. All of the date strings must have the same format.

**Example:** '24 Oct-2003 12:45:07'

**Example:** {'15-Oct-2010'; '20-Nov-2012'}

If the date string format is known, you should also specify formatIn. If you do not specify formatIn, DateString must be in one of the following formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01

Date String Format	Example
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. MATLAB considers two-character date string years (e.g., '79') to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (mm), the month value must not be greater than 12.
- However, for the format 'mm/dd/yy', if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, MATLAB considers the date string to be in 'yy/mm/dd' format.

### **formatIn - Format of the input date string**

string

Format of the input date string, specified as a string of symbolic identifiers.

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

<b>Symbolic Identifier</b>	<b>Description</b>	<b>Example</b>
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The formatIn string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-*mmm*-*dd*-*m*' because it has two month identifiers. The one exception to this is that you can combine one instance of *dd* with one instance of any of the other day identifiers. For example, '*dddd mmm dd yyyy*' is a valid input.
- When you use AM or PM, the HH field is also required.
- datevec does not accept formats that include 'QQ'

### **PivotYear - Start year of 100-year date range**

current year minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

**Example:** 2000

### **Data Types**

double

## **Output Arguments**

### **DateVector - Date vectors**

vector | matrix

Date vectors, returned as an *m*-by-6 matrix, where each row corresponds to one date vector, and *m* is the total number of input date numbers or date strings.

### **[Y, M, D, H, MN, S] - Components of the date vector**

scalar

Components of the date vector (year, month, day, hour, minute, and second), returned as individual scalar variables. Milliseconds are a fractional part of the seconds output.

## **Examples**

### **Convert Date Number to Date Vector**

format short g

```
n = 733779.651;  
datevec(n)
```

```
ans =  
      2009      1      5      15      37
```

## Convert Date String to Date Vector

```
DateString = '28.03.2005';  
formatIn = 'dd.mm.yyyy';  
datevec(DateString,formatIn)
```

```
ans =  
      2005      3      28      0      0      0
```

datevec returns a date vector for the date string with the format 'dd.mm.yyyy'.

## Convert Multiple Date Strings to Date Vectors

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};  
formatIn = 'mm/dd/yyyy';  
datevec(DateString,formatIn)
```

```
ans =  
      2007      9      16      0      0      0  
      1996      5      14      0      0      0  
      2010     11      29      0      0      0
```

## Convert Date with Milliseconds to Date Vector

```
datevec('11:21:02.647','HH:MM:SS.FFF')
```

```
ans =  
      1.0e+03 *  
      2.0120      0.0010      0.0010      0.0110      0.0210      0.0026
```

In the output date vector, milliseconds are a fractional part of the seconds field. The date string '11:21:02.647' does not contain enough information to convert to a full date vector. The days default to 1, months default to January, and years default to the current year.

### Convert Date String to Date Vector Using Pivot Year

Convert a date string to a date vector using the default pivot year.

```
DateString = '12-jun-17';
formatIn = 'dd-mmm-yy';
DateVector = datevec(DateString,formatIn)
```

```
DateVector =
```

```
          2017          6          12          0          0
```

Convert the same date string to a date vector using 1800 as the pivot year.

```
DateVector = datevec(DateString,formatIn,1800)
```

```
DateVector =
```

```
          1817          6          12          0          0
```

### Assign Elements of Returned Date Vector

Convert a date string to a date vector and return the components of the date vector.

```
[y, m, d, h, mn, s] = datevec('01.02.12','dd.mm.yy')
```

```
y =
```

```
    2012
```

```
m =
```

```
     2
```

```
d =
```

```
     1
```

```
h =
```

# datevec

---

```
    0
mn =
    0
s =
    0
```

## Limitations

- When computing date vectors, MATLAB sets month values less than 1 to 1. Day values, D, less than 1 are set to the last day of the previous month minus  $|D|$ . However, if  $0 \leq \text{DateNumber} < 1$ , then `datevec(DateNumber)` returns a date vector of the form `[0 0 0 H MN S]`, where H, MN, and S are hours, minutes, and seconds, respectively.

## Tips

- The vectorized calling syntax can offer significant performance improvement for large arrays.

## Concepts

- “Represent Dates and Times in MATLAB”
- “Carryover in Date Vectors and Strings”

**Purpose** Clear breakpoints

**Syntax**

```
dbclear all
dbclear in file ...
dbclear in file ... -completenames
dbclear if error ...
dbclear if warning ...
dbclear if naninf
dbclear if infnan
```

**Description** `dbclear all` removes all breakpoints in all MATLAB code files, as well as breakpoints set for errors, caught errors, caught error identifiers, warnings, warning identifiers, and `naninf/infnan`.

`dbclear in file ...` and `dbclear in file ... -completenames` formats are listed here:

Format	Action
<code>dbclear in file</code>	Removes all breakpoints in <code>file</code> . <code>file</code> must be the name of a MATLAB program file, and can include a MATLAB partial path.
<code>dbclear in file -completenames</code>	If the command includes the <code>-completenames</code> option, then <code>file</code> need not be on the path, as long as it is a fully qualified file name. (On Microsoft Windows platforms, this is a file name that begins with <code>\\</code> or with a drive letter followed by a colon. On UNIX platforms, this is a file name that begins with <code>/</code> or <code>~</code> .) <code>file</code> can include a <code>&gt;</code> to specify the path to a particular local function or to a nested function within a code file.
<code>dbclear in file at lineno</code>	Removes the breakpoint set at line number <code>lineno</code> in <code>file</code> .
<code>dbclear in file at lineno@</code>	Removes the breakpoint set in the anonymous function at line number <code>lineno</code> in <code>file</code> .

# dbclear

Format	Action
<code>dbclear in file at lineno@n</code>	Removes the breakpoint set in the <code>n</code> th anonymous function at line number <code>lineno</code> in <code>file</code> .
<code>dbclear in file at locfun</code>	Removes all breakpoints in local function <code>locfun</code> in <code>file</code> .

`dbclear if error ...` formats are listed here:

Format	Action
<code>dbclear if error</code>	Removes the breakpoints set using the <code>dbstop if error</code> and <code>dbstop if error</code> identifier statements.
<code>dbclear if error identifier</code>	Removes the breakpoint set using <code>dbstop if error</code> identifier for the specified identifier. Running this produces an error if <code>dbstop if error</code> or <code>dbstop if error all</code> is set.
<code>dbclear if caught error</code>	Removes the breakpoints set using the <code>dbstop if caught error</code> and <code>dbstop if caught error</code> identifier statements.
<code>dbclear if caught error identifier</code>	Removes the breakpoints set using the <code>dbstop if caught error</code> identifier statement for the specified identifier. Running this produces an error if <code>dbstop if caught error</code> or <code>dbstop if caught error all</code> is set.

`dbclear if warning ...` formats are listed here:

<code>dbclear if warning</code>	Removes the breakpoints set using the <code>dbstop if warning</code> and <code>dbstop if warning</code> identifier statements.
<code>dbclear if warning identifier</code>	Removes the breakpoint set using <code>dbstop if warning</code> identifier for the specified identifier. Running this produces an error if <code>dbstop if warning</code> or <code>dbstop if warning all</code> is set.

`dbclear if naninf` removes the breakpoint set by `dbstop if naninf` or `dbstop if infnan`.

`dbclear if infnan` removes the breakpoint set by `dbstop if infnan` or `dbstop if naninf`.

**Tips**

The **at** and **in** keywords are optional.

In the syntax, `file` can be a MATLAB program file, or the path to a function within a file. For example

```
dbclear in foo>myfun
```

clears the breakpoint at the `myfun` function in the file `foo.m`.

# dbcont

---

**Purpose** Resume execution

**Syntax** dbcont

**Description** dbcont resumes execution of a MATLAB code file from a breakpoint. Execution continues until another breakpoint is encountered, a pause condition is met, an error occurs, or MATLAB software returns to the base workspace prompt.

---

**Note** If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

# dblquad

---

## Purpose

Numerically evaluate double integral over rectangle

dblquad will be removed in a future release. Use `integral2` instead.

## Syntax

```
q = dblquad(fun,xmin,xmax,ymin,ymax)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)
```

## Description

`q = dblquad(fun,xmin,xmax,ymin,ymax)` calls the `quad` function to evaluate the double integral  $\text{fun}(x,y)$  over the rectangle  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min} \leq y \leq y_{\max}$ . The input argument, `fun`, is a function handle that accepts a vector `x`, a scalar `y`, and returns a vector of integrand values.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol)` uses a tolerance `tol` instead of the default, which is  $1.0e-6$ .

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quad1` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quad1`.

## Examples

Pass function handle `@integrnd` to `dblquad`:

```
Q = dblquad(@integrnd,pi,2*pi,0,pi);
```

where the function `integrnd.m` is:

```
function z = integrnd(x, y)
z = y*sin(x)+x*cos(y);
```

Pass anonymous function handle `F` to `dblquad`:

```
F = @(x,y)y*sin(x)+x*cos(y);
Q = dblquad(F,pi,2*pi,0,pi);
```

The `integrnd` function integrates  $y \sin(x) + x \cos(y)$  over the square  $\pi \leq x \leq 2\pi$ ,  $0 \leq y \leq \pi$ . Note that the integrand can be evaluated with a vector  $x$  and a scalar  $y$ .

Nonsquare regions can be handled by setting the integrand to zero outside of the region. For example, the volume of a hemisphere is:

```
dblquad(@(x,y) sqrt(max(1-(x.^2+y.^2),0)), -1, 1, -1, 1)
```

or

```
dblquad(@(x,y) sqrt(1-(x.^2+y.^2)).*(x.^2+y.^2<=1), -1, 1, -1, 1)
```

## How To

- “Anonymous Functions”

# dbmex

---

**Purpose** Enable MEX-file debugging (on UNIX platforms)

**Syntax**  
dbmex **on**  
dbmex **off**  
dbmex **stop**

**Description** dbmex **on** enables MEX-file debugging for UNIX platforms.

To use this option, first start the MATLAB software from a debugger by typing `matlab -Ddebugger`, where `debugger` is the name of the debugger program. You must invoke `dbmex on` before calling your MEX-file. If you have already loaded the MEX-file, remove it from memory using the `clear` function.

dbmex **off** disables MEX-file debugging.

dbmex **stop** returns to the debugger prompt.

**Tips** For more information about debugging MEX-files, see “Debug C/C++ Language MEX-Files”.

**See Also** `dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbtype` | `dbup`

**Purpose** Quit debug mode

**Syntax** dbquit  
dbquit('all')  
dbquit all

**Description** dbquit terminates debug mode. The Command Window then displays the standard prompt (>>). The file being processed is *not* completed and no results are returned. All breakpoints remain in effect, unless your file contains (and MATLAB has processed) one or more of the following commands: `clear all`, `clear function`, `clear classes`.

If you debug `file1` and step into `file2`, running dbquit terminates debugging for both files. However, if you debug `file3` and also debug `file4`, running dbquit terminates debugging for `file4`, but `file3` remains in debug mode until you run dbquit again.

dbquit('all') or the command form, dbquit all, ends debugging for all files at once.

**Examples** This example illustrates the use of dbquit relative to dbquit('all'). Set breakpoints in and run `file1` and `file2`:

```
>> dbstop in file1
>> dbstop in file2
>> file1
K>> file2
K>> dbstack
```

MATLAB software returns

```
K>> dbstack
   In file1 at 11
   In file2 at 22
```

If you use the dbquit syntax

```
K>> dbquit
```

# dbquit

---

MATLAB ends debugging for `file2` but `file1` is still in debug mode as shown here

```
K>> dbstack
      in file1 at 11
```

Run `dbquit` again to exit debug mode for `file1`.

Alternatively, `dbquit('all')` ends debugging for both files at once:

```
K>> dbstack
      In file1 at 11
      In file2 at 22
dbquit('all')
dbstack
```

returns no result.

`dbstop` | `dbstep` | `dbtype` | `dbup`

## Related Examples

- “Correct Problems and End Debugging”

**Purpose** Function call stack

**Syntax**

```
dbstack
dbstack(n)
dbstack(' -completenames' )
[ST,I] = dbstack(...)
```

**Description** dbstack displays the line numbers and file names of the function calls that led to the current breakpoint, listed in the order in which they were executed. The display lists the line number of the most recently executed function call (at which the current breakpoint occurred) first, followed by its calling function, which is followed by its calling function, and so on. This continues until the topmost MATLAB function is reached. Each line number is a hyperlink you can click to go directly to that line in the Editor. The notation `functionname>localfunctionname` is used to describe the location of the local function.

`dbstack(n)` omits the first `n` frames from the display. This is useful when issuing a `dbstack` from within an error handler, for example.

`dbstack(' -completenames' )` outputs the “complete name“ (the absolute file name and the entire sequence of functions that nests the function in the stack frame) of each function in the stack.

Either none, one, or both `n` and `' -completenames'`  can appear. If both appear, the order is irrelevant.

`[ST,I] = dbstack(...)` returns the stack trace information in an `m-by-1` structure, `ST`, with the fields:

<code>file</code>	The file in which the function appears. This field is the empty string if there is no file.
<code>name</code>	Function name within the file.
<code>line</code>	Function line number.

The current workspace index is returned in `I`.

If you step past the end of a file, `dbstack` returns a negative line number value to identify that special case. For example, if the last line to be executed is line 15, then the `dbstack` line number is 15 before you execute that line and -15 afterwards.

## Tips

In addition to using `dbstack` while debugging, you can also use `dbstack` within a MATLAB code file outside the context of debugging. In this case, to get and analyze information about the current file stack. For example, to get the name of the calling file, use `dbstack` with an output argument within the file being called. For example:

```
st=dbstack;
```

## Examples

This example shows the information returned when you issue `dbstack` while debugging a MATLAB code file:

```
dbstack
```

```
In /usr/local/matlab/toolbox/matlab/cond.m at line 13  
In test1.m at line 2  
In test.m at line 3
```

This example shows the information returned when you issue `dbstack` while debugging `lengthofline.m` to get the complete name of the file, the function name, and line number in which the function appears:

```
[ST,I] = dbstack('-completenames')  
ST =  
    file: 'I:\MATLABfiles\mymfiles\lengthofline.m'  
    name: 'lengthofline'  
    line: 28  
I =  
    1
```

## See Also

`dbcont` | `dbclear` | `dbdown` | `dbquit` | `dbstatus` | `dbstop` |  
`dbstep` | `dbtype` | `dbup` | `evalin` | `mfilename` | `whos`

**Related  
Examples**

- “Examine Values”

# dbstatus

---

**Purpose** List all breakpoints

**Syntax**

```
dbstatus
dbstatus file
dbstatus('-completenames')
s = dbstatus(...)
```

**Description** `dbstatus` lists all the breakpoints in effect including errors, caught errors, warnings, and `naninfs`.

`dbstatus file` displays a list of the line numbers for which breakpoints are set in the specified file, where `file` is a MATLAB code file function name or a MATLAB relative partial path. Each line number is a hyperlink you can click to go directly to that line in the Editor.

`dbstatus('-completenames')` displays, for each breakpoint, the absolute file name and the sequence of functions that nest the function containing the breakpoint.

`s = dbstatus(...)` returns breakpoint information in an `m`-by-1 structure with the fields listed in the following table. Use this syntax to save breakpoint status and restore it at a later time using `dbstop(s)`—see `dbstop` for an example.

<code>name</code>	Function name.
<code>file</code>	Full path for file containing breakpoints.
<code>line</code>	Vector of breakpoint line numbers.
<code>anonymous</code>	Vector of integers representing the anonymous functions in the <code>line</code> field. For example, 2 means the second anonymous function in that line. A value of 0 means the breakpoint is at the start of the line, not in an anonymous function.
<code>expression</code>	Cell vector of breakpoint conditional expression strings corresponding to lines in the <code>line</code> field.

cond	Condition string ('error', 'caught error', 'warning', or 'naninf').
identifier	When cond is 'error', 'caught error', or 'warning', a cell vector of MATLAB message identifier strings for which the particular cond state is set.

Use `dbstatus class/function`, `dbstatus private/function`, or `dbstatus class/private/function` to determine the status for methods, private functions, or private methods (for a class named `class`).

In all forms you can further qualify the function name with a local function name, as in `dbstatus function>localfunction`.

## Tips

In the syntax, `file` can be a file, or the path to a function within a file. For example

```
Breakpoint for foo>myfun is on line 9
```

means there is a breakpoint at the `myfun` local function, which is line 9 in the file `foo.m`.

## See Also

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstop` | `dbstep` | `dbtype` | `dbup` | `error` | `warning`

# dbstep

---

**Purpose** Execute one or more lines from current breakpoint

**Syntax**  
dbstep  
dbstep *nlines*  
dbstep **in**  
dbstep **out**

**Description** This function allows you to debug a MATLAB code file by following its execution from the current breakpoint. At a breakpoint, the `dbstep` function steps through execution of the current file one line at a time or at the rate specified by *nlines*.

`dbstep` executes the next executable line of the current file. `dbstep` steps over the current line, skipping any breakpoints set in functions called by that line.

`dbstep nlines` executes the specified number of executable lines.

`dbstep in` steps to the next executable line. If that line contains a call to another MATLAB code file function, execution will step to the first executable line of the called function. If there is no call to a MATLAB code file on that line, `dbstep in` is the same as `dbstep`.

`dbstep out` runs the rest of the function and stops just after leaving the function.

For all forms, MATLAB software also stops execution at any breakpoint it encounters.

---

**Note** If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

---

**See Also** `dbclean` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstop` | `dbtype` | `dbup`

**Related  
Examples**

- “Step Through a File”

# dbstop

---

**Purpose** Set breakpoints for debugging

**Syntax**

```
dbstop in file
dbstop in file at location
dbstop in file if expression
dbstop in file at location if expression
dbstop if condition
dbstop(s)
```

**Description** `dbstop in file` sets a breakpoint at the first executable line in `file`. When you run `file`, MATLAB enters debug mode and pauses execution at the first executable line.

`dbstop in file at location` sets a breakpoint at the specified location. MATLAB execution pauses immediately before that location, unless the location is an anonymous function. If the location is an anonymous function, then execution pauses just after the breakpoint.

`dbstop in file if expression` sets a breakpoint at the first executable line of the file. Execution pauses only if `expression` evaluates to 1 (true).

`dbstop in file at location if expression` sets a breakpoint at the specified location. Execution pauses at or just before that location only if the `expression` evaluates to true.

`dbstop if condition` pauses execution at the line that meets the specified condition.

`dbstop(s)` restores breakpoints you previously saved to `s`. The files containing the saved breakpoints must be on the search path or in the current folder. MATLAB assigns breakpoints by line number; therefore, the lines in the file must be the same as when you saved the breakpoints, or the results are unpredictable.

**Tips**

- Use `dbcont` or `dbstep` to resume execution after a breakpoint pauses execution. Use `dbquit` to exit debug mode.

- If you debug a file that MATLAB uses when running and debugging files, and that file is not a MATLAB code file, then some debugging features do not operate as expected. For instance, typing `help functionname` at the debug (`K>>`) prompt will not return help.
- MATLAB can become unresponsive when it stops at a breakpoint while displaying a modal dialog box or figure created by your program. Use **Ctrl+C** to exit debug mode and return to the MATLAB prompt (`>>`).
- If MATLAB pauses and displays a hyperlinked line number in the Command Window, click the hyperlink, The file opens in the Editor at the line where MATLAB paused execution. For an example of such a link, see the image in “Stop at File That Is Not a MATLAB Code File” on page 1-1446
- You can set breakpoints only at executable lines in saved files that are in the current folder or in folders on the search path.
- `dbstop if warning` has no effect when you disable warnings using `warning off all`. Similarly, `dbstop if warning identifier` has no effect when you disable warnings for the specified message identifier. See `warning` for more information about `off`, `all`, and `warning off identifier`

## Input Arguments

### **file**

File specification, typically for a MATLAB function, specified as a string. The file specification can include a partial path, but must be in a folder on the search path, or in the current folder.

If the command includes the `-completenames` option, then the file need not be on the search path, as long as the file specification is a “fully qualified name” on page 1-1443. In addition, `filespec` can include a filemarker (`>`) to specify the path to a particular local function or to a nested function within the file.

If `file` is not a MATLAB code file (for instance, it is a built-in or MDL-file), then MATLAB issues a warning. MATLAB cannot stop *in* the file, so it pauses before executing the file.

## location

Location in `file` where you want to set a breakpoint, specified as one of the following:

- `lineno`

Line number in `file` specified as a string. The default is 1.

- `lineno@n`

`n`th anonymous function on line number, `lineno`, specified as a string. The default value of `n` is 1.

- `subfun`

Name of a local function in `file`, specified as a string.

## expression

Code that evaluates (as if by `eval`) to a scalar logical value of 1 or 0, (true or false, respectively).

## condition

Condition that causes execution to pause when that condition evaluates to true. Specify `condition` as one of the following:

- `error`— Run-time error that occurs outside a `try/catch` block. You cannot resume execution after an uncaught run-time error.

If you want execution to pause only if a specific error occurs, specify the message id. For example:

- `dbstop if error` stops execution at the first run-time error that occurs outside a `try/catch` block.
- `dbstop if error MATLAB:ls:InputsMustBeStrings` pauses execution at the first run-time error outside a `try/catch` block that has a message ID of `MATLAB:ls:InputsMustBeStrings`.
- `caught error` — Run-time error that occurs within the `try` portion of a `try/catch` block. If you want execution to stop only if a specific

error occurs, specify the message id. See the error condition for an example of specifying a message id.

- **warning**— Run-time warning occurs. If you want execution to pause only if a specific warning occurs, specify the message id. See the error condition for an example of specifying a message id.

This condition has no effect if you disabled warnings with the `warning off all` command or if you disabled warnings for the specified id. For more information about disabling warnings, see `warning`.

- `naninf` and `infnan`

The code returns an infinite value (`Inf`) or a value that is not a number (`NaN`) as a result of an operator, function call, or scalar assignment. The `naninf` and `infnan` conditions have identical effects.

## **s**

Breakpoints previously saved to a structure using `s=dbstatus`.

## **Definitions**

### **fully qualified name**

- On Microsoft Windows platforms, a file name that begins with two back slashes (`\\`) or with a drive letter followed by a colon (`:`).
- On UNIX platforms, a file name that begins with a slash (`/`) or a tilde (`~`).

## **Examples**

### **Stop at First Executable Line**

This example shows how to set a breakpoint and pause execution at the first executable line in `buggy.m`.

- 1** Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

- 2** Issue the `dbstop` command.

```
dbstop in buggy
```

- 3 Run buggy.

```
buggy(2:5)
```

MATLAB displays the line where it pauses and enters debug mode.

```
2 n = length(x);  
K>>
```

- 4 Advance to the next line in the file.

```
dbstep
```

- 5 Examine the value of n in the Variable Editor.

```
openvar('n')
```

- 6 Quit debug mode.

```
dbquit
```

## Stop if Error

This example shows how to set a breakpoint and pause execution if a run-time error occurs.

- 1 Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)  
n = length(x);  
z = (1:n)./x;
```

- 2 Issue these statements in the Command Window:

```
dbstop if error  
buggy(magic(3))
```

Because `buggy.m` works on vectors only, the input in step 2 results in a run-time error. MATLAB goes into debug mode, paused at line 3 in `buggy.m`.

```
Error using ./  
Matrix dimensions must agree.
```

```
Error in buggy at 3  
z = (1:n)./x;  
3   z = (1:n)./x;
```

### 3 Quit debug mode.

```
dbquit
```

## Stop if InfNaN

This example shows how to set a breakpoint and pause execution if the code returns a NaN value.

### 1 Create a file, `buggy.m`, containing these statements.

```
function z = buggy(x)  
n = length(x);  
z = (1:n)./x;
```

### 2 Issue these commands.

```
dbstop if naninf  
buggy(0:2)
```

If any of the elements of the input, `x`, is zero, a division by zero occurs in `buggy.m`. Therefore, MATLAB returns the following message.

```
NaN/Inf breakpoint hit for buggy on line 3.
```

MATLAB is in debug mode, paused at line 3.

## Stop at Function in File

This example shows how to set a breakpoint in the `collatzall` program file at the first executable line in the `collatzplot_new` function.

- 1 Copy `collatzall.m` from the MATLAB examples folder to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...  
'examples','collatzall.m'),'.','f')
```

- 2 Open `collatzall.m` in the Editor.

```
open collatzall.m
```

- 3 Set the breakpoint.

```
dbstop in collatzall>collatzplot_new
```

## Stop at File That Is Not a MATLAB Code File

This example shows how to set a breakpoint at the built-in function `clear` when you run `myfile.m`.

- 1 Create a file, `myfile.m`, in the Editor, containing these statements.

```
function myfile(x)  
n = length(x);  
if n < 10  
    disp('length is less than 10')  
else  
    disp('length is 10 or greater')  
end  
clear  
disp('Value of n is cleared')
```

- 2 Issue these commands to set the breakpoint.

```
x = [1 2 3 4 5 6 7 8 9 10]
```

```
dbstop in clear; myfile(x)
```

MATLAB issues a warning, and pauses before the call to the `clear` function. The warning appears as shown in this image.

```
Warning: MATLAB debugger can only stop in MATLAB code files, and
"m_interpreter>clear" is not a MATLAB code file.
      Instead, the debugger will stop at the point right before
      "m_interpreter>clear" is called.
length is 10 or greater
8      clear
K>> |
```

## Restore Saved Breakpoints

This example shows how to save, and then restore, saved breakpoints.

- 1 Copy `collatzall.m` from the MATLAB examples folder to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc','matlab_env', ...
    'examples','collatzall.m'),'.','f')
```

- 2 Open `collatzall.m` in the Editor.

```
open collatzall.m
```

- 3 Set breakpoints from the Command Window.

```
dbstop at 12 in collatzall
dbstop if error
```

- 4 Run `dbstatus`.

```
dbstatus
```

MATLAB describes the breakpoints you set.

# dbstop

---

Breakpoint for `collatzall>collatzplot_new` is on line 12.  
Stop if error.

- 5 Save the breakpoints to the structure, `s`, and then save `s` to the MAT-file, `myfilebrkpnts`.

```
s=dbstatus('-completenames');  
save myfilebrkpnts s
```

Using `s=dbstatus('-completenames')` saves absolute paths and the breakpoint function nesting sequence.

- 6 Clear all breakpoints.

```
dbclean collatzall
```

- 7 Restore the breakpoints by loading the MAT-file.

```
load myfilebrkpnts  
dbstop(s)
```

The file (or files) containing the breakpoints must be on the search path or in the current folder.

- 8 Verify the breakpoints.

```
dbstatus collatzall
```

# dbup

---

**Purpose** Shift current workspace to workspace of caller, while in debug mode

**Syntax** dbup

**Description** This function allows you to examine the calling MATLAB code file to determine what caused the arguments to be passed to the called function.

dbup changes the current workspace context, while the user is in the debug mode, to the workspace of the calling file.

Multiple dbup functions change the workspace context to each previous calling file on the stack until the base workspace context is reached. (It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.)

**Tips** If you receive an error message such as the following, it means that the parent workspace is under construction so that the value of x is unavailable:

```
??? Reference to a called function result under construction x
```

**See Also** dbclear | dbcont | dbdown | dbquit | dbstack | dbstatus | dbstep | dbstop | dbtype

**Concepts**

- “Problems Viewing Variable Values from the Parent Workspace”

**Purpose**

Solve delay differential equations (DDEs) with constant delays

**Syntax**

```
sol = dde23(ddefun,lags,history,tspan)
sol = dde23(ddefun,lags,history,tspan,options)
```

**Arguments**

ddefun

Function handle that evaluates the right side of the differential equations

$y'(t) = f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$ . The function must have the form

```
dydt = ddefun(t,y,Z)
```

where  $t$  corresponds to the current  $t$ ,  $y$  is a column vector that approximates  $y(t)$ , and  $Z(:, j)$  approximates  $y(t - \tau_j)$  for delay  $\tau_j = \text{lags}(j)$ . The output is a column vector

corresponding to  $f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$ .

lags

Vector of constant, positive delays  $\tau_1, \dots, \tau_k$ .

history

Specify history in one of three ways:

- A function of  $t$  such that  $y = \text{history}(t)$  returns the solution  $y(t)$  for  $t \leq t_0$  as a column vector
- A constant column vector, if  $y(t)$  is constant
- The solution `sol` from a previous integration, if this call continues that integration

<code>tspan</code>	Interval of integration from <code>t0=tspan(1)</code> to <code>tf=tspan(end)</code> with <code>t0 &lt; tf</code> .
<code>options</code>	Optional integration argument. A structure you create using the <code>dde23set</code> function. See <code>dde23set</code> for details.

## Description

`sol = dde23(ddefun, lags, history, tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$$

on the interval  $[t_0, t_f]$ , where  $\tau_1, \dots, \tau_k$  are constant, positive delays and  $t_0, t_f$ . The input argument, `ddefun`, is a function handle.

“Parameterizing Functions” explains how to provide additional parameters to the function `ddefun`, if necessary.

`dde23` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0, tf]`.

```
yint = deval(sol, tint)
```

The structure `sol` returned by `dde23` has the following fields.

<code>sol.x</code>	Mesh selected by <code>dde23</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points in <code>sol.x</code> .
<code>sol.yp</code>	Approximation to $y'(x)$ at the mesh points in <code>sol.x</code>
<code>sol.solver</code>	Solver name, 'dde23'

`sol = dde23(ddefun, lags, history, tspan, options)` solves as above with default integration properties replaced by values in `options`, an argument created with `dde23set`. See `dde23set` and “Types of DDEs” in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance 'RelTol' ( $1e-3$  by default) and vector of absolute error tolerances 'AbsTol' (all components are  $1e-6$  by default).

Use the 'Jumps' option to solve problems with discontinuities in the history or solution. Set this option to a vector that contains the locations of discontinuities in the solution prior to  $t_0$  (the history) or in coefficients of the equations at known values of  $t$  after  $t_0$ .

Use the 'Events' option to specify a function that dde23 calls to find where functions  $g(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$  vanish. This function must be of the form

```
[value, isterminal, direction] = events(t, y, Z)
```

and contain an event function for each event to be tested. For the  $k$ th event function in events:

- `value(k)` is the value of the  $k$ th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and 0 otherwise.
- `direction(k) = 0` if you want dde23 to compute all zeros of this event function, +1 if only zeros where the event function increases, and -1 if only zeros where the event function decreases.

If you specify the 'Events' option and events are detected, the output structure `sol` also includes fields:

<code>sol.xe</code>	Row vector of locations of all events, i.e., times when an event function vanished
<code>sol.ye</code>	Matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>
<code>sol.ie</code>	Vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code>

## Examples

This example solves a DDE on the interval  $[0, 5]$  with lags 1 and 0.2. The function `ddex1de` computes the delay differential equations, and `ddex1hist` computes the history for  $t \leq 0$ .

---

**Note** The file, `ddex1.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex1` at the command line. To run it, type `ddex1` at the command line.

---

```
sol = dde23(@ddex1de,[1, 0.2],@ddex1hist,[0, 5]);
```

This code evaluates the solution at 100 equally spaced points in the interval  $[0, 5]$ , then plots the result.

```
tint = linspace(0,5);  
yint = deval(sol,tint);  
plot(tint,yint);
```

`ddex1` shows how you can code this problem using local functions. For more examples see `ddex2`.

## Algorithms

`dde23` tracks discontinuities and integrates with the explicit Runge-Kutta (2,3) pair and interpolant of `ode23`. It uses iteration to take steps longer than the lags.

## See Also

`ddesd` | `ddensd` | `ddeget` | `ddeset` | `deval` | `function_handle`

**Purpose** Extract properties from delay differential equations options structure

**Syntax**

```
val = ddeget(options,'name')  
val = ddeget(options,'name',default)
```

**Description**

`val = ddeget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = ddeget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = ddeget(opts,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `opts`.

**See Also** `dde23` | `ddesd` | `ddensd` | `ddeset`

# ddensd

## Purpose

Solve delay differential equations (DDEs) of neutral type

## Syntax

```
sol = ddensd(ddefun,dely,delyp,history,tspan)
sol = ddensd(ddefun,dely,delyp,history,tspan,options)
```

## Description

`sol = ddensd(ddefun,dely,delyp,history,tspan)` integrates a system of delay differential equations of neutral type, that has the form

$$y'(t) = f(t, y(t), y(dy_1), \dots, y(dy_p), y'(dyp_1), \dots, y'(dyp_q)) \quad (1-1)$$

where

- $t$  is the independent variable representing time.
- $dy_i$  is any of  $p$  solution delays.
- $dyp_j$  is any of  $q$  derivative delays.

`sol = ddensd(ddefun,dely,delyp,history,tspan,options)` replaces default integration parameters with those specified in `options`, a structure created with the `ddeSet` function.

## Input Arguments

### **ddefun - Derivative function**

function handle

Derivative function, specified as a function handle whose syntax is `yp = ddefun(t,y,ydel,ypdel)`. The arguments for `ddefun` are described in the table below.

<b>ddefun Argument</b>	<b>Description</b>
<code>t</code>	A scalar value representing the current value of time, $t$ .
<code>y</code>	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is $n$ -by-1, where $n$ is the number of equations in the system you want to solve.

<b>ddefun Argument</b>	<b>Description</b>
ydel	A matrix whose columns, <code>ydel(:, i)</code> , represent $y(dy_i)$ . The size of this matrix is n-by-p, where n is the number of equations in the system you want to solve, and p is the number of $y(dy)$ terms in Equation 1-1.
ypdel	A matrix whose columns, <code>ypdel(:, j)</code> represent $y'(dyp_j)$ . The size of this matrix is n-by-q, where n is the number of equations in the system you want to solve, and q is the number of $y'(dyp)$ terms in Equation 1-1.
yp	The result returned by <code>ddefun</code> . It is an n-by-1 vector whose elements represent the right side of Equation 1-1.

### **dely - Solution delays**

function handle | vector

Solution delays, specified as a function handle, which returns  $dy_1, \dots, dy_p$  in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If you specify `dely` as a function handle, the syntax must be `dy = dely(t, y)`. The arguments for this function are described in the table below.

<b>dely Argument</b>	<b>Description</b>
t	A scalar value representing the current value of time, $t$ .
y	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is n-by-1, where n is the number of equations in the system you want to solve.
dy	A vector returned by the dely function whose values are the solution delays, $dy_i$ , in Equation 1-1. The size of this vector is p-by-1, where p is the number of solution delays in the equation. Each element must be less than or equal to $t$ .

If you want to specify constant solution delays having the form  $dy_i = t - \tau_i$ , then **dely** must be a vector, where  $\text{dely}(i) = \tau_i$ . Each value in this vector must be greater than or equal to zero.

If  $dy$  is not present in the problem, set **dely** to `[]`.

### Data Types

function\_handle | single | double

### **delyp** - Derivative delays

function handle | vector

Derivative delays, specified as a function handle, which returns  $dy_{p_1}, \dots, dy_{p_q}$  in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If **delyp** is a function handle, its syntax must be `dyp = delyp(t,y)`. The arguments for this function are described in the table below.

<b>delyp Argument</b>	<b>Description</b>
<b>t</b>	A scalar value representing the current value of time, $t$ .
<b>y</b>	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is n-by-1, where n is the number of equations in the system you want to solve.
<b>dyp</b>	A vector returned by the <code>delyp</code> function whose values are the derivative delays, $dyp_j$ , in Equation 1-1. The size of this vector must be q-by-1, where q is the number of solution delays, $dyp_j$ , in the equation. Each element of <code>dyp</code> must be less than $t$ . There is one exception to this restriction: if you are solving an initial value DDE, the value of <code>dyp</code> can equal $t$ at $t = t_0$ . For more information, see “Initial Value Neutral Delay Differential Equations” on page 1-1461.

If you want specify constant derivative delays having the form  $dyp_j = t - \tau_j$ , then `delyp` must be a vector, where `delyp(j) =  $\tau_j$` . Each value in this vector must be greater than zero. An exception to this restriction occurs when you solve initial value problems for DDEs of neutral type. In such cases, a value in `delyp` can equal zero at  $t = t_0$ . See “Initial Value Neutral Delay Differential Equations” on page 1-1461 for more information.

If `dyp` is not present in the problem, set `delyp` to `[]`.

### Data Types

function\_handle | single | double

### history - Solution history

function handle | column vector | structure (sol, from previous integration) | 1-by-2 cell array

Solution history, specified as a function handle, column vector, `sol` structure (from a previous integration), or a cell array. This is the solution at  $t \leq t_0$ .

- If the history varies with time, specify the solution history as a function handle whose syntax is `y = history(t)`. This function returns an  $n$ -by-1 vector that approximates the solution,  $y(t)$ , for  $t \leq t_0$ . The length of this vector,  $n$ , is the number of equations in the system you want to solve.
- If  $y(t)$  is constant, you can specify `history` as an  $n$ -by-1 vector of the constant values.
- If you are calling `ddensd` to continue a previous integration to  $t_0$ , you can specify `history` as the output, `sol`, from the previous integration.
- If you are solving an initial value DDE, specify `history` as a cell array, `{y0, yp0}`. The first element, `y0`, is a column vector of initial values,  $y(t_0)$ . The second element, `yp0`, is a column vector whose elements are the initial derivatives,  $y'(t_0)$ . These vectors must be consistent, meaning that they satisfy Equation 1-1 at  $t_0$ . See “Initial Value Neutral Delay Differential Equations” on page 1-1461 for more information.

## Data Types

function\_handle | single | double | struct | cell

## **tspan** - Interval of integration

1-by-2 vector

Interval of integration, specified as the vector `[t0 tf]`. The first element, `t0`, is the initial value of  $t$ . The second element, `tf`, is the final value of  $t$ . The value of `t0` must be less than `tf`.

## Data Types

single | double

## **options** - Optional integration parameters

structure returned by `ddeset`

Optional integration parameters, specified as a structure created and returned by the `ddeset` function. Some commonly used properties are: 'RelTol', 'AbsTol', and 'Events'. See the `ddeset` reference page for more information about specifying options.

## Output Arguments

### **sol** - Solution

structure

Solution, returned as a structure containing the following fields.

<code>sol.x</code>	Mesh selected by <code>ddensd</code> .
<code>sol.y</code>	An approximation to $y(t)$ at the mesh points.
<code>sol.yp</code>	An approximation to $y'(t)$ at the mesh points.
<code>sol.solver</code>	A string identifying the solver, 'ddensd'.

You can pass `sol` to the `deval` function to evaluate the solution at specific points. For example, `y = deval(sol, 0.5*(sol.x(1) + sol.x(end)))` evaluates the solution at the midpoint of the interval of integration.

## Definitions

### **Initial Value Neutral Delay Differential Equations**

An initial value DDE has  $dy_i \geq t_0$  and  $dyp_j \geq t_0$ , for all  $i$  and  $j$ . At  $t = t_0$ , all delayed terms reduce to  $y(dy_i) = y(t_0)$  and  $y'(dyp_j) = y'(t_0)$ :

$$y'(t_0) = f(t_0, y(t_0), y(t_0), \dots, y(t_0), y'(t_0), \dots, y'(t_0)) \tag{1-2}$$

For  $t > t_0$ , all derivative delays must satisfy  $dyp < t$ .

When you solve initial value neutral DDEs, you must supply  $y'(t_0)$  to `ddensd`. To do this, specify `history` as a cell array `{Y0, YP0}`. Here, `Y0` is the column vector of initial values,  $y(t_0)$ , and `YP0` is a column vector of initial derivatives,  $y'(t_0)$ . These vectors must be consistent, meaning that they satisfy Equation 1-2 at  $t_0$ .

## Examples

### Neutral DDE with Two Delays

Solve the following neutral DDE, presented by Paul, for  $0 \leq t \leq \pi$ :

$$y'(t) = 1 + y(t) - 2y(t/2)^2 - y'(t - \pi)$$

with history:  $y(t) = \cos(t)$  for  $t \leq 0$ .

Create a new program file in the editor. This file will contain a main function and four local functions.

Define the first-order DDE as a local function.

```
function yp = ddefun(t,y,ydel,ypdel)
    yp = 1 + y - 2*ydel^2 - ypdel;
end
```

Define the solution delay as a local function.

```
function dy = dely(t,y)
    dy = t/2;
end
```

Define the derivative delay as a local function.

```
function dyp = delyp(t,y)
    dyp = t-pi;
end
```

Define the solution history as a local function.

```
function y = history(t)
    y = cos(t);
end
```

Define the interval of integration and solve the DDE using the `ddensd` function. Add this code to the main function.

```
tspan = [0 pi];
sol = ddensd(@ddefun,@dely,@delyp,@history,tspan);
```

Evaluate the solution at 100 equally spaced points between 0 and  $\pi$ .  
Add this code to the main function.

```
tn = linspace(0,pi);  
yn = deval(sol,tn);
```

Plot the results. Add this code to the main function.

```
plot(tn,yn);  
xlim([0 pi]);  
ylim([-1.2 1.2]);  
xlabel('time t');  
ylabel('solution y');
```

Run your program to calculate the solution and display the plot.

The file, `ddex4.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex4` at the command line.

## Algorithms

For information about the algorithm used in this solver, see Shampine [2].

## See Also

`deval` | `ddeset` | `ddesd` | `dde23` | `function_handle`

# ddesd

---

**Purpose** Solve delay differential equations (DDEs) with general delays

**Syntax**  
`sol = ddesd(ddefun,delays,history,tspan)`  
`sol = ddesd(ddefun,delays,history,tspan,options)`

## Arguments

**ddefun** Function handle that evaluates the right side of the differential equations  $y'(t) = f(t,y(t),y(d(1)),\dots,y(d(k)))$ . The function must have the form

`dydt = ddefun(t,y,Z)`

where  $t$  corresponds to the current  $t$ ,  $y$  is a column vector that approximates  $y(t)$ , and  $Z(:,j)$  approximates  $y(d(j))$  for delay  $d(j)$  given as component  $j$  of `delays(t,y)`. The output is a column vector corresponding to  $f(t,y(t),y(d(1)),\dots,y(d(k)))$ .

**delays** Function handle that returns a column vector of delays  $d(j)$ . The delays can depend on both  $t$  and  $y(t)$ . `ddesd` imposes the requirement that  $d(j) \leq t$  by using  $\min(d(j),t)$ .

If all the delay functions have the form  $d(j) = t - \tau_j$ , you can set the argument `delays` to a constant vector `delays(j) =  $\tau_j$` . With delay functions of this form, `ddesd` is used exactly like `dde23`.

history	Specify history in one of three ways: <ul style="list-style-type: none"> <li>• A function of <math>t</math> such that <math>y = \text{history}(t)</math> returns the solution <math>y(t)</math> for <math>t \leq t_0</math> as a column vector</li> <li>• A constant column vector, if <math>y(t)</math> is constant</li> <li>• The solution <code>sol</code> from a previous integration, if this call continues that integration</li> </ul>
tspan	Interval of integration from <code>t0=tspan(1)</code> to <code>tf=tspan(end)</code> with <code>t0 &lt; tf</code> .
options	Optional integration argument. A structure you create using the <code>ddeset</code> function. See <code>ddeset</code> for details.

## Description

`sol = ddesd(ddefun,delays,history,tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(d(1)), \dots, y(d(k)))$$

on the interval  $[t_0, t_f]$ , where delays  $d(j)$  can depend on both  $t$  and  $y(t)$ , and  $t_0 < t_f$ . Inputs `ddefun` and `delays` are function handles. See the `function_handle` reference page for more information.

“Parameterizing Functions” explains how to provide additional parameters to the functions `ddefun`, `delays`, and `history`, if necessary.

`ddesd` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

`yint = deval(sol,tint)`

The structure `sol` returned by `ddesd` has the following fields.

<code>sol.x</code>	Mesh selected by <code>ddesd</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points in <code>sol.x</code> .
<code>sol.yp</code>	Approximation to $y'(x)$ at the mesh points in <code>sol.x</code>
<code>sol.solver</code>	Solver name, 'ddesd'

`sol = ddesd(ddefun,delays,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and “Types of DDEs” in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance 'RelTol' ( $1e-3$  by default) and vector of absolute error tolerances 'AbsTol' (all components are  $1e-6$  by default).

Use the 'Events' option to specify a function that `ddesd` calls to find where functions  $g(t,y(t),y(d(1)),\dots,y(d(k)))$  vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the  $k$ th event function in `events`:

- `value(k)` is the value of the  $k$ th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and 0 otherwise.
- `direction(k) = 0` if you want `ddesd` to compute all zeros of this event function, +1 if only zeros where the event function increases, and -1 if only zeros where the event function decreases.

If you specify the 'Events' option and events are detected, the output structure `sol` also includes fields:

<code>sol.xe</code>	Row vector of locations of all events, i.e., times when an event function vanished
<code>sol.ye</code>	Matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>
<code>sol.ie</code>	Vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code>

## Examples

The equation

```
sol = ddesd(@ddex1de,@ddex1delays,@ddex1hist,[0,5]);
```

solves a DDE on the interval  $[0,5]$  with delays specified by the function `ddex1delays` and differential equations computed by `ddex1de`. The history is evaluated for  $t \leq 0$  by the function `ddex1hist`. The solution is evaluated at 100 equally spaced points in  $[0,5]$ :

```
tint = linspace(0,5);
yint = deval(sol,tint);
```

and plotted with

```
plot(tint,yint);
```

This problem involves constant delays. The delay function has the form

```
function d = ddex1delays(t,y)
%DDEX1DELAYS Delays for using with DDEX1DE.
d = [ t - 1
      t - 0.2];
```

The problem can also be solved with the syntax corresponding to constant delays

```
delays = [1, 0.2];
sol = ddesd(@ddex1de,delays,@ddex1hist,[0, 5]);
```

or using `dde23`:

# ddesd

---

```
sol = dde23(@ddex1de,delays,@ddex1hist,[0, 5]);
```

For more examples of solving delay differential equations see `ddex2` and `ddex3`.

## See Also

`dde23` | `ddeget` | `ddensd` | `ddeset` | `deval` | `function_handle`

**Purpose**

Create or alter delay differential equations options structure

**Syntax**

```
options = ddeset('name1',value1,'name2',value2,...)
options = ddeset(olddopts,'name1',value1,...)
options = ddeset(olddopts,newdopts)
ddeset
```

**Description**

`options = ddeset('name1',value1,'name2',value2,...)` creates an integrator options structure `options` in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. `ddeset` ignores case for property names.

`options = ddeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This overwrites any values in `olddopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = ddeset(olddopts,newdopts)` combines an existing options structure `olddopts` with a new options structure `newdopts`. Any values set in `newdopts` overwrite the corresponding values in `olddopts`.

`ddeset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `ddeget` to query the options structure for the value of a specific property.

**DDE  
Properties**

The following sections describe the properties that you can set using `ddeset`. There are several categories of properties:

- Error control
- Solver output
- Step size
- Event location
- Discontinuities

## Error Control Properties

At each step, the DDE solvers estimate an error  $e$ . The `dde23` function estimates the local truncation error, and the other solvers estimate the residual. In either case, this error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

$$|e(i)| * \max(\text{RelTol} * \text{abs}(y(i)), \text{AbsTol}(i))$$

For routine problems, the solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over “long” intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For the absolute error tolerance, the scaling of the solution components is important: if  $|y|$  is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in  $y$ . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component  $y(i)$  when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in  $y(i)$  so that you can accurately compute more interesting components.

The following table describes the error control properties.

**DDE Error Control Properties**

<b>Property</b>	<b>Value</b>	<b>Description</b>
RelTol	Positive scalar {1e-3}	<p>A relative error tolerance that applies to all components of the solution vector <math>y</math>. It is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components except those smaller than thresholds <math>AbsTol(i)</math>. The default, 1e-3, corresponds to 0.1% accuracy.</p> <p>The estimated error in each integration step satisfies <math> e(i)  \leq \max(RelTol * abs(y(i)), AbsTol(i))</math>.</p>
AbsTol	Positive scalar or vector {1e-6}	<p>Absolute error tolerances that apply to the individual components of the solution vector. <math>AbsTol(i)</math> is a threshold below which the value of the <math>i</math>th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero. Even if you are not interested in a component <math>y(i)</math> when it is small, you may have to specify <math>AbsTol(i)</math> small enough to get some correct digits in <math>y(i)</math> so that you can accurately compute more interesting components.</p> <p>If <math>AbsTol</math> is a vector, the length of <math>AbsTol</math> must be the same as the length of the solution vector <math>y</math>. If <math>AbsTol</math> is a scalar, the value applies to all components of <math>y</math>.</p>
NormControl	on   {off}	<p>Control error relative to norm of solution. Set this property on to request that the solvers control the error in each integration step with <math>norm(e) \leq \max(RelTol * norm(y), AbsTol)</math>. By default, the solvers use a more stringent component-wise error control.</p>

**Solver Output Properties**

You can use the solver output properties to control the output that the solvers generate.

## DDE Solver Output Properties

Property	Value	Description
OutputFcn	Function handle {@odeplot}	<p>The output function is a function that the solver calls after every successful integration step. To specify an output function, set 'OutputFcn' to a function handle. For example,</p> <pre>options = ddeset('OutputFcn',... @myfun)</pre> <p>sets 'OutputFcn' to @myfun, a handle to the function myfun. See the <a href="#">function_handle</a> reference page for more information.</p> <p>The output function must be of the form</p> <pre>status = myfun(t,y,flag)</pre> <p>“Parameterizing Functions” explains how to provide additional parameters to myfun, if necessary.</p> <p>The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:</p> <ul style="list-style-type: none"><li>• <code>init</code> — The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> is the input argument to the solvers. <code>y0</code> is the initial value of the solution, either from <code>history(t0)</code> or specified in the <code>initialY</code> option.</li><li>• <code>{none}</code> — The solver calls <code>status = myfun(t,y)</code> after each integration step on which output is requested. <code>t</code> contains points where output was</li></ul>

**DDE Solver Output Properties (Continued)**

Property	Value	Description
		<p>generated during the step, and <i>y</i> is the numerical solution at the points in <i>t</i>. If <i>t</i> is a vector, the <i>i</i>th column of <i>y</i> corresponds to the <i>i</i>th element of <i>t</i>.</p> <p><i>myfun</i> must return a <b>status</b> output value of 0 or 1. If <code>literal &gt; status</code>, the solver halts integration. You can use this mechanism, for instance, to implement a <b>Stop</b> button.</p> <ul style="list-style-type: none"> <li>• <b>done</b> — The solver calls <code>myfun([], [], 'done')</code> when integration is complete to allow the output function to perform any cleanup chores.</li> </ul> <p>You can use these general purpose output functions or you can edit them to create your own. Type <code>help functionname</code> at the command line for more information.</p> <ul style="list-style-type: none"> <li>• <b>odeplot</b> – time series plotting (default when you call the solver with no output argument and you have not specified an output function)</li> <li>• <b>odephas2</b> – two-dimensional phase plane plotting</li> <li>• <b>odephas3</b> – three-dimensional phase plane plotting</li> <li>• <b>odeprint</b> – print solution as the solver computes it</li> </ul>
OutputSel	Vector of indices	<p>Vector of indices specifying which components of the solution vector the solvers pass to the output function. For example, if you want to use the <code>odeplot</code> output function, but you want to plot only the first and third components of the solution, you can do this using</p> <pre>options = ddeaset... ('OutputFcn',@odeplot,...</pre>

## DDE Solver Output Properties (Continued)

Property	Value	Description
		<code>'OutputSel',[1 3]);</code>  By default, the solver passes all components of the solution to the output function.
Stats	on   {off}	Specifies whether the solver should display statistics about its computations. By default, <code>Stats</code> is <code>off</code> . If it is <code>on</code> , after solving the problem the solver displays: <ul style="list-style-type: none"> <li>• The number of successful steps</li> <li>• The number of failed attempts</li> <li>• The number of times the DDE function was called</li> </ul>

### Step Size Properties

The step size properties let you specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step size properties.

### DDE Step Size Properties

Property	Value	Description
InitialStep	Positive scalar	Suggested initial step size. <code>InitialStep</code> sets an upper bound on the magnitude of the first step size the solver tries. If you do not set <code>InitialStep</code> , the solver bases the initial step size on the slope of the solution at the initial time <code>tspan(1)</code> . The initial step size is limited by the shortest delay. If the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know

**DDE Step Size Properties (Continued)**

Property	Value	Description
		this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable <code>InitialStep</code> .
MaxStep	Positive scalar {0.1* abs(t0-tf)}	Upper bound on solver step size. If the differential equation has periodic coefficients or solutions, it may be a good idea to set MaxStep to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do <i>not</i> reduce MaxStep: <ul style="list-style-type: none"> <li>• When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance <code>RelTol</code>, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector <code>AbsTol</code>. (See “Error Control Properties” on page 1-1472 for a description of the error tolerance properties.)</li> <li>• To make sure that the solver doesn’t step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances <code>RelTol</code> and <code>AbsTol</code>. Use <code>MaxStep</code> as a last resort.</li> </ul>

**Event Location Property**

In some DDE problems, the times of specific events are important. While solving a problem, the solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the Events property.

## DDE Events Property

String	Value	Description
Events	Function handle	<p>A function handle that includes one or more event functions. For <code>dde23</code> and <code>ddesd</code>, this function has the following syntax:</p> <pre>[value, isterminal, direction] = events(t, y, YDEL)</pre> <p>For <code>ddensd</code>, the syntax is:</p> <pre>[value, isterminal, direction] = events(t, y, YDEL, YPDEL)</pre> <p>The output arguments, <code>value</code>, <code>isterminal</code>, and <code>direction</code>, are vectors for which the <code>ith</code> element corresponds to the <code>ith</code> event function:</p> <ul style="list-style-type: none"> <li>• <code>value(i)</code> is the value of the <code>ith</code> event function.</li> <li>• <code>isterminal(i) = 1</code> if you want the integration to terminate at a zero of this event function, and <code>0</code> otherwise.</li> <li>• <code>direction(i) = 0</code> if you want the solver to locate all zeros (the default), <code>+1</code> if only zeros where the event function is increasing, and <code>-1</code> if only zeros where the event function is decreasing.</li> </ul> <p>If you specify an events function and events are detected, the solver returns three additional fields in the solution structure <code>sol</code>:</p> <ul style="list-style-type: none"> <li>• <code>sol.xe</code> is a row vector of times at which events occur.</li> <li>• <code>sol.ye</code> is a matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>.</li> <li>• <code>sol.ie</code> is a vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code>.</li> </ul>

**DDE Events Property (Continued)**

String	Value	Description
		For examples that use an event function while solving ordinary differential equation problems, see “Event Location” ( <code>ballode</code> ) and “Advanced Event Location” ( <code>orbitode</code> ), in the MATLAB Mathematics documentation.

**Discontinuity Properties**

The solver functions can solve problems with discontinuities in the history or in the coefficients of the equations. The following properties enable you to provide these solvers with a different initial value, and, for `dde23`, locations of known discontinuities. For more information, see “Discontinuities in DDEs”.

The following table describes the discontinuity properties.

**DDE Discontinuity Properties**

String	Value	Description
<code>Jumps</code>	Vector	Location of discontinuities. Points $t$ where the history or solution may have a jump discontinuity in a low-order derivative. This applies only to the <code>dde23</code> solver.
<code>InitialY</code>	Vector	Initial value of solution. By default the initial value of the solution is the value returned by <code>history</code> at the initial point. Supply a different initial value as the value of the <code>InitialY</code> property.

**Examples**

To create an options structure that changes the relative error tolerance of the solver from the default value of  $1e-3$  to  $1e-4$ , enter

```
options = ddeaset('RelTol',1e-4);
```

# ddeset

---

To recover the value of 'RelTol' from options, enter

```
ddeget(options,'RelTol')
```

```
ans =
```

```
1.0000e-004
```

## See Also

**Purpose** Distribute inputs to outputs

---

**Note** Beginning with MATLAB Version 7.0 software, you can access the contents of cell arrays and structure fields without using the `deal` function. See Example 3, below.

---

**Syntax**

```
[Y1, Y2, Y3, ...] = deal(X)
[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)
[S.field] = deal(X)
[X{:}] = deal(A.field)
[Y1, Y2, Y3, ...] = deal(X{:})
[Y1, Y2, Y3, ...] = deal(S.field)
```

**Description**

`[Y1, Y2, Y3, ...] = deal(X)` copies the single input to all the requested outputs. It is the same as `Y1 = X, Y2 = X, Y3 = X, ...`

`[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)` is the same as `Y1 = X1; Y2 = X2; Y3 = X3; ...`

**Tips**

`deal` is most useful when used with cell arrays and structures via comma-separated list expansion. Here are some useful constructions:

`[S.field] = deal(X)` sets all the fields with the name `field` in the structure array `S` to the value `X`. If `S` doesn't exist, use `[S(1:m).field] = deal(X)`.

`[X{:}] = deal(A.field)` copies the values of the field with name `field` to the cell array `X`. If `X` doesn't exist, use `[X{1:m}] = deal(A.field)`.

`[Y1, Y2, Y3, ...] = deal(X{:})` copies the contents of the cell array `X` to the separate variables `Y1, Y2, Y3, ...`

`[Y1, Y2, Y3, ...] = deal(S.field)` copies the contents of the fields with the name `field` to separate variables `Y1, Y2, Y3, ...`

## Examples

### Example 1 – Assign Data From a Cell Array

Use `deal` to copy the contents of a 4-element cell array into four separate output variables.

```
C = {rand(3) ones(3,1) eye(3) zeros(3,1)};
[a,b,c,d] = deal(C{:})
```

```
a =
    0.9501    0.4860    0.4565
    0.2311    0.8913    0.0185
    0.6068    0.7621    0.8214
```

```
b =
     1
     1
     1
```

```
c =
     1     0     0
     0     1     0
     0     0     1
```

```
d =
     0
     0
     0
```

### Example 2 – Assign Data From Structure Fields

Use `deal` to obtain the contents of all the name fields in a structure array:

```
A.name = 'Pat'; A.number = 176554;
A(2).name = 'Tony'; A(2).number = 901325;
[name1,name2] = deal(A(:).name)
```

```
name1 =
    Pat
```

```
name2 =  
    Tony
```

### Example 3 – Doing the Same Without deal

Beginning with MATLAB Version 7.0 software, you can, in most cases, access the contents of cell arrays and structure fields without using the `deal` function. The two commands shown below perform the same operation as those used in the previous two examples, except that these commands do not require `deal`.

```
[a,b,c,d] = C{:}  
[name1,name2] = A(:).name
```

### See Also

```
cell | iscell | celldisp | struct | isstruct | fieldnames |  
isfield | orderfields | rmfield | cell2struct | struct2cell
```

# deblank

---

**Purpose** Strip trailing blanks from end of string

**Syntax** `str = deblank(str)`  
`c = deblank(c)`

**Description** `str = deblank(str)` removes all trailing whitespace and null characters from the end of character string `str`. A whitespace is any character for which the `isspace` function returns logical 1 (true).

`c = deblank(c)` when `c` is a cell array of strings, applies `deblank` to each element of `c`.

The `deblank` function is useful for cleaning up the rows of a character array.

## Examples

### Example 1 – Removing Trailing Blanks From a String

Compose a string `str` that contains space, tab, and null characters:

```
NL = char(0);    TAB = char(9);  
str = [NL 32 TAB NL 'AB' 32 NL 'CD' NL 32 TAB NL 32];
```

Display all characters of the string between `|` symbols:

```
['|' str '|']  
ans =  
    |    AB  CD    |
```

Remove trailing whitespace and null characters, and redisplay the string:

```
newstr = deblank(str);  
  
['|' newstr '|']  
ans =  
    |    AB  CD|
```

## Example 2- Removing Trailing Blanks From a Cell Array of Strings

Create a 2-by-2 cell array in which each cell contains a word with trailing blanks:

```
A{1,1} = 'MATLAB   ';  
A{1,2} = 'SIMULINK   ';  
A{2,1} = 'Toolboxes   ';  
A{2,2} = 'MathWorks   '  
A =  
    'MATLAB   '    'SIMULINK   '  
    'Toolboxes   '    'MathWorks   '
```

Remove the trailing blanks and redisplay the cell array:

```
deblank(A);  
A  
A =  
    'MATLAB'    'SIMULINK'  
    'Toolboxes'    'MathWorks'
```

### See Also

`strjust` | `strtrim`

# dec2base

---

**Purpose** Convert decimal to base N number in string

**Syntax** `str = dec2base(d, base)`  
`str = dec2base(d, base, n)`

**Description** `str = dec2base(d, base)` converts the nonnegative integer `d` to the specified base. `d` must be a nonnegative integer smaller than  $2^{52}$ , and `base` must be an integer between 2 and 36. The returned argument `str` is a string.

`str = dec2base(d, base, n)` produces a representation with at least `n` digits.

**Examples** The expression `dec2base(23, 2)` converts  $23_{10}$  to base 2, returning the string `'10111'`.

**See Also** `base2dec`

**Purpose** Convert decimal to binary number in string

**Syntax** `str = dec2bin(d)`  
`str = dec2bin(d,n)`

**Description** returns the  
`str = dec2bin(d)` binary representation of `d` as a string. `d` must be a nonnegative integer smaller than  $2^{52}$ .  
`str = dec2bin(d,n)` produces a binary representation with at least `n` bits.  
The output of `dec2bin` is independent of the endian settings of the computer you are using.

**Examples** Decimal 23 converts to binary 010111:

```
dec2bin(23)
ans =
    10111
```

**See Also** [bin2dec](#) | [dec2hex](#)

# dec2hex

---

**Purpose** Convert decimal to hexadecimal number in string

**Syntax** `str = dec2hex(d)`  
`str = dec2hex(d, n)`

**Description** `str = dec2hex(d)` converts the decimal integer `d` to its hexadecimal representation stored in a MATLAB string. `d` must be a nonnegative integer smaller than  $2^{52}$ . MATLAB converts noninteger inputs, such as those of class `double` or `char`, to their integer equivalents before converting to hexadecimal.

`str = dec2hex(d, n)` produces a hexadecimal representation with at least `n` digits.

**Examples** To convert decimal 1023 to hexadecimal,

```
dec2hex(1023)
ans =
    3FF
```

```
dec2hex(1023, 6)
ans =
0003FF
```

Convert 2-by-5 array `A` to hexadecimal:

```
A = [3487,    125,   8997,   1433,   189; ...
      771,   84832,   118,   9366,   212];
```

<code>A(:)</code>	<code>dec2hex(A)</code>
<code>ans =</code>	<code>ans =</code>
3487	00D9F
771	00303
125	0007D
84832	14B60
8997	02325
118	00076
1433	00599

9366	02496
189	000BD
212	000D4

## See Also

[dec2bin](#) | [format](#) | [hex2dec](#) | [hex2num](#)

# decic

---

## Purpose

Compute consistent initial conditions for ode15i

## Syntax

```
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,
    options)
[y0mod,yp0mod,resnorm] = decic(odefun,t0,y0,fixed_y0,yp0,
    fixed_yp0...)
```

## Description

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)` uses the inputs `y0` and `yp0` as initial guesses for an iteration to find output values that satisfy the requirement  $f(t_0, y_0 \text{mod}, y_0 \text{mod}) = 0$ , i.e., `y0mod` and `yp0mod` are consistent initial conditions. `odefun` is a function handle. The function `decic` changes as few components of the guesses as possible. You can specify that `decic` holds certain components fixed by setting `fixed_y0(i) = 1` if no change is permitted in the guess for `y0(i)` and 0 otherwise. `decic` interprets `fixed_y0 = []` as allowing changes in all entries. `fixed_yp0` is handled similarly.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

You cannot fix more than `length(y0)` components. Depending on the problem, it may not be possible to fix this many. It also may not be possible to fix certain components of `y0` or `yp0`. It is recommended that you fix no more components than necessary.

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0, options)` computes as above with default tolerances for consistent initial conditions, `AbsTol` and `RelTol`, replaced by the values in `options`, a structure you create with the `odeset` function.

`[y0mod,yp0mod,resnorm] = decic(odefun,t0,y0,fixed_y0,yp0, fixed_yp0...)` returns the norm of `odefun(t0,y0mod,yp0mod)` as `resnorm`. If the norm seems unduly large, use `options` to decrease `RelTol` ( $1e-3$  by default).

**Examples**

The files, `ihb1dae.m` and `iburgersode.m`, provide examples which use `decic` to solve implicit ODEs.

**See Also**

`ode15i` | `odeget` | `odeset` | `function_handle`

# deconv

---

**Purpose** Deconvolution and polynomial division

**Syntax**  $[q,r] = \text{deconv}(v,u)$

**Description**  $[q,r] = \text{deconv}(v,u)$  deconvolves vector  $u$  out of vector  $v$ , using long division. The quotient is returned in vector  $q$  and the remainder in vector  $r$  such that  $v = \text{conv}(u,q)+r$ .

If  $u$  and  $v$  are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division. The result of dividing  $v$  by  $u$  is quotient  $q$  and remainder  $r$ .

## Examples

If

```
u = [1 2 3 4]
v = [10 20 30]
```

the convolution is

```
c = conv(u,v)
c =
    10    40   100   160   170   120
```

Use deconvolution to recover  $u$ :

```
[q,r] = deconv(c,u)
q =
    10    20    30
r =
     0     0     0     0     0     0
```

This gives a quotient equal to  $v$  and a zero remainder.

**Algorithms** `deconv` uses the `filter` primitive.

**See Also** `conv` | `residue`

<b>Purpose</b>	Discrete Laplacian
<b>Syntax</b>	<code>L = del2(U)</code> <code>L = del2(U,h)</code> <code>L = del2(U,h1,...,hN)</code>
<b>Description</b>	<p><code>L = del2(U)</code> returns a discrete approximation of Laplace's differential operator applied to <code>U</code> using the default spacing, <code>h = 1</code>, between all points.</p> <p><code>L = del2(U,h)</code> specifies a uniform, scalar spacing, <code>h</code>, between points in all dimensions of <code>U</code>.</p> <p><code>L = del2(U,h1,...,hN)</code> specifies the spacing, <code>h1,...,hN</code>, between points in each corresponding dimension of <code>U</code>. For each dimension, specify the spacing as a scalar or a vector of coordinates. The number of spacing inputs must equal the number of dimensions in <code>U</code>.</p>
<b>Input Arguments</b>	<p><b>U - Input array</b> vector   matrix   multidimensional array Input array, specified as a vector, matrix, or multidimensional array.</p> <p><b>Data Types</b> single   double <b>Complex Number Support:</b> Yes</p> <p><b>h - Spacing in all dimensions</b> 1 (default)   scalar Spacing in all dimensions, specified as 1 (default), or a scalar.</p> <p><b>Data Types</b> single   double <b>Complex Number Support:</b> Yes</p> <p><b>h1,...,hN - Spacing in each dimension</b></p>

scalars | vectors

Spacing in each dimension, specified as scalars or vectors. The number of spacing inputs must be equal to the number of dimensions in  $U$ . Each spacing input defines the spacing between points in the corresponding dimension of  $U$ :

- Use a scalar to specify a uniform spacing.
- Use a vector to specify a nonuniform spacing. The coordinate vector gives the position of each point and must have the same number of elements as the corresponding dimension of  $U$  (a one-to-one match of coordinates and points).

### Data Types

single | double

**Complex Number Support:** Yes

## Output Arguments

### L - Discrete Laplacian approximation

vector | matrix | multidimensional array

Discrete Laplacian approximation, returned as a vector, matrix, or multidimensional array.  $L$  is the same size as the input,  $U$ .

## Examples

### Second Derivative of Vector

Calculate the acceleration of an object from a vector of position data.

Create a vector of position data.

```
p = [1 3 6 10 16 18 29];
```

This data corresponds to the measurement of an object's position once per second for 7 seconds.

To find the acceleration of the object, use `del2` to calculate the second numerical derivative of  $p$ . Use the default spacing  $h = 1$  between data points.

```
L = 4*del2(p)
```

```
L =
     1     1     1     2    -4     9    22
```

Each value of  $L$  is an approximation of the instantaneous acceleration at that point.

### Second Derivative of Cosine Vector

Calculate the discrete 1-D Laplacian of a cosine vector.

Define the domain of the function.

```
x = linspace(-2*pi,2*pi);
```

This produces 100 evenly spaced points in the range  $-2\pi \leq x \leq 2\pi$ .

Create a vector of cosine values in this domain.

```
U = cos(x);
```

Calculate the Laplacian of  $U$  using `del2`. Use the domain vector  $x$  to define the 1-D coordinate of each point in  $U$ .

```
L = 4*del2(U,x);
```

Analytically, the Laplacian of this function is equal to  $\Delta U = -\cos(x)$ .

Plot the results.

```
plot(x,U,x,L);legend('U(x)', 'L(x)', 'Location', 'Best')
```

The graph of  $U$  and  $L$  agrees with the analytic result for the Laplacian.

### **Laplacian of Multivariate Function**

Calculate and plot the discrete Laplacian of a multivariate function.

Define the  $x$  and  $y$  domain of the function.

```
[x,y] = meshgrid(-5:0.25:5, -5:0.25:5);
```

Define the function  $U(x,y) = \frac{1}{3}(x^4 + y^4)$  over this domain.

```
U = 1/3.*(x.^4+y.^4);
```

Calculate the Laplacian of this function using `del2`. The spacing between the points in `U` is equal in all directions, so you can specify a single spacing input, `h`.

```
h = 0.25;  
L = 4*del2(U,h);
```

Analytically, the Laplacian of this function is equal to

$$\Delta U(x,y) = 4x^2 + 4y^2.$$

Plot the discrete Laplacian, `L`.

```
figure;hold on;grid on;  
title('Plot of  $\Delta U(x,y) = 4x^2+4y^2$ ','Interpreter','latex')  
xlabel('x'); ylabel('y'); zlabel('z');  
surf(x,y,L);  
view(35,14)
```

The graph of  $L$  agrees with the analytic result for the Laplacian.

### **Laplacian of Natural Logarithm Function**

Calculate the discrete Laplacian of a natural logarithm function.

Define the  $x$  and  $y$  domain of the function on a grid of real numbers.

```
[x,y] = meshgrid(-5:5, -5:0.5:5);
```

Define the function  $U(x,y) = \frac{1}{2} \log(x^2 y)$  over this domain.

```
U = 0.5*log(x.^2.*y);
```

The logarithm is complex-valued when the argument  $y$  is negative.

Use `del2` to calculate the discrete Laplacian of this function. Specify the spacing between grid points in each direction.

```
hx = 1;  
hy = 0.5;  
L = 4*del2(U,hx,hy);
```

Analytically, the Laplacian is equal to  $\Delta U(x,y) = -\left(\frac{1}{x^2} + \frac{1}{2y^2}\right)$ . This function is not defined on the lines  $x = 0$  or  $y = 0$ .

Plot the real parts of  $U$  and  $L$  on the same graph.

```
figure;hold on;grid on;  
title('Plot of U(x,y) and  $\Delta U(x,y)$ ','Interpreter','latex')  
xlabel('x'); ylabel('y'); zlabel('z');  
surf(x,y,real(L)); surf(x,y,real(U));  
view(41,58)
```

The top surface is  $U$  and the bottom surface is  $L$ .

## Definitions

### Laplace's differential operator

If a matrix  $U$  is a function  $U(x,y)$  that is evaluated at the points of a square grid, then  $\text{del2}(U)$  is a finite difference approximation of Laplace's differential operator applied to  $U$ :

$$L = \frac{\Delta U}{4} = \frac{1}{4} \left( \frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} \right).$$

For functions of more variables,  $U(x,y,z,\dots)$ , the discrete Laplacian `del2(U)` calculates second-derivatives in each dimension,

$$L = \frac{\Delta U}{2N} = \frac{1}{2N} \left( \frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial z^2} + \dots \right),$$

where  $N$  is the number of dimensions in  $U$  and  $N \geq 2$ .

## Algorithms

If the input  $U$  is a matrix, the interior points of  $L$  are found by taking the difference between a point in  $U$  and the average of its four neighbors:

$$L_{ij} = \sum_i \sum_j \left[ \frac{(u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1})}{4} - u_{i,j} \right].$$

Then, `del2` calculates the values on the edges of  $L$  by linearly extrapolating the second differences from the interior. This formula is extended for multidimensional  $U$ .

# DelaunayTri

---

**Superclasses** TriRep

**Purpose** (Will be removed) Delaunay triangulation in 2-D and 3-D

---

**Note** DelaunayTri will be removed in a future release. Use delaunayTriangulation instead.

---

**Description** DelaunayTri creates a Delaunay triangulation object from a set of points. You can incrementally modify the triangulation by adding or removing points. In 2-D triangulations you can impose edge constraints. You can perform topological and geometric queries, and compute the Voronoi diagram and convex hull.

**Definitions** The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

**Construction** DelaunayTri (Will be removed) Construct Delaunay triangulation

**Methods**

convexHull	(Will be removed) Convex hull
inOutStatus	(Will be removed) Status of triangles in 2-D constrained Delaunay triangulation
nearestNeighbor	(Will be removed) Point closest to specified location

pointLocation	(Will be removed) Simplex containing specified location
voronoiDiagram	(Will be removed) Voronoi diagram

## Inherited methods

baryToCart	(Will be removed) Convert point coordinates from barycentric to Cartesian
cartToBary	(Will be removed) Convert point coordinates from cartesian to barycentric
circumcenters	(Will be removed) Circumcenters of specified simplices
edgeAttachments	(Will be removed) Simplices attached to specified edges
edges	(Will be removed) Triangulation edges
faceNormals	(Will be removed) Unit normals to specified triangles
featureEdges	(Will be removed) Sharp edges of surface triangulation
freeBoundary	(Will be removed) Facets referenced by only one simplex
incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information

---

size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

## Properties

Constraints	<p>Constraints is a numc-by-2 matrix that defines the constrained edge data in the triangulation, where numc is the number of constrained edges. Each constrained edge is defined in terms of its endpoint indices into <math>X</math>.</p> <p>The constraints can be specified when the triangulation is constructed or can be imposed afterwards by directly editing the constraints data.</p> <p>This feature is only supported for 2-D triangulations.</p>
$X$	<p>The dimension of <math>X</math> is mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside. If column vectors of <math>x,y</math> or <math>x,y,z</math> coordinates are used to construct the triangulation, the data is consolidated into a single matrix <math>X</math>.</p>
Triangulation	<p>Triangulation is a matrix representing the set of simplices (triangles or tetrahedra etc.) that make up the triangulation. The matrix is of size mtri-by-nv, where mtri is the number of simplices and nv is the number of vertices per simplex. The triangulation is represented by standard simplex-vertex format; each row specifies a simplex defined by indices into <math>X</math>, where <math>X</math> is the array of point coordinates.</p>

## **Instance Hierarchy**

DelaunayTri is a subclass of TriRep.

## **Copy Semantics**

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

[scatteredInterpolant](#) | [triangulation](#) | [delaunayTriangulation](#)

# DelaunayTri

---

**Purpose** (Will be removed) Construct Delaunay triangulation

---

**Note** DelaunayTri will be removed in a future release. Use delaunayTriangulation instead.

---

**Syntax**

```
DT = DelaunayTri()  
DT = DelaunayTri(X)  
DT = DelaunayTri(x,y)  
DT = DelaunayTri(x,y,z)  
DT = DelaunayTri(..., C)
```

**Description**

DT = DelaunayTri() creates an empty Delaunay triangulation.

DT = DelaunayTri(X), DT = DelaunayTri(x,y) and DT = DelaunayTri(x,y,z) create a Delaunay triangulation from a set of points. The points can be specified as an mpts-by-ndim matrix X, where mpts is the number of points and ndim is the dimension of the space where the points reside, where ndim is 2 or 3. Alternatively, the points can be specified as column vectors (x,y) or (x,y,z) for 2-D and 3-D input.

DT = DelaunayTri(..., C) creates a constrained Delaunay triangulation. The edge constraints C are defined by an numc-by-2 matrix, numc being the number of constrained edges. Each row of C defines a constrained edge in terms of its endpoint indices into the point set X. This feature is only supported for 2-D triangulations.

**Definitions**

The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

**Examples**

Compute the Delaunay triangulation of twenty random points located within a unit square.

```
x = rand(20,1);
```

```
y = rand(20,1);  
dt = DelaunayTri(x,y)  
triplot(dt);
```

For more examples, type `help demoDelaunayTri` at the MATLAB command-line prompt.

[scatteredInterpolant](#) | [triangulation](#) | [delaunayTriangulation](#)

# delaunay

---

**Purpose** Delaunay triangulation

---

**Note** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `delaunay`.

---

**Syntax**

```
TRI = delaunay(X,Y)
TRI = delaunay(X,Y,Z)
TRI = delaunay(X)
```

**Definitions** `delaunay` creates a Delaunay triangulation of a set of points in 2-D or 3-D space. A 2-D Delaunay triangulation ensures that the circumcircle associated with each triangle contains no other point in its interior. This definition extends naturally to higher dimensions.

**Description** `TRI = delaunay(X,Y)` creates a 2-D Delaunay triangulation of the points  $(X,Y)$ , where  $X$  and  $Y$  are column-vectors. `TRI` is a matrix representing the set of triangles that make up the triangulation. The matrix is of size `mtri-by-3`, where `mtri` is the number of triangles. Each row of `TRI` specifies a triangle defined by indices with respect to the points.

`TRI = delaunay(X,Y,Z)` creates a 3-D Delaunay triangulation of the points  $(X,Y,Z)$ , where  $X$ ,  $Y$ , and  $Z$  are column-vectors. `TRI` is a matrix

representing the set of tetrahedra that make up the triangulation. The matrix is of size `mtri-by-4`, where `mtri` is the number of tetrahedra. Each row of `TRI` specifies a tetrahedron defined by indices with respect to the points.

`TRI = delaunay(X)` creates a 2-D or 3-D Delaunay triangulation from the point coordinates `X`. This variant supports the definition of points in matrix format. `X` is of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . The output triangulation is equivalent to that of the dedicated functions supporting the 2-input or 3-input calling syntax.

`delaunay` produces an isolated triangulation, useful for applications like plotting surfaces via the `trisurf` function. If you wish to query the triangulation; for example, to perform nearest neighbor, point location, or topology queries, use `delaunayTriangulation` instead.

## Visualization

Use one of these functions to plot the output of `delaunay`:

- |                      |  |
|----------------------|--|
| <code>triplot</code> | Displays the triangles defined in the <code>m-by-3</code> matrix <code>TRI</code> .  |
| <code>trisurf</code> | Displays each triangle defined in the <code>m-by-3</code> matrix <code>TRI</code> as a surface in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example |

```
trisurf(TRI,x,y,zeros(size(x)))
```

# delaunay

---

`trimesh` Displays each triangle defined in the m-by-3 matrix TRI as a mesh in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example,

```
trimesh(TRI,x,y,zeros(size(x)))
```

produces almost the same result as `triplot`, except in 3-D space.

`tetramesh` Plots a triangulation composed of tetrahedra.

## Examples

### Example

Plot the Delaunay triangulation of a large dataset:

```
load seamount
tri = delaunay(x,y);
trisurf(tri,x,y,z);
```

## See Also

[delaunayTriangulation](#) | [scatteredInterpolant](#) | [plot](#) | [triplot](#) | [trimesh](#) | [trisurf](#)

# delaunayn

---

**Purpose** N-D Delaunay triangulation

**Syntax** `T = delaunayn(X)`  
`T = delaunayn(X, options)`

**Description** `T = delaunayn(X)` computes a set of simplices such that no data points of `X` are contained in any circumspheres of the simplices. The set of simplices forms the Delaunay triangulation. `X` is an `m`-by-`n` array representing `m` points in `n`-dimensional space. `T` is a `numt`-by-`(n+1)` array where each row contains the indices into `X` of the vertices of the corresponding simplex.

`T = delaunayn(X, options)` specifies a cell array of strings options. The default options are:

- `{'Qt', 'Qbb', 'Qc'}` for 2- and 3-dimensional input
- `{'Qt', 'Qbb', 'Qc', 'Qx'}` for 4 and higher-dimensional input

If `options` is `[]`, the default options used. If `options` is `{''}`, no options are used, not even the default.

**Visualization** Plotting the output of `delaunayn` depends of the value of `n`:

- For `n = 2`, use `triplot`, `trisurf`, or `trimesh` as you would for `delaunay`.
- For `n = 3`, use `tetramesh`.

For more control over the color of the facets, use `patch` to plot the output.

- You cannot plot `delaunayn` output for `n > 3`.

**Examples** **Example 1**

This example generates an `n`-dimensional Delaunay triangulation, where `n = 3`.

```
d = [-1 1];  
[x,y,z] = meshgrid(d,d,d); % A cube
```

```

x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
X = [x(:) y(:) z(:)];
Tes = delaunayn(X)

```

Tes =

4	3	9	1
4	9	2	1
7	9	3	1
7	5	9	1
7	9	4	3
7	8	4	9
6	2	9	1
6	9	5	1
6	4	9	2
6	4	8	9
6	9	7	5
6	8	7	9

You can use `tetramesh` to visualize the tetrahedrons that form the corresponding simplex. `camorbit` rotates the camera position to provide a meaningful view of the figure.

```
tetramesh(Tes,X);camorbit(20,0)
```

# delaunayn

---

**Superclasses** triangulation

**Purpose** Delaunay triangulation in 2-D and 3-D

**Description** Use the `delaunayTriangulation` class to create a 2-D or 3-D triangulation from a set of points. When your points are in 2-D, you can specify edge constraints .

You can perform a variety of topological and geometric queries on a `delaunayTriangulation`, including any triangulation query. For example, locate a facet that contains a specific point, find the vertices of the convex hull, or compute the Voronoi Diagram.

**Construction** `DT = delaunayTriangulation(P)` creates a Delaunay triangulation from the points in `P`. Matrix `P` has 2 or 3 columns, depending on whether your points are in 2-D or 3-D space.

`DT = delaunayTriangulation(P,C)` specifies the edge constraints in matrix `C`. In this case, `P` specifies points in 2-D. Each row of `C` defines the start and end vertex IDs of a constrained edge.

`DT = delaunayTriangulation(x,y)` creates a 2-D Delaunay triangulation from the point coordinates in the column vectors, `x` and `y`.

`DT = delaunayTriangulation(x,y,C)` specifies the edge constraints in matrix `C`.

`DT = delaunayTriangulation(x,y,z)` creates a 3-D Delaunay triangulation from the point coordinates in the column vectors, `x`, `y`, and `z`.

`DT = delaunayTriangulation()` creates an empty Delaunay triangulation.

## Input Arguments

**P**

# delaunayTriangulation

---

Input points, specified as a matrix whose columns are the  $x$ ,  $y$ , (and possibly  $z$ ) coordinates of the triangulation points. The row numbers of  $P$  are the vertex IDs in the triangulation.

**x**

$x$ -coordinates vector, specified as a column vector containing the  $x$ -coordinates of the triangulation points.

**y**

$y$ -coordinates vector, specified as a column vector containing the  $y$ -coordinates of the triangulation points.

**z**

$z$ -coordinates vector, specified as a column vector containing the  $z$ -coordinates of the triangulation points.

**C**

Vertex IDs of constrained edges, specified as a 2-column matrix. Each row of  $C$  corresponds to a constrained edge and contains two IDs:

- $C(j, 1)$  is the ID of the vertex at the start of an edge.
- $C(j, 2)$  is the ID of the vertex at end of the edge.

You can specify edge constraints for 2-D triangulations only.

## Properties

### Points

Points in the triangulation, represented as a matrix containing the following information:

- Each row in  $DT.Points$  contains the coordinates of a vertex.
- Each row number of  $DT.Points$  is a vertex ID.

### ConnectivityList

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `DT.ConnectivityList` is a “Triangle or Tetrahedron ID” on page 1-1519.
- Each element is a vertex ID.

## Constraints

Constrained edges, represented as a two-column matrix of vertex IDs. Each row of `DT.Constraints` corresponds to a constrained edge and contains two IDs:

- `DT.Constraints(j,1)` is the ID of the vertex at the start of an edge.
- `DT.Constraints(j,2)` is the ID of the vertex at end of the edge.

`DT.Constraints` is an empty matrix when the triangulation has no constrained edges.

## Methods

<code>convexHull</code>	Convex hull
<code>isInterior</code>	Test if triangle is in interior of 2-D constrained Delaunay triangulation
<code>nearestNeighbor</code>	Vertex closest to specified location
<code>pointLocation</code>	Triangle or tetrahedron containing specified location
<code>voronoiDiagram</code>	Voronoi diagram

# deLaunayTriangulation

---

## Inherited Methods

barycentricToCartesian	Converts point coordinates from barycentric to Cartesian
cartesianToBarycentric	Converts point coordinates from Cartesian to barycentric
circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
neighbors	Neighbors to specified triangle or tetrahedron
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

## Definitions

### Delaunay Triangulation

In a 2-D Delaunay triangulation, the circumcircle associated with each triangle does not contain any points in its interior. Similarly, a 3-D Delaunay triangulation does not have any points in the interior of the circumsphere associated with each tetrahedron. This definition extends to N-D, although `delaunayTriangulation` supports only 2-D and 3-D.

### Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

### Triangle or Tetrahedron ID

A row number of the matrix, `DT.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### 2-D Delaunay Triangulation

Create a 2-D `delaunayTriangulation` for 30 random points.

```
P = gallery('uniformdata',[30 2],0);  
DT = delaunayTriangulation(P)
```

```
DT =
```

```
    delaunayTriangulation with properties:
```

```
        Points: [30x2 double]  
    ConnectivityList: [50x3 double]  
        Constraints: []
```

Plot the triangulation.

```
figure  
triplot(DT)
```

# delaunayTriangulation

## 3-D Delaunay Triangulation

Create a 3-D delaunayTriangulation for 30 random points.

```
x = gallery('uniformdata',[30 1],0);  
y = gallery('uniformdata',[30 1],1);  
z = gallery('uniformdata',[30 1],2);
```

```
DT = delaunayTriangulation(x,y,z)
```

```
DT =
```

```
delaunayTriangulation with properties:
```

```
    Points: [30x3 double]  
ConnectivityList: [111x4 double]  
    Constraints: []
```

Plot the triangulation at 30% opacity with a light blue face color.

```
faceColor = [0.6875 0.8750 0.8984];  
figure  
tetramesh(DT, 'FaceColor', faceColor, 'FaceAlpha', 0.3);
```

# del aunayTriangulation.isInterior

---

**Purpose** Test if triangle is in interior of 2-D constrained Delaunay triangulation

**Syntax** `tf = isInterior(DT)`

**Description** `tf = isInterior(DT)` returns an array of logical values that indicate whether the triangles in a constrained Delaunay triangulation are inside the bounded geometric domain. A triangle, `DT.ConnectivityList(j, :)`, is classified as inside the domain when `tf(j)` is true. Otherwise, the triangle outside the domain.

**Input Arguments** **DT**  
A 2-D `del aunayTriangulation` that has a set of constrained edges that define a bounded geometric domain.

**Output Arguments** **tf**  
Logical values, returned as a column vector. Element `tf(j)` is true when the triangle whose ID is `j` is inside the domain of `DT`.

**Definitions** **Triangle ID**  
A row number of the matrix, `DT.ConnectivityList`. You use this ID to refer a specific triangle.

## Examples **Find and Plot Triangles within a Boundary**

Create a geometric domain whose shape is a square frame.

```
outerprofile = [-5 -5; -3 -5; -1 -5; 1 -5;  
               3 -5; 5 -5; 5 -3; 5 -1;  
               5 1; 5 3; 5 5; 3 5;  
               1 5; -1 5; -3 5; -5 5;  
               -5 3; -5 1; -5 -1; -5 -3];
```

```
innerprofile = outerprofile.*0.5;  
profile = [outerprofile; innerprofile];
```

Define the edge constraints.

```
outercons = [(1:19)' (2:20)'; 20 1;];  
innercons = [(21:39)' (22:40)'; 40 21];  
C = [outercons; innercons];
```

Create the constrained Delaunay triangulation.

```
DT = delaunayTriangulation(profile,C);
```

Plot the triangulation.

```
subplot(1,2,1);  
triplot(DT);
```

Highlight the inner square in red.

```
hold on;  
plot(DT.Points(innercons',1),DT.Points(innercons',2),...  
      '-r','LineWidth',2);
```

Highlight the outer square in red and resize the  $x$  and  $y$  axes to make the plot square.

```
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...  
      '-r','LineWidth',2);  
axis equal;
```

Plot only the triangles that lie inside of the domain.

```
hold off;  
subplot(1,2,2);  
inside = isInterior(DT);  
triplot(DT.ConnectivityList(inside, :),DT.Points(:,1),DT.Points(:,2));
```

Highlight the inner and outer squares in red.

```
hold on;  
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...
```

# del aunayTriangulation.isInterior

---

```
    '-r','LineWidth', 2);  
plot(DT.Points(innercons',1),DT.Points(innercons',2), ...  
    '-r','LineWidth', 2);  
axis equal;  
hold off;
```

**See Also** [triangulation](#) |

# delaunayTriangulation.nearestNeighbor

---

## Purpose

Vertex closest to specified location

## Syntax

```
vi = nearestNeighbor(DT,QP)
vi = nearestNeighbor(DT,qx,qy)
vi = nearestNeighbor(DT,qx,qy,qz)
[vi,d] = nearestNeighbor( ___ )
```

## Description

`vi = nearestNeighbor(DT,QP)` returns the IDs of the vertices closest to the query points in `QP`. Each row in matrix `QP` contains the  $x$ ,  $y$ , (and possibly  $z$ ) coordinates of a query point.

`vi = nearestNeighbor(DT,qx,qy)` specifies the  $x$  and  $y$  coordinates of the query points in 2-D as separate column vectors.

`vi = nearestNeighbor(DT,qx,qy,qz)` specifies the  $x$ ,  $y$ , and  $z$  coordinates of the query points in 3-D as separate column vectors.

`[vi,d] = nearestNeighbor( ___ )` also returns the Euclidean distance between each query point and its nearest neighbor. You can specify both output arguments with any of the previous syntaxes.

`nearestNeighbor` does not support constrained Delaunay triangulations.

## Input Arguments

### DT

A Delaunay triangulation, see `delaunayTriangulation`.

### QP

Query points, specified as a matrix whose columns are the  $x$ ,  $y$ , (and possibly  $z$ ) coordinates of the points to query.

### qx

Query  $x$ -coordinates, specified as a column vector containing the  $x$ -coordinates of the points to query.

### qy

Query  $y$ -coordinates, specified as a column vector containing the  $y$ -coordinates of the points to query.

# delaunayTriangulation.nearestNeighbor

---

## Output Arguments

**qz**

Query  $z$ -coordinates, specified as a column vector containing the  $z$ -coordinates of the points to query.

**vi**

Vertex IDs of nearest neighbor, returned as a column vector.  $vi(j)$  is the “Vertex ID” on page 1-1532 of the nearest neighbor to the query point  $QP(j)$ .

**d**

Distance to nearest neighbor, returned as a column vector the same length as  $vi$ . Each value in  $d$  is the Euclidean distance between a query point and its nearest neighbor.

## Definitions

### Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Nearest Neighbors of Query Points in 2-D

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);  
y = gallery('uniformdata',[20 1],1);  
DT = delaunayTriangulation(x,y);
```

Define two query points.

```
QP = [0.25 0.25; 0.5 0.5];
```

Find the nearest neighbors to the query points and the distances between them.

```
[vi,d] = nearestNeighbor(DT,QP);
```

Examine the vertex IDs of the nearest neighbors.

```
vi
```

```
vi =
```

```
    10  
     4
```

Examine the coordinates of the nearest neighbors.

```
DT.Points(vi,:)
```

```
ans =
```

```
    0.4447    0.3759  
    0.4860    0.5982
```

Examine the Euclidean distance between each query point and its nearest neighbor.

```
d
```

```
d =
```

```
    0.2319  
    0.0992
```

## See Also

[triangulation](#) | [pointLocation](#) |

# delaunayTriangulation.pointLocation

---

**Purpose** Triangle or tetrahedron containing specified location

**Syntax**

```
ti = pointLocation(DT,QP)
ti = pointLocation(DT,qx,qy)
ti = pointLocation(DT,qx,qy,qz)
[ti,B] = pointLocation( ___ )
```

**Description**

`ti = pointLocation(DT,QP)` returns the enclosing triangles or tetrahedra for each query point in `QP`. Each row in matrix `QP` contains the  $x$ ,  $y$ , (and possibly  $z$ ) coordinates of a query point.

`ti = pointLocation(DT,qx,qy)` specifies the  $x$  and  $y$  coordinates of the query points in 2-D as separate column vectors.

`ti = pointLocation(DT,qx,qy,qz)` specifies the  $x$ ,  $y$ ,  $z$  coordinates of the query points in 3-D as separate column vectors.

`[ti,B] = pointLocation( ___ )` also returns the barycentric coordinates of each query point with respect to its enclosing triangle or tetrahedron. You can specify both output arguments with any of the previous syntaxes.

## Input Arguments

**DT** A Delaunay triangulation, see `delaunayTriangulation`.

**QP** Query points, specified as a matrix whose columns are the  $x$ ,  $y$ , (and possibly  $z$ ) coordinates of the points to query.

**qx** Query  $x$ -coordinates, specified as a column vector containing the  $x$ -coordinates of the points to query.

**qy** Query  $y$ -coordinates, specified as a column vector containing the  $y$ -coordinates of the points to query.

**qz**

Query  $z$ -coordinates, specified as a column vector containing the  $z$ -coordinates of the points to query.

## Output Arguments

**ti**

IDs of enclosing triangles or tetrahedra, returned as a column vector. Each element in **ti** is the ID of a triangle or tetrahedron that encloses a query point. **ti(k)** encloses the  $k$ th query point.

**pointLocation** returns NaN values for any points outside the convex hull.

**B**

Barycentric coordinates, returned as matrix. The values at **B(j, :)** are the barycentric coordinates of the  $j$ th query point with respect to **ti(j)**.

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, **DT.ConnectivityList**. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Find Enclosing Triangles in 2-D

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);  
y = gallery('uniformdata',[20 1],1);  
DT = delaunayTriangulation(x,y);
```

Define two query points.

```
QP = [0.25 0.25; 0.5 0.5];
```

Find the IDs of the enclosing triangles for each query point.

```
ti = pointLocation(DT,QP)
```

```
ti =
```

# delaunayTriangulation.pointLocation

---

```
8
7
```

Examine the connectivity of the enclosing triangles.

```
DT.ConnectivityList(ti,:)
```

```
ans =
```

```
19    15    8
 4    10    6
```

## Find Enclosing Tetrahedra and Barycentric Coordinates in 3-D

Create a 3-D Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);
y = gallery('uniformdata',[20 1],1);
z = gallery('uniformdata',[20 1],2);
DT = delaunayTriangulation(x,y,z);
```

Find the tetrahedra that enclose the query points and calculate the barycentric coordinates of the query points.

```
QP = [0.7 0.6 0.3; 0.5 0.5 0.5];
[ti,B] = pointLocation(DT,QP)
```

```
ti =
```

```
57
56
```

```
B =
```

```
0.2796    0.0184    0.5286    0.1734
0.3687    0.0149    0.5343    0.0821
```

**See Also**     `triangulation` | `nearestNeighbor` |

# delaunayTriangulation.voronoiDiagram

---

**Purpose** Voronoi diagram

**Syntax** `[V,R] = voronoiDiagram(DT)`

**Description** `[V,R] = voronoiDiagram(DT)` returns the Voronoi vertices, `V`, and the Voronoi regions, `R`, of the points, `DT.Points`.

The *Voronoi diagram* of a set of points, such as `DT.Points`, decomposes the space around each point, `DT.Points(j,:)`, into a region of influence, `R{j}`. Locations within the region, `R{j}`, are closer to point `j` than any other point in `DT.Points`. The region of influence is called the *Voronoi region*. The collection of all the Voronoi regions is the Voronoi diagram.

The Voronoi regions associated with points that lie on the convex hull of `DT.Points` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

## Input Arguments

**DT**  
A Delaunay triangulation, see `delaunayTriangulation`.

## Output Arguments

**V**  
Voronoi vertices, returned as a matrix. Each row of `V` contains the coordinates of a Voronoi vertex.

**R**  
Voronoi regions, returned as a vector cell array the same length as `DT.Points`. The elements of `R` are row numbers of `V`. The coordinates of the Voronoi vertices bounding a region are `V(R{j},:)`. The Voronoi region associated with the point `DT.Points(j)` is `R{j}`.

## Examples

### Compute the Voronoi Diagram of a 2-D Triangulation

Create a Delaunay triangulation from a set of points.

```
P = [ 0.5    0
      0     0.5
```

# delaunayTriangulation.voronoiDiagram

---

```
        -0.5  -0.5  
        -0.2  -0.1  
        -0.1   0.1  
         0.1  -0.1  
         0.1   0.1 ];  
DT = delaunayTriangulation(P);
```

Calculate the Voronoi vertices and regions.

```
[V,R] = voronoiDiagram(DT);
```

Examine the connectivity of the Voronoi region associated with the third point in the triangulation.

```
R{3}
```

```
ans =
```

```
     1     10     7     4
```

Examine the coordinates of the Voronoi vertices bounding the region.

```
V(R{3},:)
```

```
ans =
```

```
      Inf      Inf  
    0.7000  -1.6500  
   -0.0500  -0.5250  
   -1.7500   0.7500
```

The Inf values indicate that the region contains points on the convex hull.

# delete

---

**Purpose** Remove files or objects

**Syntax**

```
delete('fileName1', 'filename2', ...)  
delete(h)  
delete(handle_array)  
delete fileName
```

**Description**

`delete('fileName1', 'filename2', ...)` deletes the files `fileName1`, `fileName2`, and so on, from the disk. `fileName` is a string and can be an absolute path or a path relative to the current folder. `fileName` also can include wildcards (\*).

`delete(h)` deletes the graphics object with handle `h`. `h` can also be a vector or matrix of handles. Delete multiple objects by appending their handles as additional arguments, separated by commas. The function deletes objects without requesting verification, even if when they are windows.

`delete(handle_array)` is a method of the `handle` class. It removes from memory the handle objects referenced by `handle_array`.

When deleted, any references to the objects in `handle_array` become invalid. To remove the handle variables, use the `clear` function.

`delete fileName` is the command syntax. Delete multiple files by appending filenames, separated by spaces. When filenames contain space characters, you must use the functional form.

As `delete` does not ask for confirmation, to avoid accidentally losing files or graphics objects, make sure to specify accurately the items to delete. To move files to a different location when running `delete`, use the **General** preference for **Deleting files**, or the `recycle` function.

The `delete` function deletes files and graphics objects only. To delete folders, use `rmdir`.

**Examples** Delete all files with a `.mat` extension in the `../mytests/` folder:

```
delete('../mytests/*.mat')
```

Create a figure and an axes, and then delete the axes:

```
hf = figure, ha = axes
```

```
hf =  
    1
```

```
ha =  
    170.0332
```

```
delete(ha)
```

The axes is deleted, but the figure remain. The axes handle `ha` remains in the workspace but no longer points to an object.

## **See Also**

`dir` | `recycle` | `rmdir`

## **How To**

- “Path Names in MATLAB”
- “Deleted Handle Objects”

# delete (COM)

---

**Purpose** Remove COM control or server

**Syntax** h.delete  
delete(h)

**Description** h.delete releases all interfaces derived from the specified COM server or control, and then deletes the server or control itself. This is different from releasing an interface, which releases and invalidates only that interface.

delete(h) is an alternate syntax.

**Tips** COM functions are available on Microsoft Windows systems only.

**See Also** release | save (COM) | load (COM) | actxcontrol | actxserver

<b>Purpose</b>	Remove file on FTP server
<b>Syntax</b>	<code>delete(ftpobj, filename)</code>
<b>Description</b>	<code>delete(ftpobj, filename)</code> removes the specified file from the current folder on the FTP server associated with <code>ftpobj</code> .
<b>Input Arguments</b>	<p><b>ftpobj</b> FTP object created by <code>ftp</code>.</p> <p><b>filename</b> String enclosed in single quotation marks that specifies the name of the file to delete.</p>
<b>Examples</b>	<p>Suppose that a hypothetical host, <code>ftp.testsite.com</code>, contains <code>myfile.m</code>. Connect to the server and delete the file:</p> <pre>test=ftp('ftp.testsite.com'); delete(test, 'myfile.m');</pre>
<b>See Also</b>	<code>rmdir</code>   <code>ftp</code>

# delete (handle)

---

**Purpose** Handle object destructor

**Syntax** `delete(h)`

**Description** `delete(h)` deletes a handle object, but does not clear the handle variable from the workspace. The handle variable is not valid once the handle object has been deleted.

A subclass of `handle` can implement a method named `delete` to perform cleanup tasks just before MATLAB destroys the handle object. MATLAB calls the `delete` method of any handle object (if it exists) when the object is destroyed. `h` is a scalar handle object.

A `delete` method should not generate errors or create new handles to the object being destroyed. If the `delete` method has a different signature (having output arguments or more than one input argument) it is not called when the handle objects is destroyed. See “Handle Class Destructor” information on defining destructors for `handle` subclasses.

**See Also** `handle` | `(handle) isvalid`

**Purpose** Remove serial port object from memory

**Syntax** `delete(obj)`

**Description** `delete(obj)` removes `obj` from memory, where `obj` is a serial port object or an array of serial port objects.

**Tips** When you delete `obj`, it becomes an *invalid* object. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command. If multiple references to `obj` exist in the workspace, then deleting one reference invalidates the remaining references.

If `obj` is connected to the device, it has a `Status` property value of `open`. If you issue `delete` while `obj` is connected, then the connection is automatically broken. You can also disconnect `obj` from the device with the `fclose` function.

If you use the `help` command to display help for `delete`, then you need to supply the pathname shown below.

```
help serial/delete
```

**Examples** This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, disconnects `s` from the device, removes `s` from memory using `delete`, and then removes `s` from the workspace using `clear`.

```
s = serial('COM1');  
fopen(s)  
fprintf(s, '*IDN?')  
idn = fscanf(s);  
fclose(s)  
delete(s)  
clear s
```

**See Also** `clear` | `fclose` | `isvalid` | `Status`

# deleteproperty

---

**Purpose** Remove custom property from COM object

**Syntax** `h.deleteproperty('propertyname')`  
`deleteproperty(h,'propertyname')`

**Description** `h.deleteproperty('propertyname')` deletes the property specified in the string `propertyname` from the custom properties belonging to object or interface `h`.

`deleteproperty(h,'propertyname')` is an alternate syntax.

You can only delete properties created with the `addproperty` function.

COM functions are available on Microsoft Windows systems only.

**Examples** Remove a custom property from an instance of the MATLAB sample control:

**1** Create an instance of the control:

```
f = figure('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.get
```

MATLAB displays its properties:

```
Label: 'Label'  
Radius: 20
```

**2** Add a custom property named `Position` and assign a value:

```
h.addproperty('Position');  
h.Position = [200 120];  
h.get
```

MATLAB displays (in part):

```
Label: 'Label'  
Radius: 20
```

```
Position: [200 120]
```

**3** Delete the custom property Position:

```
h.deleteproperty('Position');  
h.get
```

MATLAB displays the original list of properties:

```
Label: 'Label'  
Radius: 20
```

## See Also

[addproperty](#) | [get \(COM\)](#) | [set \(COM\)](#) | [inspect](#)

# delevent

---

**Purpose** Remove `tsdata.event` objects from `timeseries` object

**Syntax**

```
ts = delevent(ts,event)
ts = delevent(ts,events)
ts = delevent(ts,event,n)
```

**Description**

`ts = delevent(ts,event)` removes the `tsdata.event` object from the `ts.events` property, where `event` is an event name string.

`ts = delevent(ts,events)` removes the `tsdata.event` object from the `ts.events` property, where `events` is a cell array of event name strings.

`ts = delevent(ts,event,n)` removes the `n`th `tsdata.event` object from the `ts.events` property. `event` is the name of the `tsdata.event` object.

**Examples** The following example shows how to remove an event from a `timeseries` object:

**1** Create a time series.

```
ts = timeseries(rand(5,4))
```

**2** Create an event object called 'test' such that the event occurs at time 3.

```
e = tsdata.event('test',3)
```

**3** Add the event object to the time series `ts`.

```
ts = addevent(ts,e)
```

**4** Remove the event object from the time series `ts`.

```
ts = delevent(ts,'test')
```

**See Also** `addevent` | `timeseries` | `tsdata.event`

**Purpose** Remove sample from tscollection object

**Syntax**  
`tsc = delsamplefromcollection(tsc, 'Index', N)`  
`tsc = delsamplefromcollection(tsc, 'Value', Time)`

**Description** `tsc = delsamplefromcollection(tsc, 'Index', N)` deletes samples from the `tscollection` object `tsc`. `N` specifies the indices of the `tsc` time vector that correspond to the samples you want to delete.

`tsc = delsamplefromcollection(tsc, 'Value', Time)` deletes samples from the `tscollection` object `tsc`. `Time` specifies the time values that correspond to the samples you want to delete.

**See Also** `addsampletocollection` | `tscollection`

# demo

---

**Purpose** Access product examples in Help browser

**Syntax**  
demo  
demo type  
demo type name

**Description** demo displays the list of MATLAB examples in the Help browser.

demo type lists the examples for the specified product. Valid values for type are matlab or simulink.

demo type name lists the examples for products other than MATLAB or Simulink. Valid values for type include matlab, simulink, toolbox, or blockset.

## **Input Arguments**

**type - Product name or type**  
matlab (default) | simulink | toolbox | blockset

Product name or type, specified as one of these strings: matlab, simulink, toolbox, or blockset. For products other than MATLAB or Simulink, you must also specify a name input that corresponds to the product name.

**name - Product name other than MATLAB or Simulink**  
string

Product name other than MATLAB or Simulink, specified as a string. If name requires multiple words, enclose it in single quotes.

On non-English systems, name sometimes uses the localized language.

## **Examples**

### **MATLAB Examples**

```
demo matlab
```

### **Statistics Toolbox™ Examples**

```
demo toolbox statistics
```

### **Communications System Toolbox™ Examples**

```
demo toolbox 'communications system'
```

### **Simulink Control Design™ Examples**

```
demo simulink 'simulink control design'
```

#### **Tips**

- To access third-party and custom examples without using the demo command, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

#### **See Also**

echodemo | grabcode | help | doc

# demdir

---

**Purpose** List dependent folders for function or P-file

**Syntax**

```
list = demdir('file_name')
[list, prob_files, prob_sym,
    prob_strings] = demdir('file_name')
[...] = demdir('file_name1', 'file_name2',...)
```

**Description** The demdir function lists the folders of all the functions that a specified function or P-file needs to operate. This function is useful for finding all the folders that need to be included with a run-time application and for determining the run-time path.

`list = demdir('file_name')` creates a cell array of strings containing the folders of all the function and P-files that `file_name.m` or `file_name.p` uses. This includes the second-level files that are called directly by `file_name`, as well as the third-level files that are called by the second-level files, and so on.

`[list, prob_files, prob_sym, prob_strings] = demdir('file_name')` creates three additional cell arrays containing information about any problems with the demdir search. `prob_files` contains filenames that demdir was unable to parse. `prob_sym` contains symbols that demdir was unable to find. `prob_strings` contains callback strings that demdir was unable to parse.

`[...] = demdir('file_name1', 'file_name2',...)` performs the same operation for multiple files. The dependent folders of all files are listed together in the output cell arrays.

**Examples**

```
list = demdir('mesh')
```

**See Also** depfun

**Purpose** List dependencies of function or P-file

**Syntax**

```
list = depfun(fun)
[list,builtins] = depfun(fun)
[list,builtins,classes] = depfun(fun)
[list,builtins,classes,prob_files] = depfun(fun)
[list,builtins,classes,prob_files,~,
    eval_strings] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,
    called_from] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,called_from,
    opaque_classes] = depfun(fun)

___ = depfun(fun1,...,funN)

___ = depfun( ___,option1,...,optionM)
```

**Description** `list = depfun(fun)` returns the paths of MATLAB program files that `fun` requires to run, where `fun` is a function, a P-file, or a figure file for a user interface. The output `list` includes second-level functions that `fun` calls directly, functions that the second-level functions call, and so on. The `depfun` function also displays a report in the Command Window.

---

### Note

- `depfun` does not always list all dependent files. For example, `depfun` does not list files hidden in callbacks or files whose names are constructed dynamically for evaluation.
  - The output list often includes extra files that are not called when the function is actually evaluated.
  - If `depfun` returns a parse error for any of the required functions, then the rest of the output of `depfun` might be incomplete. Correct the problematic files and invoke `depfun` again.
-

`[list,builtins] = depfun(fun)` returns the built-in functions that `fun` requires.

`[list,builtins,classes] = depfun(fun)` returns the MATLAB classes that `fun` requires.

`[list,builtins,classes,prob_files] = depfun(fun)` returns the files that `depfun` cannot parse, find, or access. If there are problematic files (that is, if `prob_files` is not empty), then the rest of the output of `depfun` might be incomplete. Correct the problematic files, and then invoke `depfun` again.

`[list,builtins,classes,prob_files,~, eval_strings] = depfun(fun)` returns a list of files that contain calls to `eval` or related functions (`evalin`, `feval`, or `evalc`). These calls potentially use functions that are not in `list`.

The fifth output argument for `depfun` is not implemented, and returns an empty structure array. To request arguments later in the list, use the tilde symbol (`~`) as a placeholder. The tilde suppresses the creation of an extra, empty variable.

`[list,builtins,classes,prob_files,~,eval_strings,called_from] = depfun(fun)` returns a cell array of indices that maps each function in `list` to the set of functions that call it. That is, `list{called_from{k}}` returns the paths to the functions that call the function in `list{k}`.

`[list,builtins,classes,prob_files,~,eval_strings,called_from,opaque_classes] = depfun(fun)` returns the opaque classes that `fun` requires, such as Java or COM classes.

`___ = depfun(fun1,...,funN)` returns the functions required for multiple functions `fun1,...,funN`. You can request any of the outputs from the previous syntaxes.

`___ = depfun( ___,option1,...,optionM)` modifies the output as described by the specified options. For example, specify `'-toponly'` to list only the functions that `fun` calls directly. You can precede the options with one or more function names.

## Input Arguments

### fun - Function name

string | cell array of strings

Function name, specified as a string or a cell array of strings.

`fun` must be on the MATLAB path, as determined by the `which` function. If the path contains any relative folders, then files in those folders also will have a relative path in the output.

**Example:** `'plot.m'`

**Example:** `'plot.m','mesh.m'`

**Example:** `{'plot.m','mesh.m'}`

### Data Types

char | cell

### option - Reporting option

`'-toponly'` | `'-verbose'` | `'-quiet'` | `'-print'` | ...

Reporting option, specified as one of the following strings.

Option	Description
<code>'-toponly'</code>	Identify only the files used directly by the specified function(s), <code>fun</code> .
<code>'-verbose'</code>	Display additional internal messages.
<code>'-quiet'</code>	Display only error and warning messages, and not a summary report.

Option	Description
'-print', filename	Print a full report to the specified file.
'-all'	Display all outputs in the report, but return only the specified output arguments.
'-expand'	Include both indices and full paths in an exported report for the call or called_from list. Requires the '-print' option. This information does not appear in the Command Window report.
'-calltree'	Replaces the called_from list with a list of functions that each file calls, as derived from the called_from list.

**Example:** '-print', 'myreport.txt'

## Data Types

char

## Output Arguments

### **list - Paths to required files**

cell array of strings

Paths to required files, returned as a cell array of strings.

### **builtins - Required MATLAB built-in functions**

cell array of strings

Required MATLAB built-in functions, returned as a cell array of strings.

### **classes - Required MATLAB classes**

cell array of strings

Required MATLAB classes, returned as a cell array of strings.

### **prob\_files - Files that depfun cannot parse or access**

structure

Files that `depfun` cannot parse or access, returned as a structure with these fields:

- `name` — Path to the file
- `listindex` — Index of the file in `list`
- `errmsg` — Error message that describes the problem
- `errid` — Error identifier, if present

### **eval\_strings - Files that call evaluation functions**

cell array of strings

Files that call evaluation functions, returned as a cell array of strings.

### **called\_from - Indices to files that call each function in list**

cell array

Indices to files that call each function in `list`, returned as a cell array. Each element of the cell array is a numeric array of indices that correspond to elements in `list`. The `list` and `called_from` outputs have the same length.

### **opaque\_classes - Paths to opaque classes**

cell array of strings

Paths to opaque classes, such as Java or COM classes, returned as a cell array of strings.

## **Examples**

### **Identify Required Functions**

Identify the MATLAB program files that `strtok.m` requires to run.

```
fun = 'strtok.m';  
list = depfun(fun);
```

MATLAB displays a summary report in the Command Window and stores the list of files in variable `list`.

## Identify Top-Level Dependencies Only

List only the program files that `strtok.m` calls directly.

```
fun = 'strtok.m';  
list = depfun(fun, '-toponly')
```

```
=====  
depfun report summary:(top only)  
-----  
-> trace list:          2 files  (total)  
                    1 files  (total arguments)  
                    0 files  (arguments off MATLABPATH)  
                    0 files  (argument duplicates on MATLABPATH)  
-----  
Notes: 1. Use argument '-quiet' to not print this summary.  
       2. Use arguments '-print','file' to produce a full  
          report in file.  
       3. Use argument '-all' to display all possible  
          left hand side arguments in the report(s).  
=====
```

```
list =  
  
    'matlabroot\toolbox\matlab\strfun\strtok.m'  
    'matlabroot\toolbox\matlab\strfun\@cell\strtok.m'
```

## Determine Which File Invokes Each Function

One of the functions that `strtok.m` depends upon is `num2cell`. Determine which file in the dependency list calls `num2cell`.

Identify the functions that `strtok.m` requires (`list`) and the files that invoke each of those functions (`called_from`).

```
fun = 'strtok.m';  
[list,builtins,classes,prob_files,~,eval_strings,...
```

```
called_from] = depfun(fun);
```

Find the index for num2cell within the dependency list.

```
num2cell_path = which('num2cell');  
num2cell_index = find(ismember(list,num2cell_path))
```

```
num2cell_index =  
    5
```

Identify the file that calls num2cell.

```
calls_num2cell = list{called_from{num2cell_index}}
```

```
calls_num2cell =  
    matlabroot\toolbox\matlab\elmat\repmat.m
```

**See Also** `depdir`

**Concepts**

- “Identify Program Dependencies”

# det

---

**Purpose** Matrix determinant

**Syntax** `d = det(X)`

**Description** `d = det(X)` returns the determinant of the square matrix `X`.

**Tips** Testing singularity using `abs(det(X)) <= tolerance` is not recommended as it is difficult to choose the correct tolerance. The function `cond(X)` can check for singular and nearly singular matrices.

**Algorithms** The determinant is computed from the triangular factors obtained by Gaussian elimination

```
[L,U] = lu(A)
s = det(L) % This is always +1 or -1
det(A) = s*prod(diag(U))
```

**Examples** The statement `A = [1 2 3; 4 5 6; 7 8 9]` produces

```
A =
     1     2     3
     4     5     6
     7     8     9
```

This happens to be a singular matrix, so `det(A)` produces a very small number. Changing `A(3,3)` with `A(3,3) = 0` turns `A` into a nonsingular matrix. Now `d = det(A)` produces `d = 27`.

**See Also** `cond` | `condest` | `inv` | `lu` | `rref` | `mldivide`

**Purpose** Remove linear trends

**Syntax**

```
y = detrend(x)
y = detrend(x, 'constant')
y = detrend(x, 'linear', bp)
```

**Description** `detrend` removes the mean value or linear trend from a vector or matrix, usually for FFT processing.

`y = detrend(x)` removes the best straight-line fit from vector `x` and returns it in `y`. If `x` is a matrix, `detrend` removes the trend from each column.

`y = detrend(x, 'constant')` removes the mean value from vector `x` or, if `x` is a matrix, from each column of the matrix.

`y = detrend(x, 'linear', bp)` removes a continuous, piecewise linear trend from vector `x` or, if `x` is a matrix, from each column of the matrix. Vector `bp` contains the indices of the breakpoints between adjacent linear segments. The breakpoint between two segments is defined as the data point that the two segments share.

`detrend(x, 'linear')`, with no breakpoint vector specified, is the same as `detrend(x)`.

## Examples

```
sig = [0 1 -2 1 0 1 -2 1 0]; % signal with no linear trend
trend = [0 1 2 3 4 3 2 1 0]; % two-segment linear trend
```

# detrend

---

```
x = sig+trend;           % signal with added trend
y = detrend(x, 'linear',5) % breakpoint at 5th element

y =

-0.0000
 1.0000
-2.0000
 1.0000
 0.0000
 1.0000
-2.0000
 1.0000
-0.0000
```

Note that the breakpoint is specified to be the fifth element, which is the data point shared by the two segments.

## Algorithms

detrend computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data. To obtain the equation of the straight-line fit, use `polyfit`.

## See Also

`polyfit`

**Purpose** Evaluate solution of differential equation problem

**Syntax**

```
sxint = deval(sol,xint)
sxint = deval(xint,sol)
sxint = deval(sol,xint,idx)
sxint = deval(xint,sol,idx)
[sxint, spxint] = deval(...)
```

**Description** `sxint = deval(sol,xint)` and `sxint = deval(xint,sol)` evaluate the solution of a differential equation problem. `sol` is a structure returned by one of these solvers:

- An initial value problem solver (`ode45`, `ode23`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`, `ode15i`)
- A delay differential equations solver (`dde23`, `ddesd`, or `ddensd`),
- A boundary value problem solver (`bvp4c` or `bvp5c`).

`xint` is a point or a vector of points at which you want the solution. The elements of `xint` must be in the interval `[sol.x(1),sol.x(end)]`. For each `i`, `sxint(:,i)` is the solution at `xint(i)`.

`sxint = deval(sol,xint,idx)` and `sxint = deval(xint,sol,idx)` evaluate as above but return only the solution components with indices listed in the vector `idx`.

`[sxint, spxint] = deval(...)` also returns `spxint`, the value of the first derivative of the polynomial interpolating the solution.

---

**Note** For multipoint boundary value problems, the solution obtained by `bvp4c` or `bvp5c` might be discontinuous at the interfaces. For an interface point `xc`, `deval` returns the average of the limits from the left and right of `xc`. To get the limit values, set the `xint` argument of `deval` to be slightly smaller or slightly larger than `xc`.

---

## Examples

This example solves the system  $y' = \text{vdp1}(t,y)$  using `ode45`, and evaluates and plots the first component of the solution at 100 points in the interval  $[0,20]$ .

```
sol = ode45(@vdp1,[0 20],[2 0]);  
x = linspace(0,20,100);  
y = deval(sol,x,1);  
plot(x,y);
```

## See Also

**Purpose** Diagonal matrices and diagonals of matrix

**Syntax**

```
X = diag(v,k)
X = diag(v)
v = diag(X,k)
v = diag(X)
```

**Description**  $X = \text{diag}(v,k)$  when  $v$  is a vector of  $n$  components, returns a square matrix  $X$  of order  $n+\text{abs}(k)$ , with the elements of  $v$  on the  $k$ th diagonal.  $k = 0$  represents the main diagonal,  $k > 0$  above the main diagonal, and  $k < 0$  below the main diagonal.

$X = \text{diag}(v)$  puts  $v$  on the main diagonal, same as above with  $k = 0$ .

$v = \text{diag}(X,k)$  for matrix  $X$ , returns a column vector  $v$  formed from the elements of the  $k$ th diagonal of  $X$ .

$v = \text{diag}(X)$  returns the main diagonal of  $X$ , same as above with  $k = 0$ .

**Tips**  $\text{diag}(\text{diag}(X))$  is a diagonal matrix.

$\text{sum}(\text{diag}(X))$  is the trace of  $X$ .

$\text{diag}([])$  generates an empty matrix,  $([])$ .

$\text{diag}(m\text{-by-}1,k)$  generates a matrix of size  $m+\text{abs}(k)$ -by- $m+\text{abs}(k)$ .

# diag

---

`diag(1-by-n,k)` generates a matrix of size  $n+\text{abs}(k)$ -by- $n+\text{abs}(k)$ .

## Examples

The statement

```
diag(-m:m)+diag(ones(2*m,1),1)+diag(ones(2*m,1),-1)
```

produces a tridiagonal matrix of order  $2*m+1$ .

## Purpose

Summary of classes in MATLAB Diagnostics Interface

## Description

Use diagnostics to communicate relevant information in the event of a failure. To add a diagnostic message to a test case, use the `diagnostic` argument in any of the `matlab.unittest.qualifications` methods. The framework also displays diagnostic messages related to the nature of the qualification failure. The `matlab.unittest.diagnostics` package consists of the following classes:

`matlab.unittest.diagnostics.ConstraintDiagnostic` Diagnostic specific to `matlab.unittest.constraints`

`matlab.unittest.diagnostics.Diagnostic` Fundamental interface class for `matlab.unittest.diagnostics`

`matlab.unittest.diagnostics.DisplayDiagnostic` Diagnostic using a value's displayed output

`matlab.unittest.diagnostics.FunctionDiagnostic` Diagnostic function's displayed output

`matlab.unittest.diagnostics.StringDiagnostic` Diagnostic using string

# matlab.unittest.diagnostics.ConstraintDiagnostic

---

**Superclasses** Diagnostic

**Purpose** Diagnostics specific to matlab.unittest constraints

**Description** The ConstraintDiagnostic class provides various textual fields that are common to most constraints. These fields may be turned on or off depending on their applicability.

The ConstraintDiagnostic class is a helper class for displaying diagnostics when using constraints. The ConstraintDiagnostic class provides custom constraint authors a way to add a common look and feel to diagnostics produced by the getDiagnosticFor method of constraints.

Constraint diagnostics are displayed in the following order: Description, Conditions, Actual Value, and Expected Value.

## Properties

### ActVal

The actual value passed to the constraint for testing.

### ActValHeader

Header information for the actual value property, ActVal, specified as a string. The default header is 'Actual Value:'.

### Conditions

Formatted list of conditions, specified as a single string. Each condition starts on a new line and begins with an arrow (-->) delimiter. Conditions are added to the list using the addCondition and addConditionsFrom methods.

### ConditionsCount

Number of conditions in the condition list. This is a read-only property generated from the conditions list. The conditions list is defined in the Conditions property.

### Description

General diagnostic information, specified as a string.

## **DisplayActVal**

Indicator whether to display the actual value property, `ActVal`, specified as a boolean. By default, the actual value is not displayed and the value of this property is `false`.

## **DisplayConditions**

Indicator of whether to display the `Conditions` property, specified as a boolean. By default, the conditions are not displayed and the value of this property is `false`. Even if `DisplayConditions` is set to `true`, if there are no conditions on the conditions list, neither the conditions header or the conditions list are displayed.

## **DisplayDescription**

Indicator of whether to display the `Description` property, specified as a boolean. By default, the description is not displayed and the value of this property is `false`.

## **DisplayExpVal**

Indicator whether to display the expected value property, `ExpVal`, specified as a boolean. By default, the expected value is not displayed and the value of this property is `false`.

## **ExpVal**

If applicable, the expected value. This property can be turned off if the associated constraint does not contain an expected value.

## **ExpValHeader**

Header information for the expected value property, `ExpVal`, specified as a string. The default header is `'Expected Value: '`.

## **Inherited Properties**

### **DiagnosticResult**

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of

# matlab.unittest.diagnostics.ConstraintDiagnostic

---

diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

<code>addCondition</code>	Add condition to condition list
<code>addConditionsFrom</code>	Add condition from another <code>ConstraintDiagnostic</code> to condition list
<code>getDisplayableString</code>	Convert object to string for display
<code>getPostActValString</code>	Returns text to be displayed following actual value
<code>getPostConditionString</code>	Returns text to be displayed following conditions list
<code>getPostDescriptionString</code>	Returns text to be displayed following description
<code>getPostExpValString</code>	Returns text to be displayed following expected value
<code>getPostPreDescriptionString</code>	Returns text to be displayed prior to description

## Inherited Methods

<code>diagnose</code>	Execute diagnostic action
<code>join</code>	Join multiple diagnostics into a single array

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## See Also

`Diagnostic` | `matlab.unittest.diagnostics` | `matlab.unittest.constraints`

## Concepts

# matlab.unittest.diagnostics.ConstraintDiagnostic.addCondition

---

**Purpose** Add condition to condition list

**Syntax** `addCondition(diag, cond)`

**Description** `addCondition(diag, cond)` adds the condition, `cond`, to the condition list. Add conditions to the condition list one at a time. When the condition list is displayed, each condition is preceded by an arrow ( - ->) delimiter and indented.

**Input Arguments**

**cond**  
Condition, specified as a string containing information specific to the cause of the constraint failure or another Diagnostic instance, which acts as a “subdiagnostic”.

**diag**  
`matlab.unittest.diagnostics.Diagnostic` instance.

**See Also** `addConditionsFrom |`

# matlab.unittest.diagnostics.ConstraintDiagnostic.addCond

**Purpose** Add condition from another ConstraintDiagnostic to condition list

**Syntax** addConditionsFrom(constDiag, otherConstDiag)

**Description** addConditionsFrom(constDiag, otherConstDiag) adds the conditions from the ConstraintDiagnostic instance, constDiag, to the condition list in the Diagnostic instance, diag. This is useful when a constraints composes another constraint, and needs to use the conditions produced in the diagnostics of the composed constraint.

## Input Arguments

### constDiag

Diagnostic to add conditions to, specified as a matlab.unittest.diagnostics.ConstraintDiagnostic instance

### otherConstDiag

Diagnostic to add conditions from, specified as a matlab.unittest.diagnostics.ConstraintDiagnostic instance

## Examples

### Add Conditions from a Constraint

```
% This demonstrates a constraint that composes another constraint
% and uses the addConditionsFrom method to utilize the conditions
% from the composed ConstraintDiagnostic.
classdef IsDouble < matlab.unittest.constraints.Constraint

    properties(Constant, GetAccess=private)
        DoubConst=matlab.unittest.constraints.IsInstanceOf(?double)
    end

    methods
        function tf = satisfiedBy(constraint, actual)
            tf = constraint.DoubConst.satisfiedBy(actual);
        end
        function diag = getDiagnosticFor(constraint, actual)
```

# matlab.unittest.diagnostics.ConstraintDiagnostic.addConditions

---

```
        diag = ConstraintDiagnostic;

        % Now add conditions from the IsInstanceOf
        % Diagnostic
        otherDiag = constraint.DoubConst.getDiagnosticFor(actual);
        diag.addConditionsFrom(otherDiag);

        % ...
    end
end
end
```

**See Also** [addCondition](#) |

# matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString

---

**Purpose** Convert object to string for display

**Syntax** `str = matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(value)`

**Description** `str = matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(value)` converts the object, `obj` to a string, `str` for display in a diagnostic result. This conversion determines if hotlinks should be included in the string and truncates large numeric or cell arrays.

**Input Arguments**

**value**  
Object of arbitrary class

# matlab.unittest.diagnostics.ConstraintDiagnostic.getPreDescrip

---

**Purpose** Returns text to be displayed prior to description

**Syntax** `str = getPreDescriptionString(constDiag)`

**Description** `str = getPreDescriptionString(constDiag)` returns text to be displayed prior to the description. This method can be overridden to inject strings prior to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

**Input Arguments**

**constDiag**  
matlab.unittest.diagnostics.ConstraintDiagnostic instance.

**See Also** `ConstraintDiagnostic` | `getPostActValString` | `getPostDescriptionString` | `getPostConditionString` | `getPostExpValString` |

# matlab.unittest.diagnostics.ConstraintDiagnostic.getPostD

---

## Purpose

Returns text to be displayed following description

## Syntax

```
str = getPostDescriptionString(constDiag)
```

## Description

`str = getPostDescriptionString(constDiag)` returns text to be displayed following the description. This method can be overridden to inject strings subsequent to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

## Input Arguments

### **constDiag**

`matlab.unittest.diagnostics.ConstraintDiagnostic` instance.

# matlab.unittest.diagnostics.ConstraintDiagnostic.getPostExpVal

---

**Purpose** Returns text to be displayed following expected value

**Syntax** `str = getPostExpValString(constDiag)`

**Description** `str = getPostExpValString(constDiag)` returns text to be displayed following the expected value. This method can be overridden to inject strings subsequent to displaying the `ExpVal` property of the `ConstraintDiagnostic`. The location of this text is tied to the `ExpVal` property. Its placement relative to other fields is not guaranteed.

**Input Arguments**

**constDiag**  
matlab.unittest.diagnostics.ConstraintDiagnostic instance.

**See Also** `ConstraintDiagnostic` | `getPreDescriptionString` | `getPostDescriptionString` | `getPostConditionString` | `getPostActValString` |

## Purpose

Fundamental interface class for `matlab.unittest` diagnostics

## Description

The `Diagnostic` interface class is the means by which the `matlab.unittest` framework and its clients package diagnostic information. All diagnostics are derived from `Diagnostic`, whether they are user-supplied test diagnostics for an individual comparison or diagnostics associated with the `Constraint` used in the comparison.

Classes which derive from `Diagnostic` encode the diagnostic actions to be performed. They produce a diagnostic result that is displayed appropriately by the test running framework. In exchange for meeting this requirement, any `Diagnostic` implementation can be used directly with `matlab.unittest` qualifications. These qualifications execute the diagnostic action and store the result to be utilized by the test running framework.

As a convenience, the framework creates appropriate diagnostic instances for strings and function handles when they are user supplied test diagnostics. To retain good performance, these values are only converted into `Diagnostic` instances when a qualification failure occurs or when the test running framework is explicitly observing passing qualifications. The default test runner does not explicitly observe passing qualifications.

## Properties

### `DiagnosticResult`

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

<code>diagnose</code>	Execute diagnostic action
<code>join</code>	Join multiple diagnostics into a single array

# matlab.unittest.diagnostics.Diagnostic

---

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Use Diagnostic Result

```
import matlab.unittest.constraints.IsEqualTo;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Create StringDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), 'User supplied Diagnostic');

% Create FunctionHandleDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), @( ) system('ps'));

% Usage of user defined Diagnostic upon failure (see definition below)
testCase.verifyThat(1, IsEqualTo(2), ProcessStatusDiagnostic...
    ('Could not close my third party application!'));

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Diagnostic definition
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
classdef ProcessStatusDiagnostic < matlab.unittest.diagnostics.Diagnostic
    % ProcessStatusDiagnostic - an example diagnostic
    %
    % Simple example to demonstrate how to create a custom
    % diagnostic.

    properties

        % HeaderText - user-supplied header to display
        HeaderText = '(No header supplied)';
    end

    methods
        function diag = ProcessStatusDiagnostic(header)
```

```
% Constructor - construct a ProcessStatusDiagnostic
%
% The ProcessStatusDiagnostic constructor takes an
% optional header to be displayed along with process
% information.
if ( nargin > 0 )
    diag.HeaderText = header;
end
end

function diagnose(diag)

    [status processInfo] = system('ps');
    if (status ~= 0)
        processInfo = sprintf(...
            ['!!! Could not obtain status diagnostic informati
            ' [exit status code: %d]\n%s'], status, processInfo);
    end
    diag.DiagnosticResult = sprintf('%s\n%s', diag.HeaderText,
        processInfo);
    end
end

end %classdef
```

## See Also

[StringDiagnostic](#) | [FunctionHandleDiagnostic](#) |  
[matlab.unittest.diagnostics](#)

## Concepts

- “Select Qualifications”

# matlab.unittest.diagnostics.Diagnostic.diagnose

---

**Purpose** Execute diagnostic action

**Syntax** `diagnose(diag)`

**Description** `diagnose(diag)` executes diagnostic action for the `matlab.unittest.diagnostics.Diagnostic` instance, `diag`. The `diagnose` method is the means by which individual `Diagnostic` implementations can perform their respective diagnostic evaluations. Each concrete implementation is responsible for populating the `DiagnosticResult` property of the `Diagnostic` object. Typically, text printed to the Command Window during diagnostic evaluation is not considered part of the diagnostic result and is ignored by the testing framework.

**See Also** [Diagnostic](#) |

<b>Purpose</b>	Join multiple diagnostics into a single array
<b>Syntax</b>	<code>diagArray = join(diag1,...,diagN)</code>
<b>Description</b>	<code>diagArray = join(diag1,...,diagN)</code> joins multiple diagnostics, specified by <code>diag1</code> through <code>diagN</code> , into a single array, <code>diagArray</code> .
<b>Input Arguments</b>	<b>diag</b> Diagnostic content, specified as an instance of a <code>Diagnostic</code> object, a string, a function handle, or an arbitrary type.
<b>Output Arguments</b>	<b>diagArray</b> Array of joined diagnostic content. <ul style="list-style-type: none"><li>• If <code>diagN</code> is an object that derives from <code>Diagnostic</code>, it is included in the array unmodified.</li><li>• If <code>diagN</code> is a char, it is formed into a <code>StringDiagnostic</code> and included in the array.</li><li>• If <code>diagN</code> is a <code>function_handle</code>, it is formed into a <code>FunctionHandleDiagnostic</code> and included in the array.</li><li>• If <code>diagN</code> is any other type, it is formed into a <code>DisplayDiagnostic</code> and included in the array.</li></ul>
<b>Alternatives</b>	You can use array concatenation <code>join</code> diagnostics into an array if at least one of the values is a diagnostic. The <code>join</code> method prevents the need to have any <code>Diagnostics</code> in the array. Considering the following example. <pre>arbitraryValue = 5; testCase.verifyThat(false, IsTrue, ...     ['should have been true', ...     @() system('ps'), ...     arbitraryValue, ...     MyCustomDiagnostic]);</pre>

# matlab.unittest.diagnostics.Diagnostic.join

---

Since MyCustomDiagnostic is a Diagnostic, the other values are correctly converted to diagnostics as well.

## Examples

### Join Diagnostic Content

```
% The following example creates a diagnostic array of length 4,  
% demonstrating standard Diagnostic conversions. Note:  
% MyCustomDiagnostic is for example purposes and is not executable  
% code.
```

```
import matlab.unittest.diagnostics.Diagnostic;  
import matlab.unittest.constraints.IsTrue;
```

```
arbitraryValue = 5;  
testCase.verifyThat(false, IsTrue, ...  
    Diagnostic.join(...  
        'should have been true', ...  
        @() system('ps'), ...  
        arbitraryValue, ...  
        MyCustomDiagnostic))
```

**See Also** [matlab.mixin.Heterogeneous](#) |

**Superclasses** Diagnostic

**Purpose** Diagnostic using a value's displayed output

**Description** The DisplayDiagnostic class provides a diagnostic result using a value's displayed output. This output is the same text displayed using the `display` function. When the diagnostic information is accessible through a variable in the current workspace, the DisplayDiagnostic class is a means to provide quick diagnostic information.

**Construction** `DisplayDiagnostic(diagValue)` creates a new DisplayDiagnostic instance.

## Input Arguments

### diagValue

The value used by the Diagnostic to generate diagnostic information.

The resulting diagnostic information will be equivalent to displaying this value at the MATLAB command prompt. The result will be packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

**Properties** **Value**

The value which the Diagnostic uses to generate diagnostic information, specified in the `diagValue` input argument. This property is read-only.

## Inherited Properties

### DiagnosticResult

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of

# matlab.unittest.diagnostics.DisplayDiagnostic

---

diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

## Inherited Methods

<code>diagnose</code>	Execute diagnostic action
<code>join</code>	Join multiple diagnostics into a single array

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create DisplayDiagnostic Object

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.diagnostics.DisplayDiagnostic;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Provide a DisplayDiagnostic as a Test Diagnostic
testCase.verifyThat(1, IsEqualTo(2), DisplayDiagnostic(5) );
```

## See Also

## Concepts

# matlab.unittest.diagnostics.FunctionHandleDiagnostic

---

**Superclasses** Diagnostic

**Purpose** Diagnostic using a function's displayed output

**Description** The FunctionHandleDiagnostic class provides a diagnostic result using a function's displayed output. This output is the same as the text displayed at the command prompt when executing the function handle. When the diagnostic information is accessible through information displayed as output of the function handle, the FunctionHandleDiagnostic is a means to provide quick diagnostic information.

When using matlab.unittest qualifications, a function handle can be directly supplied as a test diagnostic. In this case, the testing framework automatically creates a FunctionHandleDiagnostic object.

**Construction** FunctionHandleDiagnostic(fcnHandle) creates a new FunctionHandleDiagnostic instance.

## **Input Arguments**

### **fcnHandle**

The function handle used by the Diagnostic to generate diagnostic information.

The resulting diagnostic information will be equivalent to displaying this output at the MATLAB command prompt. The result will be packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

**Properties** Fcn

The function handle used by the Diagnostic to generate diagnostic information, specified in the fcnHandle input argument. This property is read-only.

# matlab.unittest.diagnostics.FunctionHandleDiagnostic

---

## Inherited Properties

### DiagnosticResult

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

### Inherited Methods

<code>diagnose</code>	Execute diagnostic action
<code>join</code>	Join multiple diagnostics into a single array

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Create `FunctionHandleDiagnostics` Object

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.diagnostics.FunctionHandleDiagnostic;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Create a FunctionHandleDiagnostic only upon failure
testCase.verifyThat(1, IsEqualTo(2), @dir;

% Provide a FunctionHandleDiagnostic directly
testCase.verifyThat(1, IsEqualTo(2), FunctionHandleDiagnostic(@dir);
```

## See Also

## Concepts

<b>Superclasses</b>	Diagnostic	
<b>Purpose</b>	Diagnostic using string	
<b>Description</b>	<p>The StringDiagnostic class provides a diagnostic result using a string. When the diagnostic information is known at the time of construction, the StringDiagnostic is a means to provide quick diagnostic information.</p> <p>When using matlab.unittest qualifications, a string can be directly supplied as a test diagnostic. In this case, the testing framework automatically creates a StringDiagnostic object.</p>	
<b>Construction</b>	StringDiagnostic(diagString) creates a new StringDiagnostic instance.	
	<b>Input Arguments</b>	
	<b>diagString</b>	
	The string used by the Diagnostic to generate diagnostic information.	
<b>Properties</b>	<b>Inherited Properties</b>	
	<b>DiagnosticResult</b>	
	The DiagnosticResult property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the diagnose method.	
<b>Methods</b>	<b>Inherited Methods</b>	
	diagnose	Execute diagnostic action
	join	Join multiple diagnostics into a single array

# matlab.unittest.diagnostics.StringDiagnostic

---

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create StringDiagnostic Object

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.diagnostics.StringDiagnostic;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Implicitly create a StringDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), ...
    'actual was supposed to be equal to expected' );

% Provide a StringDiagnostic directly
testCase.verifyThat(1, IsEqualTo(2), ...
    StringDiagnostic('actual was supposed to be equal to expected' ) );
```

## See Also

FunctionHandleDiagnostic | matlab.unittest.diagnostics

## Concepts

**Purpose** Create and display empty dialog box

**Syntax** `h = dialog('PropertyName',PropertyValue,...)`

**Description** `h = dialog('PropertyName',PropertyValue,...)` returns a handle to a dialog box. The dialog box is a figure graphics object with properties recommended for dialog boxes. You can specify any valid figure property value except `DockControls`, which is always `off`.

The properties that `dialog` sets and their values are

Property	Value
'ButtonDownFcn'	'if isempty(allchild(gcf)), close(gcf), end'
'Colormap'	[]
'Color'	DefaultUicontrolBackgroundColor
'DockControls'	'off'
'HandleVisibility'	'callback'
'IntegerHandle'	'off'
'InvertHardcopy'	'off'
'MenuBar'	'none'
'NumberTitle'	'off'
'PaperPositionMode'	'auto'
'Resize'	'off'
'Visible'	'on'
'WindowStyle'	'modal'

# dialog

---

---

**Note** By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

The default `ButtonDownFcn`, if `isempty(allchild(gcf))`, `close(gcf)`, `end`, causes the dialog to terminate itself when clicked as long as it contains no child objects. Replace it with another callback or an empty callback if you do not want this behavior. You can do this only from a script or function if the dialog is modal (the default `WindowState`).

Any property you can specify for the figure function is valid for this function.

## Examples

Create a default modal dialog box:

```
out = dialog;
```

---

Create a nonmodal dialog box with a name on its title bar:

```
out = dialog('WindowState', 'normal', 'Name', 'My Dialog');
```

---

<b>Purpose</b>	Save Command Window text to file
<b>Syntax</b>	<pre>diary diary('filename') diary <b>off</b> diary <b>on</b> diary filename</pre>
<b>Description</b>	<p>The <code>diary</code> function creates a log of keyboard input and the resulting text output, with some exceptions (see “Tips” on page 1-1595 for details). The output of <code>diary</code> is an ASCII file, suitable for searching in, printing, inclusion in most reports and other documents. If you do not specify <code>filename</code>, the MATLAB software creates a file named <code>diary</code> in the current folder.</p> <p><code>diary</code> toggles <code>diary</code> mode on and off. To see the status of <code>diary</code>, type <code>get(0, 'Diary')</code>. MATLAB returns either <code>on</code> or <code>off</code> indicating the <code>diary</code> status.</p> <p><code>diary('filename')</code> writes a copy of all subsequent keyboard input and the resulting output (except it does not include graphics) to the named file, where <code>filename</code> is the full pathname or <code>filename</code> is in the current MATLAB folder. If the file already exists, output is appended to the end of the file. You cannot use a <code>filename</code> called <code>off</code> or <code>on</code>. To see the name of the <code>diary</code> file, use <code>get(0, 'DiaryFile')</code>.</p> <p><code>diary off</code> suspends the <code>diary</code>.</p> <p><code>diary on</code> resumes <code>diary</code> mode using the current <code>filename</code>, or the default <code>filename</code> <code>diary</code> if none has yet been specified.</p> <p><code>diary filename</code> is the unquoted form of the syntax.</p>
<b>Tips</b>	<p>Because the output of <code>diary</code> is plain text, the file does not exactly mirror input and output from the Command Window:</p> <ul style="list-style-type: none"><li>• Output does not include graphics (figure windows).</li><li>• Syntax highlighting and font preferences are not preserved.</li></ul>

- Hidden components of Command Window output such as hyperlink information generated with `matlab:` are shown in plain text. For example, if you enter the following statement

```
str = sprintf('%s%s', ...
    '<a href="matlab:magic(4)">', ...
    'Generate magic square</a>');
disp(str)
```

MATLAB displays

[Generate magic square](#)

However, the diary file, when viewed in a text editor, shows

```
str = sprintf('%s%s', ...
    '<a href="matlab:magic(4)">', ...
    'Generate magic square</a>');
disp(str)
<a href="matlab:magic(4)">Generate magic square</a>
```

If you view the output of `diary` in the Command Window, the Command Window interprets the `<a href ...>` statement and displays it as a hyperlink.

- Viewing the output of `diary` in a console window might produce different results compared to viewing `diary` output in the desktop Command Window. One example is using the `\r` option for the `fprintf` function; using the `\n` option might alleviate that problem.

`evalc`

## How To

- “Command History”

**Purpose**

Differences and Approximate Derivatives

**Syntax**

```
Y = diff(X)
Y = diff(X,n)
Y = diff(X,n,dim)
```

**Description**

$Y = \text{diff}(X)$  calculates differences between adjacent elements of  $X$  along the first array dimension whose size does not equal 1:

- If  $X$  is a vector of length  $m$ , then  $Y = \text{diff}(X)$  returns a vector of length  $m-1$ . The elements of  $Y$  are the differences between adjacent elements of  $X$ .

$$Y = [X(2)-X(1) \quad X(3)-X(2) \quad \dots \quad X(m)-X(m-1)]$$

- If  $X$  is a nonempty, nonvector  $p$ -by- $m$  matrix, then  $Y = \text{diff}(X)$  returns a matrix of size  $(p-1)$ -by- $m$ , whose elements are the differences between the rows of  $X$ .

$$Y = [X(2,:) - X(1,:); \quad X(3,:) - X(2,:); \quad \dots \quad X(p,:) - X(p-1,:)]$$

- If  $X$  is a 0-by-0 empty matrix, then  $Y = \text{diff}(X)$  returns a 0-by-0 empty matrix.

$Y = \text{diff}(X,n)$  calculates the  $n$ th difference by applying the  $\text{diff}(X)$  operator recursively  $n$  times. In practice, this means  $\text{diff}(X,2)$  is the same as  $\text{diff}(\text{diff}(X))$ .

$Y = \text{diff}(X,n,dim)$  is the  $n$ th difference calculated along the dimension specified by  $dim$ . The  $dim$  input is a positive integer scalar.

**Input Arguments****X - Input array**

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

## **n** - Difference order

positive integer scalar | []

Difference order, specified as a positive integer scalar or []. The default value of `n` is 1.

It is possible to specify `n` sufficiently large so that `dim` reduces to a single (`size(X,dim) = 1`) dimension. When this happens, `diff` continues calculating along the next array dimension whose size does not equal 1. This process continues until a 0-by-0 empty matrix is returned.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## **dim** - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional `p`-by-`m` input array, `A`:

- `diff(A,1,1)` works on successive elements in the columns of `A` and returns a `(p-1)`-by-`m` difference matrix.
- `diff(A,1,2)` works on successive elements in the rows of `A` and returns a `p`-by-`(m-1)` difference matrix.

A

diff(A,1,1)

diff(A,1,2)

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**Output Arguments****Y - Difference array**

scalar | vector | matrix | multidimensional array

Difference array, returned as a scalar, vector, matrix, or multidimensional array. If X is a nonempty array, then the dimension of X acted on by diff is reduced in size by n in the output.

**Examples****Differences Between Vector Elements**

Create a vector, then compute the differences between the elements.

```
X = [1 1 2 3 5 8 13 21];
Y = diff(X)
```

```
Y =
```

```
0     1     1     2     3     5     8
```

Note that Y has one fewer element than X.

**Differences Between Matrix Rows**

Create a 3-by-3 matrix, then compute the first difference between the rows.

```
X = [1 1 1; 5 5 5; 25 25 25];
Y = diff(X)
```

Y =

```
    4    4    4
   20   20   20
```

The output Y is a 2-by-3 difference matrix.

## Multiple Differences

Create a vector and compute the second-order difference between the elements.

```
X = [0 5 15 30 50 75 105];
Y = diff(X,2)
```

Y =

```
    5    5    5    5    5
```

## Differences Between Matrix Columns

Create a 3-by-3 matrix, then compute the first-order difference between the columns.

```
X = [1 3 5;7 11 13;17 19 23];
Y = diff(X,1,2)
```

Y =

```
    2    2
    4    2
    2    4
```

The output Y is a 3-by-2 difference matrix.

## Approximate Derivatives with diff

Use the diff function to approximate partial derivatives with the syntax `Y = diff(f)/h`, where f is a vector of function values over

some domain,  $X$ , and  $h$  is an appropriate step size. For example, the first derivative of  $\sin(x)$  with respect to  $x$  is  $\cos(x)$ , and the second derivative with respect to  $x$  is  $-\sin(x)$ . You can use `diff` to approximate these derivatives.

```
h = 0.001;          %step size
X = -pi:h:pi;      %domain
f = sin(X);        %range
Y = diff(f)/h;     %first derivative
Z = diff(Y)/h;     %second derivative
plot(X(:,1:length(Y)),Y,'r',X,f,'b', X(:,1:length(Z)),Z,'k')
```

# diff

---

In this plot the blue line corresponds to the original function, `sin`. The red line corresponds to the calculated first derivative, `cos`, and the black line corresponds to the calculated second derivative, `-sin`.

## See Also

`gradient` | `prod` | `cumsum` | `sum`

**Purpose** Calculate diffuse reflectance

**Syntax** `R = diffuse(Nx,Ny,Nz,S)`

**Description** `R = diffuse(Nx,Ny,Nz,S)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` specifies the direction to the light source. You can specify these directions as three vectors `[x,y,z]` or two vectors `[Theta Phi]` (in spherical coordinates).

Lambert's Law:  $R = \cos(\text{PSI})$  where `PSI` is the angle between the surface normal and light source.

**See Also** `specular` | `surfnorm` | `surf1`

**How To**

- “Lighting Overview”

# dir

---

**Purpose** List folder contents

**Syntax**

```
dir
dir name
listing = dir(name)
```

**Description** `dir` lists the files and folders in the MATLAB current folder. Results appear in the order returned by the operating system.

`dir name` lists the files and folders that match the string `name`. When `name` is a folder, `dir` lists the contents of the folder. Specify `name` using absolute or relative path names. You can use wildcards (\*).

`listing = dir(name)` returns attributes about `name`.

**Tips**

- To obtain a list of available drives on Microsoft Windows platforms:  
Use the DOS `net use` command in the Command Window:

```
dos('net use')
```

Or

```
[s,r] = dos('net use')
```

MATLAB returns the results to the character array `r`.

- Short DOS file name support

The MATLAB `dir` function is consistent with the Microsoft Windows operating system `dir` command in that both support short file names generated by DOS.

- Structure Results for Nonexistent Files

When you run `dir` with an output argument and the results include a nonexistent file or a file that `dir` cannot query for some other reason, then `dir` returns the following default values:

```
date: ''
bytes: []
```

isdir: 0  
datenum: []

# dir

---

The most common occurrence is on UNIX<sup>1</sup> platforms when `dir` queries a file that is a symbolic link, which points to a nonexistent target. A nonexistent target is a target that was moved, removed, or renamed. For example, if `my_file` in `my_dir` is a symbolic link to another file that was deleted, then running

```
r = dir('my_dir')
```

includes this result for `my_file`:

```
r(n) =  
  name: 'my_file'  
  date: ''  
  bytes: []  
  isdir: 0  
  datenum: []
```

where  $n$  is the index for `my_file`, found by searching `r` by the `name` field.

## Input Arguments

### **name**

A string value specifying a file or folder name.

## Output Arguments

### **listing**

Field Name	Description	Class
name	File or folder name	char array
date	Modification date timestamp	char array
bytes	Size of the file in bytes	double

1. UNIX is a registered trademark of The Open Group in the United States and other countries.

Field Name	Description	Class
isdir	1 if name is a folder; 0 if not	logical
datenum	Modification date as serial date number. The value is locale-dependent.	double

## Examples

### View the Contents of a Folder

View the contents of the matlab/audiovideo folder:

```
dir(fullfile(matlabroot, 'toolbox/matlab/audiovideo'))
```

### Find Information in the Return Structure

Return the folder listing, restricted to files with a .m extension, to the variable av\_files:

```
av_files = dir(fullfile(matlabroot, ...  
                    'toolbox/matlab/audiovideo/*.m'))
```

MATLAB returns the information in a structure array:

```
av_files =  
25x1 struct array with fields:  
    name  
    date  
    bytes  
    isdir  
    datenum
```

Index into the structure to access a particular item:

```
av_files(3).name  
ans =  
    audioplayerreg.m
```

## - Use the Wildcard Character to Find Multiple Files

View the MAT-files in the current folder that include the term `my_data` by using the wildcard character:

```
dir *my_data*.mat
```

MATLAB returns all file names that match this specification. For instance, it returns the following if they are in the current folder:

```
old_my_data.mat  my_data_final.mat  my_data_test.mat
```

## - Exclude Certain Files from the Output

Return the list of files in the current folder, excluding those files that `dir` cannot query:

```
y = dir;  
y = y(find(~cellfun(@isempty,{y(:).date})));
```

## - Find the Date a File Was Modified

To get the serial date number for the date and time a file was last modified, use the `datenum` field of the structure returned by the `dir` command:

```
DirInfo = dir('startup.m');  
filedate = DirInfo.datenum
```

Using the `datenum` function to convert the string returned in the `date` field of the structure is not recommended as this can behave differently in different locales.

```
filedate = datenum(DirInfo.date)
```

## Alternatives

Use the Current Folder browser to view the list of files in a folder.

`cd` | `fileattrib` | `isdir` | `ls` | `mkdir` | `rmdir` | `what`

## How To

- “Working with Files and Folders”

- “Path Names in MATLAB”

# FTP.dir

---

**Purpose** View contents of folder on FTP server

**Syntax**  
`dir(ftpobj)`  
`dir(ftpobj, folder)`  
`details = dir(ftpobj, folder)`

**Description** `dir(ftpobj)` lists the files in current folder on the FTP server associated with `ftpobj`.  
`dir(ftpobj, folder)` lists the files in the specified folder.  
`details = dir(ftpobj, folder)` returns the results in a structure array that contains the name, modification date, and size of each file.

**Input Arguments**  
**ftpobj**  
FTP object created by `ftp`.

**folder**  
String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

**Output Arguments**  
**details**  
`m`-by-1 structure array, where `m` is the number of files in the folder. Each element of the structure array contains the following fields:

Field Name	Description	Data Type
name	File name	char
date	Modification date timestamp	char
bytes	Number of bytes allocated to the file	double

Field Name	Description	Data Type
isdir	If a folder, isdir = 1, otherwise isdir = 0	logical
datenum	Modification date as serial date number	char

## Examples

Connect to the MathWorks FTP server and view the contents:

```
mw=ftp('ftp.mathworks.com');
dir(mw)
```

This code returns:

```
README    incoming  matlab    outgoing  pub        pubs
```

---

Continuing the previous example, save the folder contents to the structure `m`, close the connection, and view details about the `pub` subfolder:

```
m=dir(mw);
close(mw);
```

```
m(5)
```

This code returns:

```
ans =
    name: 'pub'
    date: '13-Aug-2008 00:00:00'
    bytes: 512
    isdir: 1
    datenum: 733633
```

## See Also

`cd` | `ftp` | `mkdir` | `rmdir`

# disp

---

**Purpose** Display text or array

**Syntax** disp(X)

**Description** disp(X) displays the contents of X without printing the variable name. disp does not display empty variables.

**Input Arguments** **X - Variable to display**  
variable name  
Variable to display, specified by the variable name.

## **Examples** **Display Matrix with Column Labels**

Display a matrix and label the columns as Corn, Oats, and Hay.

```
X = gallery('uniformdata',[5 3],0);  
disp('    Corn    Oats    Hay')  
disp(X)
```

```
    Corn    Oats    Hay  
0.9501    0.7621    0.6154  
0.2311    0.4565    0.7919  
0.6068    0.0185    0.9218  
0.4860    0.8214    0.7382  
0.8913    0.4447    0.1763
```

## **Display Hyperlink in Command Window**

Include the full hypertext string on a single line as input to disp.

```
X = '<a href = "http://www.mathworks.com">MathWorks Web Site</a>';  
disp(X)
```

```
MathWorks Web Site
```

The `disp` function generates a hyperlink in the Command Window. Click the link to display the MathWorks home page in a MATLAB Web browser.

### Display Multiple Items on Same Line

Concatenate strings together using the `[]` operator. Convert any numeric values to characters using the `num2str` function.

```
name = 'Alice';    age = 12;
X = [name, ' will be ', num2str(age), ' this year.'];
```

Display the string.

```
disp(X)
```

```
Alice will be 12 this year.
```

You also can use `sprintf` to create a string. Terminate the `sprintf` command with a semicolon to prevent "X = " from being displayed. Then, use `disp` to display the string.

```
name = 'Alice';    age = 12;
X = sprintf('%s will be %d this year.', name, age);
disp(X)
```

```
Alice will be 12 this year.
```

Alternatively, use `fprintf` to create and display the string. Unlike the `sprintf` function, `fprintf` does not display the "X = " text. However, you need to end the string with the newline (`\n`) metacharacter to terminate its display properly.

```
name = 'Alice';    age = 12;
X = fprintf('%s will be %d this year.\n', name, age);
```

```
Alice will be 12 this year.
```

# disp

---

## Tips

- The `disp` function accepts only one input. To display more than one array or string, you can use concatenation or the `sprintf` or `fprintf` functions as shown in the Example, “Display Multiple Items on Same Line” on page 1-1613.

## See Also

`format` | `int2str` | `num2str` | `rats` | `sprintf` | `fprintf` |  
`colon` (:)

**Purpose** Information about memory map

**Syntax** disp(m)

**Description** disp(m) displays all properties and their values for the memory map, m. MATLAB also displays this information when you create a memory map or set any of its property values, provided you do not terminate the command to do so with a semicolon.

**Examples** Construct a memory map, m:

```
m = memmapfile('records.dat', ...
               'Offset', 2048, ...
               'Format', { ...
                   'int16' [2 2] 'model'; ...
                   'uint32' [1 1] 'serialno'; ...
                   'single' [1 3] 'expenses'});
```

Use disp to display all the current properties of m:

```
disp(m)
  Filename: 'd:\matlab\records.dat'
  Writable: false
  Offset: 2048
  Format: {'int16' [2 2] 'model'
          'uint32' [1 1] 'serialno'
          'single' [1 3] 'expenses'}
  Repeat: Inf
  Data: 753x1 struct array with fields:
        model
        serialno
        expenses
```

**See Also** memmapfile | get (memmapfile)

# disp (MException)

---

**Purpose** Display MException object

**Syntax** disp(exception)  
disp(exception.property)

**Description** disp(exception) displays all properties (fields) of MException object exception.  
disp(exception.property) displays the specified property of MException object exception.

**Examples** Using the surf command without input arguments throws an exception. Use disp to display the identifier, message, stack, and cause properties of the MException object:

```
try
    surf
catch exception
    disp(exception)
end
```

MException object with properties:

```
    identifier: 'MATLAB:narginchk:notEnoughInputs'
    message: 'Not enough input arguments.'
    cause: {}
    stack: [1x1 struct]
```

Display only the stack property:

```
disp(exception.stack)
    file: 'C:\Program Files\MATLAB\toolbox\matlab\graph3d\surf.m'
graph3d\surf.m'
    name: 'surf'
    line: 54
```

# disp (serial)

---

**Purpose** Serial port object summary information

**Syntax** obj  
disp(obj)

**Description** obj or disp(obj) displays summary information for obj, a serial port object or an array of serial port objects.

**Tips** In addition to the syntax shown above, you can display summary information for obj by excluding the semicolon when:

- Creating a serial port object
- Configuring property values using the dot notation

Use the display summary to quickly view the communication settings, communication state information, and information associated with read and write operations.

**Examples** The following commands display summary information for the serial port object s. on a Windows platform

```
s = serial('COM1')
s.BaudRate = 300
s
```

**Purpose** Display text and numeric expressions

**Syntax** `display(X)`

**Description** `display(X)` prints the value of `X`. MATLAB implicitly calls `display` after any variable or expression that is not terminated by a semicolon. To customize the display of objects, overload the `disp` function instead of the `display` function. `display` calls `disp`.

**Examples** **Display a Matrix**

```
X = magic(3);  
display(X)
```

X =

```
     8     1     6  
     3     5     7  
     4     9     2
```

**Input Arguments** **X - Input value**  
`variable` | `expression`

Input value, specified as a variable or expression.

**See Also** `disp` | `ans` | `sprintf`

**Concepts**

- “Overloading Functions for Your Class”
- “Relationship Between `disp` and `display`”

# dither

---

<b>Purpose</b>	Convert image, increasing apparent color resolution by dithering
<b>Syntax</b>	<pre>X = dither(RGB, map) X = dither(RGB, map, Qm, Qe) BW = dither(I)</pre>
<b>Description</b>	<p><code>X = dither( RGB, map )</code> creates an indexed image approximation of the RGB image in the array <code>RGB</code> by dithering the colors in the colormap <code>map</code>. The colormap cannot have more than 65,536 colors.</p> <p><code>X = dither( RGB, map, Qm, Qe )</code> creates an indexed image from <code>RGB</code>, where <code>Qm</code> specifies the number of quantization bits to use along each color axis for the inverse color map, and <code>Qe</code> specifies the number of quantization bits to use for the color space error calculations. If <code>Qe &lt; Qm</code>, dithering cannot be performed, and an undithered indexed image is returned in <code>X</code>. If you omit these parameters, <code>dither</code> uses the default values <code>Qm = 5</code>, <code>Qe = 8</code>.</p> <p><code>BW = dither( I )</code> converts the grayscale image in the matrix <code>I</code> to the binary (black and white) image <code>BW</code> by dithering.</p>
<b>Class Support</b>	<code>RGB</code> can be <code>uint8</code> , <code>uint16</code> , <code>single</code> , or <code>double</code> . <code>I</code> can be <code>uint8</code> , <code>uint16</code> , <code>int16</code> , <code>single</code> , or <code>double</code> . All other input arguments must be <code>double</code> . <code>BW</code> is <code>logical</code> . <code>X</code> is <code>uint8</code> , if it is an indexed image with 256 or fewer colors; otherwise, it is <code>uint16</code> .
<b>Algorithms</b>	<code>dither</code> increases the apparent color resolution of an image by applying Floyd-Steinberg's error diffusion dither algorithm.
<b>Examples</b>	<p>Read and display the cameraman image. Display the image as a gray scale image using <code>imagesc</code>.</p> <pre>I = imread('cameraman.tif'); figure; imagesc(I); colormap(gray);</pre>

Apply dithering to get an indexed image as,

```
BW = dither(I);  
figure; imagesc(BW);  
colormap(gray);
```

# dither

---

rgb2ind

**Purpose** Compute divergence of vector field

**Syntax**

```
div = divergence(X,Y,Z,U,V,W)
div = divergence(U,V,W)
div = divergence(X,Y,U,V)
div = divergence(U,V)
```

**Description** `div = divergence(X,Y,Z,U,V,W)` computes the divergence of a 3-D vector field `U, V, W`.

The arrays `X, Y, and Z`, which define the coordinates for `U, V, and W`, must be monotonic, but do not need to be uniformly spaced. `X, Y, and Z` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V,W)` assumes `X, Y, and Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`div = divergence(X,Y,U,V)` computes the divergence of a 2-D vector field `U, V`.

The arrays `X and Y`, which define the coordinates for `U and V`, must be monotonic, but do not need to be uniformly spaced. `X and Y` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V)` assumes `X and Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

**Examples** This example displays the divergence of vector volume data as slice planes, using color to indicate divergence.

```
load wind
div = divergence(x,y,z,u,v,w);
```

# divergence

---

```
h = slice(x,y,z,div,[90 134],59,0);  
shading interp  
daspect([1 1 1])  
axis tight  
camlight  
set([h(1),h(2)], 'ambientstrength', .6)
```

## How To

- “Displaying Divergence with Stream Tubes”

**Purpose**

Read ASCII-delimited file of numeric data into matrix

**Syntax**

```
M = dlmread(filename)
M = dlmread(filename, delimiter)
M = dlmread(filename, delimiter, R, C)
M = dlmread(filename, delimiter, range)
```

**Description**

`M = dlmread(filename)` reads the ASCII-delimited numeric data file `filename`, and returns the data in output matrix `M`. The `filename` input is a string enclosed in single quotes. `dlmread` infers the delimiter from the formatting of the file.

`M = dlmread(filename, delimiter)` reads data from the file, using the specified `delimiter`. Use `'\t'` to specify a tab delimiter.

`M = dlmread(filename, delimiter, R, C)` reads data whose upper left corner is at row `R` and column `C` in the file. Values `R` and `C` are zero-based, so that `R=0, C=0` specifies the first value in the file.

`M = dlmread(filename, delimiter, range)` reads the range specified by `range = [R1 C1 R2 C2]` where `(R1,C1)` is the upper left corner of the data to read and `(R2,C2)` is the lower right corner. You can also specify the range using spreadsheet notation, such as `range = 'A1..B7'`.

**Tips**

- All data in the input file must be numeric. `dlmread` does not read files that contain nonnumeric data, even if the specified rows and columns contain only numeric data.
- When `dlmread` infers the delimiter from the formatting of the file, it treats repeated white spaces as a single delimiter. By contrast, if you specify a delimiter, `dlmread` treats any repeated delimiter character as a separate delimiter.
- If you want to specify an `R, C, or range` input, but not a `delimiter`, set the `delimiter` argument to the empty string, (two consecutive single quotes with no spaces in between, `' '`). For example,

```
M = dlmread('myfile.dat', ' ', 5, 2)
```

# dlmread

---

In this case, `dlmread` treats repeated white spaces as a single delimiter.

- `dlmread` fills empty delimited fields with zero. If each line ends with a nonspace delimiter, such as a semicolon, the output matrix contains an additional last column of zeros.
- `dlmread` imports any complex number as a whole into a complex numeric field. Valid forms for a complex number are

`--<real>--<imag>i|j`                      Example: `5.7-3.1i`

`--<imag>i|j`                                Example: `-7j`

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

## Examples

### Example 1

Export a 5-by-8 test matrix `M` to a file, and read it with `dlmread`, first with no arguments other than the filename:

```
M = gallery('integerdata', 100, [5 8], 0);
dlmwrite('myfile.txt', M, 'delimiter', '\t')
```

```
dlmread('myfile.txt')
ans =
    96    77    62    41     6    21     2    42
    24    46    80    94    36    20    75    85
    61     2    93    92    82    61    45    53
    49    83    74    42     1    28    94    21
    90    45    18    90    14    20    47    68
```

Now read a portion of the matrix by specifying the row and column of the upper left corner:

```
dlmread('myfile.txt', '\t', 2, 3)
ans =
    92    82    61    45    53
```

```

42    1    28    94    21
90    14   20    47    68

```

This time, read a different part of the matrix using a range specifier:

```

dlmread('myfile.txt', '\t', 'C1..G4')
ans =
    62    41     6    21     2
    80    94    36    20    75
    93    92    82    61    45
    74    42     1    28    94

```

## Example 2

Export matrix M to a file, and then append an additional matrix to the file that is offset one row below the first:

```

M = magic(3);
dlmwrite('myfile.txt', [M*5 M/5], ' ')

dlmwrite('myfile.txt', [M/3], '-append', ...
        'roffset', 1, 'delimiter', ' ')

```

```
type myfile.txt
```

```

40 5 30 1.6 0.2 1.2
15 25 35 0.6 1 1.4
20 45 10 0.8 1.8 0.4

```

```

2.6667 0.33333 2
1 1.6667 2.3333
1.3333 3 0.66667

```

When dlmread imports these two matrices from the file, it pads the smaller matrix with zeros:

```

dlmread('myfile.txt')
    40.0000    5.0000   30.0000    1.6000    0.2000    1.2000

```

# d1mread

15.0000	25.0000	35.0000	0.6000	1.0000	1.4000
20.0000	45.0000	10.0000	0.8000	1.8000	0.4000
2.6667	0.3333	2.0000	0	0	0
1.0000	1.6667	2.3333	0	0	0
1.3333	3.0000	0.6667	0	0	0

## See Also

[dlmwrite](#) | [textscan](#) | [readtable](#)

**Purpose** Write matrix to ASCII-delimited file

**Syntax**

```
dlmwrite(filename,M)
dlmwrite(filename,M,'-append')

dlmwrite(___,Name,Value)

dlmwrite(filename,M,delimiter)
dlmwrite(filename,M,delimiter,row,col)
```

**Description** `dlmwrite(filename,M)` writes numeric data in array `M` to an ASCII format file, `filename`, using the default delimiter (`,`) to separate array elements. If the file, `filename`, already exists, `dlmwrite` overwrites the file.

`dlmwrite(filename,M,'-append')` appends the data to the end of the existing file, `filename`.

`dlmwrite(___,Name,Value)` additionally specifies delimiter, newline character, offset, and precision options using one or more name-value pair arguments.

`dlmwrite(filename,M,delimiter)` writes array `M` to the file, `filename`, using the specified delimiter, `delimiter`, to separate array elements.

`dlmwrite(filename,M,delimiter,row,col)` writes the array starting at the specified row and column `row` and `col`, in the destination file. Empty elements separated by `delimiter` fill the leading rows and columns.

## Input Arguments

**filename - Name of file to write**

string

Name of file to write, specified as a string.

**Example:** 'myFile.txt'

## Data Types

char

## **M - Numeric data to write**

matrix | cell array of numeric values

Numeric data to write, specified as a matrix or a cell array of numeric values with one value per cell.

**Example:** [1,2,3;4,5,6]

**Example:** {1,2,3;4,5,6}

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | cell

**Complex Number Support:** Yes

## **delimiter - Delimiter to separate array elements**

',' (default) | string

Delimiter to separate array elements, specified as a string containing a single character or control character. Use '\t' to produce tab-delimited files.

**Example:** ';'

**Example:** '\t'

## Data Types

char

## **row - Row offset**

0 (default) | scalar

Row offset, specified as a scalar. The row offset indicates the number of rows to skip before writing the numeric data. `row` is zero-based, so that `row = 0` instructs MATLAB to begin writing in the first row of the destination file. Skipped rows are populated with the specified delimiter.

**col - Column offset**

0 (default) | scalar

Column offset, specified as a scalar. The column offset indicates the number of columns to skip before writing the numeric data. `col` is zero-based, so that `col = 0` instructs MATLAB to begin writing in the first column of the destination file. Skipped columns are separated with the specified delimiter.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:**

```
dlmwrite('myFile.txt',M,'precision',4,'delimiter',' ') writes  
the numeric values in array M with four significant digits and  
delimited using the whitespace character.
```

**'delimiter' - Delimiter to separate array elements**

' , ' (default) | string

Delimiter to separate array elements, specified as the comma-separated pair consisting of `'delimiter'` and string containing a single character or control character. Use `'\t'` to produce tab-delimited files.

**Example:** `'delimiter',';'`

**Example:** `'delimiter','\t'`

**Data Types**

char

**'roffset' - Row offset**

0 (default) | scalar

Row offset, specified as the comma-separated pair consisting of `'roffset'` and a scalar. The row offset indicates the number of rows to

skip before writing the numeric data. These rows are populated with the specified delimiter. When appending to an existing file, the new data is offset from the end of the existing data.

The row offset is zero-based, so that `'roffset',0` instructs MATLAB to begin writing in the first row of the destination file, which is the default. However, when appending to a file, `'roffset',0` instructs MATLAB to begin writing in the first row immediately following existing data.

**Example:** `'roffset',2`

### **'cffset' - Column offset**

0 (default) | scalar

Column offset from the left side of the destination file, specified as the comma-separated pair consisting of `'cffset'` and a scalar. The column offset indicates the number of columns to skip before writing the numeric data. These columns are separated with the specified delimiter.

The column offset is zero-based, so that `'cffset',0` instructs MATLAB to begin writing in the first column of the destination file, which is the default.

**Example:** `'cffset',1`

### **'precision' - Numeric precision**

5 (default) | scalar | C-style format string

Numeric precision to use in writing data to the file, specified as the comma-separated pair consisting of `'precision'` and a scalar or a C-style format string that begins with %, such as `'%10.5f'`. If the value of precision is a scalar, then it indicates the number of significant digits.

**Example:** `'precision',3`

**Example:** `'precision','%10.5f'`

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | char

**'newline' - Line terminator**`'pc' | 'unix'`

Line terminator, specified as the comma-separated pair consisting of 'newline' and either 'pc' to use a carriage return/line feed (CR/LF), or 'unix' to use a line feed (LF).

**Example:** 'newline', 'pc'

**Examples****Write Comma-Separated Data**

Create an array of sample data, M.

```
M = magic(3);
```

Write matrix M to a file, 'myFile.txt', using the default delimiter (,).

```
dlmwrite('myFile.txt',M)
```

View the data in the file.

```
type('myFile.txt')
```

```
8,1,6
```

```
3,5,7
```

```
4,9,2
```

**Write Tab-Delimited Data and Specify Precision**

Create an array of sample data, M.

```
M = magic(3)*pi
```

```
M =
```

```
25.1327    3.1416    18.8496
```

```
9.4248    15.7080    21.9911
```

```
12.5664    28.2743    6.2832
```

# dlmwrite

---

Write matrix `M` to a file, `'myFile.txt'`, delimited by the tab character and using a precision of 3 significant digits.

```
dlmwrite('myFile.txt',M,'delimiter','\t','precision',3)
```

View the data in the file.

```
type('myFile.txt')
```

```
25.1 3.14 18.8
9.42 15.7 22
12.6 28.3 6.28
```

## Write and Append Data to File

Create two arrays of sample numeric data.

```
M = magic(5);
N = magic(3);
```

Export matrix `M` to a file and use whitespace as the delimiter.

```
dlmwrite('myFile.txt',M,'delimiter',' ');
```

Append matrix `N` to the file, offset from the existing data by one row. Then, view the file.

```
dlmwrite('myFile.txt',N,'-append',...
'delimiter',' ','roffset',1)
type('myFile.txt')
```

```
17 24 1 8 15
23 5 7 14 16
4 6 13 20 22
10 12 19 21 3
11 18 25 2 9
```

```
8 1 6
3 5 7
```

```
4 9 2
```

Read the data in 'myFile.txt' using dlmread.

```
dlmread('myFile.txt')
```

```
ans =
```

```

17    24     1     8    15
23     5     7    14    16
 4     6    13    20    22
10    12    19    21     3
11    18    25     2     9
 8     1     6     0     0
 3     5     7     0     0
 4     9     2     0     0
```

When dlmread reads the two matrices from the file, it pads the smaller matrix with zeros.

### Write Data and Specify Precision As String

Create an array of sample numeric data.

```
M = magic(3);
```

Export matrix M to a file using a precision of 6 decimal places.

```
dlmwrite('myFile.txt',M,'precision','%.6f');
```

View the data in the file.

```
type('myFile.txt')
```

```

8.000000,1.000000,6.000000
3.000000,5.000000,7.000000
4.000000,9.000000,2.000000
```

# dlmwrite

---

## Tips

- `dlmwrite` writes a file that spreadsheet programs can read. Alternatively, if your system has Excel for Windows installed, you can create a spreadsheet using `xlswrite`.

## See Also

`dlmread` | `xlswrite` | `writetable`

## Purpose

Dulmage-Mendelsohn decomposition

## Syntax

$p = \text{dmperm}(A)$   
 $[p,q,r,s,cc,rr] = \text{dmperm}(A)$

## Description

$p = \text{dmperm}(A)$  finds a vector  $p$  such that  $p(j) = i$  if column  $j$  is matched to row  $i$ , or zero if column  $j$  is unmatched. If  $A$  is a square matrix with full structural rank,  $p$  is a maximum matching row permutation and  $A(p, :)$  has a zero-free diagonal. The structural rank of  $A$  is  $\text{sprank}(A) = \text{sum}(p>0)$ .

$[p,q,r,s,cc,rr] = \text{dmperm}(A)$  where  $A$  need not be square or full structural rank, finds the Dulmage-Mendelsohn decomposition of  $A$ .  $p$  and  $q$  are row and column permutation vectors, respectively, such that  $A(p,q)$  has a block upper triangular form.  $r$  and  $s$  are index vectors indicating the block boundaries for the fine decomposition.  $cc$  and  $rr$  are vectors of length five indicating the block boundaries of the coarse decomposition.

$C = A(p,q)$  is split into a 4-by-4 set of coarse blocks:

```
A11 A12 A13 A14
0   0  A23 A24
0   0   0  A34
0   0   0  A44
```

where  $A12$ ,  $A23$ , and  $A34$  are square with zero-free diagonals. The columns of  $A11$  are the unmatched columns, and the rows of  $A44$  are the unmatched rows. Any of these blocks can be empty. In the coarse decomposition, the  $(i,j)$ th block is  $C(rr(i):rr(i+1)-1,cc(j):cc(j+1)-1)$ . For a linear system,

- $[A11 \ A12]$  is the underdetermined part of the system—it is always rectangular and with more columns and rows, or 0-by-0,
- $A23$  is the well-determined part of the system—it is always square, and

- [A34 ; A44] is the overdetermined part of the system—it is always rectangular with more rows than columns, or 0-by-0.

The structural rank of A is  $\text{sprank}(A) = \text{rr}(4) - 1$ , which is an upper bound on the numerical rank of A.  $\text{sprank}(A) = \text{rank}(\text{full}(\text{sprand}(A)))$  with probability 1 in exact arithmetic.

The A23 submatrix is further subdivided into block upper triangular form via the fine decomposition (the strongly connected components of A23). If A is square and structurally nonsingular, A23 is the entire matrix.

$C(r(i):r(i+1)-1, s(j):s(j+1)-1)$  is the  $(i, j)$ th block of the fine decomposition. The  $(1, 1)$  block is the rectangular block [A11 A12], unless this block is 0-by-0. The  $(b, b)$  block is the rectangular block [A34 ; A44], unless this block is 0-by-0, where  $b = \text{length}(r) - 1$ . All other blocks of the form  $C(r(i):r(i+1)-1, s(i):s(i+1)-1)$  are diagonal blocks of A23, and are square with a zero-free diagonal.

## Tips

If A is a reducible matrix, the linear system  $Ax=b$  can be solved by permuting A to a block upper triangular form, with irreducible diagonal blocks, and then performing block backsubstitution. Only the diagonal blocks of the permuted matrix need to be factored, saving fill and arithmetic in the blocks above the diagonal.

In graph theoretic terms, dmperm finds a maximum-size matching in the bipartite graph of A, and the diagonal blocks of  $A(p, q)$  correspond to the strong Hall components of that graph. The output of dmperm can also be used to find the connected or strongly connected components of an undirected or directed graph. For more information see Pothen and Fan [1].

**Purpose** Reference page in Help browser

**Syntax** doc  
doc name

**Description** doc opens the Help browser. If the Help browser is already open, but not visible, then doc brings it to the foreground and opens a new tab.

doc name displays documentation for the functionality specified by name, such as a function, class, or block.

- If there is a MathWorks reference page corresponding to name, then doc displays the page in the Help browser. The doc command does not display third-party or custom HTML documentation.
- If there is no reference page corresponding to name, then doc searches for help text in a file named *name.m*. When help text is available, doc displays it in the Help browser.
- If there is no reference page and no help text associated with name, then doc searches the documentation for name and displays the search results in the Help browser.

## Input Arguments

**name - Name of function, class, block, or other functionality**  
string

Name of a function, class, block, or other functionality, specified as a string. Alternatively, an operator symbol.

Some classes and other packaged items require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, such as:

```
doc className.name  
doc packageName.name  
doc packageName.className.name
```

Methods for some classes are not accessible using the `doc` command; instead, use links on the class reference page.

## **Examples**      **Function Reference Pages**

Display the reference page for the `abs` function.

```
doc abs
```

Several products include different versions of `abs`. If your Help preferences support displaying documentation for those products, then the Help browser displays the MATLAB `abs` reference page and a message with links to other versions of `abs`. This message appears at the top of the page.

## **Class and Method Reference Pages**

Display the reference page for the `handle` class.

```
doc handle
```

Display the reference page for the `findobj` method in the `handle` class.

```
doc handle.findobj
```

Display the reference page for the `Map` class in the `containers` package.

```
doc containers.Map
```

## **Custom Class Pages**

Display formatted help text for a custom class.

MATLAB includes a set of example files that show how to create a class, including a class file named `sads.m`. Add the example folder to the path, and request documentation for `sads`.

```
addpath(...  
    fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', 'examples'))  
doc sads
```

Display the help for the `steer` method of the `sads` class.

```
doc sads.steer
```

Because the help text follows MATLAB conventions, MATLAB formats the display in the browser.

### Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

# docsearch

---

**Purpose** Help browser search

**Syntax** docsearch  
docsearch expression

**Description** docsearch opens the Help browser and displays the documentation home page. If the Help browser is already open, but not visible, then docsearch brings it to the foreground.

docsearch expression searches MathWorks documentation for pages with words that match the specified expression. The docsearch command does not search third-party or custom documentation.

## Input Arguments

**expression - Expression that defines search terms**  
string

Expression that defines search terms, specified as a string. Expressions can include:

- Quotation marks to specify exact phrases, such as "plot tools".
- Boolean operator keywords in uppercase (listed here in order of precedence): NOT, OR, AND.
- Asterisk (\*) wildcard characters, except at the beginning of a word or in an exact phrase. Searches require that at least two characters in the expression are *not* wildcard characters.

## Examples

### Single Words

Find all documentation pages that contain the word *plot*.

```
docsearch plot
```

### Multiple Words

Find documentation pages with the words *plot* and *tools*.

```
docsearch plot tools
```

Expand the search to include variations of the word *plot*, such as *plotting* or *plots*, using a wildcard character.

```
docsearch plot* tools
```

Narrow the search to pages that include an exact phrase by enclosing the phrase in quotation marks.

```
docsearch "plot tools"
```

Find pages with either word, but not necessarily both words, using the OR operator.

```
docsearch plot OR tools
```

### Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

### Concepts

- “Search Syntax and Tips”

# dos

---

## Purpose

Execute DOS command and return output

## Syntax

```
status = dos(command)
[status,cmdout] = dos(command)
[status,cmdout] = dos(command, '-echo')
```

## Description

`status = dos(command)` executes the specified DOS command for Windows platforms, and waits for the command to finish execution before returning the exit status to the `status` variable.

`[status,cmdout] = dos(command)` additionally returns the output of the DOS command to `cmdout`. This syntax is most useful for DOS console commands that do not require user input, such as `dir`.

`[status,cmdout] = dos(command, '-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for DOS console commands that require user input and that run correctly in the MATLAB Command Window, such as `comp`.

## Input Arguments

### **command** - MS-DOS® command

string

MS-DOS command, specified as a string. The command can be a Windows UI program that opens a graphical user interface, or a DOS console command that you typically run in a DOS command window. The command executes in a DOS shell, which might not be the shell from which you launched MATLAB.

**Example:** 'dir'

## Output Arguments

### **status** - Command exit status

0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, `status` is 0. Otherwise, `status` is a nonzero integer.

- If command includes the ampersand character (&), then `status` is the exit status upon command launch.
- If command does not include the ampersand character (&), then `status` is the exit status upon command completion.

### **cmdout - Output of operating system command**

string

Output of the operating system command, returned as a string.

## **Limitations**

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `dos` with a DOS command that relies on the current folder fails. MATLAB returns this error:

```
Error using dos
DOS commands may not be executed when the current directory is a UNC
```

To work around this limitation, change the folder to a mapped drive before running `dos` or a function that calls `dos`.

## **Examples**

### **Save DOS Command Exit Status**

Issue a DOS command to create a new folder named `mynew` and save the exit status to a variable.

```
command = 'mkdir mynew';
status = dos(command)
```

```
status =
```

```
0
```

The `status` of zero indicates that the `mynew` folder was created successfully.

## Open and Run a Windows UI Command

Open Notepad and immediately return the exit status to MATLAB by appending an ampersand (&) to the notepad command.

```
status = dos('notepad &')
```

```
status =
```

```
0
```

The status of zero indicates that Notepad successfully started.

## Save Successful DOS Command Status and Output

Execute the DOS command, `dir`, and view the exit status and command output.

```
[status,cmdout] = dos('dir');
```

```
status, cmdout
```

```
status =
```

```
0
```

```
cmdout =
```

```
Volume in drive C is OSDisk  
Volume Serial Number is XXX-XXXX
```

```
Directory of C:\my_MATLAB_files
```

```
04/10/2012 12:08 PM <DIR>      .  
04/10/2012 12:08 PM <DIR>      ..  
04/21/2011 09:24 AM           171 base.mat  
02/08/2010 05:14 PM           73 baseball.dat  
04/10/2012 12:08 PM          474 collatz.asv  
04/10/2012 11:56 AM          480 collatz.m
```

```
.  
. .  
. . .
```

When you issue a valid DOS command, `status` indicates success and `cmdout` contains the command output.

### **Save Unsuccessful DOS Command Status and Output**

Attempt to execute a command called `foo`. Then, view the status and results output arguments.

```
[status,results] = dos('foo');  
status, results
```

```
status =
```

```
1
```

```
results =
```

```
'foo' is not recognized as an internal or external command,  
operable program or batch file.
```

When you issue an invalid DOS command, `status` indicates failure and `results` contains the DOS error message.

### **Display DOS Command Output in MATLAB Command Window**

Display command output and prompts in the Command Window as the command executes, and also assign the command output to the `results` variable.

```
[status,results] = dos('comp', '-echo');
```

```
Name of first file to compare: collatz.m  
collatz.m
```

```
Name of second file to compare: collatz.asv
collatz.asv
Option: /A
/A
Option:

Comparing collatz.m and collatz.asv...
Files compare OK

Compare more files (Y/N) ? N
N
>>
```

## Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the command argument (for example, `'notepad &'`). The exit status is immediately returned to the status variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note** If command includes the trailing `&` character, then `cmdout` is empty.

---

## See Also

`computer` | `perl` | `system` | `unix!` (exclamation point) |

**Purpose** Vector dot product

**Syntax** `C = dot(A,B)`  
`C = dot(A,B,dim)`

**Description** `C = dot(A,B)` returns the scalar product of the vectors `A` and `B`. `A` and `B` must be vectors of the same length. When `A` and `B` are both column vectors, `dot(A,B)` is the same as `A'*B`.

For multidimensional arrays `A` and `B`, `dot` returns the scalar product along the first non-singleton dimension of `A` and `B`. `A` and `B` must have the same size.

`C = dot(A,B,dim)` returns the scalar product of `A` and `B` in the dimension `dim`.

**Examples** The dot product of two vectors is calculated as shown:

```
a = [1 2 3]; b = [4 5 6];  
c = dot(a,b)
```

```
c =  
    32
```

**See Also** `cross`

# double

---

**Purpose** Convert to double precision

**Syntax** `double(x)`

**Description** `double(x)` returns the double-precision value for X. If X is already a double-precision array, `double` has no effect.

**Tips** The `double` function should be overloaded for any object when it makes sense to convert it to a double-precision value.

**Purpose**

Drag rectangles with mouse

**Syntax**

```
[finalrect] = dragrect(initialrect)
[finalrect] = dragrect(initialrect, stepsize)
```

**Description**

[finalrect] = dragrect(initialrect) tracks one or more rectangles anywhere on the screen. The n-by-4 matrix initialrect defines the rectangles. Each row of initialrect must contain the initial rectangle position as [left bottom width height] values. dragrect returns the final position of the rectangles in finalrect.

[finalrect] = dragrect(initialrect, stepsize) moves the rectangles in increments of stepsize. The lower left corner of the first rectangle is constrained to a grid of size equal to stepsize starting at the lower left corner of the figure, and all other rectangles maintain their original offset from the first rectangle.

[finalrect] = dragrect(...) returns the final positions of the rectangles when the mouse button is released. The default step size is 1.

**Tips**

dragrect returns immediately if a mouse button is not currently pressed. Use dragrect in a ButtonDownFcn, or from the command line in conjunction with waitforbuttonpress, to ensure that the mouse button is down when dragrect is called. dragrect returns when you release the mouse button.

If the drag ends over a figure window, the positions of the rectangles are returned in that figure's coordinate system. If the drag ends over a part of the screen not contained within a figure window, the rectangles are returned in the coordinate system of the figure over which the drag began.

---

**Note** You cannot use normalized figure units with dragrect.

---

# dragrect

---

## Examples

Drag a rectangle that is 50 pixels wide and 100 pixels in height.

```
waitforbuttonpress
point1 = get(gcf, 'CurrentPoint') % button down detected
rect = [point1(1,1) point1(1,2) 50 100]
[r2] = dragrect(rect)
```

## See Also

[rbbox](#) | [waitforbuttonpress](#)

**Purpose** Flush event queue and update figure window

**Syntax** drawnow  
drawnow expose  
drawnow update

**Description** drawnow causes figure windows and their children to update, and flushes the system event queue. Any callbacks generated by incoming events (e.g., mouse or key events) are dispatched before drawnow returns.

drawnow expose causes graphics and user-interface objects to refresh with pending changes. It does not allow callbacks to execute and does not process events pending in the queue.

drawnow update causes only user-interface objects to refresh, if needed. Does not allow callbacks to execute and does not process other events pending in the queue.

Combine the expose and update options to obtain both effects:

```
drawnow expose update
```

### **Other Events That Cause Event Queue Processing**

Other events that cause the MATLAB software to flush the event queue and draw the figure include:

- Returning to the MATLAB prompt
- Executing the following functions:
  - figure
  - getframe
  - input
  - pause
  - keyboard
- Functions that wait for user input (i.e., waitforbuttonpress, waitfor, ginput)

# drawnow

---

- Any code that causes one of the above functions to execute. For example, suppose `h` is the handle of an axes. Calling `axes(h)` causes its parent figure to be made the current figure and brought to the front of all displayed figures, which results in the event queue being flushed.

## Examples

Using `drawnow` in a loop causes the display to update while the loop executes:

```
t = 0:pi/100:2*pi;
y = exp(sin(t));
h = plot(t,y,'YDataSource','y');
for k = 1:0.01:10
    y = exp(sin(t.*k));
    refreshdata(h,'caller') % Evaluate y in the function workspace
    drawnow
end
```

`snapnow` | `waitfor` | `waitforbuttonpress`

<b>Purpose</b>	N-D nearest point search
<b>Syntax</b>	<pre>k = dsearchn(X,T,XI) k = dsearchn(X,T,XI,outval) k = dsearchn(X,XI) [k,d] = dsearchn(X,...)</pre>
<b>Description</b>	<p><code>k = dsearchn(X,T,XI)</code> returns the indices <code>k</code> of the closest points in <code>X</code> for each point in <code>XI</code>. <code>X</code> is an <code>m</code>-by-<code>n</code> matrix representing <code>m</code> points in <code>n</code>-dimensional space. <code>XI</code> is a <code>p</code>-by-<code>n</code> matrix, representing <code>p</code> points in <code>n</code>-dimensional space. <code>T</code> is a <code>numt</code>-by-<code>n+1</code> matrix, a triangulation of the data <code>X</code> generated by <code>delaunay</code>. The output <code>k</code> is a column vector of length <code>p</code>.</p> <p><code>k = dsearchn(X,T,XI,outval)</code> returns the indices <code>k</code> of the closest points in <code>X</code> for each point in <code>XI</code>, unless a point is outside the convex hull. If <code>XI(J,:)</code> is outside the convex hull, then <code>K(J)</code> is assigned <code>outval</code>, a scalar double. <code>Inf</code> is often used for <code>outval</code>. If <code>outval</code> is <code>[]</code>, then <code>k</code> is the same as in the case <code>k = dsearchn(X,T,XI)</code>.</p> <p><code>k = dsearchn(X,XI)</code> performs the search without using a triangulation. With large <code>X</code> and small <code>XI</code>, this approach is faster and uses much less memory.</p> <p><code>[k,d] = dsearchn(X,...)</code> also returns the distances <code>d</code> to the closest points. <code>d</code> is a column vector of length <code>p</code>.</p>
<b>Algorithms</b>	<code>dsearchn</code> is based on Qhull [1]. For information about Qhull, see <a href="http://www.qhull.org/">http://www.qhull.org/</a> . For copyright information, see <a href="http://www.qhull.org/COPYING.txt">http://www.qhull.org/COPYING.txt</a> .
<b>References</b>	[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," <i>ACM Transactions on Mathematical Software</i> , Vol. 22, No. 4, Dec. 1996, p. 469–483.
<b>See Also</b>	<code>delaunayTriangulation</code>

# dynamicprops

---

**Purpose** Abstract class used to derive handle class with dynamic properties

**Syntax** `classdef myClass < dynamicprops`

**Description** `classdef myClass < dynamicprops` makes *myClass* a subclass of the `dynamicprops` class, which is a subclass of the `handle` class.

Use the `dynamicprops` class to derive classes that can define dynamic properties (instance properties), which are associated with a specific objects, but have no effect on the objects class definition. Dynamic properties are useful for attaching temporary data to one or more objects.

## **dynamicprops Methods**

This class defines one method `addprop` and, as a subclass of the `handle` class, inherits all the `handle` class methods.

- `addprop` — adds the named property to the specified handle objects. See “Dynamic Properties — Adding Properties to an Instance” for more information.

**See Also** `handle`

**Purpose** Display statements during function execution

**Syntax**

```
echo on
echo off
echo
echo fcnname on
echo fcnname off
echo fcnname
echo on all
echo off all
```

**Description** The echo command controls the display (or *echoing*) of statements in a function during their execution. Normally, statements in a function file are not displayed on the screen during execution. Command echoing is useful for debugging or for demonstrations, allowing the commands to be viewed as they execute.

The echo command behaves in a slightly different manner for script files and function files. For script files, the use of echo is simple; echoing can be either on or off, in which case any script used is affected.

echo on	Turns on the echoing of commands in all script files
echo off	Turns off the echoing of commands in all script files
echo	Toggles the echo state

With function files, the use of echo is more complicated. If echo is enabled on a function file, the file is interpreted, rather than compiled. Each input line is then displayed as it is executed. Since this results in inefficient execution, use echo only for debugging.

echo <i>fcnname</i> on	Turns on echoing of the named function file
echo <i>fcnname</i> off	Turns off echoing of the named function file

# echo

---

<code>echo <i>fcnname</i></code>	Toggles the echo state of the named function file
<code>echo on all</code>	Sets echoing on for all function files
<code>echo off all</code>	Sets echoing off for all function files

## Tips

- To avoid confusing syntax, do not use `on` or `off` as a function name.

## See Also

`function`

**Purpose** Run example script step-by-step in Command Window

**Syntax**  
`echodemo filename`  
`echodemo(filename,index)`

**Description** `echodemo filename` runs the script specified by `filename` step-by-step in the Command Window. The file must contain sections defined with two percent signs (%) to enable pausing after each step. At each step, you can click links in the Command Window to proceed or stop. If the Command Window is not large enough to show the links, scroll up to see them.

---

**Caution**

If variables in your base workspace have the same name as variables that the example file creates, the example could overwrite your data. Preserve your data by saving it to a MAT-file before running the example.

---

`echodemo(filename,index)` starts with the section number specified by `index`. If the example relies on results of previous steps, using this syntax can produce errors or unexpected results.

**Input Arguments****filename - Script file name**

string

Script file name, specified as a string.

When you use the function syntax for `echodemo` and specify its inputs within parentheses, enclose the `filename` input in single quotes.

**index - Section index**

scalar integer

Section index, specified as a scalar integer.

The link text in the Command Window shows the current section number,  $n$ , and the total number of sections,  $m$ , as  $n/m$ .

## Examples

### Run Example Script in Command Window

Run the Loma Prieta Earthquake example.

```
echodemo quake
```

### Start Script from Specified Section

Start the Loma Prieta Earthquake example from the third section.

```
filename = 'quake';  
index = 3;  
echodemo(filename,index)
```

This code errors because the example requires variables created in earlier sections.

## Tips

- Only use echodemo to display scripts, not functions. echodemo can run any script that you can execute, but only scripts with sections pause between steps.

**Purpose** (Will be removed) Simplices attached to specified edges

---

**Note** `edgeAttachments(TriRep)` will be removed in a future release. Use `edgeAttachments(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax**  
`SI = edgeAttachments(TR, V1, V2)`  
`SI = edgeAttachments(TR, EDGE)`

**Description**  
`SI = edgeAttachments(TR, V1, V2)` returns the simplices `SI` attached to the edges specified by `(V1, V2)`. `(V1, V2)` represents the start and end vertices of the edges to be queried.  
`SI = edgeAttachments(TR, EDGE)` specifies edges in matrix format.

**Input Arguments**

<code>TR</code>	Triangulation representation.
<code>V1, V2</code>	Column vectors of vertex indices into the array of points representing the vertex coordinates.
<code>EDGE</code>	Matrix specifying edge start and end points. <code>EDGE</code> is of size <code>m-by-2</code> , <code>m</code> being the number of edges to query.

**Output Arguments**

<code>SI</code>	Vector cell array of indices into the triangulation matrix. <code>SI</code> is a cell array because the number of simplices associated with each edge can vary.
-----------------	---

**Definitions** A simplex is a triangle/tetrahedron or higher dimensional equivalent.

**Examples**

**Example 1**

Load a 3-D triangulation to compute the tetrahedra attached to an edge.

# TriRep.edgeAttachments

---

```
load tetmesh
trep = TriRep(tet, X);
v1 = [15 21]';
v2 = [936 716]';
t1 = edgeAttachments(trep, v1, v2);
```

You can also specify the input as edges.

```
e = [v1 v2];
t2 = edgeAttachments(trep, e);
isequal(t1,t2);
```

## Example 2

Create a triangulation with `DelaunayTri`.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Query the triangles attached to edge (1,5).

```
t = edgeAttachments(dt, 1,5);
t{:};
```

## See Also

[edges](#) | [triangulation](#) | [delaunayTriangulation](#)

**Purpose** (Will be removed) Triangulation edges

---

**Note** `edges(TriRep)` will be removed in a future release. Use `edges(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `E = edges(TR)`

**Description** `E = edges(TR)` returns the edges in the triangulation in an n-by-2 matrix. n is the number of edges. The vertices of the edges index into `TR.X`, the array of points representing the vertex coordinates.

**Input Arguments**

<code>TR</code>	Triangulation representation.
-----------------	-------------------------------

**Output Arguments**

<code>E</code>	Edge matrix.
----------------	--------------

**Examples** **Example 1**

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Return all edges.

```
e = edges(trep);
```

**Example 2**

Query a 2-D DelaunayTri-generated triangulation.

```
X = rand(10,2);
```

# TriRep.edges

---

```
dt = DelaunayTri(X);  
e = edges(dt);
```

## See Also

[edgeAttachments](#) | [triangulation](#) | [delaunayTriangulation](#)

**Purpose**

Edit or create file

**Syntax**

```
edit
edit file
edit file1 ... fileN
```

**Description**

`edit` opens a new file called `Untitled` in the Editor. MATLAB does not automatically save `Untitled`.

`edit file` opens the specified file in the Editor. If `file` does not already exist, MATLAB asks if you want to create it. `file` can include a partial path, complete path, relative path, or no path. If `file` includes a partial path or no path, `edit` will look for the file on the search path. You must have write permission to the path to create `file`, otherwise, MATLAB ignores the argument.

You must specify the extension to open `.mat` and `.mdl` files. MATLAB cannot directly edit binary files, such as `.p` and `.mex` files.

`edit file1 ... fileN` opens each file, `file1 ... fileN`, in the Editor.

**Examples****Open a New File**

```
edit
```

A new file titled `Untitled` opens in the MATLAB Editor (or default editor). `Untitled` does not appear in your Current Folder.

**Create a New File**

```
mkdir tests
edit tests/new_script.m
```

A dialog box appears, asking if you want to create `new_script.m`. If you select **Yes**, MATLAB creates and opens `tests/new_script.m`.

## Open Files

```
edit file1 file2 file3 file4
```

MATLAB sequentially creates and opens the files: `file1`, `file2`, `file3`, and `file4` in sequence.

## Input Arguments

### **file** - Name of file

string

Name of file, specified as a string. If `file` specifies a path that contains a nonexistent folder, MATLAB throws an error. Specify multiple files on the same line by separating filenames with a space.

If `file` is overloaded (that is, appears in multiple folders on the search path), then include a partial path to edit the correct page, such as

```
edit folderName/file
```

If you do not specify the extension, then `edit` opens a file with the specified name and a `.m` extension.

```
edit name
```

If the file is part of a class or package, then either specify the path and extension, or separate the components of the name with periods, such as:

```
edit className.name  
edit packageName.name  
edit packageName.className.name  
edit packageName.name
```

### **Data Types**

char

**Purpose**

Eigenvalues and eigenvectors

**Syntax**

```
lambda = eig(A)  
lambda = eig(A,balanceOption)
```

```
lambda = eig(A,B)  
lambda = eig(A,B,algorithm)
```

```
[V,D] = eig( ___ )
```

**Description**

`lambda = eig(A)` returns a vector containing the eigenvalues, with multiplicity, that satisfy the equation,

$$Av = \lambda v$$

where  $A$  is an  $n$ -by- $n$  matrix,  $v$  is a column vector of length  $n$ , and  $\lambda$  is a scalar. The values of  $\lambda$  that satisfy the equation are the eigenvalues. The corresponding values of  $v$  that satisfy the equation are right eigenvectors.

`lambda = eig(A,balanceOption)` specifies a balancing option as one of two strings: 'balance', which enables a preliminary balancing step, or 'nobalance' which disables it.

`lambda = eig(A,B)` returns a vector containing the generalized eigenvalues of the pair,  $(A,B)$ , that satisfy the equation,

$$Av = \lambda Bv$$

where  $A$  and  $B$  are  $n$ -by- $n$  matrices,  $v$  is a column vector of length  $n$ , and  $\lambda$  is a scalar. The values of  $\lambda$  that satisfy the equation are the generalized eigenvalues. The corresponding values of  $v$  are generalized right eigenvectors.

`lambda = eig(A,B,algorithm)` specifies the generalized eigenvalue algorithm as one of two strings: 'qz', which uses the QZ algorithm, or 'chol', which uses the Cholesky factorization of B.

`[V,D] = eig( ___ )` returns two optional outputs for any of the previous syntaxes. V is a matrix whose columns are eigenvectors. D is a diagonal matrix containing the eigenvalues along the main diagonal. The form and scaling of V depends on the combination of input arguments:

- `[V,D] = eig(A)` returns matrix V, whose columns are eigenvectors of A that satisfy  $A*V = V*D$ . The eigenvectors in V are scaled so that the 2-norm of each is 1.
- `[V,D] = eig(A, 'nobalance')` also returns matrix V. However, the 2-norm of each eigenvector is not necessarily 1.
- `[V,D] = eig(A,B)` and `[V,D] = eig(A,B,algorithm)` return V as a matrix whose columns are generalized eigenvectors that satisfy  $A*V = B*V*D$ . The 2-norm of each eigenvector is not necessarily 1. In this case, D contains the generalized eigenvalues of the pair, (A,B), along the main diagonal.

## Input Arguments

### A - Input matrix

square matrix

Input matrix, specified as a real or complex square matrix.

#### Data Types

double | single

**Complex Number Support:** Yes

### B - Generalized eigenvalue problem input matrix

square matrix

Generalized eigenvalue problem input matrix, specified as a square matrix of real or complex values. B must be the same size as A.

#### Data Types

double | single

**Complex Number Support:** Yes

**balanceOption - Balance option**`'balance'` (default) | `'nobalance'`

Balance option, specified as one two strings: `'balance'`, which enables a preliminary balancing step, or `'nobalance'` which disables it. In most cases, the balancing step improves the conditioning of  $A$  to produce more accurate results. However, there are cases in which balancing produces incorrect results. Specify `'nobalance'` when  $A$  contains values whose scale differs dramatically. For example, if  $A$  contains nonzero integers, as well as very small (near zero) values, then the balancing step might scale the small values to make them as significant as the integers and produce inaccurate results.

`'balance'` is the default behavior. The `eig` function ignores `balanceOption` when  $A$  is symmetric.

**Data Types**

char

**algorithm - Generalized eigenvalue algorithm**`'chol'` | `'qz'`

Generalized eigenvalue algorithm, specified as `'chol'` or `'qz'`, which selects the algorithm to use for calculating the generalized eigenvalues of a pair.

algorithm	Description
<code>'chol'</code>	Computes the generalized eigenvalues of $A$ and $B$ using the Cholesky factorization of $B$ .
<code>'qz'</code>	Uses the QZ algorithm, also known as the generalized Schur decomposition. This algorithm ignores the symmetry of $A$ and $B$ .

In general, the two algorithms return the same result. The QZ algorithm can be more stable for certain problems, such as those involving badly conditioned matrices.

When you omit the `algorithm` argument, the `eig` function selects an algorithm based on the properties of A and B. It uses the 'chol' algorithm for symmetric (Hermitian) A and symmetric (Hermitian) positive definite B. Otherwise, it uses the 'qz' algorithm.

Regardless of the algorithm you specify, the `eig` function always uses the QZ algorithm when A or B are not symmetric.

## Output Arguments

### **lambda - Eigenvalues**

column vector

Eigenvalues, returned as a column vector containing the eigenvalues (or generalized eigenvalues of a pair) with multiplicity.

The values of `lambda` that satisfy  $Av = \lambda v$  are always real and sorted in descending order whenever A is:

- real and symmetric
- or complex Hermitian

### **V - Eigenvectors**

square matrix

Eigenvectors, returned as a square matrix whose columns are eigenvectors of A or generalized eigenvectors of the pair, (A,B).

### **D - Diagonal eigenvalues matrix**

diagonal matrix

Diagonal eigenvalues matrix, returned a matrix containing the eigenvalues of A or the generalized eigenvalues of the pair, (A,B), with multiplicity.

When the eigenvalues in D satisfy the equation,  $Av = \lambda v$ , the eigenvalues are always real. In this case, MATLAB sorts them in descending order

(from upper-left to lower-right) as long as  $A$  is real and symmetric, or complex Hermitian.

## Examples

### Eigenvalues of Real Symmetric Matrix

Use the gallery function to create symmetric positive definite matrix.

```
A = gallery('lehmer',4)
```

```
A =
```

```
    1.0000    0.5000    0.3333    0.2500
    0.5000    1.0000    0.6667    0.5000
    0.3333    0.6667    1.0000    0.7500
    0.2500    0.5000    0.7500    1.0000
```

Calculate the eigenvalues of  $A$ .

```
lambda = eig(A)
```

```
lambda =
```

```
    0.2078
    0.4078
    0.8482
    2.5362
```

### Eigenvalues and Eigenvectors of Nonsymmetric Matrix

Use the gallery function to create a circulant matrix.

```
A = gallery('circul',3)
```

```
A =
```

```
    1    2    3
    3    1    2
    2    3    1
```

Calculate the eigenvalues and eigenvectors of A.

```
[V,D] = eig(A)
```

```
V =
```

```
-0.5774 + 0.0000i    0.2887 - 0.5000i    0.2887 + 0.5000i  
-0.5774 + 0.0000i   -0.5774 + 0.0000i   -0.5774 + 0.0000i  
-0.5774 + 0.0000i    0.2887 + 0.5000i    0.2887 - 0.5000i
```

```
D =
```

```
6.0000 + 0.0000i    0.0000 + 0.0000i    0.0000 + 0.0000i  
0.0000 + 0.0000i   -1.5000 + 0.8660i    0.0000 + 0.0000i  
0.0000 + 0.0000i    0.0000 + 0.0000i   -1.5000 - 0.8660i
```

Verify that matrix V diagonalizes A, since the eigenvalues are distinct and the eigenvectors are independent.

```
V\A*V
```

```
ans =
```

```
6.0000 + 0.0000i    0.0000 - 0.0000i   -0.0000 + 0.0000i  
-0.0000 - 0.0000i   -1.5000 + 0.8660i   -0.0000 - 0.0000i  
-0.0000 + 0.0000i   -0.0000 + 0.0000i   -1.5000 - 0.8660i
```

## **Eigenvalues and Eigenvectors of a Matrix Whose Elements Differ Dramatically in Scale**

```
A = [ 3.0    -2.0    -0.9    2*eps;  
     -2.0     4.0     1.0   -eps;  
     -eps/4   eps/2   -1.0    0;  
     -0.5    -0.5     0.1    1.0];
```

Calculate the eigenvalues and eigenvectors using the default (balancing) behavior.

```
[VB,DB] = eig(A)
```

```
VB =
```

```
    0.6153   -0.4176   -0.0000   -0.1437
   -0.7881   -0.3261   -0.0000    0.1264
   -0.0000   -0.0000   -0.0000   -0.9196
    0.0189    0.8481    1.0000    0.3432
```

```
DB =
```

```
    5.5616    0    0    0
    0    1.4384    0    0
    0    0    1.0000    0
    0    0    0   -1.0000
```

Check to see if the results satisfy  $A*VB = VB*DB$ .

```
A*VB - VB*DB
```

```
ans =
```

```
    0.0000    0.0000   -0.0000    0.0000
    0   -0.0000    0.0000   -0.0000
    0.0000   -0.0000    0.0000    0.0000
    0    0.0000    0.0000    0.6031
```

This result does not satisfy  $A*VB = VB*DB$ . Ideally, the eigenvalue decomposition satisfies this relationship. Since MATLAB performs the decomposition using floating-point computations, then  $A*V$  can, at best, approach  $V*D$ . In other words,  $A*V - V*D$  is close to, but not exactly, 0.

Now, try calculating the eigenvalues and eigenvectors without the balancing step.

```
[VN,DN] = eig(A,'nobalance')
```

VN =

0.6153	-0.4176	-0.0000	-0.1528
-0.7881	-0.3261	0	0.1345
-0.0000	-0.0000	-0.0000	-0.9781
0.0189	0.8481	-1.0000	0.0443

DN =

5.5616	0	0	0
0	1.4384	0	0
0	0	1.0000	0
0	0	0	-1.0000

Verify that the results satisfy  $A*VN = VN*DN$ .

$A*VN - VN*DN$

ans =

1.0e-14 \*

-0.1776	-0.0111	-0.0559	-0.0167
0.3553	0.1055	0.0336	-0.0194
0.0017	0.0002	0.0007	0
0.0264	-0.0222	0.0222	0.0097

$A*VN - VN*DN$  is much closer to 0, so the 'nobalance' option produces more accurate results in this case.

## Left Eigenvectors

$A = [1 \ 7 \ 3; 2 \ 9 \ 12; 5 \ 22 \ 7];$

Pass the transpose of A to the eig function.

$[VL,D] = \text{eig}(A')$

VL =

```
-0.1791   -0.9587   -0.1881
-0.8127    0.0649   -0.7477
-0.5545    0.2768    0.6368
```

D =

```
25.5548    0    0
    0   -0.5789    0
    0    0   -7.9759
```

Matrix VL contains the transpose of the left eigenvectors.

Transpose VL to get the left eigenvectors.

```
VL = VL';
```

Verify the results satisfy  $VL * A = D * VL$ .

```
VL * A - D * VL
```

ans =

```
1.0e-13 *
    0.1243    0.2132    0.0178
   -0.0167   -0.0644   -0.0339
   -0.0289   -0.0444    0.0089
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since MATLAB performs the decomposition using floating-point computations, then  $VL * A$  can, at best, approach  $D * VL$ . In other words,  $VL * A - D * VL$  is close to, but not exactly, 0.

## Eigenvalues and Eigenvectors of Nondiagonalizable (Defective) Matrix

```
A = [3 1 0; 0 3 1; 0 0 3];
```

Calculate the eigenvalues and eigenvectors of A.

```
[V,D] = eig(A)
```

```
V =
```

```
    1.0000   -1.0000    1.0000
         0    0.0000   -0.0000
         0         0    0.0000
```

```
D =
```

```
    3     0     0
     0     3     0
     0     0     3
```

A has repeated eigenvalues and the eigenvectors are not independent. This means that A is not diagonalizable and is, therefore, defective.

Verify that V and D satisfy the equation,  $A*V = V*D$ , even though A is defective.

```
A*V - V*D
```

```
ans =
```

```
1.0e-15 *
         0    0.8882   -0.8882
         0         0    0.0000
         0         0         0
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since MATLAB performs the decomposition using floating-point

computations, then  $A*V$  can, at best, approach  $V*D$ . In other words,  $A*V - V*D$  is close to, but not exactly, 0.

### Generalized Eigenvalues and Eigenvectors

```
A = [1/sqrt(2) 0; 0 1];
B = [0 1; -1/sqrt(2) 0];
[V,D]=eig(A,B)
```

V =

```
1.0000 + 0.0000i  1.0000 + 0.0000i
0.0000 - 0.7071i  0.0000 + 0.7071i
```

D =

```
0.0000 + 1.0000i  0.0000 + 0.0000i
0.0000 + 0.0000i  0.0000 - 1.0000i
```

Verify that the results satisfy  $A*V = B*V*D$ .

```
A*V - B*V*D
```

ans =

```
0 0
0 0
```

### Generalized Eigenvalues Using QZ Algorithm for Badly Conditioned Matrices

Create a badly conditioned symmetric matrix containing values close to machine precision.

```
format long e
A = diag([10^-16, 10^-15])
```

A =

# eig

---

```
1.0000000000000000e-16      0
0      1.0000000000000000e-15
```

Calculate the generalized eigenvalues and a set of eigenvectors using the default algorithm. In this case, the default algorithm is 'chol'.

```
[V1,D1] = eig(A,A)
```

V1 =

```
1.0000000000000000e+08      0
0      3.162277660168380e+07
```

D1 =

```
9.999999999999999e-01      0
0      1.0000000000000000e+00
```

Now, calculate the generalized eigenvalues and a set of eigenvectors using the 'qz' algorithm.

```
[V2,D2] = eig(A,A,'qz')
```

V2 =

```
1      0
0      1
```

D2 =

```
1      0
0      1
```

Check to see how well the 'chol' result satisfies  $A*V1 = A*V1*D1$ .

format

```
A*V1 - A*V1*D1
```

```
ans =
```

```
1.0e-23 *
    0.1654      0
         0    -0.6617
```

Now, check to see how well the 'qz' result satisfies  $A*V2 = A*V2*D2$ .

```
A*V2 - A*V2*D2
```

```
ans =
```

```
    0    0
    0    0
```

When both matrices are Hermitian, `eig` uses the 'chol' algorithm by default. In this case, the QZ algorithm returns more accurate results.

### Generalized Eigenvalues and Eigenvectors of a Pair in Which One Matrix is Singular

Create a 2-by-2 identity matrix, A, and a singular matrix, B.

```
A = eye(2);
B = [3 6; 4 8];
```

Try to calculate the generalized eigenvalues of the matrix,  $B^{-1}A$ .

```
[V,D] = eig(B\A)
```

```
Warning: Matrix is singular to working precision.
Error using eig
Input to EIG must not contain NaN or Inf.
```

Now calculate the generalized eigenvalues and eigenvectors by passing both matrices to the `eig` function.

```
[V,D] = eig(A,B)
```

```
V =
```

```
   -0.7500   -1.0000  
   -1.0000    0.5000
```

```
D =
```

```
   0.0909    0  
    0      Inf
```

It's better to pass both matrices separately, and let `eig` choose the best algorithm to solve the problem. In this case, `eig(A,B)` returned a set of eigenvectors and at least one real eigenvalue, even though `B` is not invertible.

Verify  $Av = \lambda Bv$  for the first eigenvalue and the first eigenvector.

```
eigval = D(1,1);  
eigvec = V(:,1);  
A*eigvec - eigval*B*eigvec
```

```
ans =
```

```
1.0e-15 *  
  
   0.1110  
   0.2220
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since the decomposition is performed using floating-point computations, then `A*eigvec` can, at best, approach `eigval*B*eigvec`, as it does in this case.

## Tips

- The `eig` function returns the eigenvalues of a real, symmetric, sparse matrix for the syntax, `lambda = eig(A)`. Use the `eigs` function for all other sparse eigenvalue and eigenvector problems.

**See Also**

balance | condeig | eigs | hess | qz | schur

# eigs

---

**Purpose** Largest eigenvalues and eigenvectors of matrix

**Syntax**

```
d = eigs(A)
[V,D] = eigs(A)
[V,D,flag] = eigs(A)
eigs(A,B)
eigs(A,k)
eigs(A,B,k)
eigs(A,k,sigma)
eigs(A,B,k,sigma)
eigs(A,K,sigma,opts)
eigs(A,B,k,sigma,opts)
eigs(Afun,n,...)
```

**Description** `d = eigs(A)` returns a vector of  $A$ 's six largest magnitude eigenvalues.  $A$  must be a square matrix.  $A$  should be large and sparse, though `eigs` will work on full matrices as well. See “Tips” below.

`[V,D] = eigs(A)` returns a diagonal matrix  $D$  of  $A$ 's six largest magnitude eigenvalues and a matrix  $V$  whose columns are the corresponding eigenvectors.

`[V,D,flag] = eigs(A)` also returns a convergence flag. If `flag` is 0 then all the eigenvalues converged; otherwise not all converged.

`eigs(A,B)` solves the generalized eigenvalue problem  $A*V == B*V*D$ .  $B$  must be the same size as  $A$ . `eigs(A,[],...)` indicates the standard eigenvalue problem  $A*V == V*D$ .

`eigs(A,k)` and `eigs(A,B,k)` return the  $k$  largest magnitude eigenvalues.

`eigs(A,k,sigma)` and `eigs(A,B,k,sigma)` return  $k$  eigenvalues based on  $\sigma$ , which can take any of the following values:

scalar (real or complex, including 0)	The eigenvalues closest to $\sigma$ . If $A$ is a function, $A_{\text{fun}}$ must return $Y = (A - \sigma * B) \backslash x$ (i.e., $Y = A \backslash x$ when $\sigma = 0$ ).
'lm'	Largest magnitude (default).
'sm'	Smallest magnitude. Same as $\sigma = 0$ . If $A$ is a function, $A_{\text{fun}}$ must return $Y = A \backslash x$ .

For real symmetric problems, the following are also options:

'la'	Largest algebraic ('lr')
'sa'	Smallest algebraic ('sr')
'be'	Both ends (one more from high end if $k$ is odd)

For nonsymmetric and complex problems, the following are also options:

'lr'	Largest real part
'sr'	Smallest real part
'li'	Largest imaginary part
'si'	Smallest imaginary part

---

**Note** The syntax `eigs(A,k,...)` is not valid when  $A$  is scalar. To pass a value for  $k$ , you must specify  $B$  as the second argument and  $k$  as the third (`eigs(A,B,k,...)`). If necessary, you can set  $B$  equal to `[]`, the default.

---

`eigs(A,K,sigma,opts)` and `eigs(A,B,k,sigma,opts)` specify an options structure. Default values are shown in brackets ({}).

Parameter	Description	Values
opts.issym	1 if A or A- $\sigma$ *B represented by Afun is symmetric, 0 otherwise.	[{0}   1]
opts.isreal	1 if A or A- $\sigma$ *B represented by Afun is real, 0 otherwise.	[0   {1}]
opts.tol	Convergence: Ritz estimate residual $\leq$ tol*norm(A).	[scalar   {eps}]
opts.maxit	Maximum number of iterations.	[integer   {300}]
opts.p	Number of Lanczos basis vectors. p $\geq$ 2k (p $\geq$ 2k+1 real nonsymmetric) advised. p must satisfy k < p $\leq$ n for real symmetric, k+1 < p $\leq$ n otherwise. Note: If you do not specify a p value, the default algorithm uses at least 20 Lanczos vectors.	[integer   {2*k}]
opts.v0	Starting vector.	[n-by-1 vector   {randomly generated by rand}]
opts.disp	Diagnostic information display level.	[{0}   1   2]
opts.cholB	1 if B is really its Cholesky factor chol(B), 0 otherwise.	[{0}   1]
opts.permB	Permutation vector permB if sparse B is really chol(B(permB,permB)).	[permB   {1:n}]

`eigs(Afun,n,...)` accepts a function handle, `Afun`, instead of the matrix `A`.

`y = Afun(x)` should return:

<code>A*x</code>	if <i>sigma</i> is not specified, or is a string other than 'sm'
<code>A\x</code>	if <i>sigma</i> is 0 or 'sm'
<code>(A-sigma*I)\x</code>	if <i>sigma</i> is a nonzero scalar (standard eigenvalue problem). <code>I</code> is an identity matrix of the same size as <code>A</code> .
<code>(A-sigma*B)\x</code>	if <i>sigma</i> is a nonzero scalar (generalized eigenvalue problem)

“Parameterizing Functions” explains how to provide additional parameters to the function `Afun`, if necessary.

The matrix `A`, `A-sigma*I` or `A-sigma*B` represented by `Afun` is assumed to be real and nonsymmetric unless specified otherwise by `opts.isreal` and `opts.issym`. In all the `eigs` syntaxes, `eigs(A,...)` can be replaced by `eigs(Afun,n,...)`.

## Tips

`d = eigs(A,k)` is not a substitute for

```
d = eig(full(A))
d = sort(d)
d = d(end-k+1:end)
```

but is most appropriate for large sparse matrices. If the problem fits into memory, it may be quicker to use `eig(full(A))`.

Unless you provide a start vector with `opts.v0`, the default start vector is generated by `rand`, possibly leading to different iterations each run, and perhaps even different convergence behavior. In order to control this, specify your start vector via `opts.v0`.

## Examples

### Example 1

```
A = delsq(numgrid('C',15));  
d1 = eigs(A,5,'sm')
```

returns

```
d1 =  
    0.5520  
    0.4787  
    0.3469  
    0.2676  
    0.1334
```

### Example 2

This example replaces the matrix *A* in example 1 with a handle to a function *dnRk*. The example is contained in file *run\_eigs* that

- Calls *eigs* with the function handle *@dnRk* as its first argument.
- Contains *dnRk* as a nested function, so that all variables in *run\_eigs* are available to *dnRk*.

The following shows the code for *run\_eigs*:

```
function d2 = run_eigs  
n = 139;  
opts.issym = 1;  
R = 'C';  
k = 15;  
d2 = eigs(@dnRk,n,5,'sm',opts);  
  
    function y = dnRk(x)  
        y = (delsq(numgrid(R,k))) \ x;  
    end  
end
```

### Example 3

`west0479` is a real 479-by-479 sparse matrix with both real and pairs of complex conjugate eigenvalues. `eig` computes all 479 eigenvalues. `eigs` easily picks out the largest magnitude eigenvalues.

This plot shows the 8 largest magnitude eigenvalues of `west0479` as computed by `eig` and `eigs`.

```
load west0479
d = eig(full(west0479))
d1m = eigs(west0479,8)
[dum,ind] = sort(abs(d));
plot(d1m,'k+')
hold on
plot(d(ind(end-7:end)),'ks')
hold off
legend('eigs(west0479,8)', 'eig(full(west0479))')
```

## Example 4

`A = delsq(numgrid('C',30))` is a symmetric positive definite matrix of size 632 with eigenvalues reasonably well-distributed in the interval (0 8), but with 18 eigenvalues repeated at 4. The `eig` function computes all 632 eigenvalues. It computes and plots the six largest and smallest magnitude eigenvalues of `A` successfully with:

```
A = delsq(numgrid('C',30));  
d = eig(full(A));  
[dum,ind] = sort(abs(d));  
d1m = eigs(A);  
dsm = eigs(A,6,'sm');
```

```
subplot(2,1,1)  
plot(d1m,'k+')
```

```

hold on
plot(d(ind(end:-1:end-5)), 'ks')
hold off
legend('eigs(A)', 'eig(full(A))', 3)
set(gca, 'XLim', [0.5 6.5])

subplot(2,1,2)
plot(dsm, 'k+')
hold on
plot(d(ind(1:6)), 'ks')
hold off
legend('eigs(A,6, 'sm')', 'eig(full(A))', 2)
set(gca, 'XLim', [0.5 6.5])

```

# eigs

However, the repeated eigenvalue at 4 must be handled more carefully. The call `eigs(A,18,4.0)` to compute 18 eigenvalues near 4.0 tries to find eigenvalues of  $A - 4.0 \cdot I$ . This involves divisions of the form  $1/(\lambda - 4.0)$ , where  $\lambda$  is an estimate of an eigenvalue of  $A$ . As  $\lambda$  gets closer to 4.0, `eigs` fails. We must use `sigma` near but not equal to 4 to find those 18 eigenvalues.

```
sigma = 4 - 1e-6  
[V,D] = eigs(A,18,sigma)
```

The plot shows the 20 eigenvalues closest to 4 that were computed by `eig`, along with the 18 eigenvalues closest to  $4 - 1e-6$  that were computed by `eigs`.

# ellipj

---

**Purpose** Jacobi elliptic functions

**Syntax** [SN,CN,DN] = ellipj(U,M)  
[SN,CN,DN] = ellipj(U,M,tol)

**Definitions** The Jacobi elliptic functions are defined in terms of the integral:

$$u = \int_0^\phi \frac{d\theta}{\sqrt{1 - m \sin^2 \theta}}.$$

Then

$$sn(u) = \sin \phi, \quad cn(u) = \cos \phi, \quad dn(u) = \sqrt{1 - m \sin^2 \phi}.$$

Some definitions of the elliptic functions use the modulus  $k$  instead of the parameter  $m$ . They are related by

$$k^2 = m = \sin^2 \alpha,$$

where  $\alpha$  is the modular angle.

The Jacobi elliptic functions obey many mathematical identities; for a good sample, see [1].

**Description** [SN,CN,DN] = ellipj(U,M) returns the Jacobi elliptic functions SN, CN, and DN, evaluated for corresponding elements of argument U and parameter M. Inputs U and M must be the same size (or either can be scalar).

[SN,CN,DN] = ellipj(U,M,tol) computes the Jacobi elliptic functions to accuracy tol. The default is eps; increase this for a less accurate but more quickly computed answer.

**Algorithms** ellipj computes the Jacobi elliptic functions using the method of the arithmetic-geometric mean of [1]. It starts with the triplet of numbers:

$$a_0 = 1, b_0 = \sqrt{1-m}, c_0 = \sqrt{m}$$

ellipj computes successive iterates with

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1})$$

$$b_i = (a_{i-1} b_{i-1})^{\frac{1}{2}}$$

$$c_i = \frac{1}{2}(a_{i-1} - b_{i-1})$$

Next, it calculates the amplitudes in radians using:

$$\sin(2\phi_{n-1} - \phi_n) = \frac{c_n}{a_n} \sin(\phi_n)$$

being careful to unwrap the phases correctly. The Jacobian elliptic functions are then simply:

$$sn(u) = \sin \phi_0$$

$$cn(u) = \cos \phi_0$$

$$dn(u) = \sqrt{1-m \cdot sn(u)^2}$$

## Limitations

The ellipj function is limited to the input domain  $0 \leq m \leq 1$ . Map other values of  $m$  into this range using the transformations described in [1], equations 16.10 and 16.11.  $u$  is limited to real values.

## See Also

ellipke

# ellipke

---

**Purpose** Complete elliptic integrals of first and second kind

**Syntax**  
`K = ellipke(M)`  
`[K,E] = ellipke(M)`  
`[K,E] = ellipke(M,tol)`

**Description** `K = ellipke(M)` returns the complete elliptic integral of the first kind for the each element in `M`.

`[K,E] = ellipke(M)` returns the complete elliptic integral of the first and second kinds.

`[K,E] = ellipke(M,tol)` computes the complete elliptic integral to accuracy `tol`. The default is `eps(class(M))`; increase the tolerance for a less accurate but more quickly computed answer.

**Limitations** `ellipke` is limited to the input domain  $0 \leq m \leq 1$ .

**Definitions** The *complete* elliptic integral of the first kind is

$$[K(m)] = \int_0^1 [(1-t^2)(1-mt^2)]^{-\frac{1}{2}} dt.$$

where  $m$  is the first argument of `ellipke`.

The complete elliptic integral of the second kind is

$$E(m) = \int_0^1 (1-t^2)^{-\frac{1}{2}} (1-mt^2)^{\frac{1}{2}} dt.$$

Some definitions of `K` and `E` use the elliptical modulus  $k$  or modular angle  $\alpha$  instead of the parameter  $m$ . They are related by

$$k^2 = m = \sin^2 \alpha.$$

**References** [1] Abramowitz, M., and I.A. Stegun. *Handbook of Mathematical Functions*. Dover Publications, 1965.

# ellipsoid

---

## Purpose

Generate ellipsoid

## Syntax

```
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)
ellipsoid(axes_handle,...)
ellipsoid(...)
```

## Description

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)` generates a surface mesh described by three  $n+1$ -by- $n+1$  matrices, enabling `surf(x,y,z)` to plot an ellipsoid with center  $(xc,yc,zc)$  and semi-axis lengths  $(xr,yr,zr)$ .

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)` uses  $n = 20$ .

`ellipsoid(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`ellipsoid(...)` with no output arguments plots the ellipsoid as a surface.

## Algorithms

`ellipsoid` generates the data using the following equation:

$$\frac{(x-xc)^2}{xr^2} + \frac{(y-yc)^2}{yr^2} + \frac{(z-zc)^2}{zr^2}$$

Note that `ellipsoid(0,0,0, .5, .5, .5)` is equivalent to a unit sphere.

## Examples

Generate ellipsoid with size and proportions of a standard U.S. football:

```
[x, y, z] = ellipsoid(0,0,0,5.9,3.25,3.25,30);  
surf1(x, y, z)  
colormap copper  
axis equal
```

## See Also

# else

---

**Purpose** Optional keyword within an if statement

**Syntax**

```
if expression
    statements
elseif expression
    statements
else
    statements
end
```

**Description** An if statement evaluates an expression, and executes a group of statements when the expression is true.

`elseif` and `else` are optional, and execute only when previous expressions in the if statement are false.

For more information about valid expressions and when they are true, see the if reference page.

**Examples** Find the indices of values in a vector that are greater than a specified limit.

```
A = rand(1,10);
limit = .75;

B = (A > limit); % B is a vector of logical values
if any(B)
    fprintf('Indices of values > %4.2f: \n', limit);
    disp(find(B))
else
    disp('All values are below the limit.')
end
```

**See Also** if | end | for | while | switch

**Purpose**

Optional keyword within an if statement

**Syntax**

```
if expression
    statements
elseif expression
    statements
else
    statements
end
```

**Description**

An if statement evaluates an expression, and executes a group of statements when the expression is true.

`elseif` and `else` are optional, and execute only when previous expressions in the if statement are false.

For more information about valid expressions and when they are true, see the if reference page.

**Tips**

- Avoid adding a space within the `elseif` keyword (`else if`). The space creates a nested if statement that requires its own end keyword.

**Examples**

Assign to a matrix values that depend on their indices.

```
% Preallocate a matrix
nrows = 10;
ncols = 10;
myData = ones(nrows, ncols);

% Loop through the matrix
for r = 1:nrows
    for c = 1:ncols

        if r == c
            myData(r,c) = 2;
        elseif abs(r - c) == 1
```

# elseif

---

```
        myData(r,c) = -1;
    else
        myData(r,c) = 0;
    end

    end
end
```

---

<b>Purpose</b>	Create empty array
<b>Syntax</b>	<pre>A = <i>ClassName</i>.empty A = <i>ClassName</i>.empty(n,m,p,...) A = <i>ClassName</i>.empty([n,m,p,...])</pre>
<b>Description</b>	<p>Use <code>empty</code> to create empty arrays of the specified class, <i>ClassName</i>. Specify at least one dimension of the array as 0. MATLAB treats negative values as 0.</p> <p><code>A = <i>ClassName</i>.empty</code> returns an empty 0-by-0 array of the class of <i>ClassName</i>.</p> <p><code>A = <i>ClassName</i>.empty(n,m,p,...)</code> returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0.</p> <p><code>A = <i>ClassName</i>.empty([n,m,p,...])</code> returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0. This syntax is useful when using the values returned by the <code>size</code> function to define an empty array that is the same size as an existing empty array:</p> <pre>A = <i>ClassName</i>.empty(size(otherEmptyArray));</pre>
<b>Input Arguments</b>	<p><b>n,m,p,...</b></p> <p>Dimensions of the empty array. At least one of the specified dimensions must be 0.</p>
<b>Output Arguments</b>	<p><b>A</b></p> <p>An empty array of the specified dimensions and of the class used in the method invocation.</p>
<b>Attributes</b>	<p><code>empty</code> is a hidden, public, static method of all nonabstract MATLAB classes.</p>

# empty

---

Access	Public
Hidden	true
Static	true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Use `empty` to create a rectangular empty array of class `int16`:

```
A = int16.empty(5,0);
whos
  Name      Size      Bytes  Class  Attributes
  ---      ---      ---      ---      ---
  A         5x0         0  int16
```

Using the `empty` method of the `int16` class to produce an empty array in which some dimensions are not zero is simpler than using conversion and reshape operations:

```
A = int16([]);
A = reshape(A,5,0);
whos
  Name      Size      Bytes  Class  Attributes
  ---      ---      ---      ---      ---
  A         5x0         0  int16
```

Given the following definition for a class,

```
classdef ExEmpty
  properties
    Color = [1,0,0];
  end
  methods
    function obj = ExEmpty(c)
      if nargin > 0
        obj.Color = c;
      end
    end
  end
end
```

```

        end
    end
end

```

Create an empty array of class ExEmpty:

```

A = ExEmpty.empty;
whos
  Name      Size      Bytes  Class      Attributes

  A         0x0       104    ExEmpty

```

One dimension of an empty array must be zero:

```

A5 = ExEmpty.empty(0,5);
whos
  Name      Size      Bytes  Class      Attributes

  A5         0x5       104    ExEmpty

```

Empty object arrays follow array concatenation behavior:

```

B = [A,A5]
B =

```

0x5 ExEmpty array with properties:

```

  Color

```

You cannot index into an empty array:

```

A5(1)
Index exceeds matrix dimensions.

```

You can use the `isempty`, `size`, and `length` functions to identify empty object arrays:

```

isempty(A5)

```

# empty

---

```
ans =  
    1  
size(A5)
```

```
ans =  
    0    5  
length(A5)
```

```
ans =  
    0
```

## **Class of Empty Object Array**

The empty method enables you to initialize arrays of a specific class:

```
C = char.empty(0,7)
```

```
C =
```

```
Empty string: 0-by-7
```

```
class(C)  
ans =
```

```
char
```

Initializing an array with empty brackets ([]):

```
a = [];
```

produces an array of class double:

```
class(a)  
ans =
```

double

# enableNETfromNetworkDrive

---

<b>Purpose</b>	Enable access to .NET commands from network drive
<b>Syntax</b>	<code>enableNETfromNetworkDrive</code>
<b>Description</b>	<code>enableNETfromNetworkDrive</code> adds an entry for the MATLAB interface to .NET module to the security policy on your machine. You must have administrative privileges to make changes to your configuration.
<b>Compatibility</b>	Use <code>enableNETfromNetworkDrive</code> for MATLAB releases R2012b or earlier, which support installed versions 2.0, 3.0, and 3.5 of the Microsoft .NET Framework.
<b>Related Examples</b>	<ul style="list-style-type: none"><li>• “Troubleshooting Security Policy Settings From Network Drives”</li></ul>

**Purpose** Enable, disable, or report status of MATLAB Automation server

**Syntax**

```
state = enableservice('AutomationServer',enable)
state = enableservice('AutomationServer')
```

**Description**

`state = enableservice('AutomationServer',enable)` enables or disables the MATLAB Automation server. If `enable` is true (logical 1), `enableservice` converts an existing MATLAB session into an Automation server. If `enable` is false (logical 0), `enableservice` disables the MATLAB Automation server. `state` indicates the previous state of the Automation server. If `state = 1`, MATLAB was an Automation server. If `state = 0`, MATLAB was not an Automation server.

`state = enableservice('AutomationServer')` returns the current state of the Automation server. If `state` is logical 1 (true), MATLAB is an Automation server.

COM functions are available on Microsoft Windows systems only.

**Examples** Enable the Automation server in the current MATLAB session:

```
state = enableservice('AutomationServer',true);
```

---

Show the current state of the MATLAB session. MATLAB displays true:

```
state = enableservice('AutomationServer')
```

---

Enable the Automation server and show the previous state. MATLAB displays true. The previous state can be the same as the current state:

```
state = enableservice('AutomationServer',true)
```

**See Also** `actxserver`

# enableservice

---

## **How To**

- “MATLAB COM Automation Server Interface”

**Purpose** Terminate block of code, or indicate last array index

**Syntax** end

**Description** end terminates for, while, switch, try, if, and parfor statements. Without an end statement, for, while, switch, try, if, and parfor wait for further input. Each end is paired with the closest previous unpaired for, while, switch, try, if, or parfor and serves to delimit its scope.

end also marks the termination of a function, although in many cases it is optional. If your function contains one or more nested functions, then you must terminate every function in the file, whether nested or not, with end. This includes primary, nested, private, and local functions.

The end function also serves as the last index in an indexing expression. In that context, end = (size(x,k)) when used as part of the kth index. Examples of this use are X(3:end) and X(1,1:2:end-1). When using end to grow an array, as in X(end+1)=5, make sure X exists first.

You can overload the end statement for a user object by defining an end method for the object. The end method should have the calling sequence end(obj,k,n), where obj is the user object, k is the index in the expression where the end syntax is used, and n is the total number of indices in the expression. For example, consider the expression

```
A(end-1,:)
```

The MATLAB software calls the end method defined for A using the syntax

```
end(A,1,2)
```

**Examples** This example shows end used with the for and if statements.

```
for k = 1:n
    if a(k) == 0
        a(k) = a(k) + 2;
    end
end
```

# end

---

In this example, `end` is used in an indexing expression.

```
A = magic(5)
```

```
A =
```

```
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

```
B = A(end,2:end)
```

```
B =
```

```
    18    25     2     9
```

<b>Purpose</b>	Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method
<b>Syntax</b>	<pre>result = EndInvoke(asyncResult) [res0,...,resN] = EndInvoke(res0,...,resN,asyncResult)</pre>
<b>Description</b>	<p>result = EndInvoke(asyncResult) retrieves result of asynchronous call initiated by BeginInvoke method.</p> <p>[res0,...,resN] = EndInvoke(res0,...,resN,asyncResult) for methods with out and/or ref parameters.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• If the delegate contains out or ref parameters, the signature for the EndInvoke method follows the MATLAB mapping rules. For information, see “Call Delegates With out and ref Type Arguments”.</li></ul>
<b>Input Arguments</b>	<p><b>asyncResult</b> .NET System.IAsyncResult object returned by BeginInvoke.</p> <p><b>res0,...,resN</b> For methods with out and/or ref parameters, results of the asynchronous call. The number of arguments is the sum of:</p> <ul style="list-style-type: none"><li>• Number of return values (0 or 1).</li><li>• Number of out and ref arguments.</li></ul>
<b>Output Arguments</b>	<p><b>result</b> Results of the asynchronous call.</p> <p><b>res0,...,resN</b> For methods with out and/or ref parameters, results of the asynchronous call,</p>

## Examples

The following examples show how to call delegates with various input and output arguments. Each example contains:

- 1** The C# delegate signature. In order to execute the MATLAB code, you must build the delegate code into an assembly named `SignatureExamples` and load it into MATLAB. For information, see “Building a .NET Application for MATLAB Examples”.
  - 2** An example MATLAB function to use with the delegate, which must exist on your path.
  - 3** The `BeginInvoke` and `EndInvoke` signatures MATLAB creates. To display the signatures, create a delegate instance, `myDel`, and call the `methodsview` function.
  - 4** Simple MATLAB example.
- 

This examples shows how to use a delegate that has no return value.

- 1** C# delegate:

```
public delegate void delint(Int32 arg);
```

- 2** MATLAB function to call:

```
%Display input argument  
function dispfnc(A)  
%A = number  
['Input is ' num2str(A)]  
end
```

- 3** MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResultRetVal  
BeginInvoke (  
    SignatureExamples.delint this,  
    int32 scalar arg,
```

```
System.AsyncCallback callback,  
System.Object object)
```

The EndInvoke signature:

```
EndInvoke (  
    SignatureExamples.delint this,  
    System.IAsyncResult result)
```

#### 4 Call dispfnc:

```
myDel = SignatureExamples.delint(@dispfnc);  
asyncRes = myDel.BeginInvoke(6, [], []);  
while asyncRes.IsCompleted ~= true  
    pause(0.05); % Use pause() to let MATLAB process event  
end  
myDel.EndInvoke(asyncRes)
```

MATLAB displays:

```
Input is 6
```

---

This example shows how to use a delegate with a return value. The delegate does not have out or ref parameters.

#### 1 C# delegate:

```
public delegate Int32 del2int(Int32 arg1, Int32 arg2);
```

#### 2 MATLAB function to call:

```
%Add input arguments  
function res = addfnc(A, B)  
%A and B are numbers  
res = A + B;  
end
```

# EndInvoke

---

**3** MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResultRetVal
BeginInvoke (
    SignatureExamples.del2int this,
    int32 scalar arg1,
    int32 scalar arg2,
    System.AsyncCallback callback,
    System.Object object)
```

The `EndInvoke` signature:

```
int32 scalarRetVal
EndInvoke (
    SignatureExamples.del2int this,
    System.IAsyncResult result)
```

**4** Call `addfnc`:

```
myDel = SignatureExamples.del2int(@addfnc);
asyncRes = myDel.BeginInvoke(6,8,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
result = myDel.EndInvoke(asyncRes)
```

MATLAB displays:

```
result =
    14
```

---

This example shows how to use a delegate with a `ref` parameter, `refArg`, and no return value.

**1** C# delegate:

```
public delegate void delrefvoid(ref Double refArg);
```

- 2** MATLAB maps the ref argument as both RHS and LHS arguments. MATLAB function to call:

```
%Increment input argument
function res = incfnc(A)
%A = number
res = A + 1;
end
```

- 3** MATLAB creates the following signatures. For BeginInvoke:

```
[System.IAsyncResult RetVal,
double scalar refArg]
BeginInvoke (
    SignatureExamples.delrefvoid this,
    double scalar refArg,
    System.AsyncCallback callback,
    System.Object object)
```

The EndInvoke signature:

```
double scalar refArg
EndInvoke (
    SignatureExamples.delrefvoid this,
    double scalar refArg,
    System.IAsyncResult result)
```

- 4** Call incfnc:

```
x = 6;
myDel = SignatureExamples.delrefvoid(@incfnc);
asyncRes = myDel.BeginInvoke(x,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
myRef = 0;
result = myDel.EndInvoke(myRef,asyncRes);
```

# EndInvoke

---

```
disp(['Increment of ' num2str(x) ' = ' num2str(result)]);
```

MATLAB displays:

```
Increment of 6 = 7
```

---

This example shows how to use a delegate with an out parameter, `argOut`, and one return value.

**1** C# delegate:

```
public delegate Single deloutsingle(Single argIn, out Single argOut);
```

**2** MATLAB maps the out argument as a return value for a total of two return values. MATLAB function to call:

```
%Double input argument  
function [res1 res2] = times2fnc(A)  
res1 = A*2;  
res2 = res1;  
end
```

**3** MATLAB creates the following signatures. For `BeginInvoke`:

```
[System.IAsyncResult RetVal,  
single scalar argOut]  
BeginInvoke (  
    SignatureExamples.deloutsingle this,  
    single scalar argIn,  
    System.AsyncCallback callback,  
    System.Object object)
```

The `EndInvoke` signature:

```
[single scalar RetVal,  
single scalar argOut]  
EndInvoke (  
    SignatureExamples.deloutsingle this,  
    single scalar argIn,  
    System.AsyncCallback callback,  
    System.Object object)
```

```
SignatureExamples.deloutsingle this,  
System.IAsyncResult result)
```

#### 4 Call times2fnc:

```
myDel = SignatureExamples.deloutsingle(@times2fnc);  
asyncRes = myDel.BeginInvoke(6,[],[]);  
while asyncRes.IsCompleted ~= true  
    pause(0.05); % Use pause() to let MATLAB process event  
end  
[a1 a2] = myDel.EndInvoke(asyncRes);  
a1
```

MATLAB displays:

```
a1 =  
    12
```

- [MSDN Calling Synchronous Methods Asynchronously](#)

# eomday

---

**Purpose** Last day of month

**Syntax** E = eomday(Y, M)

**Description** E = eomday(Y, M) returns the last day of the year and month given by corresponding elements of arrays Y and M.

**Examples** Show the end of month for January through September for the year 1900:

```
eomday(1900, 1:9)
ans =
    31    28    31    30    31    30    31    31    30
```

Find the number of days during that period:

```
sum(eomday(1900, 1:9))
ans =
    273
```

Because 1996 is a leap year, the statement eomday(1996,2) returns 29. To show all the leap years in the twentieth century, try:

```
y = 1900:1999;
E = eomday(y, 2);
y(find(E == 29))

ans =
Columns 1 through 6
    1904    1908    1912    1916    1920    1924

Columns 7 through 12
    1928    1932    1936    1940    1944    1948

Columns 13 through 18
    1952    1956    1960    1964    1968    1972
```

Columns 19 through 24

1976      1980      1984      1988      1992      1996

**See Also**

`datenum` | `datevec` | `weekday`

# enumeration

---

**Purpose** Display class enumeration members and names

**Syntax**

```
enumeration ClassName
enumeration(obj)
m = enumeration(ClassName)
m = enumeration(obj)
[m,s] = enumeration(ClassName)
[m,s] = enumeration(obj)
```

**Description**

`enumeration ClassName` displays the names of the enumeration members for the MATLAB class with the name `ClassName`.

`enumeration(obj)` displays the names of the enumeration members for the class of `obj`.

`m = enumeration(ClassName)` returns the enumeration members for the class in the column vector `m` of objects.

`m = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

`[m,s] = enumeration(ClassName)` returns the names of the enumeration members in the cell array of strings `s`. The names in `s` correspond element-wise to the enumeration members in `m`.

`[m,s] = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

- Tips**
- An enumeration class that derives from a built-in class can specify more than one name for a given enumeration member.
  - When you call the `enumeration` function with no output arguments, MATLAB displays only the first name for each enumeration member (as specified in the class definition). To see all available enumeration members and their names, use the two output arguments (for example, `[m, s] = enumeration(obj);`).

**Input Arguments**

**ClassName**  
The name of the enumeration class, in single quotes.

**obj**

A instance of an enumeration class.

**Output Arguments****m**

Column vector of enumeration members.

**s**

Cell array of strings containing the enumeration names.

**Examples**

All examples use the following enumeration class.

```
classdef Boolean < logical
    enumeration
        No (0)
        Yes (1)
        Off (0)
        On (1)
    end
end
```

---

Display the names of the enumeration members for class Boolean:

```
enumeration Boolean
Enumerations for class Boolean:
```

```
    No
    Yes
```

---

Get the enumeration members for class Boolean in a column vector of objects:

```
members = enumeration('Boolean')
members =
```

# enumeration

---

```
No  
Yes
```

---

Get all available enumeration members and their names:

```
[members, names] = enumeration('Boolean')  
members =
```

```
No  
Yes  
No  
Yes
```

```
names =
```

```
'No '  
'Yes '  
'Off '  
'On '
```

## See Also

classdef

## Tutorials

- “Working with Enumerations”

**Purpose** Floating-point relative accuracy

**Syntax**

```
eps
d = eps(X)
eps('double')
eps('single')
```

**Description** eps returns the distance from 1.0 to the next largest double-precision number, that is  $\text{eps} = 2^{-52}$ .

$d = \text{eps}(X)$  is the positive distance from  $\text{abs}(X)$  to the next larger in magnitude floating point number of the same precision as  $X$ .  $X$  may be either double precision or single precision. For all  $X$ ,

$$\text{eps}(X) = \text{eps}(-X) = \text{eps}(\text{abs}(X))$$

$\text{eps}('double')$  is the same as  $\text{eps}$  or  $\text{eps}(1.0)$ .

$\text{eps}('single')$  is the same as  $\text{eps}(\text{single}(1.0))$  or  $\text{single}(2^{-23})$ .

Except for numbers whose absolute value is smaller than  $\text{realmin}$ , if  $2^E \leq \text{abs}(X) < 2^{(E+1)}$ , then

$$\begin{aligned} \text{eps}(X) &= 2^{(E-23)} \text{ if } \text{isa}(X, 'single') \\ \text{eps}(X) &= 2^{(E-52)} \text{ if } \text{isa}(X, 'double') \end{aligned}$$

For all  $X$  of class double such that  $\text{abs}(X) \leq \text{realmin}$ ,  $\text{eps}(X) = 2^{-1074}$ . Similarly, for all  $X$  of class single such that  $\text{abs}(X) \leq \text{realmin}('single')$ ,  $\text{eps}(X) = 2^{-149}$ .

Replace expressions of the form:

```
if Y < eps * ABS(X)
```

with

```
if Y < eps(X)
```

**Examples**

```
double precision
eps(1/2) = 2^(-53)
```

```
eps(1) = 2^(-52)
eps(2) = 2^(-51)
eps(realmax) = 2^971
eps(0) = 2^(-1074)

if(abs(x) <= realmin, eps(x) = 2^(-1074)
eps(realmin/2) = 2^(-1074)
eps(realmin/16) = 2^(-1074)
eps(Inf) = NaN
eps(NaN) = NaN

single precision
eps(single(1/2)) = 2^(-24)
eps(single(1)) = 2^(-23)
eps(single(2)) = 2^(-22)
eps(realmax('single')) = 2^104
eps(single(0)) = 2^(-149)
eps(realmin('single')/2) = 2^(-149)
eps(realmin('single')/16) = 2^(-149)
if(abs(x) <= realmin('single'), eps(x) = 2^(-149)
eps(single(Inf)) = single(NaN)
eps(single(NaN)) = single(NaN)
```

## See Also

[realmax](#) | [realmin](#) | [intmax](#)

**Purpose** Determine equality

**Syntax** A == B  
eq(A,B)

**Description** A == B returns a logical array with elements set to logical 1 (true) where arrays A and B are equal; otherwise, it returns logical 0 (false). The test compares both real and imaginary parts of numeric arrays. eq returns logical 0 (false) where A or B have NaN or undefined categorical elements.

eq(A,B) is an alternative way to execute A == B, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Left array

numeric array | logical array | character array | categorical array

Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### B - Right array

numeric array | logical array | character array | categorical array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Equality of Two Vectors

Create two vectors containing both real and imaginary numbers.

```
A = [1+i 3 2 4+i];  
B = [1 3+i 2 4+i];
```

Compare the two vectors for equality.

```
A == B
```

```
ans =
```

```
0     0     1     1
```

The `eq` function tests both real and imaginary parts for equality, and returns logical 1 (true) only where both parts are equal.

### Find Characters in String

Create a string of characters.

```
M = 'masterpiece';
```

Test the string for the presence of a specific character using ==.

```
M == 'e'
```

```
ans =
```

```
    0    0    0    0    1    0    0    0    1    0    1
```

The value of logical 1 (true) in the vector indicates the presence of the character 'e' in the string.

### Find Values in Categorical Array

Create a categorical array.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =
```

```
    heads    heads    tails
    tails    heads    tails
```

The array has two categories: 'heads' and 'tails'.

Find all values in the 'heads' category.

```
A == 'heads'
```

```
ans =
```

```
    1    1    0
    0    1    0
```

A value of logical 1 (true) indicates a value in the category.

Compare the rows of A for equality.

```
A(1,:) == A(2,:)
```

```
ans =  
      0      1      1
```

The function returns logical 1 (true) where the rows have equal category values.

## Compare Floating-Point Numbers

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the == operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in `C`.

```
C = 0.5-0.4-0.1
```

```
C =  
-2.7756e-17
```

Intuitively, `C` should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare `C` to zero for equality.

```
C == 0
```

```
ans =  
      0
```

The result is logical 0 (false).

Compare floating-point numbers using a tolerance, `tol`, instead of ==.

```
tol = eps;  
abs(C-0) < tol
```

```
ans =
```

```
1
```

The two numbers, `C` and `0`, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

**Tips**

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.

**See Also**

`ge` | `gt` | `le` | `lt` | `ne`

## eq (MException)

---

**Purpose** Compare scalar MException objects for equality

**Syntax** eObj1 == eObj2

**Description** eObj1 == eObj2 tests scalar MException objects eObj1 and eObj2 for equality, returning logical 1 (true) if the two objects are identical, otherwise returning logical 0 (false).

**See Also** try | catch | error | assert | MException | isequal(MException) | ne(MException) | getReport(MException) | disp(MException) | throw(MException) | rethrow(MException) | throwAsCaller(MException) | addCause(MException) | | last(MException)

**Purpose** Error function

**Syntax**  $Y = \text{erf}(X)$

**Definitions** The error function  $\text{erf}(X)$  is twice the integral of the Gaussian distribution with 0 mean and variance of 1/2.

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

**Description**  $Y = \text{erf}(X)$  returns the value of the error function for each element of real array  $X$ .

**See Also** [erfc](#) | [erfcinv](#) | [erfcx](#) | [erfinv](#)

# erfc

---

**Purpose** Complementary error function

**Syntax**  $Y = \text{erfc}(X)$

**Definitions** The complementary error function  $\text{erfc}(X)$  is defined as

$$\begin{aligned}\text{erfc}(x) &= \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt \\ &= 1 - \text{erf}(x)\end{aligned}$$

**Description**  $Y = \text{erfc}(X)$  computes the value of the complementary error function.

**Tips** The relationship between the complementary error function  $\text{erfc}$  and the standard normal probability distribution returned by the Statistics Toolbox function  $\text{normcdf}$  is

$$\text{normcdf}(x) = \left(\frac{1}{2}\right) \times \text{erfc}\left(\frac{-x}{\sqrt{2}}\right)$$

**See Also** [erf](#) | [erfcinv](#) | [erfcx](#) | [erfinv](#)

**Purpose** Inverse complementary error function

**Syntax** `X = erfcinv(Y)`

**Description** `X = erfcinv(Y)` returns the value of the inverse of the complementary error function for each element of `Y`. Elements of `Y` must be in the interval `[0 2]`. The function `erfcinv` satisfies  $y = \text{erfc}(x)$  for  $2 \geq y \geq 0$  and  $-\infty \geq x \geq \infty$ .

**Tips** The relationship between the inverse complementary error function `erfcinv` and the inverse standard normal probability distribution returned by the Statistics Toolbox function `norminv` is:

$$\text{norminv}(p) = (-\sqrt{2}) \times \text{erfcinv}(2p).$$

**See Also** `erf` | `erfc` | `erfcx` | `erfinv`

# erfcx

---

**Purpose** Scaled complementary error function

**Syntax**  $Y = \text{erfcx}(X)$

**Definitions** The scaled complementary error function  $\text{erfcx}(X)$  is defined as

$$\text{erfcx}(x) = e^{x^2} \text{erfc}(x)$$

For large  $X$ ,  $\text{erfcx}(X)$  is approximately  $\left(\frac{1}{\sqrt{\pi}}\right)\frac{1}{x}$

**Description**  $Y = \text{erfcx}(X)$  computes the value of the scaled complementary error function.

**See Also** erf | erfcinv | erfc | erfinv

<b>Purpose</b>	Inverse error function
<b>Syntax</b>	<code>X = erfinv(Y)</code>
<b>Description</b>	<code>X = erfinv(Y)</code> returns the value of the inverse error function for each element of <code>Y</code> . Elements of <code>Y</code> should be in the interval <code>[-1 1]</code> or the function will return NaN. The function <code>erfinv</code> satisfies $y = \text{erf}(x)$ for $-1 \leq y \leq 1$ and $-\infty \leq x \leq \infty$ .
<b>Examples</b>	<code>erfinv(1)</code> is Inf <code>erfinv(-1)</code> is -Inf.
<b>See Also</b>	<code>erf</code>   <code>erfcinv</code>   <code>erfcx</code>   <code>erfc</code>

# error

---

**Purpose** Display message and abort function

**Syntax**

```
error('msgIdent', 'msgString', v1, v2, ..., vN)
error('msgString', v1, v2, ...)
error('msgString')
error(msgStruct)
```

**Description** `error('msgIdent', 'msgString', v1, v2, ..., vN)` generates an exception if the currently-running function tests for and confirms a faulty or unexpected condition. Depending on how the program has been designed to respond to the error, MATLAB either enters a catch block to handle the error condition, or exits the program.

The *msgIdent* argument is a unique *message identifier* string that MATLAB attaches to the error message when it throws the error. A message identifier has the format `component:mnemonic`. Its purpose is to better identify the source of the error (see Message Identifiers for more information).

The *msgString* argument is a character string that informs the user about the cause of the error and can also suggest how to correct the faulty condition. The *msgString* string can include escape sequences such as `\t` or `\n`, as well as any of the format specifiers supported by the `sprintf` function (such as `%s` or `%d`). Additional arguments *v1*, *v2*, ..., *vN* provide values that correspond to and replace the conversion specifiers.

For example, if *msgString* is “Error on line %d, command %s”, then *v1* is the line number at which the error was detected, and *v2* is the command that failed. See “Formatting Strings” for more detailed information on using string formatting commands.

All string input arguments must be enclosed in single quotation marks. If *msgString* is an empty string, the error command has no effect.

`error('msgString', v1, v2, ...)` reports an error without including a message identifier in the error report. Although including a message identifier in an error report is recommended, it is not required.

`error('msgString')` is the same as the above syntax, except that the `msgString` string contains no conversion specifiers, no escape sequences, and no substitution value (`v1, v2, ...`) arguments. All characters in `msgString` are interpreted exactly as they appear in the `msgString` argument. MATLAB displays the `\t` in `'C:\testFolder'` for example, as a backslash character followed by the letter `t`, and not as a horizontal tab.

`error(msgStruct)` accepts a scalar error structure input `msgStruct` with at least one of the fields `message`, `identifier`, and `stack`. When the `msgStruct` input includes a `stack` field, the `stack` field of the error will be set according to the contents of the `stack` input. When specifying a `stack` input, use the absolute file name and the entire sequence of functions that nests the function in the stack frame. This is the same as the string returned by `dbstack('-completenames')`. If `msgStruct` is an empty structure, no action is taken and `error` returns without exiting the function.

## Tips

The `error` function captures what information it can about the error that occurred and stores it in a data structure that is an object of the `MException` class. This *error record* contains the error message string, message identifier, the error stack, and optionally an array of other exception objects that are intended to provide information as to the cause of the exception. See “Capture Information About Exceptions” for more information on how to access and use an exception object.

You can access information in the exception object using the `catch` function as documented in the `catch` reference page. If your program terminates because of an exception and returns control to the Command Prompt, you can access the exception object using the `MException.last` command.

The `error` function also determines where the error occurred and provides this information in the `stack` field of the `MException` object. This field contains a structure array that has the same format as the output of the `dbstack` function. This stack points to the line where the `error` function was called.

## error

---

The following table shows the MATLAB functions that can be useful for throwing an exception:

Function	Description
<code>error</code>	Throw exception with specified error message.
<code>assert</code>	Evaluate given expression and throw exception if false.
<code>throw</code>	Throw exception based on specified <code>MException</code> object.
<code>throwAsCaller</code>	Throw exception that appears to have been thrown by the calling function.
<code>rethrow</code>	Reissue previously caught exception.

### Examples

#### Example 1 – Simple Error Message

Write a short function `errtest1` that throws an error when called with an incorrect number of input arguments. Include a message identifier `'myApp:argChk'` and error message:

```
function errtest1(x, y)
if nargin ~= 2
    error('myApp:argChk', 'Wrong number of input arguments')
end
```

Call the function with an incorrect number of inputs. The call to `nargin`, a function that checks the number of inputs, fails and the program calls `error`:

```
errtest1(pi)
```

```
Error using errtest1 (line 3)
Wrong number of input arguments
```

If you run this function from the Command Window, you can use the `MException.last` method to view the exception object:

```
err = MException.last
err =
    MException

    Properties:
        identifier: 'myApp:argChk'
        message: 'Wrong number of input arguments'
        cause: {}
        stack: [1x1 struct]
    Methods

err.stack
ans =
    file: 'c:\work\errtest1.m'
    name: 'errtest1'
    line: 3
```

## Example 2 – Special Characters

MATLAB converts special characters (like `\n` and `%d`) in the error message string only when you specify more than one input argument with `error`. In the single-argument case shown below, `\n` is taken to mean backslash-n. It is not converted to a newline character:

```
error('In this case, the newline \n is not converted.')
```

In this case, the newline `\n` is not converted.

But, when more than one argument is specified, MATLAB does convert special characters. This holds true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
error('ErrorTests:convertTest', ...
    'In this case, the newline \n is converted.')
```

In this case, the newline  
is converted.

## error

getReport(MException) | last(MException)

**Purpose** Plot error bars along curve

**Syntax**

```
errorbar(Y,E)
errorbar(X,Y,E)
errorbar(X,Y,L,U)
errorbar(...,LineStyle)
h = errorbar(...)
```

**Description** Error bars show the confidence intervals of data or the deviation along a curve.

`errorbar(Y,E)` plots  $Y$  and draws an error bar at each element of  $Y$ . The error bar is a distance of  $E(i)$  above and below the curve so that each bar is symmetric and  $2 \cdot E(i)$  long.

`errorbar(X,Y,E)` plots  $Y$  versus  $X$  with symmetric error bars  $2 \cdot E(i)$  long.  $X$ ,  $Y$ ,  $E$  must be the same size. When they are vectors, each error bar is a distance of  $E(i)$  above and below the point defined by  $(X(i), Y(i))$ . When they are matrices, each error bar is a distance of  $E(i, j)$  above and below the point defined by  $(X(i, j), Y(i, j))$ .

`errorbar(X,Y,L,U)` plots  $X$  versus  $Y$  with error bars  $L(i)+U(i)$  long specifying the lower and upper error bars.  $X$ ,  $Y$ ,  $L$ , and  $U$  must be the same size. When they are vectors, each error bar is a distance of  $L(i)$  below and  $U(i)$  above the point defined by  $(X(i), Y(i))$ . When they are matrices, each error bar is a distance of  $L(i, j)$  below and  $U(i, j)$  above the point defined by  $(X(i, j), Y(i, j))$ .

`errorbar(...,LineStyle)` uses the color and line style specified by the string '`LineStyle`'. The color is applied to the data line and error bars. The linestyle and marker are applied to the data line only. See `linespec` for examples of styles.

`h = errorbar(...)` returns handles to the `errorbarseries` objects created. `errorbar` creates one object for vector input arguments and

# errorbar

---

one object per column for matrix input arguments. See `errorbarseries` properties for more information.

When the arguments are all matrices, `errorbar` draws one line per matrix column. If `X` and `Y` are vectors, they specify one curve.

## Examples

### Symmetric Error Bars

Draw symmetric error bars that are two standard deviation units in length.

```
x = 0:pi/10:pi;  
y = sin(x);  
e = std(y)*ones(size(x));
```

```
figure  
errorbar(x,y,e)
```

### Change Error Bar Marker and Color

Load the count data set to get the three-column matrix count that contains traffic volume for three street locations over the course of a day. Compute the mean of count for each row.

```
load count.dat;  
y = mean(count,2);
```

## errorbar

---

Compute the standard deviation of count for each row and normalize by the number of elements in the sample by setting the second input argument to 1.

```
e = std(count,1,2);
```

Plot the computed average traffic volume,  $y$ , and the computed standard deviations,  $e$ , for the three street locations. Set the `LineStyle` to specify a red color, cross markers, and no line.

```
figure  
errorbar(y,e,'rx')
```

**How To**

- `ConfidenceBounds`

# Errorbarseries Properties

---

## Purpose

Description of errorbarseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property editor (`propertyeditor`).

Note that you cannot define default property values for errorbarseries objects. See “Plot Objects” for more information on errorbarseries objects.

## Errorbarseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

Annotation

`hg.Annotation` object (read-only)

*Control the display of errorbarseries objects in legends.* Specifies whether this errorbarseries object is represented in a figure legend.

Querying the Annotation property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the errorbarseries object is displayed in a figure legend.

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Include the errorbarseries object in a legend as one entry, but not its children objects
off	Do not include the errorbarseries or its children in a legend (default)
children	Include only the children of the errorbarseries as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to

# Errorbarseries Properties

---

perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the errorbarseries object.* An array containing the handles of all line objects parented to the errorbarseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

# Errorbarseries Properties

---

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

`CreateFcn`  
string | function handle

*Not available on errorbarseries objects.*

`DeleteFcn`  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the errorbarseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

### `EraseMode`

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

# Errorbarseries Properties

---

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

# Errorbarseries Properties

---

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

`{on}` | `off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the curve or error bars that compose the graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

`on` | `{off}`

*Select the object by clicking lines or area of extent.* Select plot objects by:

- Clicking curve or error bars (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the curve or error bars to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the lines).

## Interruptible

`off` | `{on}`

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Errorbarseries Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LData

array equal in size to XData and YData

*Errorbar length below data point.* The `errorbar` function uses this data to determine the length of the errorbar below each data point. Specify these values in data units. See also UData.

## LDataSource

string (MATLAB variable)

*Link LData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the LData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change LData.

You can use the `refreshdata` function to force an update of the object’s data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

## LineStyle

{-} | -- | : | -. | none

*Line style of errorbarseries object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
'.'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`  
size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

`Marker`  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle

# Errorbarseries Properties

---

Specifier	Marker Type
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ''	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`  
handle of parent axes, `hgroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

`Selected`  
on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this

# Errorbarseries Properties

---

property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

**SelectionHighlight**  
{on} | off

*Objects are highlighted when selected.* When the **Selected** property is on, MATLAB indicates the selected state by drawing selection handles on the curve and error bars. When **SelectionHighlight** is off, MATLAB does not draw the handles.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the **Tag** property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `errorbarseries` object and set the **Tag** property:

```
t = errorbar(Y,E,'Tag','errorbar1')
```

To access the `errorbarseries` object, use `findobj` to find the `errorbarseries` object's handle.

The following statement changes the `MarkerFaceColor` property of the object whose **Tag** is `errorbar1`.

```
set(findobj('Tag','errorbar1'),'MarkerFaceColor','red')
```

**Type**  
string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For errorbarseries objects, Type is 'hggroup'. The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UData

array equal in size to XData and YData

*Errorbar length above data point.* The errorbar function uses this data to determine the length of the errorbar above each data point. Specify these values in data units.

## UDataSource

MATLAB variable, as a string

*Link UData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the UData. The default value is an empty array.

```
set(h, 'UDataSource', 'Udatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's UDataSource does not change the object's UData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the errorbarseries object.* Assign this property the handle of a uicontextmenu object created in the errorbarseries object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the

# Errorbarseries Properties

---

context menu whenever you right-click over the errorbarseries object.

**UserData**  
array

*User-specified data.* Data you want to associate with the errorbarseries object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

**Visible**  
{on} | off

*Visibility of errorbarseries object and its children.* By default, errorbarseries object visibility is on. This means all children of the errorbarseries object are visible unless the child object's `Visible` property is off. Setting an errorbarseries object's `Visible` property to off also makes its children invisible.

**XData**  
array

*X-coordinates of the curve.* The `errorbar` function plots a curve using the *x*-axis coordinates in the `XData` array. `XData` must be the same size as `YData`.

If you do not specify `XData` (which is the input argument `X`), the `errorbar` function uses the indices of `YData` to create the curve. See the `XDataMode` property for related information.

**XDataMode**  
{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the input argument `x`), the `errorbar` function sets this property to `manual`.

If you set `XDataMode` to `auto` after having specified `XData`, the `errorbar` function resets the `x` tick-mark labels to the indices of the `YData`.

**XDataSource**  
string (MATLAB variable)

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `XData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**YData**  
scalar | vector | matrix

*Data defining curve.* `YData` contains the data defining the curve. If `YData` is a matrix, the `errorbar` function displays a curve with error bars for each column in the matrix.

The input argument `Y` in the `errorbar` function calling syntax assigns values to `YData`.

# Errorbarseries Properties

---

## YDataSource

string (MATLAB variable)

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change YData.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose** Create and open error dialog box

**Syntax**

```
h = errorDlg
h = errorDlg(errorstring)
h = errorDlg(errorstring,dlgname)
h = errorDlg(errorstring,dlgname,createmode)
```

**Description**

`h = errorDlg` creates and displays a dialog box with title Error Dialog that contains the string This is the default error string. The `errorDlg` function returns the handle of the dialog box in `h`.

`h = errorDlg(errorstring)` displays a dialog box with title Error Dialog that contains the string `errorstring`.

`h = errorDlg(errorstring,dlgname)` displays a dialog box with titledlgname that contains the string `errorstring`.

`h = errorDlg(errorstring,dlgname,createmode)` specifies whether the error dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `errorstring` and `dlgname`. The `createmode` argument can be a string or a structure.

If `createmode` is a string, it must be one of the values shown in the following table.

createmode Value	Description
modal	Replaces the error dialog box having the specified Title, that was last created or clicked on, with a modal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
non-modal (default)	Creates a new nonmodal error dialog box with the specified parameters. Existing

# errordlg

---

createmode Value	Description
	error dialog boxes with the same title are not deleted.
replace	Replaces the error dialog box having the specified Title, that was last created or clicked on, with a nonmodal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

If you open a dialog with `errordlg`, `msgbox`, or `warndlg` using 'CreateMode', 'modal' and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see `WindowStyle` in the `Figure Properties`.

---

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings 'tex' or 'none'. The default value for `Interpreter` is 'none'.

## Tips

MATLAB sizes the dialog box to fit the string 'errorstring'. The error dialog box has an **OK** push button and remains on the screen until you press the **OK** button or the **Return** key. After pressing the button, the error dialog box disappears.

The appearance of the dialog box depends on the platform you use.

**Examples**

This code,

```
errordlg('File not found','File Error');
```

displays this dialog box:

This code,

```
mode = struct('WindowStyle','non-modal',...  
             'Interpreter','tex')  
h = errordlg('Try this equation instead: f(x) = x^2','Equation Error');
```

displays this dialog box:

# etime

---

**Purpose** Time elapsed between date vectors

**Syntax** `e = etime(t2,t1)`

**Description** `e = etime(t2,t1)` returns the number of seconds between two date vectors or matrices of date vectors, `t1` and `t2`.

**Input Arguments** **t2,t1 - Date vectors**  
1-by-6 vector | m-by-6 matrix

Date vectors, specified as 1-by-6 vectors or m-by-6 matrices containing `m` full date vectors in the format:[Year Month Day Hour Minute Second].

**Example:** [2012 03 27 11 50 01]

**Data Types**  
double

## Examples **Compute Elapsed Time**

Compute the time elapsed between a specific time and the current time, to 0.01-second accuracy.

Define the initial date and time and convert to date vector form.

```
format shortg
str = 'March 28, 2012 11:51:00';
t1 = datevec(str,'mmm dd, yyyy HH:MM:SS')
```

```
t1 =
    2012         3         28         11         51         0
```

Determine the current date and time.

```
t2 = clock
```

```
t2 =
```

2012

3

28

11

52

The `clock` function returns the current date and time as a date vector.

Use `etime` to compute the number of seconds between `t1` and `t2`.

```
e = etime(t2,t1)
```

```
e =
```

```
62.357
```

## Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

## Algorithms

`etime` does not account for the following:

- Leap seconds.
- Daylight savings time adjustments.
- Differences in time zones.

## See Also

`tic` | `toc` | `cputime` | `clock` | `now` | `timeit`

# etree

---

**Purpose** Elimination tree

**Syntax**  
`p = etree(A)`  
`p = etree(A, 'col')`  
`p = etree(A, 'sym')`  
`[p,q] = etree(...)`

**Description** `p = etree(A)` returns an elimination tree for the square symmetric matrix whose upper triangle is that of `A`. `p(j)` is the parent of column `j` in the tree, or 0 if `j` is a root.

`p = etree(A, 'col')` returns the elimination tree of  $A^*A$ .

`p = etree(A, 'sym')` is the same as `p = etree(A)`.

`[p,q] = etree(...)` also returns a postorder permutation `q` of the tree.

**See Also** `treelayout` | `treeplot` | `etreeplot`

<b>Purpose</b>	Plot elimination tree
<b>Syntax</b>	<code>etreeplot(A)</code> <code>etreeplot(A,nodeSpec,edgeSpec)</code>
<b>Description</b>	<code>etreeplot(A)</code> plots the elimination tree of $A$ (or $A+A'$ , if non-symmetric). <code>etreeplot(A,nodeSpec,edgeSpec)</code> allows optional parameters <code>nodeSpec</code> and <code>edgeSpec</code> to set the node or edge color, marker, and linestyle. Use <code>' '</code> to omit one or both.
<b>See Also</b>	<code>etree</code>   <code>treepplot</code>   <code>treelayout</code>

# eval

---

**Purpose** Execute MATLAB expression in text string

**Syntax** `eval(expression)`  
`[output1,...,outputN] = eval(expression)`

**Description** `eval(expression)` evaluates the MATLAB code in the string `expression`. If you use `eval` within an anonymous function, nested function, or function that contains a nested function, the evaluated expression cannot create a variable.

`[output1,...,outputN] = eval(expression)` stores output from `expression` in the specified variables.

- Tips**
- Many common uses of the `eval` function are less efficient and are more difficult to read and debug than other MATLAB functions and language constructs. For more information, see “Alternatives to the `eval` Function”.
  - Whenever possible, do not include output arguments within the input to the `eval` function, such as `eval(['output = ',expression])`. The preferred syntax,

```
output = eval(expression)
```

allows the MATLAB parser to perform stricter checks on your code, preventing untrapped errors and other unexpected behavior.

**Input Arguments** **expression**  
String that contains a valid MATLAB expression.  
To include a numeric value in the expression, convert it to a string with `int2str`, `num2str`, or `sprintf`.

**Output Arguments** **output1,...,outputN**  
Outputs from the evaluated expression.

## Examples

### Variable Name Evaluation

Select a matrix to plot at runtime.

This example requires that you have a matrix in the current workspace. For example:

```
aMatrix = magic(5);
```

Interactively request the name of a matrix to plot, and call `eval` to use its value.

```
expression = input('Enter the name of a matrix: ','s');  
if (exist(expression,'var'))  
    mesh(eval(expression))  
end
```

If you type `aMatrix` at the input prompt, this code creates a mesh plot of `magic(5)`.

## Tutorials

- “Alternatives to the `eval` Function”
- “Variables in Nested and Anonymous Functions”

# evalc

---

**Purpose** Evaluate MATLAB expression with capture

**Syntax** `T = evalc(S)`  
`[T, X, Y, Z, ...] = evalc(S)`

**Description** `T = evalc(S)` is the same as `eval(S)` except that anything that would normally be written to the command window, except for error messages, is captured and returned in the character array `T` (lines in `T` are separated by `\n` characters).

`[T, X, Y, Z, ...] = evalc(S)` is the same as `[X, Y, Z, ...] = eval(S)` except that any output is captured into `T`.

**Tips** When you are using `evalc`, functions `diary`, `more`, and `input` are disabled.

**See Also** `eval` | `evalin` | `assignin` | `feval` | `diary` | `input` | `more`

**Purpose**

Execute MATLAB expression in specified workspace

**Syntax**

```
evalin(ws, expression)  
[a1, a2, a3, ...] = evalin(ws, expression)
```

**Description**

`evalin(ws, expression)` executes *expression*, a string containing any valid MATLAB expression, in the context of the workspace *ws*. *ws* can have a value of 'base' or 'caller' to denote the MATLAB base workspace or the workspace of the caller function. You can construct *expression* by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2,...]
```

`[a1, a2, a3, ...] = evalin(ws, expression)` executes *expression* and returns the results in the specified output variables. Using the `evalin` output argument list is recommended over including the output arguments in the expression string:

```
evalin(ws, '[a1, a2, a3, ...] = function(var)')
```

The above syntax avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

**Tips**

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line.

`evalin('caller', expression)` finds only *variables* in the caller's workspace; it does not find *functions* in the caller. For this reason, you cannot use `evalin` to construct a handle to a function that is defined in the caller.

If you use `evalin('caller', expression)` in the MATLAB debugger after having changed your local workspace context with `dbup` or `dbdown`,

# evalin

---

MATLAB evaluates the expression in the context of the function that is one level up in the stack from your current workspace context.

## Examples

This example extracts the value of the variable `var` in the MATLAB base workspace and captures the value in the local variable `v`:

```
v = evalin('base', 'var');
```

## Limitation

`evalin` cannot be used recursively to evaluate an expression. For example, a sequence of the form `evalin('caller', 'evalin(''caller'', ''x'')` doesn't work.

## See Also

`assignin` | `eval` | `evalc` | `feval` | `catch` | `try`

- Purpose** Base class for all data objects passed to event listeners
- Description** The event package contains the `event.EventData` class, which defines the data objects passed to event listeners. If you want to provide additional information to event listeners, you can do so by subclassing `event.EventData`. See “Defining Event-Specific Data” for more information.
- Properties** The `event.EventData` class defines two properties and no methods:
- `EventName` — The name of the event described by this data object.
  - `Source` — The source object whose class defines the event described by the data object.
- See Also** `event.PropertyEvent`
- How To**
- “Learning to Use Events and Listeners”

# event.listener

---

**Purpose** Class defining listener objects

**Syntax** `lh = event.listener(Hobj, 'EventName', @CallbackFunction)`

**Description** The `event.listener` class defines listener objects. Listener objects respond to the specified event and identify the callback function to invoke when the event is triggered.

`lh = event.listener(Hobj, 'EventName', @CallbackFunction)` creates an `event.listener` object, `lh`, for the event named in `EventName`, on the specified object, `Hobj`.

If `Hobj` is an array of object handles, the listener responds to the named event on any of the objects referenced in the array.

The listener callback function must accept at least two input arguments. For example,

```
function CallbackFunction(source, eventData)
    ...
end
```

where `source` is the object that is the source of the event and `eventData` is an `event.EventData` object.

The `event.listener` class is a handle class.

## Limiting Listener Lifecycle

Generally, you create a listener object using `addListener`. However, you can call the `event.listener` constructor directly to create a listener. When you use the `event.listener` constructor, the listener's lifecycle is not tied to the object(s) being listened to—once the listener object goes out of scope, the listener no longer exists. See “Ways to Create Listeners” for more information on creating listener objects.

## Removing a Listener

If you call `delete(lh)` on the listener object, the listener ceases to exist, which means the event no longer causes the listener callback function to execute.

## Disabling a Listener

You can enable or disable a listener by setting the value of the listener's `Enabled` property (see Properties table below).

## More Information on Events and Listeners

See “Events” for more information and examples of how to use events and listeners.

## Properties

Property	Purpose
Source	Cell array of source objects
EventName	Name of the event
Callback	Function to execute when the event is triggered and the <code>Enabled</code> property is set to <code>true</code>
Enabled	The callback executes when the event occurs if and only if <code>Enabled</code> is set to <code>true</code> (the default).
Recursive	<p>When <code>false</code> (the default), this listener does not execute recursively. Therefore, if the callback triggers its own event, the listener does not execute again.</p> <p>When <code>true</code>, the listener callback can cause the same event that triggered the callback. This scheme can lead to infinite recursion, which ends when the MATLAB recursion limit eventually triggers an error.</p>

## See Also

`addlistener` | `delete` | `event.proplistener`

# event.PropertyEvent

---

**Purpose** Data for property events

**Description** The `event.PropertyEvent` class defines the data objects passed to listeners of the `meta.property` events:

- `PreGet`
- `PostGet`
- `PreSet`
- `PostSet`

`event.PropertyEvent` is a sealed subclass of `event.EventData` (i.e., you cannot subclass `event.PropertyEvent`).

**Properties** `event.PropertyEvent` inherits the first two properties from the `event.EventData`, and defines one new property:

- `EventName` — One of the four event names listed in the Description section
- `Source` — `meta.property` object that triggers the event
- `AffectedObject` — The object whose property is affected.

**See Also** `event.EventData` | `meta.property`

**How To** • “Listen for Changes to Property Values”

**Purpose**

Define listener object for property events

**Syntax**

```
lh = event.proplistener(Hobj, Properties, 'PropEvent',  
    @CallbackFunction)
```

**Description**

lh = event.proplistener(Hobj, Properties, 'PropEvent', @CallbackFunction) creates a property listener object for one or more properties on the specified object.

- **Hobj** — handle of object whose property or properties are to be listened to. If Hobj is an array, the listener responds to the named event on all objects in the array.
- **Properties** — an object array or a cell array of meta.property object handles representing the properties to which you want to listen.
- **PropEvent** — must be one of the strings: PreSet, PostSet, PreGet, PostGet
- **@CallbackFunction** — function handle to the callback function that executes when the event occurs.

The event.proplistener class defines property event listener objects. It is a subclass of the event.listener class and adds one property to those defined by event.listener:

- **Object** — Cell array of objects whose property events are being listened to.

You can call the event.proplistener constructor instead of calling addlistener to create a property listener. However, when you do not use addlistener, the listener's lifecycle is not tied to the object(s) being listened to.

See “Listen for Changes to Property Values”.

See “Getting Information About Properties” for more information on using meta.property objects.

**See Also**

event.listener | addlistener

# eventlisteners

---

**Purpose** List event handler functions associated with COM object events

**Syntax** `info = h.eventlisteners`  
`info = eventlisteners(h)`

**Description** `info = h.eventlisteners` lists the events and their event handler routines registered with COM object `h`. The function returns a cell array of strings `info`, with each row containing the name of a registered event and the handler routine for that event. If the object has no registered events, `eventlisteners` returns an empty cell array. You can register events either when you create the control, using `actxcontrol`, or at any time afterwards, using `registerevent`.

`info = eventlisteners(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Manage events for an instance of the MATLAB control `mwsamp`:

```
f = figure('position', [100 200 200 200]);
%Create an mwsamp control and
%register the Click event
h = actxcontrol('mwsamp.mwsampctrl.2', ...
    [0 0 200 200], f, ...
    {'Click' 'myclick'});
h.eventlisteners
```

MATLAB displays the event name and its event handler, `myclick`:

```
ans =
    'Click'    'myclick'
```

---

Register two more events, `Db1Click` and `MouseDown`:

```
h.registerevent({'Db1Click', 'my2click'; 'MouseDown' 'mymoused'});
h.eventlisteners
```

MATLAB displays all event names and handlers:

```
ans =  
    'Click'          'myclick'  
    'Dblclick'      'my2click'  
    'MouseDown'     'mymoused'
```

---

Unregister all events for the control:

```
h.unregisterallevents  
h.eventlisteners
```

MATLAB displays an empty cell array, indicating the control has no registered events:

```
ans =  
    {}
```

## See Also

# events

---

**Purpose** Event names

**Syntax**  
`events('classname')`  
`events(obj)`  
`e = events(...)`

**Description** `events('classname')` displays the names of the public events for the MATLAB class *classname*, including events inherited from superclasses.

`events(obj)` `obj` is a scalar or array of objects of a MATLAB class.

`e = events(...)` returns the event names in a cell array of strings.

An event is public when the value of its `ListenAccess` attribute is `public` and its `Hidden` attribute value is `false` (default values for both attributes). See “Event Attributes” for a complete list of attributes.

`events` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

**Examples** Get the names of the public events for the `handle` class:

```
events('handle')  
Events for class handle:  
  
    ObjectBeingDestroyed
```

**See Also** `properties` | `methods`

**Tutorials** • “Events”

**Purpose** List of events COM object can trigger

**Syntax**  
`S = h.events`  
`S = events(h)`

**Description** `S = h.events` returns structure array `S` containing all events, both registered and unregistered, known to the COM object, and the function prototype used when calling the event handler routine. For each array element, the structure field is the event name and the contents of that field is the function prototype for that event's handler.

`S = events(h)` is an alternate syntax.

**Tips** COM functions are available on Microsoft Windows systems only.

## Examples **List Control Events Example**

Create an `mwsamp` control and list all events:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.events
```

MATLAB software displays information similar to:

```
Click = void Click()
Db1Click = void Db1Click()
MouseDown = void MouseDown(int16 Button, int16 Shift,
    Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort, int32 typelong,
    double typedouble, string typestring, bool typebool)
```

Assign the output to a variable and get one field of the returned structure:

```
ev = h.events;
ev.MouseDown
```

## events (COM)

---

MATLAB displays:

```
ans =  
    void MouseDown(int16 Button, int16 Shift, Variant x, Variant y)
```

### List Workbook Events Example

Open a Microsoft Excel application and list all events for a Workbook object:

```
myApp = actxserver('Excel.Application');  
wbs = myApp.Workbooks;  
wb = wbs.Add;  
wb.events
```

The MATLAB software displays all events supported by the Workbook object.

```
Open = void Open()  
Activate = void Activate()  
Deactivate = void Deactivate()  
BeforeClose = void BeforeClose(bool Cancel)  
:  
:
```

### See Also

[isevent](#) | [eventlisteners](#) | [registerevent](#) | [unregisterevent](#)  
| [unregisterallevnts](#)

**Purpose** Execute MATLAB command in Automation server

**Syntax** **MATLAB Client**

```
result = h.Execute('command')  
result = Execute(h, 'command')  
result = invoke(h, 'Execute', 'command')
```

**IDL Method Signature**

```
BSTR Execute([in] BSTR command)
```

**Microsoft Visual Basic® Client**

```
Execute(command As String) As String
```

**Description**

The `Execute` function executes the MATLAB statement specified by the string `command` in the MATLAB Automation server attached to handle `h`.

The server returns output from the command in the string, `result`. The `result` string also contains any warning or error messages that might have been issued by MATLAB software as a result of the command.

Note that if you terminate the MATLAB command string with a semicolon and there are no warnings or error messages, `result` might be returned empty.

**Tips**

If you want to be able to display output from `Execute` in the client window, you must specify an output variable (i.e., `result` in the above syntax statements).

Server function names, like `Execute`, are case sensitive when used with dot notation (the first syntax shown).

All three versions of the MATLAB client syntax perform the same operation.

If there is an error, the `Execute` function returns the MATLAB error message with the characters `???` prepended to the text.

COM functions are available on Microsoft Windows systems only.

# Execute

---

## Examples

Execute the MATLAB version function in the server and return the output to the MATLAB client.

### **MATLAB Client**

```
h = actxserver('matlab.application');
server_version = h.Execute('version')
server_version =
ans =
    6.5.0.180913a (R13)
```

### **Visual Basic .NET Client**

```
Dim Matlab As Object
Dim server_version As String
Matlab = CreateObject("matlab.application")
server_version = Matlab.Execute("version")
```

## See Also

[Feval](#) | [PutFullMatrix](#) | [GetFullMatrix](#) | [PutCharArray](#) | [GetCharArray](#)

**Purpose** Read EXIF information from JPEG and TIFF image files

**Syntax**

---

**Note** exifread will be removed in a future release. Use `imfinfo` instead.

---

```
output = exifread(filename)
```

**Description**

`output = exifread(filename)` reads the Exchangeable Image File Format (EXIF) data from the file specified by the string `filename`. `filename` must specify a JPEG or TIFF image file. `output` is a structure containing metadata values about the image or images in `imagefile`.

---

**Note** `exifread` returns all EXIF tags and does not process them in any way.

---

EXIF is a standard used by digital camera manufacturers to store information in the image file, such as, the make and model of a camera, the time the picture was taken and digitized, the resolution of the image, exposure time, and focal length. For more information about EXIF and the meaning of metadata attributes, see <http://www.exif.org/>.

**See Also**

`imfinfo` | `imread`

# exist

---

**Purpose** Check existence of variable, function, folder, or class

**Syntax**  
`exist name`  
`exist name kind`  
`A = exist('name','kind')`

**Description** `exist name` returns the status of `name`:

0	name does not exist.
1	name is a variable in the workspace.
2	One of the following is true: <ul style="list-style-type: none"><li>• <code>name</code> exists on your MATLAB search path as a file with extension <code>.m</code>.</li><li>• <code>name</code> is the name of an ordinary file on your MATLAB search path.</li><li>• <code>name</code> is the full pathname to any file.</li></ul>
3	<code>name</code> exists as a MEX-file on your MATLAB search path.
4	<code>name</code> exists as a Simulink model or library file on your MATLAB search path.
5	<code>name</code> is a built-in MATLAB function.
6	<code>name</code> is a P-file on your MATLAB search path.
7	<code>name</code> is a folder.
8	<code>name</code> is a class. ( <code>exist</code> returns 0 for Java classes if you start MATLAB with the <code>-nojvm</code> option.)

If `name` is a class, then `exist('name')` returns an 8. However, if `name` is a class file, then `exist('name')` returns a 2.

If a file or folder is not on the search path, then `name` must specify either a full pathname, a partial pathname relative to `MATLABPATH`, a partial

pathname relative to your current folder, or the file or folder must reside in your current working folder.

If `name` specifies a filename, that filename may include an extension to preclude conflicting with other similar filenames. For example, `exist('file.ext')`.

`exist name kind` returns the status of `name` for the specified `kind`. If `name` of type `kind` does not exist, it returns 0. The `kind` argument may be one of the following:

<code>builtin</code>	Checks only for built-in functions.
<code>class</code>	Checks only for classes.
<code>dir</code>	Checks only for folders.
<code>file</code>	Checks only for files or folders.
<code>var</code>	Checks only for variables.

If you do not specify a `kind` argument, and `name` belongs to more than one of these categories, `exist` returns one value according to the order of evaluation shown in the table below. For example, if `name` matches both a folder and a file that defines a MATLAB function, `exist` returns 7, identifying it as a folder.

<b>Order of Evaluation</b>	<b>Return Value</b>	<b>Type of Entity</b>
1	1	Variable
2	5	Built-in
3	7	Folder
4	3	MEX-file
5	4	SLX or MDL-file
6	6	P-file

# exist

---

Order of Evaluation	Return Value	Type of Entity
7	2	MATLAB function
8	8	Class

`A = exist('name', 'kind')` is the function form of the syntax.

## Tips

If `name` specifies a filename, MATLAB attempts to locate the file, examines the filename extension, and determines the value to return based on the extension alone. MATLAB does not examine the contents or internal structure of the file.

You can specify a partial path to a folder or file. A partial pathname is a pathname relative to the MATLAB path that contains only the trailing one or more components of the full pathname. For example, both of the following commands return 2, identifying `mkdir.m` as a MATLAB function. The first uses a partial pathname:

```
exist('matlab/general/mkdir.m')
exist([matlabroot '/toolbox/matlab/general/mkdir.m'])
```

To check for the existence of more than one variable, use the `ismember` function. For example,

```
a = 5.83;
c = 'teststring';
ismember({'a', 'b', 'c'}, who)
```

```
ans =
     1     0     1
```

## Examples

This example uses `exist` to check whether a MATLAB function is a built-in function or a file:

```
type = exist('plot')
type =
```

5

This indicates that `plot` is a built-in function.

Run `exist` on a class folder and then on the constructor within that folder:

```
exist('@portfolio')
ans =
     7                % @portfolio is a folder

exist('@portfolio\portfolio')
ans =
     2                % portfolio is a MATLAB function
```

The following example indicates that `testresults` is both a variable in the workspace and a folder on the search path:

```
exist('testresults','var')
ans =
     1
exist('testresults','dir')
ans =
     7
```

# exit

---

<b>Purpose</b>	Terminate MATLAB program (same as <code>quit</code> )
<b>Alternatives</b>	As an alternative to the <code>exit</code> function, click the Close box in the MATLAB desktop.
<b>Syntax</b>	<code>exit</code> <code>exit(code)</code>
<b>Description</b>	<p><code>exit</code> terminates the current session of MATLAB after running <code>finish.m</code>, if the file <code>finish.m</code> exists. It performs the same as <code>quit</code> and takes the same termination options, such as <b>force</b>.</p> <p><code>exit(code)</code> returns exit code when calling a MATLAB command from the system command line.</p>
<b>See Also</b>	<code>quit</code>   <code>finish</code>

---

<b>Purpose</b>	Exponential
<b>Syntax</b>	$Y = \exp(X)$
<b>Description</b>	$Y = \exp(X)$ returns the exponential for each element of $X$ . <code>exp</code> operates element-wise on arrays. For complex $x + i * y$ , <code>exp</code> returns the complex exponential $e^z = e^x(\cos y + i \sin y)$ . Use <code>expm</code> for matrix exponentials.
<b>Examples</b>	Find the value of $e^{i\pi}$ :  <pre>y=exp(i*pi)</pre> returns  <pre>y =  -1.0000 + 0.0000i</pre>
<b>See Also</b>	<code>expm</code>   <code>log</code>

# expint

---

**Purpose** Exponential integral

**Syntax**  $Y = \text{expint}(X)$

**Definitions** The exponential integral computed by this function is defined as

$$E_1(x) = \int_x^{\infty} e^{-t} / t dt$$

Another common definition of the exponential integral function is the Cauchy principal value integral

$$\text{Ei}(x) = \int_{-\infty}^x e^t / t dt$$

which, for real positive  $x$ , is related to  $\text{expint}$  as

$$E_1(-x) = -\text{Ei}(x) - i\pi$$

**Description**  $Y = \text{expint}(X)$  evaluates the exponential integral for each element of  $X$ .

**References** [1] Abramowitz, M. and I. A. Stegun. *Handbook of Mathematical Functions*. Chapter 5, New York: Dover Publications, 1965.

**Purpose** Matrix exponential

**Syntax**  $Y = \text{expm}(X)$

**Description**  $Y = \text{expm}(X)$  computes the matrix exponential of  $X$ .

Although it is not computed this way, if  $X$  has a full set of eigenvectors  $V$  with corresponding eigenvalues  $D$ , then

$$[V,D] = \text{EIG}(X) \text{ and } \text{EXPM}(X) = V \cdot \text{diag}(\exp(\text{diag}(D))) / V$$

Use `exp` for the element-by-element exponential.

**Algorithms** `expm` uses the Padé approximation with scaling and squaring. See reference [3], below.

---

**Note** The files, `expdemo1.m`, `expdemo2.m`, and `expdemo3.m` illustrate the use of Padé approximation, Taylor series approximation, and eigenvalues and eigenvectors, respectively, to compute the matrix exponential. References [1] and [2] describe and compare many algorithms for computing a matrix exponential.

---

**Examples** This example computes and compares the matrix exponential of  $A$  and the exponential of  $A$ .

```
A = [ 1      1      0
      0      0      2
      0      0     -1 ];
```

```
expm(A)
ans =
  2.7183    1.7183    1.0862
  0         1.0000    1.2642
  0         0         0.3679
```

```
exp(A)
ans =
    2.7183    2.7183    1.0000
    1.0000    1.0000    7.3891
    1.0000    1.0000    0.3679
```

Notice that the diagonal elements of the two results are equal. This would be true for any triangular matrix. But the off-diagonal elements, including those below the diagonal, are different.

# export2wsdlg

---

## Purpose

Export variables to workspace

## Syntax

```
export2wsdlg(checkboxlabels,defaultvariablenames,  
itemstoexport)  
export2wsdlg(checkboxlabels,defaultvariablenames,  
itemstoexport,title)  
export2wsdlg(checkboxlabels,defaultvariablenames,  
itemstoexport,title,selected)  
export2wsdlg(checkboxlabels,defaultvariablenames,  
itemstoexport,title,selected,helpfunction)  
export2wsdlg(checkboxlabels,defaultvariablenames,  
itemstoexport,title,selected,helpfunction,functionlist)  
hdialog = export2wsdlg(...)  
[hdialog,ok_pressed] = export2wsdlg(...)
```

## Description

`export2wsdlg(checkboxlabels,defaultvariablenames,itemstoexport)` creates a dialog with a series of check boxes and edit fields. `checkboxlabels` is a cell array of labels for the check boxes. `defaultvariablenames` is a cell array of strings that serve as a basis for variable names that appear in the edit fields. `itemstoexport` is a cell array of the values to be stored in the variables. If there is only one item to export, `export2wsdlg` creates a text control instead of a check box.

---

**Note** By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding.

---

`export2wsdlg(checkboxlabels,defaultvariablenames,itemstoexport,title)` creates the dialog with `title` as its title.

`export2wsdlg(checkboxlabels,defaultvariablenames,itemstoexport,title,selected)` creates the dialog allowing the user to control which check boxes are checked. `selected` is a logical array whose length is the same as `checkboxlabels`. True indicates that the check box should initially be checked, false unchecked.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction)` creates the dialog with a help button. `helpfunction` is a callback that displays help.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction,functionlist)` creates a dialog that enables the user to pass in `functionlist`, a cell array of functions and optional arguments that calculate, then return the value to export. `functionlist` should be the same length as `checkboxlabels`.

`hdialog = export2wsdlg(...)` returns the handle of the dialog.

`[hdialog,ok_pressed] = export2wsdlg(...)` sets `ok_pressed` to true if the OK button is pressed, or false otherwise. If two return arguments are requested, `hdialog` is [] and the function does not return until the dialog is closed.

The user can edit the text fields to modify the default variable names. If the same name appears in multiple edit fields, `export2wsdlg` creates a structure using that name. It then uses the `defaultvariablenames` as field names for that structure.

The lengths of `checkboxlabels`, `defaultvariablenames`, `itemstoexport` and `selected` must all be equal.

The strings in `defaultvariablenames` must be unique.

## Examples

This example creates a dialog box that enables the user to save the variables `sumA` and/or `meanA` to the workspace. The dialog box title is `Save Sums to Workspace`.

```
A = randn(10,1);
checkLabels = {'Save sum of A to variable named:' ...
              'Save mean of A to variable named:'};
varNames = {'sumA','meanA'};
items = {sum(A),mean(A)};
export2wsdlg(checkLabels,varNames,items,...
             'Save Sums to Workspace');
```

## Purpose

Identity matrix

## Syntax

```
I = eye
I = eye(n)
I = eye(n,m)
I = eye(sz)

I = eye(classname)
I = eye(n,classname)
I = eye(n,m,classname)
I = eye(sz,classname)

I = eye('like',p)
I = eye(n,'like',p)
I = eye(n,m,'like',p)
I = eye(sz,'like',p)
```

## Description

`I = eye` returns the scalar, 1.

`I = eye(n)` returns an n-by-n identity matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(n,m)` returns an n-by-m matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(sz)` returns an array with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)`. For example, `eye([2,3])` returns a 2-by-3 array with ones on the main diagonal and zeros elsewhere.

`I = eye(classname)` returns a scalar, 1, where the string, `classname`, specifies the data type. For example, `eye('int8')` returns a scalar, 8-bit integer.

`I = eye(n,classname)` returns an n-by-n identity matrix of data type `classname`.

`I = eye(n,m,classname)` returns an n-by-m matrix of data type `classname` with ones on the main diagonal and zeros elsewhere.

`I = eye(sz,classname)` returns a matrix with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)` and `classname` defines `class(I)`.

`I = eye('like',p)` returns a scalar, 1, with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`I = eye(n, 'like', p)` returns an n-by-n identity matrix like `p`.

`I = eye(n,m, 'like', p)` returns an n-by-m matrix like `p`.

`I = eye(sz, 'like', p)` returns a matrix like `p` where the size vector, `sz`, defines `size(I)`.

## Input Arguments

### **n - Size of first dimension of I**

integer value

Size of first dimension of I, specified as an integer value.

- If `n` is the only integer input argument, then I is a square n-by-n identity matrix.
- If `n` is 0, then I is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**m - Size of second dimension of I**

integer value

Size of second dimension of I, specified as an integer value.

- If m is 0, then I is an empty matrix.
- If m is negative, then it is treated as 0.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**sz - Size of I**

row vector of no more than two integer values

Size of I, specified as a row vector of no more than two integer values.

- If an element of sz is 0, then I is an empty matrix.
- If an element of sz is negative, then the element is treated as 0.

**Example:** sz = [2,3] defines I as a 2-by-3 matrix.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**classname - Output class**

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

**Data Types**

char

**p - Prototype**

numeric variable

Prototype, specified as a numeric variable.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**Complex Number Support:** Yes

**Examples****Square Identity Matrix**

Create a 4-by-4 identity matrix.

```
I = eye(4)
```

```
I =
```

```
    1    0    0    0
    0    1    0    0
    0    0    1    0
    0    0    0    1
```

**Rectangular Matrix**

Create a 2-by-3 identity matrix.

```
I = eye(2,3)
```

```
I =
```

```
    1    0    0
    0    1    0
```

**Identity Vector**

Create a 3-by-1 identity vector.

```
sz = [3,1];
```

```
I = eye(sz)
```

```
I =
```

```
    1
    0
```

0

### **Nondefault Numeric Data Type**

Create a 3-by-3 identity matrix whose elements are 32-bit unsigned integers.

```
I = eye(3, 'uint32'),  
class(I)
```

I =

```
     1     0     0  
     0     1     0  
     0     0     1
```

ans =

uint32

### **Complex Identity Matrix**

Create a 2-by-2 identity matrix that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create an identity matrix that is complex like p.

```
I = eye(2, 'like', p)
```

I =

```
 1.0000 + 0.0000i  0.0000 + 0.0000i  
 0.0000 + 0.0000i  1.0000 + 0.0000i
```

### Sparse Identity Matrix

Define a 5-by-5 sparse matrix.

```
p = sparse(5,5,pi);
```

Create a 5-by-5 identity matrix that is sparse like P.

```
I = eye(5, 'like', p)
```

```
I =
```

```
    (1,1)    1
    (2,2)    1
    (3,3)    1
    (4,4)    1
    (5,5)    1
```

### Size and Numeric Data Type Defined by Existing Array

Define a 2-by-2 matrix of single precision.

```
p = single([1 3 ; 2 4]);
```

Create an identity matrix that is the same size and data type as P.

```
I = eye(size(p), 'like', p),  
class(I)
```

```
I =
```

```
    1    0
    0    1
```

```
ans =
```

```
single
```

## **See Also**

## **Concepts**

**Purpose** Easy-to-use contour plotter

**Syntax**

```
ezcontour(fun)
ezcontour(fun,domain)
ezcontour(...,n)
ezcontour(axes_handle,...)
h = ezcontour(...)
```

**Description** `ezcontour(fun)` plots the contour lines of `fun(x,y)` using the `contour` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle for a MATLAB file function or an anonymous function (see [function handle](#) and “Anonymous Functions”) or a string (see [Tips](#)).

`ezcontour(fun,domain)` plots `fun(x,y)` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezcontour(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontour(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezcontour(...)` returns the handle to a contour object in `h`. `ezcontour` automatically adds a title and axis labels.

**Tips** **Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontour`. For example, the MATLAB syntax for a contour plot of the expression

```
sqrt(x.^2 + y.^2)
```

is written as

```
ezcontour('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezcontour`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontour('u^2 - v^3', [0,1], [3,6])` plots the contour lines for  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontour`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);  
ezcontour(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezcontour` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)  
z = x.^k - y.^k - 1;
```

then use an anonymous function to specify that parameter:

```
ezcontour(@(x,y)myfun(x,y,2))
```

## Examples

### Create Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables,  $x$  and  $y$ .

$$f(x, y) = 3(1 - x)^2 e^{-x^2 - (y+1)^2} - 10 \left( \frac{x}{5} - x^3 - y^5 \right) e^{-x^2 - y^2} - \frac{1}{3} e^{-(x+1)^2 - y^2}$$

The ezcontour function requires a function handle argument. Write this mathematical expression in MATLAB syntax as an anonymous function with handle f. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...  
- 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...  
- 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, f, to ezcontour. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontour(f, [-3,3], 49)
```

## ezcontour

In this particular case, the title string is too long to fit at the top of the graph so MATLAB abbreviates the string.

**Purpose** Easy-to-use filled contour plotter

**Syntax**

```
ezcontourf(fun)
ezcontourf(fun, domain)
ezcontourf(..., n)
ezcontourf(axes_handle, ...)
h = ezcontourf(...)
```

**Description** `ezcontourf(fun)` plots the contour lines of `fun(x,y)` using the `contourf` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see Tips).

`ezcontourf(fun, domain)` plots `fun(x,y)` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]`, where  $\min < x < \max$ ,  $\min < y < \max$ .

`ezcontourf(..., n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontourf(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = ezcontourf(...)` returns the handle to a contour object in `h`.

`ezcontourf` automatically adds a title and axis labels.

**Tips** **Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontourf`. For example, the MATLAB syntax for a filled contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezcontourf('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezcontourf`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontourf('u^2 - v^3',[0,1],[3,6])` plots the contour lines for  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontourf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);  
ezcontourf(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezcontourf` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)  
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezcontourf(@(x,y)myfun(x,y,2))
```

## Examples

### Create Filled Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables,  $x$  and  $y$ .

$$f(x, y) = 3(1 - x)^2 e^{-x^2 - (y+1)^2} - 10 \left( \frac{x}{5} - x^3 - y^5 \right) e^{-x^2 - y^2} - \frac{1}{3} e^{-(x+1)^2 - y^2}$$

The `ezcontourf` function requires a function handle argument. Write this mathematical expression in MATLAB syntax as an anonymous function with handle `f`. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...  
    - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...  
    - 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, `f`, to `ezcontourf`. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontourf(f, [-3,3],49)
```

# ezcontourf

In this particular case, the title string is too long to fit at the top of the graph so MATLAB abbreviates the string.

## How To

- [Anonymous Functions](#)

**Purpose**

Easy-to-use 3-D mesh plotter

**Syntax**

```
ezmesh(fun)
ezmesh(fun, domain)
ezmesh(funx, funy, funz)
ezmesh(funx, funy, funz, [smin, smax, tmin, tmax])
ezmesh(funx, funy, funz, [min, max])
ezmesh(..., n)
ezmesh(..., 'circ')
ezmesh(axes_handle, ...)
h = ezmesh(...)
```

**Description**

`ezmesh(fun)` creates a graph of  $\text{fun}(x, y)$  using the mesh function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezmesh(fun, domain)` plots `fun` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\text{min} < x < \text{max}$ ,  $\text{min} < y < \text{max}$ ).

`ezmesh(funx, funy, funz)` plots the parametric surface  $\text{funx}(s, t)$ ,  $\text{funy}(s, t)$ , and  $\text{funz}(s, t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezmesh(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezmesh(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezmesh(..., n)` plots `fun` over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezmesh(..., 'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmesh(...)` returns the handle to a surface object in `h`.

## Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmesh`. For example, the MATLAB syntax for a mesh plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmesh('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezmesh`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmesh('u^2 - v^3',[0,1],[3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmesh`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);  
ezmesh(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezmesh` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)  
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmesh(@(x,y)myfun(x,y,2))
```

**Examples**

This example visualizes the function

$$f(x,y) = ex^{-x^2-y^2}$$

with a mesh plot drawn on a 40-by-40 grid. The mesh lines are set to a uniform blue color by setting the colormap to a single color:

```
fh = @(x,y) x.*exp(-x.^2-y.^2);  
ezmesh(fh,40)  
colormap([0 0 1])
```

# ezmesh

---

## See Also

[ezmeshc](#) | [function\\_handle](#) | [mesh](#)

## How To

- [Anonymous Functions](#)

**Purpose**

Easy-to-use combination mesh/contour plotter

**Syntax**

```
ezmeshc(fun)
ezmeshc(fun,domain)
ezmeshc(funx,funy,funz)
ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])
ezmeshc(funx,funy,funz,[min,max])
ezmeshc(...,n)
ezmeshc(...,'circ')
ezmesh(axes_handle,...)
h = ezmeshc(...)
```

**Description**

`ezmeshc(fun)` creates a graph of `fun(x,y)` using the `meshc` function. `fun` is plotted over the default domain  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezmeshc(fun,domain)` plots `fun` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezmeshc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmeshc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmeshc(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmeshc(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmeshc(...)` returns the handle to a surface object in `h`.

## Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmeshc`. For example, the MATLAB syntax for a mesh/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmeshc('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezmeshc`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmeshc('u^2 - v^3',[0,1],[3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmeshc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);  
ezmeshc(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezmeshc` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)  
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmeshc(@(x,y)myfun(x,y,2))
```

**Examples**

Create a mesh/contour graph of the expression

$$f(x,y) = \frac{y}{1+x^2+y^2}$$

over the domain  $-5 < x < 5$ ,  $-2\pi < y < 2\pi$ :

```
ezmeshc('y/(1 + x^2 + y^2)', [-5,5, -2*pi,2*pi])  
view(-65.5,26)
```

Use the mouse to rotate the axes to better observe the contour lines  
(this picture uses a view of azimuth = -65.5 and elevation = 26)

## See Also

[ezmesh](#) | [ezsurf](#) | [function\\_handle](#) | [meshc](#)

## How To

- [Anonymous Functions](#)

**Purpose**

Easy-to-use function plotter

**Syntax**

```
ezplot(fun)
ezplot(fun, [xmin,xmax])
ezplot(fun2)
ezplot(fun2, [xymin,xymax])
ezplot(fun2, [xmin,xmax,ymin,ymax])
ezplot(funx,funy)
ezplot(funx,funy, [tmin,tmax])
ezplot(...,figure_handle)
ezplot(axes_handle,...)
h = ezplot(...)
```

**Description**

`ezplot(fun)` plots the expression  $\text{fun}(x)$  over the default domain  $-2\pi < x < 2\pi$ , where  $\text{fun}(x)$  is an explicit function of only  $x$ .

`fun` can be a function handle or a string.

`ezplot(fun, [xmin,xmax])` plots  $\text{fun}(x)$  over the domain:  $x_{\min} < x < x_{\max}$ .

For an implicit function, `fun2(x,y)`:

`ezplot(fun2)` plots  $\text{fun2}(x,y) = 0$  over the default domain  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`ezplot(fun2, [xymin,xymax])` plots  $\text{fun2}(x,y) = 0$  over  $xy_{\min} < x < xy_{\max}$  and  $xy_{\min} < y < xy_{\max}$ .

`ezplot(fun2, [xmin,xmax,ymin,ymax])` plots  $\text{fun2}(x,y) = 0$  over  $x_{\min} < x < x_{\max}$  and  $y_{\min} < y < y_{\max}$ .

`ezplot(funx,funy)` plots the parametrically defined planar curve  $\text{funx}(t)$  and  $\text{funy}(t)$  over the default domain  $0 < t < 2\pi$ .

`ezplot(funx,funy, [tmin,tmax])` plots  $\text{funx}(t)$  and  $\text{funy}(t)$  over  $t_{\min} < t < t_{\max}$ .

`ezplot(..., figure_handle)` plots the given function over the specified domain in the figure window identified by the handle `figure`.

`ezplot(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot(...)` returns the handle to all the plot objects in `h`.

## Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot`. For example, the MATLAB syntax for a plot of the expression

```
x.^2 - y.^2
```

which represents an implicitly defined function, is written as

```
ezplot('x^2 - y^2')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezplot`.

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot`,

```
fh = @(x,y) sqrt(x.^2 + y.^2 - 1);  
ezplot(fh)  
axis equal
```

which plots a circle. Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
```

```
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezplot(@(x,y)myfun(x,y,2))
```

### Controlling Line Color

ezplot colors lines according to the type of graphics object it chooses to plot the input function.

- For an implicit function, ezplot uses a `LineSeries` object to generate the graph. To change the color, you should set the `Color` property.
- For an explicit function, the graph generated is a `Hgggroup` object. So, to change the color, you should set the `LineColor` property.

### Example

#### Plot an Explicit Function

Plot the explicit function  $x^2$  over the domain  $[-2\pi, 2\pi]$ .

```
ezplot('x^2')
```

# ezplot

---

## Plot an Implicit Function

Plot the implicitly defined function  $x^2 - y^4 = 0$  over the domain  $[-2\pi, 2\pi]$ .

```
ezplot('x^2-y^4')
```

**See Also** [ezplot3](#) | [ezpolar](#) | [function\\_handle](#) | [plot](#)

**How To**

- [Anonymous Functions](#)

# ezplot3

---

**Purpose** Easy-to-use 3-D parametric curve plotter

**Syntax**

```
ezplot3(funx,funy,funz)
ezplot3(funx,funy,funz,[tmin,tmax])
ezplot3(...,'animate')
ezplot3(axes_handle,...)
h = ezplot3(...)
```

**Description**

`ezplot3(funx,funy,funz)` plots the spatial curve  $\text{funx}(t)$ ,  $\text{funy}(t)$ , and  $\text{funz}(t)$  over the default domain  $0 < t < 2\pi$ .

`funx`, `funy`, and `funz` can be function handles or strings (see the Tips section).

`ezplot3(funx,funy,funz,[tmin,tmax])` plots the curve  $\text{funx}(t)$ ,  $\text{funy}(t)$ , and  $\text{funz}(t)$  over the domain  $t_{\min} < t < t_{\max}$ .

`ezplot3(...,'animate')` produces an animated trace of the spatial curve.

`ezplot3(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot3(...)` returns the handle to the plotted objects in `h`.

**Tips** **Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot3`. For example, the MATLAB syntax for a plot of the expression

```
x = s./2, y = 2.*s, z = s.^2;
```

which represents a parametric function, is written as

```
ezplot3('s/2','2*s','s^2')
```

That is,  $s/2$  is interpreted as `s./2` in the string you pass to `ezplot3`.

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot3`.

```
fh1 = @(s) s./2; fh2 = @(s) 2.*s; fh3 = @(s) s.^2;
ezplot3(fh1,fh2,fh3)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezplot3` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfunkt`:

```
function s = myfunkt(t,k)
s = t.^k.*sin(t);
```

then you can use an anonymous function to specify that parameter:

```
ezplot3(@cos,@(t)myfunkt(t,1),@sqrt)
```

## Examples

### Plot a Parametric Curve

Plot this parametric curve over the domain  $[0, 6\pi]$ .

$$x = \sin(t), \quad y = \cos(t), \quad z = t$$

```
ezplot3('sin(t)', 'cos(t)', 't', [0,6*pi])
```

# ezplot3

---

## See Also

[ezplot](#) | [ezpolar](#) | [function\\_handle](#) | [plot3](#)

## How To

- [Anonymous Functions](#)

**Purpose**

Easy-to-use polar coordinate plotter

**Syntax**

```
ezpolar(fun)
ezpolar(fun,[a,b])
ezpolar(axes_handle,...)
h = ezpolar(...)
```

**Description**

`ezpolar(fun)` plots the polar curve  $\rho = \text{fun}(\theta)$  over the default domain  $0 < \theta < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezpolar(fun,[a,b])` plots `fun` for  $a < \theta < b$ .

`ezpolar(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezpolar(...)` returns the handle to a line object in `h`.

**Tips****Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezpolar`. For example, the MATLAB syntax for a plot of the expression

```
t.^2.*cos(t)
```

which represents an implicitly defined function, is written as

```
ezpolar('t^2*cos(t)')
```

That is, `t^2` is interpreted as `t.^2` in the string you pass to `ezpolar`.

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezpolar`.

```
fh = @(t) t.^2.*cos(t);  
ezpolar(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezpolar` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k1` and `k2` in `myfun`:

```
function s = myfun(t,k1,k2)  
s = sin(k1*t).*cos(k2*t);
```

then you can use an anonymous function to specify the parameters:

```
ezpolar(@(t)myfun(t,2,3))
```

## Examples

### Polar Plot of Mathematical Function

Plot the function  $1 + \cos(t)$  over the domain  $[0, 2\pi]$ .

```
figure  
ezpolar('1+cos(t)')
```

**See Also**

**How To**

- [Anonymous Functions](#)

## Purpose

Easy-to-use 3-D colored surface plotter

## Syntax

```
ezsurf(fun)
ezsurf(fun, domain)
ezsurf(funx, funy, funz)
ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])
ezsurf(funx, funy, funz, [min, max])
ezsurf(..., n)
ezsurf(..., 'circ')
ezsurf(axes_handle, ...)
h = ezsurf(...)
```

## Description

`ezsurf(fun)` creates a graph of  $\text{fun}(x, y)$  using the `surf` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun, domain)` plots `fun` over the specified domain. `domain` must be a vector. See the “Algorithms” on page 1-1840 section for details on vector inputs vs axes limit outputs.

`ezsurf(funx, funy, funz)` plots the parametric surface  $\text{funx}(s, t)$ ,  $\text{funy}(s, t)$ , and  $\text{funz}(s, t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezsurf(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezsurf(..., n)` plots `fun` over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezsurf(..., 'circ')` plots `fun` over a disk centered on the domain.

`ezsurf(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handle to a surface object in `h`.

## Tips

ezsurf and ezsurfz do not accept complex inputs.

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezsurf. For example, the MATLAB syntax for a surface plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to ezsurf.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints  $u_{\min}$ ,  $u_{\max}$ ,  $v_{\min}$ , and  $v_{\max}$  are sorted alphabetically. Thus, `ezsurf('u^2 - v^3', [0,1], [3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to ezsurf.

```
fh = @(x,y) sqrt(x.^2 + y.^2);  
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since ezsurf does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)  
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

## Examples

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

ezsurf does not graph points where the mathematical function is not defined (these data points are set to NaNs, which do not plot). This example illustrates this filtering of singularities/discontinuous points by graphing the function

$$f(x, y) = \text{real}(a \tan(x + iy))$$

over the default domain  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ :

```
ezsurf('real(atan(x+i*y))')
```

Using `surf` to plot the same data produces a graph without filtering of discontinuities (as well as requiring more steps):

```
[x,y] = meshgrid(linspace(-2*pi,2*pi,60));  
z = real(atan(x+1i.*y));  
surf(x,y,z)
```

Note also that `ezsurf` creates graphs that have axis labels, a title, and extend to the axis limits.

## Algorithms

`ezsurf` determines the  $x$ - and  $y$ -axes limits in different ways depending on how you input the domain (if at all). In the following table,  $R$  is the vector  $[x_{\min}, x_{\max}, y_{\min}, y_{\max}]$  and  $v$  is the manually entered domain vector.

Number of domain values specified:	Resulting domain vector:
<code>v = [ ];</code>	<code>R = [-2*pi, 2*pi, -2*pi, 2*pi];</code>
<code>v = [ v(1) ];</code>	<code>R = double([-abs(v),abs(v),-abs(v),abs(v)]);</code>
<code>v = [ v(1) v(2) ];</code>	<code>R = double([v(1),v(2),v(1),v(2)]);</code>
<code>v = [ v(1) v(2) v(3) ];</code>	<code>R = double([-v(1),v(2),-abs(v(3)),abs(v(3))]);</code>
<code>v = [ v(1) v(2) v(3) v(4) ];</code>	<code>R = double(v);</code>
<code>v = [ v(1)..v(n) ];</code> <code>n&gt;4</code>	<code>R = double([-abs(v(1)), abs(v(1)), -abs(v(1)), abs(v(1))]);</code>

If you specify a single number in non-vector format (without square brackets, [ ]), ezsurf interprets it as the n, the number of points desired between the axes max and min values.

By default, ezsurf uses 60 points between the max and min values of an axes. When the min and max values are the default values (R = [-2\*pi, 2\*pi, -2\*pi, 2\*pi]); ezsurf ensures the 60 points fall within the non-complex range of the specified equation. For example,

$\sqrt{1-x^2-y^2}$  is only real when  $x^2-y^2 \leq 1$ . The default graph of this function looks like this:

```
ezsurf('sqrt(1-x^2-y^2)')
```

You can see that there are 60 points between the minimum and maximum values for which  $\sqrt{1-x^2-y^2}$  has real values. However, when you specify the domain values to be the same as the default ( $R = [-2*\pi, 2*\pi, -2*\pi, 2*\pi]$ ), a different result appears:

```
ezsurf('sqrt(1-x^2-y^2)',[-2*pi 2*pi])
```

In this case, the graphic limits are the same, but ezsurf used 60 points between the user-defined limits instead of checking to see if all those points would have real answers.

### How To

- [Anonymous Functions](#)

## Purpose

Easy-to-use combination surface/contour plotter

## Syntax

```
ezsurf(fun)
ezsurf(fun,domain)
ezsurf(funx,funy,funz)
ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])
ezsurf(funx,funy,funz,[min,max])
ezsurf(...,n)
ezsurf(...,'circ')
ezsurf(axes_handle,...)
h = ezsurf(...)
```

## Description

`ezsurf(fun)` creates a graph of  $fun(x,y)$  using the `surf` function. The function `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun,domain)` plots `fun` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezsurf(funx,funy,funz)` plots the parametric surface  $funx(s,t)$ ,  $funy(s,t)$ , and  $funz(s,t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezsurf(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezsurf(...,n)` plots  $f$  over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezsurf(...,'circ')` plots  $f$  over a disk centered on the domain.

`ezsurf(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handles to the graphics objects in `h`.

## Tips

`ezsurf` and `ezsurf` do not accept complex inputs.

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurf`. For example, the MATLAB syntax for a surface/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurf`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurf('u^2 - v^3', [0,1], [3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezsurf` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

## Examples

Create a surface/contour plot of the expression

$$f(x,y) = \frac{y}{1+x^2+y^2}$$

over the domain  $-5 < x < 5$ ,  $-2\pi < y < 2\pi$ , with a computational grid of size 35-by-35:

```
ezsurf('y/(1 + x^2 + y^2)', [-5,5, -2*pi,2*pi], 35)
```

Put the plot in `rotate3d` mode to use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26).

**How To**

- [Anonymous Functions](#)

# TriRep.faceNormals

---

**Purpose** (Will be removed) Unit normals to specified triangles

---

**Note** `faceNormals(TriRep)` will be removed in a future release. Use `faceNormal(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `FN = faceNormals(TR, TI)`

**Description** `FN = faceNormals(TR, TI)` returns the unit normal vector to each of the specified triangles `TI`.

---

**Note** This query is only applicable to triangular surface meshes.

---

## Input Arguments

`TR` Triangulation representation.  
`TI` Column vector of indices that index into the triangulation matrix `TR.Triangulation`.

## Output Arguments

`FN` `m`-by-3 matrix. `m = length(TI)`, the number of triangles to be queried. Each row `FN(i, :)` represents the unit normal vector to triangle `TI(i)`.  
If `TI` is not specified the unit normal information for the entire triangulation is returned, where the normal associated with triangle `i` is the `i`'th row of `FN`.

## Examples

Triangulate a sample of random points on the surface of a sphere and use the `TriRep` to compute the normal to each triangle:

```
numpts = 100;
```

```
theta = rand(numpts,1)*2*pi;
phi = rand(numpts,1)*pi;
x = cos(theta).*sin(phi);
y = sin(theta).*sin(phi);
z = cos(phi);
dt = DelaunayTri(x,y,z);
[tri Xb] = freeBoundary(dt);
tr = TriRep(tri, Xb);
P = incenters(tr);
fn = faceNormals(tr);
trisurf(tri,Xb(:,1),Xb(:,2),Xb(:,3), ...
        'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

Display the result using a quiver plot:

```
quiver3(P(:,1),P(:,2),P(:,3), ...
        fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```

# TriRep.faceNormals

**See Also** prod

# false

---

**Purpose** Logical 0 (false)

**Syntax**  
`false`  
`false(n)`  
`false(m, n)`  
`false(m, n, p, ...)`  
`false(size(A))`  
`false(..., 'like', p)`

**Description** `false` is shorthand for `logical(0)`.  
`false(n)` is an  $n$ -by- $n$  matrix of logical zeros.  
`false(m, n)` or `false([m, n])` is an  $m$ -by- $n$  matrix of logical zeros.  
`false(m, n, p, ...)` or `false([m n p ...])` is an  $m$ -by- $n$ -by- $p$ -by-... array of logical zeros.

---

**Note** The size inputs  $m, n, p, \dots$  should be nonnegative integers. Negative integers are treated as 0.

---

`false(size(A))` is an array of logical zeros that is the same size as array  $A$ .

`false(..., 'like', p)` is an array of logical zeros of the same data type and sparsity as the logical array  $p$ .

**Tips** `false(n)` is much faster and more memory efficient than `logical(zeros(n))`.

**See Also** `true` | `logical`

**Purpose** Close one or all open files

**Syntax** `fclose(fileID)`  
`fclose('all')`  
`status = fclose(...)`

**Description** `fclose(fileID)` closes an open file. *fileID* is an integer file identifier obtained from `fopen`.  
`fclose('all')` closes all open files.  
`status = fclose(...)` returns a *status* of 0 when the close operation is successful. Otherwise, it returns -1.

**See Also** `ferror` | `fopen` | `frewind` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf` | `fread` | `fwrite`

# fclose (serial)

---

**Purpose** Disconnect serial port object from device

**Syntax** `fclose(obj)`

**Description** `fclose(obj)` disconnects `obj` from the device, where `obj` is a serial port object or an array of serial port objects.

**Tips** If `obj` was successfully disconnected, then the `Status` property is configured to `closed` and the `RecordStatus` property is configured to `off`. You can reconnect `obj` to the device using the `fopen` function.

An error is returned if you issue `fclose` while data is being written asynchronously. In this case, you should abort the write operation with the `stopasync` function, or wait for the write operation to complete.

If you use the `help` command to display help for `fclose`, then you need to supply the pathname shown below.

```
help serial/fclose
```

**Examples** This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, and then disconnects `s` from the device using `fclose`.

```
s = serial('COM1');  
fopen(s)  
fprintf(s, '*IDN?')  
idn = fscanf(s);  
fclose(s)
```

At this point, the device is available to be connected to a serial port object. If you no longer need `s`, you should remove from memory with the `delete` function, and remove it from the workspace with the `clear` command.

**See Also** `clear` | `delete` | `fopen` | `stopasync` | `RecordStatus` | `Status`

**Purpose**

Plot velocity vectors

**Syntax**

```
feather(U,V)
feather(Z)
feather(...,LineStyle)
feather(axes_handle,...)
h = feather(...)
```

**Description**

A feather plot displays vectors emanating from equally spaced points along a horizontal axis. You express the vector components relative to the origin of the respective vector.

`feather(U,V)` displays the vectors specified by `U` and `V`, where `U` contains the  $x$  components as relative coordinates, and `V` contains the  $y$  components as relative coordinates.

`feather(Z)` displays the vectors specified by the complex numbers in `Z`. This is equivalent to `feather(real(Z), imag(Z))`.

`feather(...,LineStyle)` draws a feather plot using the line type, marker symbol, and color specified by `LineStyle`.

`feather(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = feather(...)` returns the handles to line objects in `h`.

**Examples****Create Feather Plot**

Define `theta` as values between  $-2\pi$  and  $2\pi$ . Define `r` as a vector the same size as `theta`.

```
theta = -pi/2:pi/16:pi/2;
r = 2*ones(size(theta));
```

# feather

---

Create a feather plot showing the direction of `theta`. Since `feather` uses Cartesian coordinates, convert `theta` and `r` to Cartesian coordinates using `pol2cart`.

```
[u,v] = pol2cart(theta,r);  
feather(u,v);
```

**See Also**    [compass](#) | [LineSpec](#) | [rose](#)

**Purpose** (Will be removed) Sharp edges of surface triangulation

---

**Note** `featureEdges(TriRep)` will be removed in a future release. Use `featureEdges(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `FE = featureEdges(TR, filterangle)`

**Description** `FE = featureEdges(TR, filterangle)` returns an edge matrix `FE`. This method is typically used to extract the sharp edges in the surface mesh for the purpose of display. Edges that are shared by only one triangle and edges that are shared by more than two triangles are considered to be feature edges by default.

---

**Note** This query is only applicable to triangular surface meshes.

---

## Input Arguments

<code>TR</code>	Triangulation representation.
<code>filterangle</code>	The threshold angle in radians. Must be in the range $(0, \pi)$ . <code>featureEdges</code> will return adjacent triangles that have a dihedral angle that deviates from $\pi$ by an angle greater than <code>filterangle</code> .

## Output Arguments

<code>FE</code>	Edges of the triangulation. <code>FE</code> is of size <code>m-by-2</code> where <code>m</code> is the number of computed feature edges in the mesh. The vertices of the edges index into the array of points representing the vertex coordinates, <code>TR.X</code> .
-----------------	--

# TriRep.featureEdges

---

## Examples

Create a surface triangulation:

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
dt = DelaunayTri(x,y);
tri = dt(:,:);
```

Elevate the 2-D mesh to create a surface:

```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(tri,x,y,z, 'FaceColor', 'cyan');
axis equal;
% TRISURF display of surface mesh
% showing mesh edges
```

Compute the feature edges using a filter angle of  $\pi/6$ :

```
tr = TriRep(tri, x,y,z);
fe = featureEdges(tr,pi/6)';
subplot(1,2,2);
trisurf(tr, 'FaceColor', 'cyan', 'EdgeColor','none', ...
        'FaceAlpha', 0.8); axis equal;
```

Add the feature edges to the plot:

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
% TRISURF display of surface mesh
% suppressing mesh edges
% and showing feature edges
```

## See Also

`edges` | `delaunayTriangulation` | `triangulation`

# feof

---

**Purpose** Test for end-of-file

**Syntax** `status = feof(fileID)`

**Description** `status = feof(fileID)` returns 1 if a previous operation set the end-of-file indicator for the specified file. Otherwise, `feof` returns 0. `fileID` is an integer file identifier obtained from `fopen`.

Opening an empty file does *not* set the end-of-file indicator. Read operations, and the `fseek` and `frewind` functions, move the file position indicator.

**Examples** Read `bench.dat`, which contains MATLAB benchmark data, one character at a time:

```
fid = fopen('bench.dat');

k = 0;
while ~feof(fid)
    curr = fscanf(fid,'%c',1);
    if ~isempty(curr)
        k = k+1;
        benchstr(k) = curr;
    end
end

fclose(fid);
```

**See Also** `fclose` | `ferror` | `fopen` | `frewind` | `fseek` | `ftell`

**How To** • “Testing for End of File (EOF)”

---

<b>Purpose</b>	Information about file I/O errors
<b>Syntax</b>	<pre><i>message</i> = ferror(<i>fileID</i>) [<i>message</i>, <i>errnum</i>] = ferror(<i>fileID</i>) [...] = ferror(<i>fileID</i>, 'clear')</pre>
<b>Description</b>	<p><i>message</i> = ferror(<i>fileID</i>) returns the error message for the most recent file I/O operation on the specified file. If the operation was successful, <i>message</i> is an empty string. <i>fileID</i> is an integer file identifier obtained from fopen, or an identifier reserved for standard input (0), standard output (1), or standard error (2).</p> <p>[<i>message</i>, <i>errnum</i>] = ferror(<i>fileID</i>) returns the error number. If the most recent file I/O operation was successful, <i>errnum</i> is 0. Negative error numbers correspond to MATLAB error messages. Positive error numbers correspond to C library error messages for your system.</p> <p>[...] = ferror(<i>fileID</i>, 'clear') clears the error indicator for the specified file.</p>
<b>See Also</b>	<code>fclose</code>   <code>fopen</code>   <code>fseek</code>   <code>ftell</code>   <code>feof</code>   <code>fscanf</code>   <code>fprintf</code>   <code>fread</code>   <code>fwrite</code>

# feval

---

**Purpose** Evaluate function

**Syntax** `[y1, y2, ...] = feval(fhandle, x1, ..., xn)`  
`[y1, y2, ...] = feval(fname, x1, ..., xn)`

**Description** `[y1, y2, ...] = feval(fhandle, x1, ..., xn)` evaluates the function handle, `fhandle`, using arguments `x1` through `xn`. If the function handle is bound to more than one built-in or `.m` function, (that is, it represents a set of overloaded functions), then the data type of the arguments `x1` through `xn` determines which function is dispatched to.

---

**Note** It is not necessary to use `feval` to call a function by means of a function handle. This is explained in “Calling a Function Using Its Handle” in the MATLAB Programming Fundamentals documentation.

---

`[y1, y2, ...] = feval(fname, x1, ..., xn)`. If `fname` is a quoted string containing the name of a function (usually defined within a file having a `.m` file extension), then `feval(fname, x1, ..., xn)` evaluates that function at the given arguments. The `fname` parameter must be a simple function name; it cannot contain path information.

**Tips** The following two statements are equivalent.

```
[V,D] = eig(A)
[V,D] = feval(@eig, A)
```

Nested functions are not accessible to `feval`. To call a nested function, you must either call it directly by name, or construct a function handle for it using the `@` operator.

**Examples** The following example passes a function handle, `fhandle`, in a call to `fminbnd`. The `fhandle` argument is a handle to the `humps` function.

```
fhandle = @humps;
x = fminbnd(fhandle, 0.3, 1);
```

The `fminbnd` function uses `feval` to evaluate the function handle that was passed in.

```
function [xf, fval, exitflag, output] = ...  
    fminbnd(funfcn, ax, bx, options, varargin)  
    .  
    .  
    .  
fx = feval(funfcn, x, varargin{:});
```

# Feval (COM)

---

**Purpose** Evaluate MATLAB function in Automation server

**Syntax**

**MATLAB Client**

```
result = h.Feval('functionname', numout, arg1, arg2, ...)  
result = Feval(h, 'functionname', numout, arg1, arg2, ...)  
result = invoke(h, 'Feval', 'functionname', numout, ...  
arg1, arg2, ...)
```

**IDL Method Signature**

```
HRESULT Feval([in] BSTR functionname, [in] long nargout,  
[out] VARIANT* result, [in, optional] VARIANT arg1, arg2, ...)
```

**Microsoft Visual Basic Client**

```
Feval(String functionname, long numout,  
arg1, arg2, ...) As Object
```

**Description** Feval executes the MATLAB function specified by the string functionname in the Automation server attached to handle h.

Indicate the number of outputs to be returned by the function in a 1-by-1 double array, numout. The server returns output from the function in the cell array, result.

You can specify as many as 32 input arguments to be passed to the function. These arguments follow numout in the Feval argument list. The following table shows ways to pass an argument.

Passing Mechanism	Description
Pass the value itself	To pass any numeric or string value, specify the value in the Feval argument list:  <code>a = h.Feval('sin', 1, -pi:0.01:pi);</code>
Pass a client variable	To pass an argument assigned to a variable in the client, specify the variable name alone:  <code>x = -pi:0.01:pi;</code>

Passing Mechanism	Description
	<pre>a = h.Feval('sin', 1, x);</pre>
Reference a server variable	<p>To reference a variable defined in the server, specify the variable name followed by an equals (=) sign:</p> <pre>h.PutWorkspaceData('x', 'base', -pi:0.01:pi); a = h.Feval('sin', 1, 'x=');</pre> <p>MATLAB does not reassign the server variable.</p>

## Tips

To display the output from `Feval` in the client window, assign a return value.

Server function names, like `Feval`, are case sensitive when using the first two syntaxes shown in the `Syntax` section.

COM functions are available on Microsoft Windows systems only.

## Examples

### Passing Arguments – MATLAB Client

This section contains a number of examples showing how to use `Feval` to execute MATLAB commands on a MATLAB Automation server.

- Concatenate two strings in the server by passing the input strings in a call to `strcat` through `Feval` (`strcat` deletes trailing spaces; use leading spaces):

```
h = actxserver('matlab.application');
a = h.Feval('strcat', 1, 'hello', ' world')
```

MATLAB displays:

```
a =
    'hello world'
```

- Perform the same concatenation, passing a string and a local variable `clistr` that contains the second string:

# Feval (COM)

---

```
clistr = ' world';  
a = h.Feval('strcat', 1, 'hello', clistr)
```

MATLAB displays:

```
a =  
    'hello world'
```

- In this example, the variable `srvstr` is defined in the server, not the client. Putting an equals sign after a variable name (for example, `srvstr=`) indicates it is a server variable, and the variable is not defined in the client:

```
% Define the variable srvstr on the server.  
h.PutCharArray('srvstr', 'base', ' world')  
  
% Pass the name of the server variable using 'name=' syntax  
a = h.Feval('strcat', 1, 'hello', 'srvstr=')
```

MATLAB displays:

```
a =  
    'hello world'
```

## Visual Basic .NET Client

Here are the same examples shown above, but written for a Visual Basic .NET client. These examples return the same strings as shown above.

- Pass the two strings to the MATLAB function `strcat` on the server:

```
Dim Matlab As Object  
Dim out As Object  
out = Nothing  
Matlab = CreateObject("matlab.application")  
Matlab.Feval("strcat", 1, out, "hello", " world")
```

- Define `clistr` locally and pass this variable:

```
Dim clistr As String
```

```
clistr = " world"  
Matlab.Feval("strcat", 1, out, "hello", clistr)
```

- Pass the name of a variable defined on the server:

```
Matlab.PutCharArray("srvstr", "base", " world")  
Matlab.Feval("strcat", 1, out, "hello", "srvstr=")
```

**Feval Return Values – MATLAB Client.** Feval returns data from the evaluated function in a cell array. The cell array has one row for every return value. You control the number of return values using the numout argument.

The numout argument in the following example specifies that Feval return three outputs from the fileparts function.

```
a = h.Feval('fileparts', 3, 'd:\work\ConsoleApp.cpp')
```

MATLAB displays:

```
a =  
    'd:\work'  
    'ConsoleApp'  
    '.cpp'
```

Convert the returned values from the cell array a to char arrays:

```
a{:}
```

MATLAB displays:

```
ans =  
d:\work
```

```
ans =  
ConsoleApp
```

```
ans =  
.cpp
```

# Feval (COM)

---

## Feval Return Values – Visual Basic .NET Client

Here is the same example, but coded in Visual Basic. Define the argument returned by Feval as an Object.

```
Dim Matlab As Object
Dim out As Object
Matlab = CreateObject("matlab.application")
Matlab.Feval("fileparts", 3, out, "d:\work\ConsoleApp.cpp")
```

**Purpose** Fast Fourier transform

**Syntax**

```
Y = fft(x)
Y = fft(X,n)
Y = fft(X,[],dim)
Y = fft(X,n,dim)
```

**Definitions** The functions  $Y = \text{fft}(x)$  and  $y = \text{ifft}(X)$  implement the transform and inverse transform pair given for vectors of length  $N$  by:

$$X(k) = \sum_{j=1}^N x(j)\omega_N^{(j-1)(k-1)}$$

$$x(j) = (1/N) \sum_{k=1}^N X(k)\omega_N^{-(j-1)(k-1)}$$

where

$$\omega_N = e^{(-2\pi i)/N}$$

is an  $N$ th root of unity.

## Description

$Y = \text{fft}(x)$  returns the discrete Fourier transform (DFT) of vector  $x$ , computed with a fast Fourier transform (FFT) algorithm.

If the input  $X$  is a matrix,  $Y = \text{fft}(X)$  returns the Fourier transform of each column of the matrix.

If the input  $X$  is a multidimensional array,  $\text{fft}$  operates on the first nonsingleton dimension.

$Y = \text{fft}(X, n)$  returns the  $n$ -point DFT.  $\text{fft}(X)$  is equivalent to  $\text{fft}(X, n)$  where  $n$  is the size of  $X$  in the first nonsingleton dimension. If the length of  $X$  is less than  $n$ ,  $X$  is padded with trailing zeros to length  $n$ . If the length of  $X$  is greater than  $n$ , the sequence  $X$  is truncated. When  $X$  is a matrix, the length of the columns are adjusted in the same manner.

$Y = \text{fft}(X, [], \text{dim})$  and  $Y = \text{fft}(X, n, \text{dim})$  applies the FFT operation across the dimension  $\text{dim}$ .

## Examples

A common use of Fourier transforms is to find the frequency components of a signal buried in a noisy time domain signal. Consider data sampled at 1000 Hz. Form a signal containing a 50 Hz sinusoid of amplitude 0.7 and 120 Hz sinusoid of amplitude 1 and corrupt it with some zero-mean random noise:

```
Fs = 1000;           % Sampling frequency
T = 1/Fs;           % Sample time
L = 1000;           % Length of signal
t = (0:L-1)*T;      % Time vector
% Sum of a 50 Hz sinusoid and a 120 Hz sinusoid
x = 0.7*sin(2*pi*50*t) + sin(2*pi*120*t);
y = x + 2*randn(size(t)); % Sinusoids plus noise
plot(Fs*t(1:50),y(1:50))
title('Signal Corrupted with Zero-Mean Random Noise')
xlabel('time (milliseconds)')
```

It is difficult to identify the frequency components by looking at the original signal. Converting to the frequency domain, the discrete Fourier transform of the noisy signal  $y$  is found by taking the fast Fourier transform (FFT):

```
NFFT = 2^nextpow2(L); % Next power of 2 from length of y
Y = fft(y,NFFT)/L;
f = Fs/2*linspace(0,1,NFFT/2+1);

% Plot single-sided amplitude spectrum.
plot(f,2*abs(Y(1:NFFT/2+1)))
title('Single-Sided Amplitude Spectrum of y(t)')
xlabel('Frequency (Hz)')
ylabel('|Y(f)|')
```

The main reason the amplitudes are not exactly at 0.7 and 1 is because of the noise. Several executions of this code (including recomputation of  $y$ ) will produce different approximations to 0.7 and 1. The other reason is that you have a finite length signal. Increasing  $L$  from 1000 to

10000 in the example above will produce much better approximations on average.

## Algorithms

The FFT functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, `ifftn`) are based on a library called FFTW [3],[4]. To compute an  $N$ -point DFT when  $N$  is composite (that is, when  $N = N_1 N_2$ ), the FFTW library decomposes the problem using the Cooley-Tukey algorithm [1], which first computes  $N_1$  transforms of size  $N_2$ , and then computes  $N_2$  transforms of size  $N_1$ . The decomposition is applied recursively to both the  $N_1$ - and  $N_2$ -point DFTs until the problem can be solved using one of several machine-generated fixed-size "codelets." The codelets in turn use several algorithms in combination, including a variation of Cooley-Tukey [5], a prime factor algorithm [6], and a split-radix algorithm [2]. The particular factorization of  $N$  is chosen heuristically.

When  $N$  is a prime number, the FFTW library first decomposes an  $N$ -point problem into three  $(N - 1)$ -point problems using Rader's algorithm [7]. It then uses the Cooley-Tukey decomposition described above to compute the  $(N - 1)$ -point DFTs.

For most  $N$ , real-input DFTs require roughly half the computation time of complex-input DFTs. However, when  $N$  has large prime factors, there is little or no speed difference.

The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fft` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

---

## Data Type Support

`fft` supports inputs of data types `double` and `single`. If you call `fft` with the syntax `y = fft(X, ...)`, the output `y` has the same data type as the input `X`.

# fft2

---

**Purpose** 2-D fast Fourier transform

**Syntax**  
`Y = fft2(X)`  
`Y = fft2(X,m,n)`

**Description** `Y = fft2(X)` returns the two-dimensional discrete Fourier transform (DFT) of `X`. The DFT is computed with a fast Fourier transform (FFT) algorithm. The result, `Y`, is the same size as `X`.

If the dimensionality of `X` is greater than 2, the `fft2` function returns the 2-D DFT for each higher dimensional slice of `X`. For example, if `size(X) = [100 100 3]`, then `fft2` computes the DFT of `X(:, :, 1)`, `X(:, :, 2)` and `X(:, :, 3)`.

`Y = fft2(X,m,n)` truncates `X`, or pads `X` with zeros to create an `m`-by-`n` array before doing the transform. The result is `m`-by-`n`.

**Algorithms** `fft2(X)` can be simply computed as

```
fft(fft(X).').'
```

This computes the one-dimensional DFT of each column `X`, then of each row of the result. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fft2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

**Data Type Support** `fft2` supports inputs of data types `double` and `single`. If you call `fft2` with the syntax `y = fft2(X, ...)`, the output `y` has the same data type as the input `X`.

**See Also**

`fft` | `fftn` | `fftw` | `fftshift` | `ifft2`

**Purpose** N-D fast Fourier transform

**Syntax**  
`Y = fftn(X)`  
`Y = fftn(X,siz)`

**Description** `Y = fftn(X)` returns the discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`Y = fftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the transform. The size of the result `Y` is `siz`.

**Algorithms** `fftn(X)` is equivalent to

```
Y = X;  
for p = 1:length(size(X))  
    Y = fft(Y,[],p);  
end
```

This computes in-place the one-dimensional fast Fourier transform along each dimension of `X`. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fftn` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

---

**Data Type Support** `fftn` supports inputs of data types `double` and `single`. If you call `fftn` with the syntax `y = fftn(X, ...)`, the output `y` has the same data type as the input `X`.

**See Also**

`fft` | `fft2` | `fftw` | `ifftn`

# fftshift

---

**Purpose** Shift zero-frequency component to center of spectrum

**Syntax**  $Y = \text{fftshift}(X)$   
 $Y = \text{fftshift}(X, \text{dim})$

**Description**  $Y = \text{fftshift}(X)$  rearranges the outputs of `fft`, `fft2`, and `fftn` by moving the zero-frequency component to the center of the array. It is useful for visualizing a Fourier transform with the zero-frequency component in the middle of the spectrum.

For vectors, `fftshift(X)` swaps the left and right halves of  $X$ . For matrices, `fftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth.

For higher-dimensional arrays, `fftshift(X)` swaps “half-spaces” of  $X$  along each dimension.

$Y = \text{fftshift}(X, \text{dim})$  applies the `fftshift` operation along the dimension `dim`.

For dim = 1:

For dim = 2:

---

**Note** `ifftshift` will undo the results of `fftshift`. If the matrix  $X$  contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original  $X$ . Simply performing `fftshift(X)` twice will not produce  $X$ .

---

## Examples

For any matrix  $X$

```
Y = fft2(X)
```

has  $Y(1,1) = \text{sum}(\text{sum}(X))$ ; the zero-frequency component of the signal is in the upper-left corner of the two-dimensional FFT. For

```
Z = fftshift(Y)
```

this zero-frequency component is near the center of the matrix.

The difference between `fftshift` and `ifftshift` is important for input sequences of odd-length.

```
N = 5;
X = 0:N-1;
Y = fftshift(fftshift(X));
Z = ifftshift(fftshift(X));
```

Notice that  $Z$  is a correct replica of  $X$ , but  $Y$  is not.

# fftshift

---

```
isequal(X,Y),isequal(X,Z)
```

```

**Purpose**

Interface to FFTW library run-time algorithm tuning control

**Syntax**

```
fftw('planner', method)
method = fftw('planner')
str = fftw('dwisdom')
str = fftw('swisdom')
fftw('dwisdom', str)
fftw('swisdom', str)
```

**Description**

fftw enables you to optimize the speed of the MATLAB FFT functions `fft`, `ifft`, `fft2`, `ifft2`, `fftn`, and `ifftn`. You can use `fftw` to set options for a tuning algorithm that experimentally determines the fastest algorithm for computing an FFT of a particular size and dimension at run time. MATLAB software records the optimal algorithm in an internal data base and uses it to compute FFTs of the same size throughout the current session. The tuning algorithm is part of the FFTW library that MATLAB software uses to compute FFTs.

`fftw('planner', method)` sets the method by which the tuning algorithm searches for a good FFT algorithm when the dimension of the FFT is not a power of 2. You can specify `method` to be one of the following. The default method is `estimate`:

- 'estimate'
- 'measure'
- 'patient'
- 'exhaustive'
- 'hybrid'

When you call `fftw('planner', method)`, the next time you call one of the FFT functions, such as `fft`, the tuning algorithm uses the specified method to optimize the FFT computation. Because the tuning involves trying different algorithms, the first time you call an FFT function, it might run more slowly than if you did not call `fftw`. However, subsequent calls to any of the FFT functions, for a problem of the same size, often run more quickly than they would without using `fftw`.

---

**Note** The FFT functions only use the optimal FFT algorithm during the current MATLAB session. “Reusing Optimal FFT Algorithms” on page 1-1888 explains how to reuse the optimal algorithm in a future MATLAB session.

---

If you set the method to 'estimate', the FFTW library does not use run-time tuning to select the algorithms. The resulting algorithms might not be optimal.

If you set the method to 'measure', the FFTW library experiments with many different algorithms to compute an FFT of a given size and chooses the fastest. Setting the method to 'patient' or 'exhaustive' has a similar result, but the library experiments with even more algorithms so that the tuning takes longer the first time you call an FFT function. However, subsequent calls to FFT functions are faster than with 'measure'.

If you set 'planner' to 'hybrid', MATLAB software

- Sets method to 'measure' method for FFT dimensions 8192 or smaller.
- Sets method to 'estimate' for FFT dimensions greater than 8192.

`method = fftw('planner')` returns the current planner method.

`str = fftw('dwisdom')` returns the information in the FFTW library's internal double-precision database as a string. The string can be saved and then later reused in a subsequent MATLAB session using the next syntax.

`str = fftw('swisdom')` returns the information in the FFTW library's internal single-precision database as a string.

`fftw('dwisdom', str)` loads fftw wisdom represented by the string `str` into the FFTW library's internal double-precision wisdom database. `fftw('dwisdom', '')` or `fftw('dwisdom', [])` clears the internal wisdom database.

`fftw('swisdom', str)` loads fftw wisdom represented by the string `str` into the FFTW library's internal single-precision wisdom database. `fftw('swisdom', '')` or `fftw('swisdom', [])` clears the internal wisdom database.

---

**Note on large powers of 2** For FFT dimensions that are powers of 2, between  $2^{14}$  and  $2^{22}$ , MATLAB software uses special preloaded information in its internal database to optimize the FFT computation. No tuning is performed when the dimension of the FFT is a power of 2, unless you clear the database using the command `fftw('wisdom', [])`.

---

For more information about the FFTW library, see <http://www.fftw.org>.

## Examples

### Comparison of Speed for Different Planner Methods

The following example illustrates the run times for different settings of `planner`. The example first creates some data and applies `fft` to it using the default method, `estimate`.

```
t=0:.001:5;
x = sin(2*pi*50*t)+sin(2*pi*120*t);
y = x + 2*randn(size(t));
```

```
tic; Y = fft(y,1458); toc
Elapsed time is 0.000521 seconds.
```

If you execute the commands

```
tic; Y = fft(y,1458); toc
Elapsed time is 0.000151 seconds.
```

a second time, MATLAB software reports the elapsed time as essentially 0. To measure the elapsed time more accurately, you can execute the command `Y = fft(y,1458)` 1000 times in a loop.

```
tic; for k=1:1000
Y = fft(y,1458);
end; toc
Elapsed time is 0.056532 seconds.
```

This tells you that it takes on order of 1/10000 of a second to execute `fft(y, 1458)` a single time.

For comparison, set `planner` to `patient`. Since this planner explores possible algorithms more thoroughly than `hybrid`, the first time you run `fft`, it takes longer to compute the results.

```
fftw('planner','patient')
tic;Y = fft(y,1458);toc
Elapsed time is 0.100637 seconds.
```

However, the next time you call `fft`, it runs at approximately the same speed as before you ran the method `patient`.

```
tic;for k=1:1000
Y=fft(y,1458);
end;toc
Elapsed time is 0.057209 seconds.
```

### **Reusing Optimal FFT Algorithms**

In order to use the optimized FFT algorithm in a future MATLAB session, first save the “wisdom” using the command

```
str = fftw('wisdom')
```

You can save `str` for a future session using the command

```
save str
```

The next time you open a MATLAB session, load `str` using the command

```
load str
```

and then reload the “wisdom” into the FFTW database using the command

```
fftw('wisdom', str)
```

# fgetl

---

**Purpose** Read line from file, removing newline characters

**Syntax** `tline = fgetl(fileID)`

**Description** `tline = fgetl(fileID)` returns the next line of the specified file, removing the newline characters. `fileID` is an integer file identifier obtained from `fopen`. `tline` is a text string unless the line contains only the end-of-file marker. In this case, `tline` is the numeric value `-1`.

`fgetl` reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use `fopen`.

**Examples** Read and display the file `fgetl.m` one line at a time:

```
fid = fopen('fgetl.m');

tline = fgetl(fid);
while ischar(tline)
    disp(tline)
    tline = fgetl(fid);
end

fclose(fid);
```

Compare these results to the `fgets` example, which replaces the calls to `fgetl` with `fgets`.

**See Also** `fclose` | `feof` | `ferror` | `fgets` | `fopen` | `fprintf` | `fread` | `fscanf` | `fwrite`

**How To**

- “Testing for EOF with `fgetl` and `fgets`”

**Purpose** Read line of text from device and discard terminator

**Syntax**

```
tline = fgetl(obj)
[tline,count] = fgetl(obj)
[tline,count,msg] = fgetl(obj)
```

**Description** `tline = fgetl(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data does not include the terminator with the text line. To include the terminator, use `fgets`.

`[tline,count] = fgetl(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgetl(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

**Tips** Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgetl` is issued.

If you use the `help` command to display help for `fgetl`, then you need to supply the pathname shown below.

```
help serial/fgetl
```

## Rules for Completing a Read Operation with fgetl

A read operation with `fgetl` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.

# fgetl (serial)

---

- The time specified by the Timeout property passes.
- The input buffer is filled.

## Examples

On a Windows platform, create the serial port object `s`, connect `s` to a Tektronix® TDS 210 oscilloscope, and write the RS232? command with the `fprintf` function. RS232? instructs the scope to return serial port communications settings.

```
s = serial('COM1');  
fopen(s)  
fprintf(s, 'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable  
ans =  
    17
```

Use `fgetl` to read the data returned from the previous write operation, and discard the terminator.

```
settings = fgetl(s)  
settings =  
9600;0;0;NONE;LF  
length(settings)  
ans =  
    16
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)  
delete(s)  
clear s
```

# fgets

---

**Purpose** Read line from file, keeping newline characters

**Syntax** `tline = fgets(fileID)`  
`tline = fgets(fileID, nchar)`

**Description** `tline = fgets(fileID)` reads the next line of the specified file, including the newline characters. `fileID` is an integer file identifier obtained from `fopen`. `tline` is a text string unless the line contains only the end-of-file marker. In this case, `tline` is the numeric value `-1`. `fgets` reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use `fopen`.

`tline = fgets(fileID, nchar)` returns at most `nchar` characters of the next line. `tline` does not include any characters after the newline characters or the end-of-file marker.

**Examples** Read and display the file `fgets.m`. Because `fgets` keeps newline characters and `disp` adds a newline character, this code displays the file with double-spacing:

```
fid = fopen('fgets.m');  
  
tline = fgets(fid);  
while ischar(tline)  
    disp(tline)  
    tline = fgets(fid);  
end  
  
fclose(fid);
```

Compare these results to the `fgetl` example, which replaces the calls to `fgets` with `fgetl`.

**See Also** `fclose` | `feof` | `ferror` | `fgetl` | `fopen` | `fprintf` | `fread` | `fscanf` | `fwrite`

**How To** • “Testing for EOF with `fgetl` and `fgets`”

**Purpose** Read line of text from device and include terminator

**Syntax**

```
tline = fgets(obj)
[tline,count] = fgets(obj)
[tline,count,msg] = fgets(obj)
```

**Description** `tline = fgets(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data includes the terminator with the text line. To exclude the terminator, use `fgetl`.

`[tline,count] = fgets(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgets(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

**Tips** Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgets` is issued.

If you use the `help` command to display help for `fgets`, then you need to supply the pathname shown below.

```
help serial/fgets
```

## Rules for Completing a Read Operation with fgets

A read operation with `fgets` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.

# fgets (serial)

---

- The time specified by the Timeout property passes.
- The input buffer is filled.

## Examples

Create the serial port object `s`, connect `s` to a Tektronix TDS 210 oscilloscope, and write the RS232? command with the `fprintf` function. RS232? instructs the scope to return serial port communications settings.

```
s = serial('COM1');  
fopen(s)  
fprintf(s, 'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable  
ans =  
    17
```

Use `fgets` to read the data returned from the previous write operation, and include the terminator.

```
settings = fgets(s)  
settings =  
9600;0;0;NONE;LF  
length(settings)  
ans =  
    17
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)  
delete(s)  
clear s
```

# fieldnames

---

**Purpose** Field names of structure, or public fields of object

**Syntax**

```
names = fieldnames(s)
names = fieldnames(obj)
names = fieldnames(obj, '-full')
```

**Description**

`names = fieldnames(s)` returns a cell array of strings containing the names of the fields in structure `s`.

`names = fieldnames(obj)` returns a cell array of strings containing the names of the public properties of `obj`. MATLAB objects can overload `fieldnames` and define their own behavior.

`names = fieldnames(obj, '-full')` returns a cell array of strings containing the name, type, attributes, and inheritance of the properties of `obj`. Only supported for COM or Java objects.

## Examples

### Structure Fields

Create a structure array and view its fields.

```
s(1,1).name = 'alice';
s(1,1).ID = 0;
s(2,1).name = 'gertrude';
s(2,1).ID = 1;
```

```
names = fieldnames(s)
```

```
names =
    'name'
    'ID'
```

### Java Object Properties

Create a Java object and view its public properties.

```
obj = java.lang.Integer(0);
names = fieldnames(obj)
```

```
names =  
    'MIN_VALUE'  
    'MAX_VALUE'  
    'TYPE'  
    'SIZE'
```

## See Also

## How To

- “Generate Field Names from Variables”

# figure

---

**Purpose** Create figure graphics object

**Syntax**

```
figure
figure('PropertyName',propertyvalue,...)
figure(h)
h = figure(...)
```

**Properties** For a list of properties, see [Figure Properties](#).

**Description** `figure` creates figure graphics objects. Figure objects are the individual windows on the screen in which the MATLAB software displays graphical output.

`figure` creates a new figure object using default property values. This automatically becomes the current figure and raises it above all other figures on the screen until a new figure is either created or called.

`figure('PropertyName',propertyvalue,...)` creates a new figure object using the values of the properties specified. For a description of the properties, see [Figure Properties](#). MATLAB uses default values for any properties that you do not explicitly define as arguments.

`figure(h)` does one of two things, depending on whether or not a figure with handle `h` exists. If `h` is the handle to an existing figure, `figure(h)` makes the figure identified by `h` the current figure, makes it visible, and raises it above all other figures on the screen. The current figure is the target for graphics output. If `h` is not the handle to an existing figure, but is an integer, `figure(h)` creates a figure and assigns it the handle `h`. `figure(h)` where `h` is not the handle to a figure, and is not an integer, is an error.

`h = figure(...)` returns the handle to the figure object.

**Tips** To create a figure object, MATLAB creates a new window whose characteristics are controlled by default figure properties (both factory installed and user defined) and properties specified as arguments. See [Figure Properties](#) for a description of these properties.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

Use `set` to modify the properties of an existing figure or `get` to query the current values of figure properties.

The `gcf` command returns the handle to the current figure and is useful as an argument to the `set` and `get` commands.

Figures can be docked in the desktop. The `DockControls` property determines whether you can dock the figure.

### **Making a Figure Current**

The current figure is the target for graphics output. There are two ways to make a figure `h` the current figure.

- Make the figure `h` current, visible, and displayed on top of other figures:

```
figure(h)
```

- Make the figure `h` current, but do not change its visibility or stacking with respect to other figures:

```
set(0, 'CurrentFigure', h)
```

## **Examples**

### **Specifying Figure Size and Screen Location**

To create a figure window that is one quarter the size of your screen and is positioned in the upper left corner, use the root object's `ScreenSize` property to determine the size. `ScreenSize` is a four-element vector: `[left, bottom, width, height]`:

```
scrsz = get(0, 'ScreenSize');  
figure('Position', [1 scrsz(4)/2 scrsz(3)/2 scrsz(4)/2])
```

To position the full figure window including the menu bar, title bar, tool bars, and outer edges, use the `OuterPosition` property in the same manner.

# figure

---

## Specifying the Figure Window Title

You can add your own title to a figure by setting the `Name` property and you can turn off the figure number with the `NumberTitle` property:

```
figure('Name','Simulation Plot Window','NumberTitle','off')
```

See [Figure Properties](#) for a description of all properties.

## Setting Default Properties

You can set default figure properties only on the `root` object level.

```
set(0,'DefaultFigureProperty',PropertyValue...)
```

where *Property* is the name of the figure property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access figure properties.

See “Setting Default Property Values” for more information.

## See Also

[axes](#) | [close](#) | [clf](#) | [gcf](#) | [ishghandle](#) | [rootobject](#) | [uicontrol](#) | [uimenu](#) | [Figure Properties](#)

## Purpose

Define figure properties

## Creating Figure Objects

Use `figure` to create figure objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of Handle Graphics properties.

To change the default values of properties, see “Setting Default Property Values” in the Handle Graphics Objects documentation.

## Figure Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Alphamap

m-by-1 matrix of alpha values

*Figure alphamap.* An array of non-NaN alpha values. MATLAB accesses alpha values by their row number. For example, an index of 1 specifies the first alpha value, an index of 2 specifies the second alpha value, and so on. Alphamaps can be any length. The default alphamap contains 64 values that progress linearly from 0 to 1.

Alphamaps affect the rendering of surface, image, and patch objects, but do not affect other graphics objects.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted`

# Figure Properties

---

property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

See the `close` and `delete` function reference pages for related information.

## `BusyAction`

`cancel` | `{queue}`

*Callback function interruption.* The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callback functions. If there is a callback function executing, callback functions invoked subsequently always attempt to interrupt it. If the `Interruptible` property of the object whose callback is executing is `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback function.
- `queue` — Queue the event that attempted to execute a second callback function until the current callback finishes.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is in the figure window, but not over a child object (i.e., `uicontrol`, `uipanel`, `axes`, or `axes child`).

Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure).

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Using the `ButtonDownFcn`

This example creates a figure and defines a function handle callback for the `ButtonDownFcn` property. When the user **Ctrl**-clicks the figure, the callback creates a new figure having the same callback.

[Click to view in editor](#) — This link opens the MATLAB Editor with the following example.

[Click to run example](#) — **Ctrl**-click the figure to create a new figure.

```
fh_cb = @newfig; % Create function handle for newfig function
figure('ButtonDownFcn',fh_cb);

function newfig(src,evnt)
    if strcmp(get(src,'SelectionType'),'alt')
        figure('ButtonDownFcn',fh_cb)
    else
        disp('Use control-click to create a new figure')
    end
end
```

Children  
vector of handles

# Figure Properties

---

*Children of the figure.* A vector containing the handles of all axes, user-interface objects displayed within the figure. You can change the order of the handles and thereby change the stacking of the objects on the display.

When an object's `HandleVisibility` property is `off`, it is not listed in its parent's `Children` property. See `HandleVisibility` for more information.

## Clipping

{on} | off

*Clipping mode.* This property has no effect on figures.

## CloseRequestFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Function executed on figure close.* Executes whenever you issue the `close` command (either a `close(figure_handle)` or a `close all`), when you close a figure window from the computer's window manager menu, or when you quit MATLAB.

The `CloseRequestFcn` provides a mechanism to intervene in the closing of a figure. It allows you to, for example, display a dialog box to ask a user to confirm or cancel the close operation or to prevent users from closing a figure that contains a GUI.

The basic mechanism is:

- 1 A user issues the `close` command from the command line, by closing the window from the computer's window manager menu, or by quitting MATLAB.
- 2 The close operation executes the function defined by the figure `CloseRequestFcn`. The default function is `closereq`.

`closereq` unconditionally deletes the current figure, destroying the window. `closereq` takes advantage of the fact that the

`close` command makes each figure specified as arguments the current figure before calling its respective close request function.

Note that `closereq` honors the `ShowHiddenHandles` setting during figure deletion and will not delete hidden figures.

## Redefining the `CloseRequestFcn`

Define the `CloseRequestFcn` as a function handle. For example:

```
set(gcf, 'CloseRequestFcn', @my_closefcn)
```

Where `@my_closefcn` is a function handle referencing function `my_closefcn`.

Unless the close request function calls `delete` or `close`, MATLAB never closes the figure. (Note that you can always call `delete(figure_handle)` from the command line if you have created a window with a nondestructive close request function.)

A useful application of the close request function is to display a question dialog box asking the user to confirm the close operation. The following function illustrates how to do this.

[Click to view in editor](#) — This link opens the MATLAB editor with the following example.

[Click to run example](#) — **Ctrl-click** the figure to create a new figure.

```
function my_closereq(src, evnt)
% User-defined close request function
% to display a question dialog box
    selection = questdlg('Close This Figure?', ...
        'Close Request Function', ...
        'Yes', 'No', 'Yes');
    switch selection,
```

# Figure Properties

---

```
        case 'Yes',  
            delete(gcf)  
        case 'No'  
            return  
    end  
end
```

Now create a figure using the `CloseRequestFcn`:

```
figure('CloseRequestFcn',@my_closereq)
```

To make this function your default close request function, set a default value on the root level.

```
set(0,'DefaultFigureCloseRequestFcn',@my_closereq)
```

MATLAB then uses this setting for the `CloseRequestFcn` of all subsequently created figures.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## Color

### ColorSpec

*Background color.* Controls the figure window background color. You can specify a color using a three-element vector of RGB values or one of the MATLAB predefined names. See `ColorSpec` for more information.

## Colormap

m-by-3 matrix of RGB values

*Figure colormap.* An array of red, green, and blue (RGB) intensity values that define *m* individual colors. MATLAB accesses colors by their row number. For example, an index of 1 specifies the first RGB triplet, an index of 2 specifies the second RGB triplet, and so on.

## Number of Colors Allowed

Colormaps can be any length, but must be three columns wide. The default figure colormap contains 64 predefined colors.

## Objects That Use Colormaps

Colormaps affect the rendering of surface, image, and patch objects, but generally do not affect other graphics objects. See `colormap` and `ColorSpec` for more information.

### CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during figure creation.* Executes when MATLAB creates a figure object. You must define this property as a default value on the root level. For example, the statement:

```
set(0,'DefaultFigureCreateFcn',@fig_create)
```

defines a default value on the root level that causes all figures created to execute the setup function `fig_create`, which is defined below:

```
function fig_create(src,evnt)
set(src,'Color',[.2 .1 .5],...
    'IntegerHandle','off',...
    'MenuBar','none',...
    'ToolBar','none')
end
```

MATLAB executes the create function after setting all properties for the figure. Setting this property on an existing figure object has no effect.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

# Figure Properties

---

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo` or the handle of the object generating the callback (the source of the event). For example, this,

```
f = figure('CreateFcn',@(o,e) keyboard)
K>> gcbo
```

and this each return 1:

```
f = figure('CreateFcn',@(o,e) keyboard)
K>> o
```

## CurrentAxes

handle of current axes

*Target axes in this figure.* MATLAB sets this property to the handle of the figure's current axes (the handle returned by the `gca` command when this figure is the current figure). In all figures for which axes children exist, there is always a current axes. The current axes does not have to be the topmost axes, and setting an axes to be the `CurrentAxes` does not restack it above all other axes.

You can make an axes current using the `axes` and `set` commands. For example, `axes(axes_handle)` and `set(gcf, 'CurrentAxes', axes_handle)` both make the axes identified by the handle *axes\_handle* the current axes. In addition, `axes(axes_handle)` restacks the axes above all other axes in the figure.

If a figure contains no axes, `get(gcf, 'CurrentAxes')` returns the empty matrix. Note that the `gca` function actually creates an axes if one does not exist.

## CurrentCharacter

single character

*Last key pressed.* MATLAB sets this property to the last key pressed in the figure window. Use `CurrentCharacter` to obtain user input.

`CurrentObject`  
object handle

*Handle of current object.* MATLAB sets this property to the handle of the last object clicked on by the mouse. This object is the foremost object in the view. You can use this property to determine which object a user has selected. The function `gco` provides a convenient way to retrieve the `CurrentObject` of the `CurrentFigure`.

Note that the `HitTest` property controls whether an object can become the `CurrentObject`.

## Hidden Handle Objects

Clicking an object whose `HandleVisibility` property is `off` (such as axis labels and title) causes the `CurrentObject` property to be set to empty `[]`. To avoid returning an empty value when users click hidden objects, set the hidden object's `HitTest` property to `off`.

## Mouse Over

Note that cursor motion over objects does not update the `CurrentObject`; you must click objects to update this property. See the `CurrentPoint` property for related information.

`CurrentPoint`  
two-element vector: [*x*-coordinate, *y*-coordinate]

*Location of last button click in this figure.* MATLAB sets this property to the location of the pointer at the time of the most recent mouse button press. MATLAB updates this property

# Figure Properties

---

whenever you press the mouse button while the pointer is in the figure window.

Note that if you select a point in the figure and then use the values returned by the `CurrentPoint` property to plot that point, there can be differences in the position due to round-off errors.

## CurrentPoint and Cursor Motion

In addition to the behavior described above, MATLAB updates `CurrentPoint` before executing callback routines defined for the figure `WindowButtonMotionFcn` and `WindowButtonUpFcn` properties. This enables you to query `CurrentPoint` from these callback routines. It behaves like this:

- If there is no callback routine defined for the `WindowButtonMotionFcn` or the `WindowButtonUpFcn`, then MATLAB updates the `CurrentPoint` only when the mouse button is pressed down within the figure window.
- If there is a callback routine defined for the `WindowButtonMotionFcn`, then MATLAB updates the `CurrentPoint` just before executing the callback. Note that the `WindowButtonMotionFcn` executes only within the figure window unless the mouse button is pressed down within the window and then held down while the pointer is moved around the screen. In this case, the routine executes (and the `CurrentPoint` is updated) anywhere on the screen until the mouse button is released.
- If there is a callback routine defined for the `WindowButtonUpFcn`, MATLAB updates the `CurrentPoint` just before executing the callback. Note that the `WindowButtonUpFcn` executes only while the pointer is within the figure window unless the mouse button is pressed down initially within the window. In this case, releasing the button anywhere on the screen triggers callback execution, which is preceded by an update of the `CurrentPoint`.

The figure `CurrentPoint` is updated only when certain events occur, as previously described. In some situations (such as when the `WindowButtonMotionFcn` takes a long time to execute and the pointer is moved very rapidly), the `CurrentPoint` might not reflect the actual location of the pointer, but rather the location at the time when the `WindowButtonMotionFcn` began execution.

The `CurrentPoint` is measured from the lower-left corner of the figure window, in units determined by the `Units` property.

The root `PointerLocation` property contains the location of the pointer updated synchronously with pointer movement. However, the location is measured with respect to the screen, not a figure window.

See `uicontrol` for information on how this property is set when you click a `uicontrol` object.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete figure callback function.* Executes when the figure object is deleted (for example, when you issue a `delete` or a `close` command). MATLAB executes the function before destroying the object's properties so these values are available to the callback routine.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

The handle of the object whose `DeleteFcn` is being executed is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See also the figure `CloseRequestFcn` property

# Figure Properties

---

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

DockControls  
{on} | off

*Displays controls used to dock figure.* Determines whether the figure enables the **Desktop** menu item and the dock figure button in the title bar that allow you to dock the figure into the MATLAB desktop.

- on — Figure docking controls are visible.
- off — The **Desktop** menu item that enables you to dock the figure is disabled and the figure dock button is not displayed.

See the `WindowState` property for more information on docking figure.

DoubleBuffer  
{on} | off

---

**Note** This property is now obsolete and has no effect. It was provided for older computer systems to produce flash-free animations.

---

*Flash-free rendering for simple animations.* Double buffering is the process of drawing to an off-screen pixel buffer and then printing the buffer contents to the screen once the drawing is complete. Double buffering generally produces flash-free rendering for simple animations (such as those involving lines, as opposed to objects containing large numbers of polygons). Use double buffering with the animated objects’ `EraseMode` property set to `normal`. Use the `set` command to disable double buffering.

```
set(figure_handle, 'DoubleBuffer', 'off')
```

Double buffering works only when the figure `Renderer` property is `painters`.

**FileName**  
String

*GUI FIG-file name.* GUIDE stores the name of the FIG-file used to save the GUI layout in this property. In non-GUIDE GUIs, by default `FileName` is empty. You can set the `FileName` property in non-GUIDE GUIs as well, and get it to verify what GUI is running or whether it has been previously saved.

**FixedColors**  
m-by-3 matrix of RGB values (read-only)

*Noncolormap colors.* Fixed colors define all colors appearing in a figure window that are not from the figure colormap. These colors include axis lines and labels, the colors of `line`, `text`, `uicontrol`, and `uimenu`, and `text` objects, and any colors explicitly defined, for example, with a statement like:

```
set(gcf, 'Color', [0.3,0.7,0.9])
```

Fixed color definitions reside in the system color table and do not appear in the figure colormap. For this reason, fixed colors can limit the number of simultaneously displayed colors if the number of fixed colors plus the number of entries in the figure colormap exceed your system's maximum number of colors.

(See the root `ScreenDepth` property for information on determining the total number of colors supported on your system. See the `MinColorMap` property for information on how MATLAB shares colors between applications.)

---

**Note** The `FixedColors` property is being deprecated and will be removed in a future release

---

# Figure Properties

---

`HandleVisibility`  
`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

Handles are always visible when `HandleVisibility` is `on`.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Visibility and Handles Returned by Other Functions

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Making All Handles Visible

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

## Validity of Hidden Handles

Handles that are hidden are still valid. If you know an object's handle, you can pass it to any function that operates on handles, and set and get its properties.

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines if the figure can become the current object (as returned by the `gco` command and the `figure.CurrentObject` property) as a result of a mouse click on the figure. If `HitTest` is `off`, clicking the figure sets the `CurrentObject` to the empty matrix.

`IntegerHandle`  
{on} | off

*Figure handle mode.* Figure object handles are integers by default. When creating a new figure, MATLAB uses the lowest integer that is not used by an existing figure. If you delete a figure, its integer handle can be reused.

If you set this property to `off`, MATLAB assigns nonreusable real-number handles (for example, `67.0001221`) instead of integers. This feature is designed for dialog boxes where removing the handle from integer values reduces the likelihood of inadvertently drawing into the dialog box.

`Interruptible`  
{on} | off

*Callback routine interruption mode.* Controls whether a figure callback function can be interrupted by subsequently invoked callbacks.

## How Callbacks Are Interrupted

MATLAB checks for queued events that can interrupt a callback function only when it encounters a call to `drawnow`, `figure`, `getframe`, or `pause` in the executing callback function. When executing one of these functions, MATLAB processes all pending events, including executing all waiting callback functions. The interrupted callback then resumes execution.

## What Property Callbacks Are Interruptible

The `Interruptible` property only affects callback functions defined for the `ButtonDownFcn`, `KeyPressFcn`, `KeyReleaseFcn`, `WindowButtonDownFcn`, `WindowButtonMotionFcn`, `WindowButtonUpFcn`, `WindowKeyPressFcn`, `WindowKeyReleaseFcn`, and `WindowScrollWheelFcn`.

See the `BusyAction` property for related information.

`InvertHardcopy`  
{on} | off

*Change hardcopy to black objects on white background.* Affects only printed output. Printing a figure having a background color (`Color` property) that is not white results in poor contrast between graphics objects and the figure background and also consumes a lot of printer toner.

When `InvertHardCopy` is on, MATLAB eliminates this effect by changing the color of the figure and axes to white and the axis lines, tick marks, axis labels, etc., to black. Lines, text, and the edges of patches and surfaces might be changed, depending on the print command options specified.

If you set `InvertHardCopy` to `off`, the printed output matches the colors displayed on the screen.

See `print` for more information on printing MATLAB figures.

## `KeyPressFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Key press callback function.* Callback function invoked by a key press that occurs while the figure window has focus. Define the `KeyPressFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key press and an event structure).

See `Function Handle Callbacks` for information on how to use function handles to define the callback function.

When no callback is specified for this property (which is the default state), MATLAB passes any key presses to the Command Window. However, when you define a callback for this property, the figure retains focus with each key press and executes the specified callback with each key press.

## **KeyPressFcn Event Structure**

When you specify the callback as a function handle, MATLAB passes to it a structure to containing the following fields.

# Figure Properties

---

Field	Contents
Character	The character displayed as a result of the pressing the key(s), which can be empty or unprintable
Key	The key being pressed, identified by the lowercase label on key or a descriptive string
Modifier	A cell array containing the names of one or more modifier keys being pressed (i.e., <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when pressing the <b>command</b> modifier key

## ExploreKeyPressFcn Behavior

To view the values of the event data fields for any key or key combination, run the following code:

```
figure('NumberTitle','off','Menubar','none',...
      'Name','Press keys to put event data in Command Window',...
      'Position',[560 728 560 200],...
      'KeyPressFcn',@(obj,evt)disp(evt));
```

Each time you press a key, the `KeyPressFcn` uses `disp` to display the event data in the Command Window.

You can also view and run an example GUI, `ex_KeyPressFcn.m`, which displays keystroke event data in the figure window, and provides an option to write the event data structure to your workspace.

- [Click here to view the example in the MATLAB editor](#)
- [Click here to add the example to the MATLAB path](#)
- [Click to run the example](#) — Press and release various key combinations while the figure has focus. The callback displays event data in text fields in the figure window. The **Char**

**Code** data is the Character field displayed as a number, not a separate event data field.

Event data passed to a `KeyPressFcn` and `KeyReleaseFcn` callbacks have the following characteristics:

- The **Key** field is always in lower case (contains the non-shifted symbol).
- Modifier keys (**Alt**, **Ctrl**, **Shift**,) return data when pressed alone as well as when pressed in combination with other keys.
- **Modifier** fields contain a cell array with zero or more strings.
- Modifier keys can affect the **Character** field, but do not change the **Key** field.
- Certain keys, plus keys modified with **Ctrl**, put unprintable characters in the **Character** field.
- **Ctrl**, **Alt**, **Shift**, function and several other keys generate no **Character** field data.

## Using the `KeyPressFcn`

This example creates a figure and defines a function handle callback for the `KeyPressFcn` property. When you press the **p** key, the callback exports the figure as a PNG image file. When you press **Ctrl+p**, the callback exports the figure as a PDF file.

```
function figure_keypress
    figure('KeyPressFcn',@printfig);
    surf(peaks)

function printfig(src,event)
% Callback to parse keypress event data to print a figure
    if event.Character == 'p'
        % On some systems you must send the file to a printer manually
        if length(event.Modifier) == 1 && ...
            strcmp(event.Modifier{:},'control')
```

# Figure Properties

---

```
        % Create PDF file of figure when Ctrl key is down
        print ('-dpdf', ['-f' num2str(src)])
    elseif isempty(event.Modifier)
        % Print PNG image of figure when Ctrl is not pressed
        print ('-dpng', '-r200', ['-f' num2str(src)])
    end
end
end
end
```

## KeyReleaseFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Key release callback function.* Callback function invoked by a key release that occurs while the figure window has focus. Define the `KeyReleaseFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## KeyReleaseFcn Event Structure

When the callback is a function handle, MATLAB passes a structure as the second argument to the callback function that contains the following fields.

Field	Contents
Character	The character displayed as a result of the releasing the key(s), which can be empty or unprintable
Key	The key being released, identified by the lowercase label on key or a descriptive string
Modifier	A cell array containing the names of one or more modifier keys being released (i.e., <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when releasing the <b>command</b> modifier key

## Properties Affected by the KeyReleaseFcn

When a callback is defined for the KeyReleaseFcn property, MATLAB updates the CurrentCharacter figure property just before executing the callback.

## Multiple-Key Press Events and a Single-Key Release Event

Consider a figure having callbacks defined for both the KeyPressFcn and KeyReleaseFcn. In the case where you press multiple keys at close to the same time, MATLAB generates repeated KeyPressFcn events only for the last key pressed.

For example, suppose you press and hold down the **a** key, then press and hold down the **s** key. MATLAB generates repeated KeyPressFcn events for the **a** key until you press the **s** key, at which point MATLAB generates repeated KeyPressFcn events for the **s** key. If you then release the **s** key, MATLAB generates a KeyReleaseFcn event for the **s** key, but no new KeyPressFcn events for the **a** key. When you then release the **a** key, the KeyReleaseFcn again executes. The KeyReleaseFcn executes its callback every time you release a key while the figure is in focus, regardless of what any KeyPressFcn does.

# Figure Properties

---

Event structures passed to a `KeyPressFcn` and `KeyReleaseFcn` callbacks have the following characteristics:

- The `Key` field is always in lower case (contains the non-shifted symbol).
- Modifier keys (**Alt**, **Ctrl**, **Shift**,) return data when pressed alone as well as when pressed in combination with other keys.
- `Modifier` fields contain a cell array with zero or more strings.
- Modifier keys can affect the `Character` field, but do not change the `Key` field.
- Certain keys, plus keys modified with **Ctrl**, put unprintable characters in the `Character` field.
- **Ctrl**, **Alt**, **Shift**, function and several other keys generate no `Character` field data.

## Modifier Keys

When you press and release a key and a modifier key, the modifier key is returned in the event structure `Modifier` field. If you press and release a modifier key only, its name is not returned in the event structure of the `KeyReleaseFcn`, but is returned in the event structure of the `KeyPressFcn`.

## Explore `KeyReleaseFcn` Behavior

The following code example creates a figure and defines a function handle callback for the `KeyReleaseFcn` property which reports the event data that the callback receives.

- [Click here to view the example in the MATLAB editor](#)
- [Click here to add the example to the MATLAB path](#)
- [Click to run the example](#) — Press and release various key combinations while the figure has focus. The callback displays event data in the Command Window.

```
function key_releaseFcn
figure('KeyReleaseFcn',@cb)
function cb(src,evt)
if ~isempty(evt.Modifier)
for ii = 1:length(evt.Modifier)
out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',...
evt.Character,evt.Modifier{ii},evt.Key);
disp(out)
end
else
out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',...
evt.Character,'No modifier key',evt.Key);
disp(out)
end
end
end
```

## MenuBar

none | {figure}

*Enable-disable figure menu bar.* Enables you to display or hide the menu bar that MATLAB places at the top of a figure window. The default (figure) is to display the menu bar.

This property affects only built-in menus. This property does not affect menus defined with the `uimenu` command.

Changing the `WindowStyle` of a window to 'modal' hides both its toolbar and menu bar, if they exist. Changing `WindowStyle` from 'modal' to 'normal' or 'docked' displays any toolbar or menu bar a figure has.

## MinColormap

scalar (default = 64)

*Minimum number of color table entries used.* Specifies the minimum number of system color table entries used by MATLAB to store the colormap defined for the figure (see the `Colormap`

# Figure Properties

---

property). In certain situations, you might need to increase this value to ensure proper use of colors.

For example, suppose you run color-intensive applications in addition to MATLAB and have defined a large figure colormap (for example, 150 to 200 colors). MATLAB might select colors that are close but not exact from the existing colors in the system color table because there are not enough slots available to define all the colors you specified.

To ensure that MATLAB uses exactly the colors you define in the figure colormap, set `MinColormap` equal to the length of the colormap.

```
set(gcf, 'MinColormap', length(get(gcf, 'ColorMap')))
```

Note that the larger the value of `MinColormap`, the greater the likelihood that other windows (including other MATLAB figure windows) will be displayed in false colors.

---

**Note** The `MinColormap` property is being deprecated and will be removed in a future release

---

Name

string

*Figure window title.* Specifies the title displayed in the figure window. By default, Name is empty and the figure title is displayed as Figure 1, Figure 2, and so on. When you set this parameter to a string, the figure title becomes Figure 1: `<string>`. See the `NumberTitle` property.

NextPlot

new | {add} | replace | replacechildren

*How to add next plot.* Determines which figure MATLAB uses to display graphics output. If the value of the current figure is:

- `new` — Create a new figure to display graphics (unless an existing parent is specified in the graphing function as a property/value pair).
- `add` — Use the current figure to display graphics (the default).
- `replace` — Reset all figure properties except `Position` to their defaults and delete all figure children before displaying graphics (equivalent to `clf reset`).
- `replacechildren` — Remove all child objects, but do not reset figure properties (equivalent to `clf`).

The `newplot` function provides an easy way to handle the `NextPlot` property. For more information, see the axes `NextPlot` property and “Controlling Graphics Output”.

`NumberTitle`

`{on} | off` (GUIDE default `off`)

*Figure window title number.* Determines whether the string `Figure No. N` (where `N` is the figure number) is prefixed to the figure window title. See the `Name` property.

`OuterPosition`

four-element vector

*Figure position including title bar, menu bar, tool bars, and outer edges.* Specifies the size and location on the screen of the full figure window including the title bar, menu bar, tool bars, and outer edges. Specify the position rectangle with a four-element vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` and `bottom` define the distance from the lower-left corner of the screen to the lower-left corner of the full figure

# Figure Properties

---

window. `width` and `height` define the dimensions of the window. See the `Units` property for information on the units used in this specification. The `left` and `bottom` elements can be negative on systems that have more than one monitor.

## Position of Docked Figures

If the figure is docked in the MATLAB desktop, then the `OuterPosition` property is specified with respect to the figure group container instead of the screen.

## Moving and Resizing Figures

Use the `get` function to obtain this property and determine the position of the figure. Use the `set` function to resize and move the figure to a new location. You cannot set the figure `OuterPosition` when it is docked.

---

**Note** On Microsoft Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the `OuterPosition` property.

---

`PaperOrientation`  
{portrait} | landscape

*Horizontal or vertical paper orientation.* Determines how to orient printed figures on the page.

- `portrait` — Orients the longest page dimension vertically.
- `landscape` — Orients the longest page dimension horizontally.

See the `orient` command for more information.

`PaperPosition`  
four-element rect vector

*Location on printed page.* A rectangle that determines the location of the figure on the printed page. Specify this rectangle with a vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` specifies the distance from the left side of the paper to the left side of the rectangle and `bottom` specifies the distance from the bottom of the page to the bottom of the rectangle. Together these distances define the lower-left corner of the rectangle. `width` and `height` define the dimensions of the rectangle. The `PaperUnits` property specifies the units used to define this rectangle.

`PaperPositionMode`  
auto | {manual}

*WYSIWYG printing of figure.*

- `manual` — MATLAB honors the value specified by the `PaperPosition` property.
- `auto` — MATLAB prints the figure the same size as it appears on the computer screen, centered on the page.

`PaperSize`  
[width height]

*Paper size.* Size of the current `PaperType`, measured in `PaperUnits`. See `PaperType` to select standard paper sizes.

`PaperType`  
Select a value from the following table.

*Selection of standard paper size.* Sets the `PaperSize` to one of the following standard sizes.

# Figure Properties

---

**Paper Sizes Table**

<b>Property Value</b>	<b>Size (Width x Height)</b>
usletter (default)	8.5-by-11 inches
uslegal	8.5-by-14 inches
tabloid	11-by-17 inches
A0	841-by-1189 mm
A1	594-by-841 mm
A2	420-by-594 mm
A3	297-by-420 mm
A4	210-by-297 mm
A5	148-by-210 mm
B0	1029-by-1456 mm
B1	728-by-1028 mm
B2	514-by-728 mm
B3	364-by-514 mm
B4	257-by-364 mm
B5	182-by-257 mm
arch-A	9-by-12 inches
arch-B	12-by-18 inches
arch-C	18-by-24 inches
arch-D	24-by-36 inches
arch-E	36-by-48 inches
A	8.5-by-11 inches
B	11-by-17 inches
C	17-by-22 inches

Property Value	Size (Width x Height)
D	22-by-34 inches
E	34-by-43 inches

Note that you might need to change the `PaperPosition` property in order to position the printed figure on the new paper size. One solution is to use normalized `PaperUnits`, which enables MATLAB to automatically size the figure to occupy the same relative amount of the printed page, regardless of the paper size.

## PaperUnits

normalized | {inches} | centimeters | points

*Hardcopy measurement units.* Specifies the units used to define the `PaperPosition` and `PaperSize` properties. MATLAB measures all units from the lower-left corner of the page. normalized units map the lower-left corner of the page to (0, 0) and the upper-right corner to (1.0, 1.0). inches, centimeters, and points are absolute units (one point equals 1/72 of an inch).

If you change the value of `PaperUnits`, it is good practice to return the property to its default value after completing your computation so as not to affect other functions that assume `PaperUnits` is set to the default value.

## Parent

handle

*Handle of figure's parent.* The parent of a figure object is the root object `object`. The handle to the root is always 0.

## Pointer

crosshair | {arrow} | watch | topl |  
topr | botl | botr | circle | cross |  
fleur | left | right | top | bottom |  
fullcrosshair | ibeam | custom | hand

# Figure Properties

---

*Pointer symbol selection.* Determines the symbol used to indicate the pointer (cursor) position in the figure window. Setting `Pointer` to `custom` allows you to define your own pointer symbol. See the `PointerShapeCData` property and “Specifying the Figure Pointer” for more information.

`PointerShapeCData`  
16-by-16 matrix

*User-defined pointer.* Defines the pointer used when you set the `Pointer` property to `custom`. It is a 16-by-16 element matrix defining the 16-by-16 pixel pointer using the following values:

- 1 — Color pixel black.
- 2 — Color pixel white.
- NaN — Make pixel transparent (underlying screen shows through).

Element (1,1) of the `PointerShapeCData` matrix corresponds to the upper-left corner of the pointer. Setting the `Pointer` property to one of the predefined pointer symbols does not change the value of the `PointerShapeCData`. Computer systems supporting 32-by-32 pixel pointers fill only one quarter of the available pixmap.

`PointerShapeHotSpot`  
two-element vector

*Pointer active area.* Specifies the row and column indices in the `PointerShapeCData` matrix defining the pixel indicating the pointer location. The location is contained in the `CurrentPoint` property and the root object’s `PointerLocation` property. The default value is element (1,1), which is the upper-left corner.

`Position`  
four-element vector

*Figure position.* Specifies the size and location on the screen of the figure window, not including title bar, menu bar, tool bars, and outer edges. Specify the position rectangle with a four-element vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` and `bottom` define the distance from the lower-left corner of the screen to the lower-left corner of the figure window. `width` and `height` define the dimensions of the window. See the `Units` property for information on the units used in this specification. The `left` and `bottom` elements can be negative on systems that have more than one monitor.

## Position of Docked Figures

If the figure is docked in the MATLAB desktop or in a figure window container, then the `Position` property is specified with respect to the figure group container instead of the screen.

## Moving and Resizing Figures

You can use the `get` function to obtain this property and determine the position of the figure and you can use the `set` function to resize and move the figure to a new location. You cannot set the figure `Position` when it is docked.

---

**Note** On Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the `Position` property.

Also, the figure window includes the area to which MATLAB can draw; it does not include the title bar, menu bar, tool bars, and outer edges. To place the full window, use the `OuterPosition` property.

---

# Figure Properties

---

## Renderer

painters | zbuffer | OpenGL

*Rendering method used for screen and printing.* Selects the method used to render MATLAB graphics. The choices are:

- **painters** — The original rendering method used by MATLAB is faster when the figure contains only simple or small graphics objects.
- **zbuffer** — MATLAB draws graphics objects faster and more accurately because it colors objects on a per-pixel basis and MATLAB renders only those pixels that are visible in the scene (thus eliminating front-to-back sorting errors). Note that this method can consume a lot of system memory if MATLAB is displaying a complex scene.
- **OpenGL** — OpenGL is a renderer that is available on many computer systems. This renderer is generally faster than **painters** or **zbuffer** and in some cases enables MATLAB to access graphics hardware that is available on some systems.

## Hardware vs. Software OpenGL Implementations

There are two kinds of OpenGL implementations — hardware and software.

The hardware implementation uses special graphics hardware to increase performance and is therefore significantly faster than the software version. Many computers have this special hardware available as an option or might come with this hardware right out of the box.

Software implementations of OpenGL are much like the ZBuffer renderer that is available on MATLAB Version 5.0 and later; however, OpenGL generally provides superior performance to ZBuffer.

## OpenGL Availability

OpenGL is available on all computers that run MATLAB. MATLAB automatically finds hardware-accelerated versions of OpenGL if such versions are available. If the hardware-accelerated version is not available, then MATLAB uses the software version (except on Macintosh systems, which do not support software OpenGL).

The following software versions are available:

- On UNIX systems, MATLAB uses the software version of OpenGL that is included in the MATLAB distribution.
- On Windows, OpenGL is available as part of the operating system. If you experience problems with OpenGL, contact your graphics driver vendor to obtain the latest qualified version of OpenGL.
- On Macintosh systems, software OpenGL is not available.

MATLAB issues a warning if it cannot find a usable OpenGL library.

## Selecting Hardware-Accelerated or Software OpenGL

MATLAB enables you to switch between hardware-accelerated and software OpenGL. However, Windows and UNIX systems behave differently:

- On Windows systems, you can toggle between software and hardware versions any time during the MATLAB session.
- On UNIX systems, you must set the OpenGL version before MATLAB initializes OpenGL. Therefore, you cannot issue the `opengl info` command or create graphs before you call `opengl software`. To reenabling hardware accelerated OpenGL, you must restart MATLAB.
- On Macintosh systems, software OpenGL is not available.

# Figure Properties

---

If you do not want to use hardware OpenGL, but do want to use object transparency, you can issue the following command.

```
opengl software
```

This command forces MATLAB to use software OpenGL. Software OpenGL is useful if your hardware-accelerated version of OpenGL does not function correctly and you want to use image, patch, or surface transparency, which requires the OpenGL renderer. To reenable hardware OpenGL, use the command:

```
opengl hardware
```

on Windows systems or restart MATLAB on UNIX systems.

By default, MATLAB uses hardware-accelerated OpenGL.

See the `opengl` reference page for additional information

## Determining the OpenGL Library Version

To determine the version and vendor of the OpenGL library that MATLAB is using on your system, type the following command at the MATLAB prompt:

```
opengl info
```

The returned information contains a line that indicates if MATLAB is using software (`Software = true`) or hardware-accelerated (`Software = false`) OpenGL.

This command also returns a string of extensions to the OpenGL specification that are available with the particular library MATLAB is using. Include this information if you report a bug.

Note that issuing the `opengl info` command causes MATLAB to initialize OpenGL.

## OpenGL vs. Other MATLAB Renderers

There are some differences between drawings created with OpenGL and those created with other renderers. The OpenGL specific differences include:

- OpenGL does not do colormap interpolation. If you create a surface or patch using indexed color and interpolated face or edge coloring, OpenGL interpolates the colors through the RGB color cube instead of through the colormap.
- OpenGL does not support the `phong` value for the `FaceLighting` and `EdgeLighting` properties of surfaces and patches.
- OpenGL does not support logarithmic-scale axes.
- OpenGL and Zbuffer renderers display objects sorted in front to back order, as seen on the monitor, and lines always draw in front of faces when at the same location on the plane of the monitor. Painters sorts by child order (order specified).

## XServer Connection Lost

When using Linux or Macintosh systems, MATLAB can crash with a segmentation violation if the connection to the XServer is broken. If this occurs, ensure that the system has the latest XServer installed.

You can also try using software OpenGL and upgrade the OpenGL driver on a Linux system.

Try these workarounds:

- 1** Upgrade you XServer to the latest version
- 2** Upgrade your OpenGL driver to the latest version
- 3** Switch to software OpenGL by entering this command:

```
opengl software
```

RendererMode  
{auto} | manual

*Automatic or user selection of renderer.* Specifies whether MATLAB should choose the `Renderer` based on the contents of the figure window, or whether the `Renderer` should remain unchanged.

When the `RendererMode` property is `auto`, MATLAB selects the rendering method for printing as well as for screen display based on the size and complexity of the graphics objects in the figure.

For printing, MATLAB switches to `zbuffer` at a greater scene complexity than for screen rendering because printing from a z-buffered figure can be considerably slower than one using the `painters` rendering method, and can result in large PostScript® files. However, the output does always match what is on the screen. The same holds true for OpenGL: the output is the same as that produced by the `zbuffer` renderer — a bitmap with a resolution determined by the `print` command's `-r` option.

### **Criteria for Autoselection of the OpenGL Renderer**

When the `RendererMode` property is `auto`, MATLAB uses the following criteria to determine whether to select the OpenGL renderer:

If the `opengl` autoselection mode is `autoselect`, MATLAB selects OpenGL if

- The host computer has OpenGL installed and is in True Color mode (OpenGL does not fully support 8-bit color mode).
- The figure contains no logarithmic axes (OpenGL does not support logarithmic axes).
- MATLAB would select `zbuffer` based on figure contents.

- Patch objects' faces have no more than three vertices (some OpenGL implementations of patch tessellation are unstable).
- The figure contains less than 10 uicontrols (OpenGL clipping around uicontrols is slow).
- No line objects use markers (drawing markers is slow).
- You do not specify Phong lighting (OpenGL does not support Phong lighting; if you specify Phong lighting, MATLAB uses the ZBuffer renderer).

Or

- Figure objects use transparency (OpenGL is the only MATLAB renderer that supports transparency).

When the `RendererMode` property is `manual`, MATLAB does not change the `Renderer`, regardless of changes to the figure contents.

## Resize

{on} | off

*Window resize mode.* Determines if you can resize the figure window with the mouse. `on` means you can resize the window, `off` means you cannot. When `Resize` is `off`, the figure window does not display any resizing controls (such as boxes at the corners), to indicate that it cannot be resized.

## ResizeFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Window resize callback function.* Executes whenever you resize the figure window and also when the figure is created. You can query the figure's `Position` property to determine the new size and position of the figure. During execution of the callback routine, the handle to the figure being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

## Figure Properties

---

You can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB Position/Units paradigm.

For example, consider a GUI layout that maintains an object at a constant height in pixels and attached to the top of the figure, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the `uicontrol` whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the `uicontrol` handle, and the `gcbo` function to retrieve the figure handle. Also note the defensive programming regarding figure `Units`, which the callback requires to be in pixels in order to work correctly, but which the callback also restores to their previous value afterwards.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within the `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

Note that the `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Introduction” for an example of how to implement a resize function for a GUI.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

Selected  
on | off

*Is object selected?* This property indicates whether the figure is selected. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

SelectionHighlight  
{on} | off

Figures do not indicate selection.

SelectionType  
{normal} | extend | alt | open

*Mouse selection type.* MATLAB maintains this property to provide information about the last mouse button press that occurred within the figure window. This information indicates the type of selection made. Selection types are actions that MATLAB generally associates with particular responses from the user interface software (for example, single-clicking a graphics object places it in move or resize mode; double-clicking a file name opens it, etc.).

The physical action required to make these selections varies on different platforms. However, all selection types exist on all platforms.

Selection Type	Microsoft Windows	X-Windows
Normal	Click left mouse button.	Click left mouse button.
Extend	<b>Shift</b> - click left mouse button or click both left and right mouse buttons.	<b>Shift</b> -click left mouse button or click middle mouse button.

# Figure Properties

---

Selection Type	Microsoft Windows	X-Windows
Alternate	<b>Control</b> - click left mouse button or click right mouse button.	<b>Control</b> -click left mouse button or click right mouse button.
Open	Double-click any mouse button.	Double-click any mouse button.

---

**Note** For uicontrols whose Enable property is on, a single left-click, **Ctrl**-left click, or **Shift**-left click sets the figure SelectionType property to normal. For a list box uicontrol whose Enable property is on, the second click of a double-click sets the figure SelectionType property to open. All clicks on uicontrols whose Enable property is inactive or off and all right-clicks on uicontrols whose Enable property is on set the figure SelectionType property as specified in the preceding table.

---

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, suppose you want to direct all graphics output from a file to a particular figure, regardless of user actions that might have changed the current figure. To do this, identify the figure with a Tag.

```
figure('Tag','Plotting Figure')
```

Then make that figure the current figure before drawing by searching for the Tag with `findobj`.

```
figure(findobj('Tag','Plotting Figure'))
```

## Toolbar

none | {auto} | figure

*Control display of figure toolbar.* Control whether MATLAB displays the default figure toolbar on figures. The possible values are:

- none — Do not display the figure toolbar.
- auto — Display the figure toolbar, but remove it if a uicontrol is added to the figure.
- figure — Display the figure toolbar.

Note that this property affects only the figure toolbar; it does not affect other toolbars (for example, the Camera Toolbar or Plot Edit Toolbar). Selecting **Figure Toolbar** from the figure **View** menu sets this property to `figure`.

Changing the `WindowStyle` of a window to `'modal'` hides both its toolbar and menu bar, if they exist. Changing `WindowStyle` from `'modal'` to `'normal'` or `'docked'` displays any toolbar or menu bar a figure has.

## Type

string (read-only)

*Object class.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For figures, `Type` is always `'figure'`.

## UIContextMenu

handle of uicontextmenu object

# Figure Properties

---

*Associate a context menu with the figure.* Assign this property the handle of a `uicontextmenu` object created in the figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the figure.

## Units

inches | centimeters | normalized | points | {pixels}  
| characters

*Units of measurement.* Specifies the units MATLAB uses to interpret size and location data. All units are measured from the lower-left corner of the window.

- `normalized` — Units map the lower-left corner of the figure window to (0,0) and the upper-right corner to (1.0,1.0).
- `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.
- `pixels` — Size depends on screen resolution.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter x, and the height of one `characters` unit is the distance between the baselines of two lines of text.

This property affects the `CurrentPoint` and `Position` properties. If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is the default value.

When specifying the units as property/value pairs during object creation, you must set the `Units` property before specifying the properties that you want to use these units.

## UserData

matrix

*User-specified data.* Data you want to associate with the figure object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`  
{on} | off

*Object visibility.* The `Visible` property determines whether an object is displayed on the screen. If the `Visible` property of a figure is `off`, the entire figure window is invisible.

## A Note About Using the Window Button Properties

Your window button callback functions might need to update the display by calling `drawnow` or `pause`, which causes MATLAB to process all events in the queue. Processing the event queue can cause your window button callback functions to be reentered. For example, a `drawnow` in the `WindowButtonDownFcn` might result in the `WindowButtonDownFcn` being called again before the first call has finished. You should design your code to handle reentrancy and you should not depend on global variables that might change state during reentrance.

You can use the `Interruptible` and `BusyAction` figure properties to control how events interact.

`WindowButtonDownFcn`  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is in the figure window. See the `WindowButtonMotionFcn` property for an example.

# Figure Properties

---

---

**Note** When using a two- or three-button mouse on Macintosh systems, right-button and middle-button presses are not always reported. This happens *only* when a new figure window appears under the mouse cursor and the mouse is clicked without first moving it. In this circumstance, for the `WindowButtonDownFcn` to work, the user needs to do one of the following:

- Move the mouse after the figure is created, then click any mouse button
  - Press **Shift** or **Ctrl** while clicking the left mouse button to perform the Extend and Alternate selection types
- Pressing the left mouse button (or single mouse button) works without having to take either of the above actions.
- 

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## `WindowButtonMotionFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Mouse motion callback function.* Executes whenever you move the pointer within the figure window. Define the `WindowButtonMotionFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## Example Using All Window Button Properties

Click to view in editor — This example enables you to use mouse motion to draw lines. It uses all three window button functions.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

---

**Note** On some computer systems, the `WindowButtonMotionFcn` is executed when a figure is created even though there has been no mouse motion within the figure.

---

## `WindowButtonUpFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button release callback function.* Executes whenever you release a mouse button. Define the `WindowButtonUpFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

The button up event is associated with the figure window in which the preceding button down event occurred. Therefore, the pointer need not be in the figure window when you release the button to generate the button up event.

If the callback routines defined by `WindowButtonDownFcn` or `WindowButtonMotionFcn` contain `drawnow` commands or call other functions that contain `drawnow` commands and the `Interruptible` property is off, the `WindowButtonUpFcn` might not be called. You can prevent this problem by setting `Interruptible` to on.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## `WindowKeyPressFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

## Figure Properties

---

*Key press callback function for the figure window.* Executes whenever a key press occurs. This is a callback function invoked by a key press that occurs while either the figure window or any of its children has focus. Define the `WindowKeyPressFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

When no callback is specified for this property (which is the default state), MATLAB passes any key presses to the Command Window. However, when you define a callback for this property, the figure retains focus with each key press and executes the specified callback with each key press.

## WindowKeyPressFcn Event Structure

When you specify the callback as a function handle, MATLAB passes to it a structure to containing the following fields.

Field	Contents
Character	The character displayed as a result of the releasing the key(s), which can be empty or unprintable
Key	The key being released, identified by the lowercase label on key or a descriptive string
Modifier	A cell array containing the names of one or more modifier keys being released (i.e., <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when releasing the <b>command</b> modifier key

For more information and examples of use, see the `KeyPressFcn` property description.

## WindowKeyReleaseFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Key release callback function for the figure window.* Executes whenever a key release occurs. This is a callback function invoked by a key release that occurs while the figure window or any of its children has focus. Define the `WindowKeyReleaseFcn` as a function handle. The function must define at least two input arguments (handle of the figure associated with key release and an event structure).

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## WindowKeyReleaseFcn Event Structure

When you specify the callback as a function handle, MATLAB passes to it a structure containing the following fields.

Field	Contents
Character	The character displayed as a result of the releasing the key(s), which can be empty or unprintable
Key	The key being released, identified by the lowercase label on key or a descriptive string
Modifier	A cell array containing the names of one or more modifier keys being released (i.e., <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when releasing the <b>command</b> modifier key

For more information and examples of use, see the `KeyReleaseFcn` property description.

### WindowScrollWheelFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Respond to mouse scroll wheel.* Executes when the mouse wheel is scrolled while the figure has focus. MATLAB executes the callback with each single mouse wheel click.

Note that it is possible for another object to capture the event from MATLAB. For example, if the figure contains Java or ActiveX control objects that are listening for mouse scroll wheel events, then these objects can consume the events and prevent the `WindowScrollWheelFcn` from executing.

There is no default callback defined for this property.

## WindowScrollWheelFcn Event Structure

When the callback is a function handle, MATLAB passes a structure to the callback function that contains the following fields.

Field	Contents
VerticalScrollCount	A positive or negative integer that indicates the number of scroll wheel clicks. Positive values indicate clicks of the wheel scrolled in the down direction. Negative values indicate clicks of the wheel scrolled in the up direction.
VerticalScrollAmount	The current system setting for the number of lines that are scrolled for each click of the scroll wheel. If the mouse property setting for scrolling is set to One screen at a time, VerticalScrollAmount returns a value of 1.

## Effects on Other Properties

- **CurrentObject** property — Mouse scrolling does not update this figure property.
- **CurrentPoint** property — If there is no callback defined for the **WindowScrollWheelFcn** property, then MATLAB does not update the **CurrentPoint** property as the scroll wheel is turned. However, if there is a callback defined for the **WindowScrollWheelFcn** property, then MATLAB updates the **CurrentPoint** property just before executing the callback. This enables you to determine the point at which the mouse scrolling occurred.
- **HitTest** property — The **WindowScrollWheelFcn** callback executes regardless of the setting of the figure **HitTest** property.
- **SelectionType** property — The **WindowScrollWheelFcn** callback has no effect on this property.

## Values Returned by VerticalScrollCount

When a user moves the mouse scroll wheel by one click, MATLAB increments the count by +/- 1, depending on the direction of the scroll (scroll down being positive). When MATLAB calls the **WindowScrollWheelFcn** callback, the counter is reset. In most cases, this means that the absolute value of the returned value is 1. However, if the **WindowScrollWheelFcn** callback takes a long enough time to return and/or the user spins the scroll wheel very fast, then the returned value can have an absolute value greater than one.

The actual value returned by **VerticalScrollCount** is the algebraic sum of all scroll wheel clicks that occurred since last processed. This enables your callback to respond correctly to the user's action.

## Example

Click to view in editor — This example creates a graph of a function and enables you to use the mouse scroll wheel to change the range over which a mathematical function is evaluated and update the graph to reflect the new limits as you turn the scroll wheel.

Click to run example — Mouse over the figure and scroll your mouse wheel.

## Related Information

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

### WindowState

`{normal} | modal | docked`

*Normal, modal, or dockable window behavior.* When `WindowState` is `modal`:

- The figure window traps all keyboard and mouse events over all MATLAB windows as long as they are visible.
- Windows belonging to applications other than MATLAB are unaffected.
- Modal figures remain stacked above all normal figures and the MATLAB Command Window.
- When multiple modal windows exist, the most recently created window keeps focus and stays above all other windows until it becomes invisible, or is returned to `WindowState normal`, or is deleted. At that time, focus reverts to the window that last had focus.

Use modal figures to create dialog boxes that force the user to respond without being able to interact with other windows. Typing **Ctrl+C** while the figure has focus causes all figures with

# Figure Properties

---

`WindowStyle modal` to revert to `WindowStyle normal`, allowing you to type at the command line.

## Invisible Modal Figures

Figures with `WindowStyle modal` and `Visible` do not behave modally until they are made visible, so it is acceptable to hide a modal window for later reuse instead of destroying it.

## Stacking Order of Modal Figures

Creating a figure with `WindowStyle modal` stacks it on top of all existing figure windows, making them inaccessible as long as the top figure exists and remains modal. However, any new figures created after a modal figure is displayed (for example, plots created by a modal GUI) stack on top of it and are accessible; they can be modal as well.

## Changing Modes

You can change the `WindowStyle` of a figure at any time, including when the figure is visible and contains children. However, on some systems this might cause the figure to flash or disappear and reappear, depending on the windowing system's implementation of normal and modal windows. For best visual results, you should set `WindowStyle` at creation time or when the figure is invisible.

## Window Decorations on Modal Figures

Modal figures do not display `uimenu` children, built-in menus, or toolbars but it is not an error to create `uimenu`s in a modal figure or to change `WindowStyle` to modal on a figure with `uimenu` children. The `uimenu` objects exist and their handles are retained by the figure. If you reset the figure's `WindowStyle` to normal, the `uimenu`s are displayed.

## Docked WindowStyle

When `WindowState` is `docked`, the figure is docked in the desktop or a document window. When you issue the following command:

```
set(figure_handle, 'WindowState', 'docked')
```

MATLAB docks the figure identified by *figure\_handle* and sets the `DockControls` property to `on`, if it was `off`.

Note that if `WindowState` is `docked`, you cannot set the `DockControls` property to `off`.

The value of the `WindowState` property is not changed by calling `reset` on a figure.

## WVisual

identifier string (Windows only)

*Specify pixel format for figure.* MATLAB automatically selects a pixel format for figures based on your current display settings, the graphics hardware available on your system, and the graphical content of the figure.

Usually, MATLAB chooses the best pixel format to use in any given situation. However, in cases where graphics objects are not rendered correctly, you might be able to select a different pixel format and improve results. See “Understanding the WVisual String” for more information.

## Querying Available Pixel Formats on Window Systems

You can determine what pixel formats are available on your system for use with MATLAB using the following statement:

```
set(gcf, 'WVisual')
```

MATLAB returns a list of the currently available pixel formats for the current figure. For example, the following are the first three entries from a typical list:

# Figure Properties

---

01 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, OpenGL, GDI, Window)

02 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, OpenGL, Double Buffered, Window)

03 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, OpenGL, Double Buffered, Window)

Use the number at the beginning of the string to specify which pixel format to use. For example:

```
set(gcf, 'WVisual', '02')
```

specifies the second pixel format in the list above. Note that pixel formats might differ on your system.

## Understanding the WVisual String

The string returned by querying the WVisual property provides information on the pixel format. For example:

- **RGB 16 bits(05 06 05 00)** — Indicates true color with 16-bit resolution (5 bits for red, 6 bits for green, 5 bits for blue, and 0 for alpha (transparency). MATLAB requires true color.
- **zdepth 24** — Indicates 24-bit resolution for sorting object's front to back position on the screen. Selecting pixel formats with higher (24 or 32) zdepth might solve sorting problems.
- **Hardware Accelerated** — Some graphics functions might be performed by hardware for increased speed. If there are incompatibilities between your particular graphic hardware and MATLAB, select a pixel format in which the term **Generic** appears instead of **Hardware Accelerated**.
- **Opengl** — Supports OpenGL. See the preceding “Pixel Formats and OpenGL” for more information.
- **GDI** — Supports for Windows 2-D graphics interface.

- **Double Buffered** — Support for double buffering with the OpenGL renderer. Note that the figure `DoubleBuffer` property applies only to the painters renderer.
- **Bitmap** — Support for rendering into a bitmap (as opposed to drawing in the window).
- **Window** — Support for rendering into a window.

## Pixel Formats and OpenGL

If you are experiencing problems using hardware OpenGL on your system, you can try using generic OpenGL, which is implemented in software. To do this, first instruct MATLAB to use the software version of OpenGL with the following statement:

```
opengl software
```

Then allow MATLAB to select best pixel format to use.

See the `Renderer` property for more information on how MATLAB uses OpenGL.

`WVisualMode`  
{auto} | manual (Windows only)

*Auto or manual selection of pixel format.* `WVisualMode` can take on two values — `auto` (the default) and `manual`. In `auto` mode, MATLAB selects the best pixel format to use based on your computer system and the graphical content of the figure. In `manual` mode, MATLAB does not change the visual from the one currently in use. Setting the `WVisual` property sets this property to `manual`.

`XDisplay`  
display identifier (UNIX only)

*Contains the display used for MATLAB.* You can query this property to determine the name of the display that MATLAB is

# Figure Properties

---

using. For example, if MATLAB is running on a system called mycomputer, querying XDisplay returns a string of the following form:

```
get(gcf, 'XDisplay')
ans
mycomputer:0.0
```

## Setting XDisplay on Motif

If your computer uses Motif-based figures, you can specify the display MATLAB uses for a figure by setting the value of the figure's XDisplay property. For example, to display the current figure on a system called fred, use the command:

```
set(gcf, 'XDisplay', 'fred:0.0')
```

## XVisual

visual identifier (UNIX only)

*Select visual used by MATLAB.* You can select the visual used by MATLAB by setting the XVisual property to the desired visual ID. This can be useful if you want to test your application on an 8-bit or grayscale visual. To see what visuals are available on your system, use the UNIX xdpinfo command. From MATLAB, type:

```
!xdpinfo
```

The information returned contains a line specifying the visual ID. For example:

```
visual id:    0x23
```

To use this visual with the current figure, set the XVisual property to the ID.

```
set(gcf, 'XVisual', '0x23')
```

To see which of the available visuals MATLAB can use, call `set` on the `XVisual` property:

```
set(gcf, 'XVisual')
```

The following typical output shows the visual being used (in curly braces) and other possible visuals. Note that MATLAB requires a `TrueColor` visual.

```
{ 0x23 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff) }
 0x24 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
 0x25 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
 0x26 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
 0x27 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
 0x28 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
 0x29 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
 0x2a (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
```

You can also use the `glxinfo` UNIX command to see what visuals are available for use with the OpenGL renderer. From MATLAB, type:

```
!glxinfo
```

After providing information about the implementation of OpenGL on your system, `glxinfo` returns a table of visuals. The partial listing below shows typical output:

```
visual x bf lv rg d st colorbuffer ax dp st accumbuffer ms cav
id dep cl sp sz l ci b ro r g b a bf th cl r g b a ns b eat
-----
-
0x23 24 tc 0 24 0 r y . 8 8 8 8 0 0 0 0 0 0 0 0 0 0 0 0 None
0x24 24 tc 0 24 0 r . . 8 8 8 8 0 0 0 0 0 0 0 0 0 0 0 0 None
0x25 24 tc 0 24 0 r y . 8 8 8 8 0 24 8 0 0 0 0 0 0 0 0 0 None

0x27 24 tc 0 24 0 r y . 8 8 8 8 0 0 0 0 16 16 16 0 0 0 0 Slow
```

# Figure Properties

---

The third column is the class of visual. `tc` means a true color visual. Note that some visuals might be labeled `Slow` under the caveat column. Such visuals should be avoided.

To determine which visual MATLAB will use by default with the OpenGL renderer, use the MATLAB `opengl info` command. The returned entry for the visual might look like the following:

```
Visual = 0x23 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
```

Experimenting with a different TrueColor visual might improve certain rendering problems.

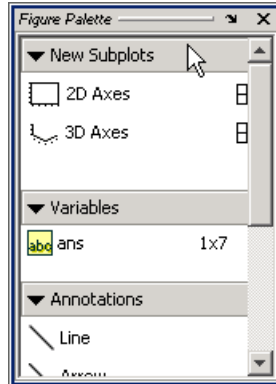

`XVisualMode`  
{auto} | manual (UNIX only)

*Auto or manual selection of visual.* `XVisualMode` can take on two values — `auto` (the default) and `manual`. In `auto` mode, MATLAB selects the best visual to use based on the number of colors, availability of the OpenGL extension, etc. In `manual` mode, MATLAB does not change the visual from the one currently in use. Setting the `XVisual` property sets this property to `manual`.

## See Also

`figure`

**Purpose** Show or hide **Figure Palette**

**Syntax**

```
figurepalette('show')
figurepalette('hide')
figurepalette
figurepalette(figure_handle,...)
```

**Description**

`figurepalette('show')` displays the palette on the current figure.

`figurepalette('hide')` hides the palette on the current figure.

`figurepalette` toggles the visibility of the palette on the current figure. You can also use `figurepalette('toggle')` instead for the same functionality.

`figurepalette(figure_handle,...)` shows or hides the palette on the figure specified by `figure_handle`.

**Tips**

If you call `figurepalette` in a MATLAB program and subsequent lines depend on the Figure Palette being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Alternatives**

To collectively enable **Plotting Tools**, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the **Plotting Tools**,

# figurepalette

---

use the smaller icon . Open or close the **Figure Palette** tool from the figure's **View** menu.

## **See Also**

[plottools](#) | [plotbrowser](#) | [propertyeditor](#)

**Purpose** Set or get attributes of file or folder

**Syntax**

```
fileattrib
fileattrib(name)

fileattrib(name,attribs)
fileattrib(name,attribs,users)
fileattrib(name,attribs,users,'s')

[status,message,messageid] = fileattrib(name,attribs, __ )
[status,message] = fileattrib(name)
```

**Description**

fileattrib gets attribute values for the current folder, using the following structure, where Name is always a string containing the current folder name. For the other fields, a value of 0 indicates that the attribute is off, 1 indicates that the attribute is on, and NaN indicates that the attribute does not apply:

```
Name
archive
system
hidden
directory
UserRead
UserWrite
UserExecute
GroupRead
GroupWrite
GroupExecute
OtherRead
```

fileattrib(name) gets the attribute values for the named file or folder.

# fileattrib

---

`fileattrib(name,attrs)` sets the specified attributes for the named file or folder.

`fileattrib(name,attrs,users)` sets the file or folder attributes for the specified subset of users.

`fileattrib(name,attrs,users,'s')` sets the specified attributes for the specified users for the contents of the named folder.

`[status,message,messageid] = fileattrib(name,attrs,___)` sets the specified file attributes and gets the function status:

- If `status` is 0, then `message` is the error message, and `messageid` is the error message identifier.
- If `status` is 1, then `message` is a structure containing the attributes of the named file or folder, and `messageid` is an empty string.

`[status,message] = fileattrib(name)` gets `status` and the last *successfully* set attribute structure values for the named file or folder and returns the structure to `message`. (`status` is always 1.)

## Input Arguments

### **name - File or folder name**

string

The absolute or relative path for a folder or file, specified as a string. To specify all names beginning with certain characters, add the wildcard character, `*`.

**Example:** `fileattrib('myfile.m')`

### **attrs - File or folder attribute values**

'a' | 'h' | 's' | 'w' | 'x'

File or folder attribute values, specified as a space delimited string. Use the plus (+) qualifier before an attribute to set it, and the minus (-) qualifier before an attribute to clear it.

attribvalue	Description
'a'	Archive (Microsoft Windows platform only).
'h'	Hidden file (Windows platform only).
's'	System file (Windows platform only).
'w'	Write access (Windows and UNIX platforms). Results differ by platform and application. For example, even though fileattrib disables the “write” privilege for a folder, making it read only, files in the folder could be writable for some platforms or applications.
'x'	Executable (UNIX platform only).

**Example:** `fileattrib('myfile.m', '+w -h')`

#### users - Subset of users

'a' | 'g' | 'o' | 'u' | ''

Subset of users (on UNIX platforms only), specified as a string. For all platforms other than UNIX, specify the `users` argument as an empty string, ''. This value is not returned by `fileattrib` get operations.

Value for UNIX Users	Description
'a'	All users on UNIX platforms
'g'	Group of users
'o'	All other users
'u'	Current user

**Example:** `fileattrib('D:/work/results', '-w', 'a')`

## Output Arguments

#### status - Indication of whether attempt to set attribute was successful

0 | 1

# fileattrib

---

If attempt to set attribute was unsuccessful, status is 0. Otherwise, status is 1.

## **message - Attribute structure or error message**

string | structure array

Attribute structure or error message, depending on whether you are setting or getting attributes and status.

<b>Getting or Setting Attributes</b>	<b>Status</b>	<b>Message contents</b>
Setting	0	Error message
Setting	1	Empty string
Getting	1	Structure containing file attributes and values

When you are getting file attributes, the structure contains these fields and possible values.

<b>Field name</b>	<b>Possible Values</b>
Name	String containing name of file or folder
archive	0 (not set), 1 (set), or NaN (not applicable)
system	0, 1, or NaN
hidden	0, 1, or NaN
directory	0, 1, or NaN
UserRead	0, 1, or NaN
UserWrite	0, 1, or NaN
UserExecute	0, 1, or NaN
GroupRead	0, 1, or NaN

Field name	Possible Values
GroupWrite	0, 1, or NaN
GroupExecute	0, 1, or NaN
OtherRead	0, 1, or NaN
OtherWrite	0, 1, or NaN
OtherExecute	0, 1, or NaN

**messageid - Error message identifier**

string

Error message identifier when the attempt to set attribute is unsuccessful (`status` is 0), returned as a string. If `status` is 1, then `messageid` is an empty string.

# fileattrib

---

## Tips

- `fileattrib` is like the DOS `attrib` command, or the UNIX `chmod` command. <sup>2</sup>

## Examples

### View Current Folder Attributes

View attributes of the current folder, assuming the current folder is `C:\my_MATLAB_files`.

```
fileattrib
```

```
ans =
```

```
          Name: 'C:\my_MATLAB_files'  
    archive: 0  
    system: 0  
    hidden: 0  
  directory: 1  
   UserRead: 1  
   UserWrite: 1  
  UserExecute: 1  
   GroupRead: NaN  
   GroupWrite: NaN  
  GroupExecute: NaN  
   OtherRead: NaN  
   OtherWrite: NaN  
  OtherExecute: NaN
```

The attributes indicate that you have read, write, and execute permissions for the current folder.

### View File Attributes

View attributes of file `collatz.m`.

```
fileattrib('collatz.m')
```

2. UNIX is a registered trademark of The Open Group in the United States and other countries.

```
ans =  
  
        Name: 'C:\my_MATLAB_files\collatz.m'  
    archive: 1  
    system: 0  
    hidden: 0  
  directory: 0  
    UserRead: 1  
    UserWrite: 0  
  UserExecute: 1  
    GroupRead: NaN  
    GroupWrite: NaN  
  GroupExecute: NaN  
    OtherRead: NaN  
    OtherWrite: NaN  
  OtherExecute: NaN
```

The attributes indicate that the specified item is a file. You can read and execute the file, but cannot update it. The file is archived.

### **View Folder Attributes on a Windows System**

View attributes for the folder C:\my\_MATLAB\_files\doc.

```
fileattrib('C:\my_MATLAB_files\doc')
```

```
ans =  
  
        Name: 'C:\my_MATLAB_files\doc'  
    archive: 0  
    system: 0  
    hidden: 0  
  directory: 1  
    UserRead: 1  
    UserWrite: 1  
  UserExecute: 1  
    GroupRead: NaN  
    GroupWrite: NaN
```

# fileattrib

---

```
GroupExecute: NaN
OtherRead: NaN
OtherWrite: NaN
OtherExecute: NaN
```

The attributes indicate that you have read, write, and execute permissions for the specified folder.

## View Folder Attributes on a UNIX System

View attributes for the folder /public on a UNIX system.

```
fileattrib('/public')

ans =

    Name: '/public'
  archive: NaN
   system: NaN
   hidden: NaN
 directory: 1
  UserRead: 1
  UserWrite: 1
 UserExecute: 1
  GroupRead: 1
  GroupWrite: 0
 GroupExecute: 1
   OtherRead: 1
   OtherWrite: 0
 OtherExecute: 1
```

The attributes indicate that you have read, write, and execute permissions for the specified folder. In addition, users in your UNIX group and all others have read and execute permissions for the specified folder, but not write permissions.

## Set File Attributes

Make myfile.m writeable.

```
fileattrib('myfile.m','+w')
```

### Set File Attributes for Specific Users on UNIX

Make the folder `/home/work/results` a read-only folder for *all users* on UNIX platforms.

```
fileattrib('/home/work/results','-w','a')
```

The minus (-) preceding the write attribute, `w`, removes the write status.

### Set Attributes for Folder and Its Contents

On Windows platforms, make the folder `D:\work\results` and all its contents read only and hidden.

```
fileattrib('D:\work\results','+h -w','','s')
```

Because a value for the `users` argument is not applicable on Windows systems, the argument is an empty string. The `s` argument applies the hidden and read-only attributes to the contents of the folder.

### Get Attributes Structure for a Folder

Get the attributes for the folder `results` and return them to a structure:

```
[stat, struc]=fileattrib('results')
```

```
stat =  
    1
```

```
struc =  
    Name: 'D:\work\results'  
    archive: 0  
    system: 0  
    hidden: 0  
    directory: 1  
    UserRead: 1  
    UserWrite: 1  
    UserExecute: 1  
    GroupRead: NaN
```

# fileattrib

---

```
GroupWrite: NaN
GroupExecute: NaN
OtherRead: NaN
OtherWrite: NaN
OtherExecute: NaN
```

The operation is successful as indicated by the status, `stat`, value of 1. The structure, `struc`, contains the file attributes.

Access the name attribute value in the structure. MATLAB returns the path for results.

```
struc.Name
```

```
ans =
D:\work\results
```

## Get Attributes Structure for Multiple Files

Get the attributes for all files in the current folder with names that begin with `new`.

```
[stat,struc]=fileattrib('new*')
```

```
stat =
    1
```

```
mess =
1x3 struct array with fields:
    Name
    archive
    system
    hidden
    directory
    UserRead
    UserWrite
    UserExecute
    GroupRead
    GroupWrite
```

```
GroupExecute
OtherRead
OtherWrite
OtherExecute
```

The results indicate there are three matching files.

View the file names.

```
struc.Name
```

```
ans =
D:\work\results\newname.m
```

```
ans =
D:\work\results\newone.m
```

```
ans =
D:\work\results\newtest.m
```

View just the second file name.

```
struct(2).Name
```

```
ans =
D:\work\results\newname.m
```

### **Successfully Set Attributes for a File and Get Messages**

Show output that results when an attempt to set file attributes is successful.

```
[status, message, messageid] = fileattrib('C:/my_MATLAB_files\doc', '+')
```

```
status =
```

```
1
```

```
message =
```

# fileattrib

---

```
''  
  
messageid =  
  
''
```

The status value of 1 indicates the set operation was successful; therefore, no error message or messageid is returned.

## Unsuccessfully Set Attributes for a File and Get Messages

Show output that results when an attempt to set file attributes is unsuccessful.

```
[status, message, messageid] = fileattrib('C:/my_MATLAB_files\doc','+h w-'  
  
status =  
  
0  
  
message =  
  
Illegal file mode characters on the current platform.  
  
messageid =  
  
MATLAB:FILEATTRIB:ModeSyntaxError
```

The status value of 0 indicates the set operation was unsuccessful. The minus sign incorrectly appears after w, instead of before it.

rmdir
```

<b>Purpose</b>	Open Current Folder browser, or select it if already open
<b>Syntax</b>	<code>filebrowser</code>
<b>Description</b>	<code>filebrowser</code> opens the Current Folder browser, or if it is already open, makes it the selected tool.
<b>See Also</b>	<code>cd</code>   <code>copyfile</code>   <code>fileattrib</code>   <code>ls</code>   <code>mkdir</code>   <code>movefile</code>   <code>pwd</code>   <code>rmdir</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Working with Files and Folders”</li></ul>

# filemarker

---

<b>Purpose</b>	Character to separate file name and internal function name
<b>Syntax</b>	<code>M = filemarker</code>
<b>Description</b>	<code>M = filemarker</code> returns the character that separates a file and a within-file function name.
<b>Examples</b>	<p>On the Microsoft Windows platform, for example, <code>filemarker</code> returns the <code>'&gt;'</code> character:</p> <pre>filemarker  ans =     &gt;</pre> <p>You can use the following command on any platform to get the help text for the local function <code>pdeodes</code> defined in <code>pdepe.m</code>:</p> <pre>helptext = help(['imwrite' filemarker 'validateSizes'])  helptext =     How many bytes does each element occupy in memory?</pre> <p>You can use the <code>filemarker</code> character to indicate a location within a MATLAB program file where you want to set a breakpoint, for example. On all platforms, if you need to distinguish between two nested functions with the same name, use the forward slash (<code>/</code>) character to indicate the path to a particular instance of a function.</p> <p>For instance, suppose <code>myfile.m</code> contains the following code:</p> <pre>function x = A(p1, p2) ...     function y = B(p3)         ...     end     function m = C(p4)         ...</pre>

```
        end
    end

    function z = C(p5)
    ...
        function y = D(p6)
        ...
        end
    end
end
```

To indicate that you want to set a breakpoint at function `y` nested within function `x`, use the following command on the Windows platform:

```
dbstop myfile>x/y
```

To indicate that you want to set a breakpoint at function `m` nested within function `x` use the following command on the Windows platform:

```
dbstop myfile>m
```

In the first case, you specify `x/y` because `myfile.m` contains two nested functions named `y`. In the second case, there is no need to specify `x/m` because there is only one function `m` within `myfile.m`.

## See Also

`filesep`

# fileparts

---

## Purpose

Parts of file name and path

---

**Note** The fourth output argument of `fileparts` (file version) is no longer supported and has been removed. Calling the function with more than three output arguments generates an error.

---

## Syntax

```
[pathstr,name,ext] = fileparts(filename)
```

## Description

`[pathstr,name,ext] = fileparts(filename)` returns the path name, file name, and extension for the specified file. The file does not have to exist. `filename` is a string enclosed in single quotes. The returned `ext` field contains a dot (.) before the file extension.

## Tips

- `fileparts` only parses file names. It does not verify that a file or a folder exists.
- You can reconstruct the file from the parts using:

```
fullfile(pathstr,[name ext])
```

- On Microsoft Windows systems, you can use either forward (/) or back (\) slashes as path delimiters, even within the same string. On UNIX and Macintosh systems, use only / as a delimiter. You can use the `filesep` function to insert the correct separator character for the platform on which your code executes:

```
sep = filesep;  
file = ['H:' sep 'user4' sep 'matlab' sep 'myfile.txt'];
```

```
file =  
H:\user4\matlab\myfile.txt
```

- If the input consists of a folder name only, be sure that the right-most character is a delimiter (/ or \). Otherwise, `fileparts` parses the trailing portion of `filename` as the name of a file and returns it in `name` instead of in `pathstr`.

## Input Arguments

### **filename**

String containing a name of a file or folder, which can include a path and file extension. The function interprets all characters following the right-most delimiter as a file name plus extension.

## Output Arguments

### **pathstr**

String containing the part of `filename` interpreted as a path name

### **name**

String containing the name of the file without any extension

### **ext**

String containing the file extension only, beginning with a period (.)

## Definitions

### **Path Name**

The full or partial path to a destination folder location, always the initial portion of the filename string. Path names end with a slash character and, where appropriate, can begin with a drive letter. Windows paths use backward slashes (\). UNIX and Macintosh paths use forward slashes (/).

## Examples

Return the pieces of a file specification string to the separate string outputs `pathstr`, `name`, and `ext`. The full file specification is:

```
file = 'H:\user4\matlab\myfile.txt';  
[pathstr,name,ext] = fileparts(file)
```

```
pathstr =  
H:\user4\matlab
```

```
name =  
myfile
```

```
ext =
```

# fileparts

---

```
.txt
```

---

Query parts of a user `.cshrc` file:

```
[pathstr,name,ext] = fileparts('/home/jsmith/.cshrc')
```

```
pathstr =  
/home/jsmith
```

```
name =  
    Empty string: 1-by-0
```

```
ext =  
.cshrc
```

`fileparts` interprets the entire file name as an extension because it begins with a period.

## Alternatives

Use `uigetfile` to interactively select and return a file name and path, or `uigetdir` to interactively select and return a path name. If you call `fileparts` with the output of `uigetfile`, you can parse out the file name and extension.

## See Also

`filesep` | `fullfile` | `pathsep` | `uigetdir` | `uigetfile`

## Tutorials

- “Path Names in MATLAB”

**Purpose** Read contents of file into string

**Syntax** `text = fileread(filename)`

**Description** `text = fileread(filename)` returns the contents of the file *filename* as a MATLAB string.

**Examples** Read and search the file `Contents.m` in the MATLAB `iofun` directory for the reference to `fileread`:

```
% find the correct directory and file
io_contents = ...
    fullfile(matlabroot, 'toolbox', 'matlab', 'iofun', 'Contents.m');

% read the file
filetext = fileread(io_contents);

% search for the line of code that includes 'fileread'
% each line is separated by a newline ('\n')

expr = '[^\n]*fileread[^\n]*';
fileread_info = regexp(filetext, expr, 'match');
```

**See Also** `fgetl` | `fgets` | `fscanf` | `fread` | `importdata` | `textscan` | `type`

# filesep

---

**Purpose** File separator for current platform

**Syntax** `f = filesep`

**Description** `f = filesep` returns the platform-specific file separator character. The file separator is the character that separates individual folder and file names in a path string.

**Examples** Create a path to the `iofun` folder on a Microsoft Windows platform:

```
iofun_dir = ['toolbox' filesep 'matlab' filesep 'iofun']
```

```
iofun_dir =  
    toolbox\matlab\iofun
```

Create a path to `iofun` on a UNIX<sup>3</sup> platform.

```
iodir = ['toolbox' filesep 'matlab' filesep 'iofun']
```

```
iodir =  
    toolbox/matlab/iofun
```

**See Also** `fullfile` | `fileparts` | `pathsep`

3. UNIX is a registered trademark of The Open Group in the United States and other countries.

**Purpose**

Filled 2-D polygons

**Syntax**

```
fill(X,Y,C)
fill(X,Y,ColorSpec)
fill(X1,Y1,C1,X2,Y2,C2,...)
fill(...,'PropertyName',PropertyValue)
h = fill(...)
```

**Description**

The `fill` function creates colored polygons.

`fill(X,Y,C)` creates filled polygons from the data in `X` and `Y` with vertex color specified by `C`. `C` is a vector or matrix used as an index into the colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`. If necessary, `fill` closes the polygon by connecting the last vertex to the first.

`fill(X,Y,ColorSpec)` fills two-dimensional polygons specified by `X` and `Y` with the color specified by `ColorSpec`.

`fill(X1,Y1,C1,X2,Y2,C2,...)` specifies multiple two-dimensional filled areas.

`fill(...,'PropertyName',PropertyValue)` allows you to specify property names and values for a patch graphics object.

`h = fill(...)` returns a vector of handles to patch graphics objects, one handle per patch object.

**Tips**

If `X` or `Y` is a matrix, and the other is a column vector with the same number of elements as rows in the matrix, `fill` replicates the column vector argument to produce a matrix of the required size. `fill` forms a vertex from corresponding elements in `X` and `Y` and creates one polygon from the data in each column.

The type of color shading depends on how you specify color in the argument list. If you specify color using `ColorSpec`, `fill` generates flat-shaded polygons by setting the patch object's `FaceColor` property to the corresponding RGB triple.

If you specify color using `C`, `fill` scales the elements of `C` by the values specified by the axes property `CLim`. After scaling `C`, `C` indexes the current colormap.

If `C` is a row vector, `fill` generates flat-shaded polygons where each element determines the color of the polygon defined by the respective column of the `X` and `Y` matrices. Each patch object's `FaceColor` property is set to `'flat'`. Each row element becomes the `CData` property value for the  $n$ th patch object, where  $n$  is the corresponding column in `X` or `Y`.

If `C` is a column vector or a matrix, `fill` uses a linear interpolation of the vertex colors to generate polygons with interpolated colors. It sets the patch graphics object `FaceColor` property to `'interp'` and the elements in one column become the `CData` property value for the respective patch object. If `C` is a column vector, `fill` replicates the column vector to produce the required sized matrix.

## Examples

Create a red octagon.

```
t = (1/16:1/8:1)'*2*pi;
x = sin(t);
y = cos(t);
fill(x,y,'r')
axis square
```

**See Also**

[axis](#) | [caxis](#) | [colormap](#) | [ColorSpec](#) | [fill3](#) | [patch](#)

# fill3

---

## Purpose

Filled 3-D polygons

## Syntax

```
fill3(X,Y,Z,C)
fill3(X,Y,Z,ColorSpec)
fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)
fill3(...,'PropertyName',PropertyValue)
h = fill3(...)
```

## Description

The `fill3` function creates flat-shaded and Gouraud-shaded polygons.

`fill3(X,Y,Z,C)` fills three-dimensional polygons.  $X$ ,  $Y$ , and  $Z$  triplets specify the polygon vertices. If  $X$ ,  $Y$ , or  $Z$  is a matrix, `fill3` creates  $n$  polygons, where  $n$  is the number of columns in the matrix. `fill3` closes the polygons by connecting the last vertex to the first when necessary.

$C$  specifies color, where  $C$  is a vector or matrix of indices into the current colormap. If  $C$  is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if  $C$  is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`.

`fill3(X,Y,Z,ColorSpec)` fills three-dimensional polygons defined by  $X$ ,  $Y$ , and  $Z$  with color specified by `ColorSpec`.

`fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)` specifies multiple filled three-dimensional areas.

`fill3(...,'PropertyName',PropertyValue)` allows you to set values for specific patch properties.

`h = fill3(...)` returns a vector of handles to patch graphics objects, one handle per patch.

## Algorithms

If  $X$ ,  $Y$ , and  $Z$  are matrices of the same size, `fill3` forms a vertex from the corresponding elements of  $X$ ,  $Y$ , and  $Z$  (all from the same matrix location), and creates one polygon from the data in each column.

If  $X$ ,  $Y$ , or  $Z$  is a matrix, `fill3` replicates any column vector argument to produce matrices of the required size.

If you specify color using `ColorSpec`, `fill3` generates flat-shaded polygons and sets the patch object `FaceColor` property to an RGB triple.

If you specify color using  $C$ , `fill3` scales the elements of  $C$  by the axes property `CLim`, which specifies the color axis scaling parameters, before indexing the current colormap.

If  $C$  is a row vector, `fill3` generates flat-shaded polygons and sets the `FaceColor` property of the patch objects to 'flat'. Each element becomes the `CData` property value for the respective patch object.

If  $C$  is a column vector or a matrix, `fill3` generates polygons with interpolated colors and sets the patch object `FaceColor` property to 'interp'. `fill3` uses a linear interpolation of the vertex colormap indices when generating polygons with interpolated colors. The elements in one column become the `CData` property value for the respective patch object. If  $C$  is a column vector, `fill3` replicates the column vector to produce the required sized matrix.

## Examples

Create four triangles with interpolated colors.

```
X = [0 1 1 2;1 1 2 2;0 0 1 1];
Y = [1 1 1 1;1 0 1 0;0 0 0 0];
Z = [1 1 1 1;1 0 1 0;0 0 0 0];
C = [0.5000 1.0000 1.0000 0.5000;
     1.0000 0.5000 0.5000 0.1667;
     0.3330 0.3330 0.5000 0.5000];
fill3(X,Y,Z,C)
```

# fill3

---

**Purpose**

1-D digital filter

**Syntax**

```
y = filter(b,a,X)
[y,zf] = filter(b,a,X)
[y,zf] = filter(b,a,X,zi)
y = filter(b,a,X,zi,dim)
[... ] = filter(b,a,X,[],dim)
```

**Description**

The `filter` function filters a data sequence using a digital filter which works for both real and complex inputs. The filter is a *direct form II transposed* implementation of the standard difference equation (see “Algorithm”).

`y = filter(b,a,X)` filters the data in vector `X` with the filter described by numerator coefficient vector `b` and denominator coefficient vector `a`. If `a(1)` is not equal to 1, `filter` normalizes the filter coefficients by `a(1)`. If `a(1)` equals 0, `filter` returns an error.

If `X` is a matrix, `filter` operates on the columns of `X`. If `X` is a multidimensional array, `filter` operates on the first nonsingleton dimension.

`[y,zf] = filter(b,a,X)` returns the final conditions, `zf`, of the filter delays. If `X` is a row or column vector, output `zf` is a column vector of  $\max(\text{length}(a), \text{length}(b)) - 1$ . If `X` is a matrix, `zf` is an array of such vectors, one for each column of `X`, and similarly for multidimensional arrays.

`[y,zf] = filter(b,a,X,zi)` accepts initial conditions, `zi`, and returns the final conditions, `zf`, of the filter delays. Input `zi` is a vector of length  $\max(\text{length}(a), \text{length}(b)) - 1$ , or an array with the leading dimension of size  $\max(\text{length}(a), \text{length}(b)) - 1$  and with remaining dimensions matching those of `X`.

`y = filter(b,a,X,zi,dim)` and `[... ] = filter(b,a,X,[],dim)` operate across the dimension `dim`.

# filter

---

## Examples

You can use `filter` to find a running average without using a `for` loop. This example finds the running average of a 16-element vector, using a window size of 5.

```
data = [1:0.2:4]';
windowSize = 5;
filter(ones(1,windowSize)/windowSize,1,data)
```

```
ans =
    0.2000
    0.4400
    0.7200
    1.0400
    1.4000
    1.6000
    1.8000
    2.0000
    2.2000
    2.4000
    2.6000
    2.8000
    3.0000
    3.2000
    3.4000
    3.6000
```

## Algorithms

The `filter` function is implemented as a direct form II transposed structure,

$$a(1)*y(n) = b(1)*x(n) + b(2)*x(n-1) + \dots + b(nb+1)*x(n-nb) \\ - a(2)*y(n-1) - \dots - a(na+1)*y(n-na)$$

where  $n-1$  is the filter order, which handles both FIR and IIR filters [1],  $na$  is the feedback filter order, and  $nb$  is the feedforward filter order. Due to normalization, assume  $a(1) = 1$ .

or

# filter2

---

**Purpose** 2-D digital filter

**Syntax**  
`Y = filter2(h,X)`  
`Y = filter2(h,X,shape)`

**Description** `Y = filter2(h,X)` filters the data in `X` with the two-dimensional FIR filter in the matrix `h`. It computes the result, `Y`, using two-dimensional correlation, and returns the central part of the correlation that is the same size as `X`.

`Y = filter2(h,X,shape)` returns the part of `Y` specified by the `shape` parameter. `shape` is a string with one of these values:

`'full'` Returns the full two-dimensional correlation. In this case, `Y` is larger than `X`.

`'same'` (default) Returns the central part of the correlation. In this case, `Y` is the same size as `X`.

`'valid'` Returns only those parts of the correlation that are computed without zero-padded edges. In this case, `Y` is smaller than `X`.

**Tips** Two-dimensional correlation is equivalent to two-dimensional convolution with the filter matrix rotated 180 degrees. See the Algorithm section for more information about how `filter2` performs linear filtering.

**Algorithms** Given a matrix `X` and a two-dimensional FIR filter `h`, `filter2` rotates your filter matrix 180 degrees to create a convolution kernel. It then calls `conv2`, the two-dimensional convolution function, to implement the filtering operation.

`filter2` uses `conv2` to compute the full two-dimensional convolution of the FIR filter with the input matrix. By default, `filter2` then extracts the central part of the convolution that is the same size as the input

matrix, and returns this as the result. If the `shape` parameter specifies an alternate part of the convolution for the result, `filter2` returns the appropriate part.

# find

---

**Purpose** Find indices and values of nonzero elements

**Syntax**

```
ind = find(X)
ind = find(X, k)
ind = find(X, k, 'first')
ind = find(X, k, 'last')
[row,col] = find(X, ...)
[row,col,v] = find(X, ...)
```

**Description** `ind = find(X)` locates all nonzero elements of array `X`, and returns the linear indices of those elements in vector `ind`. If `X` is a row vector, then `ind` is a row vector; otherwise, `ind` is a column vector. If `X` contains no nonzero elements or is an empty array, then `ind` is an empty array.

`ind = find(X, k)` or `ind = find(X, k, 'first')` returns at most the first `k` indices corresponding to the nonzero entries of `X`. `k` must be a positive integer, but it can be of any numeric data type.

`ind = find(X, k, 'last')` returns at most the last `k` indices corresponding to the nonzero entries of `X`.

`[row,col] = find(X, ...)` returns the row and column indices of the nonzero entries in the matrix `X`. This syntax is especially useful when working with sparse matrices. If `X` is an `N`-dimensional array with `N > 2`, `col` contains linear indices for the columns. For example, for a 5-by-7-by-3 array `X` with a nonzero element at `X(4,2,3)`, `find` returns 4 in `row` and 16 in `col`. That is, (7 columns in page 1) + (7 columns in page 2) + (2 columns in page 3) = 16.

`[row,col,v] = find(X, ...)` returns a column or row vector `v` of the nonzero entries in `X`, as well as row and column indices. If `X` is a logical expression, then `v` is a logical array. Output `v` contains the non-zero elements of the logical array obtained by evaluating the expression `X`. For example,

```
A= magic(4)
A =
    16     2     3    13
     5    11    10     8
```

```

     9     7     6    12
     4    14    15     1

```

```
[r,c,v]= find(A>10);
```

```
r', c', v'
```

```
ans =
```

```
     1     2     4     4     1     3
```

```
ans =
```

```
     1     2     2     3     4     4
```

```
ans =
```

```
     1     1     1     1     1     1
```

Here the returned vector  $v$  is a logical array that contains the nonzero elements of  $N$  where

```
N=(A>10)
```

## Examples

### Example 1

```
X = [1 0 4 -3 0 0 0 8 6];
```

```
indices = find(X)
```

returns linear indices for the nonzero entries of  $X$ .

```
indices =
```

```
     1     3     4     8     9
```

### Example 2

You can use a logical expression to define  $X$ . For example,

```
find(X > 2)
```

returns linear indices corresponding to the entries of  $X$  that are greater than 2.

```
ans =
```

```
     3     8     9
```

# find

---

## Example 3

The following `find` command

```
X = [3 2 0; -5 0 7; 0 0 1];  
[r,c,v] = find(X)
```

returns a vector of row indices of the nonzero entries of X

```
r =  
    1  
    2  
    1  
    2  
    3
```

a vector of column indices of the nonzero entries of X

```
c =  
    1  
    1  
    2  
    3  
    3
```

and a vector containing the nonzero entries of X.

```
v =  
    3  
   -5  
    2  
    7  
    1
```

## Example 4

The expression

```
X = [3 2 0; -5 0 7; 0 0 1];  
[r,c,v] = find(X>2)
```

returns a vector of row indices of the nonzero entries of N where  $N=(X>2)$

```
r =  
    1  
    2
```

a vector of column indices of the nonzero entries of N where  $N=(X>2)$

```
c =  
    1  
    3
```

and a logical array that contains the nonzero elements of N where  $N=(X>2)$ .

```
v =  
    1  
    1
```

Recall that when you use `find` on a logical expression, the output vector `v` does not contain the nonzero entries of the input array. Instead, it contains the nonzero values returned after evaluating the logical expression.

### **Example 5**

Some operations on a vector

```
x = [11  0  33  0  55]';
```

```
find(x)  
ans =  
    1  
    3  
    5
```

```
find(x == 0)  
ans =  
    2
```

# find

---

```
4
find(0 < x & x < 10*pi)
ans =
    1
```

## Example 6

For the matrix

```
M = magic(3)
M =
     8     1     6
     3     5     7
     4     9     2
```

```
find(M > 3, 4)
```

returns the indices of the first four entries of M that are greater than 3.

```
ans =
     1
     3
     5
     6
```

## Example 7

If X is a vector of all zeros, `find(X)` returns an empty matrix. For example,

```
indices = find([0;0;0])
indices =
    Empty matrix: 0-by-1
```

<b>Purpose</b>	Find all graphics objects
<b>Syntax</b>	<pre>object_handles = findall(handle_list) object_handles = findall(handle_list, 'property', 'value', ...)</pre>
<b>Description</b>	<p><code>object_handles = findall(handle_list)</code> returns the handles, including hidden handles, of all objects in the hierarchy under the objects identified in <code>handle_list</code>.</p> <p><code>object_handles = findall(handle_list, 'property', 'value', ...)</code> returns the handles of all objects in the hierarchy under the objects identified in <code>handle_list</code> that have the specified properties set to the specified values.</p>
<b>Tips</b>	<code>findall</code> is similar to <code>findobj</code> , except that it finds objects even if their <code>HandleVisibility</code> is set to <code>off</code> .
<b>Examples</b>	<pre>plot(1:10) xlabel xlab a = findall(gcf) b = findobj(gcf) c = findall(b, 'Type', 'text') % return the xlabel handle twice d = findobj(b, 'Type', 'text') % can't find the xlabel handle</pre>
<b>See Also</b>	<code>allchild</code>   <code>findobj</code>

# findfigs

---

**Purpose** Find visible offscreen figures

**Syntax** `findfigs`

**Description** `findfigs` finds all visible figure windows whose display area is off the screen and positions them on the screen.

A window appears to the MATLAB software to be offscreen when its display area (the area not covered by the window's title bar, menu bar, and toolbar) does not appear on the screen.

This function is useful when you are bringing an application from a larger monitor to a smaller one (or one with lower resolution). Windows visible on the larger monitor may appear offscreen on a smaller monitor. Using `findfigs` ensures that all windows appear on the screen.

**Purpose**

Locate graphics objects with specific properties

**Syntax**

```
findobj
h = findobj
h = findobj('PropertyName',PropertyValue,...)
h =
findobj('PropertyName',PropertyValue,'-logicaloperator',
        PropertyName',PropertyValue,...)
h = findobj('-regexp','PropertyName','regexp',...)
h = findobj('-property','PropertyName')
h = findobj(objhandles,...)
h = findobj(objhandles,'-depth',d,...)
h = findobj(objhandles,'flat','PropertyName',PropertyValue,
        ...)
```

**Description**

findobj returns handles of the root object and all its descendants without assigning the result to a variable.

h = findobj returns handles of the root object and all its descendants.

h = findobj('PropertyName',PropertyValue,...) returns handles of all graphics objects having the property *PropertyName*, set to the value *PropertyValue*. You can specify more than one property/value pair, in which case, findobj returns only those objects having all specified values.

h =  
findobj('PropertyName',PropertyValue,'-logicaloperator',  
*PropertyName*',PropertyValue,...) applies the logical operator to the property value matching. Possible values for *-logicaloperator* are:

- -and
- -or
- -xor
- -not

See “Logical Operators” for an explanation of logical operators.

`h = findobj('-regex','PropertyName','regex',...)` matches objects using regular expressions as if the value of you passed the property `PropertyName` to the `regex` function as

```
regex(PropertyValue,'regex')
```

If a match occurs, `findobj` returns the object handle. See the `regex` function for information on how the MATLAB software uses regular expressions.

`h = findobj('-property','PropertyName')` finds all objects having the specified property.

`h = findobj(objhandles,...)` restricts the search to objects listed in `objhandles` and their descendants.

`h = findobj(objhandles,'-depth',d,...)` specifies the depth of the search. The depth argument `d` controls how many levels under the handles in `objhandles` MATLAB traverses. Specify `d` as `inf` to get the default behavior of all levels. Specify `d` as `0` to get the same behavior as using the `flat` argument.

`h = findobj(objhandles,'flat','PropertyName',PropertyValue,...)` restricts the search to those objects listed in `objhandles` and does not search descendants.

`findobj` returns an error if a handle refers to a nonexistent graphics object.

`findobj` correctly matches any legal property value. For example,

```
findobj('Color','r')
```

finds all objects having a `Color` property set to red, `r`, or `[1 0 0]`.

When a graphics object is a descendant of more than one object identified in `objhandles`, MATLAB searches the object each time `findobj` encounters its handle. Therefore, implicit references to a graphics object can result in multiple returns of its handle.

To find handle objects that meet specified conditions, use `handle.findobj`.

## Examples

Find all line objects in the current axes:

```
h = findobj(gca,'Type','line')
```

---

Find all objects having a Label set to 'foo' and a String set to 'bar':

```
h = findobj('Label','foo','-and','String','bar');
```

---

Find all objects whose String is not 'foo' and is not 'bar':

```
h = findobj('-not','String','foo','-not','String','bar');
```

---

Find all objects having a String set to 'foo' and a Tag set to 'button one' and whose Color is not 'red' or 'blue':

```
h = findobj('String','foo','-and','Tag','button one',...  
  '-and','-not',{'Color','red','-or','Color','blue'})
```

---

Find all objects for which you have assigned a value to the Tag property (that is, the value is not the empty string ''):

```
h = findobj('-regexp','Tag','[^\']')
```

---

Find all children of the current figure that have their BackgroundColor property set to a certain shade of gray ([.7 .7 .7]). This statement also searches the current figure for the matching property value pair.

```
h = findobj(gcf,'-depth',1,'BackgroundColor',[.7 .7 .7])
```

## See Also

| regexp | set

## **Tutorials**

- “Example — Using Logical Operators and Regular Expression”

## Purpose

Find handle objects matching specified conditions

## Syntax

```
Hmatch = findobj(Hobj,<conditions>)  
Hmatch = findobj(Hobj,'-property','PropertyName')
```

## Description

`Hmatch = findobj(Hobj,<conditions>)` finds handle class objects that meet the specified conditions. Specify conditions as property name/property value pairs, indicating that the objects you are trying to find have specific property values.

The `Hobj` argument must be an array of handle objects. The returned value, `Hmatch` contains an array of object handles that match the conditions.

`Hmatch = findobj(Hobj,'-property','PropertyName')` finds all object in `Hobj` having the specified property.

`findobj` has access only to public members of the objects in `Hobj`. `findobj` can find dynamic properties. See “Find Handle Objects” for more information on using `findobj`.

You cannot use regular expression with handle class objects.

## Examples

Find the object with a specific property value. Given the handle class, `BasicHandle`:

```
classdef BasicHandle < handle  
    properties  
        Prop1  
    end  
    methods  
        function obj = BasicHandle(val)  
            if nargin > 0  
                obj.Prop1 = val;  
            end  
        end  
    end  
end  
end
```

# findobj (handle)

---

Create an array of BasicHandle objects:

```
h(1) = BasicHandle(7);  
h(2) = BasicHandle(11);  
h(3) = BasicHandle(27);
```

Find the handle of the object whose Prop1 property has a value of 7:

```
h7 = findobj(h, 'Prop1', 7);  
h7.Prop1
```

```
ans =
```

```
7
```

Find the object with a specific dynamic property. Given the button class:

```
classdef button < dynamicprops  
    properties  
        UiHandle  
    end  
    methods  
        function obj = button(pos)  
            if nargin > 0  
                if length(pos) == 4  
                    obj.UiHandle = uicontrol('Position', pos, ...  
                        'Style', 'pushbutton');  
                else  
                    error('Improper position')  
                end  
            end  
        end  
    end  
end
```

Create an array of button objects, only one element of which defines a dynamic property. Use `findobj` to get the handle of the object with the dynamic property named `ButtonCoord`:

```
b(1) = button([20 40 80 20]);
b(1).addprop('ButtonCoord');
b(1).ButtonCoord = [2,3];
b(2) = button([120 40 80 20]);
b(3) = button([220 40 80 20]);

h = findobj(b, '-property', 'ButtonCoord');
h.ButtonCoord

ans =

     2     3
```

## See Also

[findprop](#) | [handle](#)

# findprop (handle)

---

**Purpose** Find meta.property object associated with property name

**Syntax** `p = findprop(h, 'Name')`

**Description** `p = findprop(h, 'Name')` returns the meta.property object associated with the property Name of the object h. Name can be a property defined by the class of h or a dynamic property defined only for the object h.

**Examples** Use findprop to view property attribute settings:

```
findprop(containers.Map, 'Count')

ans =

meta.property handle
Package: meta

Properties:
      Name: 'Count'
      Description: 'Number of pairs in the collection'
DetailedDescription: ''
      GetAccess: 'public'
      SetAccess: 'private'
      Dependent: 1
      Constant: 0
      Abstract: 0
      Transient: 1
      Hidden: 0
      GetObservable: 0
      SetObservable: 0
      AbortSet: 0
      GetMethod: []
      SetMethod: []
      DefiningClass: [1x1 meta.class]

Methods, Events, Superclasses
```

# findstr

---

**Purpose** Find string within another, longer string

---

**Note** `findstr` is not recommended. Use `strfind` instead.

---

**Syntax** `k = findstr(str1, str2)`

**Description** `k = findstr(str1, str2)` searches the longer of the two input strings for any occurrences of the shorter string, returning the starting index of each such occurrence in the double array `k`. If no occurrences are found, then `findstr` returns the empty array, `[]`.

The search performed by `findstr` is case sensitive. Any leading and trailing blanks in either input string are explicitly included in the comparison.

Unlike the `strfind` function, the order of the input arguments to `findstr` is not important. This can be useful if you are not certain which of the two input strings is the longer one.

**Examples** `s = 'Find the starting indices of the shorter string.';`

```
findstr(s, 'the')
ans =
     6     30
```

```
findstr('the', s)
ans =
     6     30
```

**See Also** `strfind` | `strtok` | `strcmp` | `strncmp` | `strcmpi` | `strncmpi` | `regex` | `regexp` | `regpi` | `regprep`

**Purpose**

Termination file for MATLAB program

**Description**

When the MATLAB program quits, it runs a script called `finish.m`, if the script exists and is on the search path MATLAB uses or in the current directory. This is a file you create yourself that instructs MATLAB to perform any final tasks just prior to terminating. For example, you might want to save the data in your workspace to a MAT-file before MATLAB exits.

`finish.m` is invoked whenever you do one of the following:

# finish

---

- Click the Close box  in the MATLAB desktop on Microsoft Windows platforms or the equivalent on UNIX<sup>4</sup> platforms
- Type `quit` or `exit` at the Command Window prompt

## Tips

When using Handle Graphics features in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible. See the reference pages for these functions for more information.

## Examples

Two sample termination files are provided with MATLAB in `matlabroot/toolbox/local`.

- `finishsav.m` — Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m` — Displays a dialog allowing you to cancel quitting and saves the workspace. See also the “Confirmation Dialogs Preferences” and the option for exiting MATLAB.

To create a termination file, make a copy of one of these sample files, changing the name to `finish.m`, and add it to the path to use it. You can modify the file to include any operations you want the termination file to perform.

## See Also

`quit` | `exit` | `startup`

## How To

- “Exit MATLAB”

# fitsdisp

---

## Examples

Display metadata in the 2nd HDU in the FITS file.

```
fitsdisp('tst0012.fits', 'Index', 2);
```

Display the metadata in the 1st, 3rd, and 5th HDUs in a file.

```
fitsdisp('tst0012.fits', 'Index', [1 3 5]);
```

Display all metadata in the 5th HDU in a file

```
fitsdisp('tst0012.fits', 'Index', 5, 'Mode', 'full');
```

**Purpose** Information about FITS file

**Syntax** `info = fitsinfo(filename)`

**Description** `info = fitsinfo(filename)` returns the structure, `info`, with fields that contain information about the contents of a Flexible Image Transport System (FITS) file. `filename` is a string enclosed in single quotes that specifies the name of the FITS file.

The `info` structure contains the following fields, listed in the order they appear in the structure. In addition, the `info` structure can also contain information about any number of optional file components, called *extensions* in FITS terminology. For more information, see “FITS File Extensions” on page 1-2016.

Field Name	Description	Return Type
Filename	Name of the file	String
FileModDate	File modification date	String
FileSize	Size of the file in bytes	Double
Contents	List of extensions in the file in the order that they occur	Cell array of strings
PrimaryData	Information about the primary data in the FITS file	Structure array

### PrimaryData

The `PrimaryData` field is a structure that describes the primary data in the file. The following table lists the fields in the order they appear in the structure.

Field Name	Description	Return Type
DataType	Precision of the data	String
Size	Array containing the size of each dimension	Double array

Field Name	Description	Return Type
DataSize	Size of the primary data in bytes	Double
MissingDataValue	Value used to represent undefined data	Double
Intercept	Value, used with Slope, to calculate actual pixel values from the array pixel values, using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$	Double
Slope	Value, used with Intercept, to calculate actual pixel values from the array pixel values, using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$	Double
Offset	Number of bytes from beginning of the file to the location of the first data value	Double
Keywords	A number-of-keywords-by-3 cell array containing keywords, values, and comments of the header in each column	Cell array of strings

## FITS File Extensions

A FITS file can also include optional extensions. If the file contains any of these extensions, the info structure can contain these additional fields.

- AsciiTable — Numeric information in tabular format, stored as ASCII characters

- BinaryTable — Numeric information in tabular format, stored in binary representation
- Image — A multidimensional array of pixels
- Unknown — Nonstandard extension

### AsciiTable Extension

The AsciiTable structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
Rows	Number of rows in the table	Double
RowSize	Number of characters in each row	Double
NFields	Number of fields in each row	Double array
FieldFormat	A 1-by-NFields cell containing formats in which each field is encoded. The formats are FORTRAN-77 format codes.	Cell array of strings
FieldPrecision	A 1-by-NFields cell containing precision of the data in each field	Cell array of strings
FieldWidth	A 1-by-NFields array containing the number of characters in each field	Double array
FieldPos	A 1-by-NFields array of numbers representing the starting column for each field	Double array
DataSize	Size of the data in the table in bytes	Double
MissingDataValue	A 1-by-NFields array of numbers used to represent undefined data in each field	Cell array of strings

Field Name	Description	Return Type
Intercept	A 1-by-NFields array of numbers used along with Slope to calculate actual data values from the array data values using the equation: $actual\_value = Slope * array\_value + Intercept$	Double array
Slope	A 1-by-NFields array of numbers used with Intercept to calculate true data values from the array data values using the equation: $actual\_value = Slope * array\_value + Intercept$	Double array
Offset	Number of bytes from beginning of the file to the location of the first data value in the table	Double
Keywords	A number-of-keywords-by-3 cell array containing all the Keywords, Values and Comments in the ASCII table header	Cell array of strings

## BinaryTable Extension

The BinaryTable structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
Rows	Number of rows in the table	Double
RowSize	Number of bytes in each row	Double
NFields	Number of fields in each row	Double

Field Name	Description	Return Type
FieldFormat	A 1-by-NFields cell array containing the data type of the data in each field. The data type is represented by a FITS binary table format code.	Cell array of strings
FieldPrecision	A 1-by-NFields cell containing precision of the data in each field	Cell array of strings
FieldSize	A 1-by-NFields array, where each element contains the number of values in the Nth field	Double array
DataSize	Size of the data in the Binary Table, in bytes. Includes any data past the main table.	Double
MissingDataValue	An 1-by-NFields array of numbers used to represent undefined data in each field	Cell array of double
Intercept	A 1-by-NFields array of numbers used along with Slope to calculate actual data values from the array data values using the equation: $\text{actual\_value} = \text{slope} * \text{array\_value} + \text{Intercept}$	Double array
Slope	A 1-by-NFields array of numbers used with Intercept to calculate true data values from the array data values using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$	Double array

Field Name	Description	Return Type
Offset	Number of bytes from beginning of the file to the location of the first data value	Double
ExtensionSize	Size of any data past the main table, in bytes	Double
ExtensionOffset	Number of bytes from the beginning of the file to any data past the main table	Double
Keywords	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

## Image Extension

The Image structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
DataType	Precision of the data	String
Size	Array containing sizes of each dimension	Double array
DataSize	Size of the data in the Image extension in bytes	Double
Offset	Number of bytes from the beginning of the file to the first data value	Double
MissingDataValue	Value used to represent undefined data	Double

Field Name	Description	Return Type
Intercept	Value, used with Slope, to calculate actual pixel values from the array pixel values, using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$	Double
Slope	Value, used with Intercept, to calculate actual pixel values from the array pixel values, using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$	Double
Keywords	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

### Unknown Structure

The Unknown structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
DataType	Precision of the data	String
Size	Sizes of each dimension	Double array
DataSize	Size of the data in nonstandard extensions, in bytes	Double
Offset	Number of bytes from beginning of the file to the first data value	Double

# fitsinfo

---

Field Name	Description	Return Type
MissingDataValue	Representation of undefined data	Double
Intercept	Value, used with Slope, to calculate actual data values from the array data values, using the equation: $actual\_value = Slope * array\_value + Intercept$	Double
Slope	Value, used with Intercept, to calculate actual data values from the array data values, using the equation: $actual\_value = Slope * array\_value + Intercept$	Double
Keywords	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

## Examples

Use `fitsinfo` to obtain information about the FITS file `tst0012.fits`. In addition to its primary data, the file also contains an example of the extensions `BinaryTable`, `Unknown`, `Image`, and `AsciiTable`.

```
S = fitsinfo('tst0012.fits');
S =
    Filename: [1x71 char]
    FileModDate: '12-Mar-2001 18:37:46'
    FileSize: 109440
    Contents: {'Primary' 'Binary Table' 'Unknown'
'Image' 'ASCII Table'}
    PrimaryData: [1x1 struct]
    BinaryTable: [1x1 struct]
```

```

Unknown: [1x1 struct]
Image: [1x1 struct]
AsciiTable: [1x1 struct]

```

The PrimaryData field describes the data in the file. For example, the Size field indicates the data is a 102-by-109 matrix.

```

S.PrimaryData
  DataType: 'single'
  Size: [102 109]
  DataSize: 44472
MissingDataValue: []
Intercept: 0
Slope: 1
Offset: 2880
Keywords: {25x3 cell}

```

The AsciiTable field describes the AsciiTable extension. For example, using the FieldWidth and FieldPos fields you can determine the length and location of each field within a row.

```

S.AsciiTable
ans =

  Rows: 53
  RowSize: 59
  NFields: 8
  FieldFormat: {'A9' 'F6.2' 'I3' 'E10.4' 'D20.15' 'A5' 'A1' 'I4'}
  FieldPrecision: {1x8 cell}
  FieldWidth: [9 6.2000 3 10.4000 20.1500 5 1 4]
  FieldPos: [1 11 18 22 33 54 54 55]
  DataSize: 3127
MissingDataValue: {'*' '---' ' ' ' *' [] '*' '*' '*' ''}
Intercept: [0 0 -70.2000 0 0 0 0 0]
Slope: [1 1 2.1000 1 1 1 1 1]
Offset: 103680
Keywords: {65x3 cell}

```

[fitsread](#) | [fitswrite](#) | [fitsdisp](#)

# fitsread

---

**Purpose** Read data from FITS file

**Syntax**

```
data = fitsread(filename)
data = fitsread(filename,extname)
data = fitsread(filename,extname,index)
data = fitsread(filename,Name,Value)
```

**Description** `data = fitsread(filename)` reads the primary data of the Flexible Image Transport System (FITS) file specified by the text string `filename`. The function replaces undefined data values with NaN and scales numeric data by the slope and intercept values, always returning double precision values.

`data = fitsread(filename,extname)` reads data from the FITS file extension specified by `extname`.

`data = fitsread(filename,extname,index)` reads data from the FITS file extension specified by `extname`. If there is more than one of the specified extensions in the file, `index` specifies the one to read.

`data = fitsread(filename,Name,Value)` reads data from the FITS file with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

### **filename**

Text string specifying the name of a FITS file.

### **extname**

One of the following text strings specifying the name of a data array or extension in the FITS file. To determine the contents of a FITS, view the `Contents` field of the structure returned by `fitsinfo`.

## Data Arrays or Extensions

Extname	Description
'primary'	Read data from the primary data array.
'asciitable'	Read data from the ASCII Table extension. The return value, <code>data</code> , is a 1-D cell array.
'binarytable'	Read data from the Binary Table extension. The return value, <code>data</code> , is a 1-D cell array.
'image'	Read data from the Image extension.
'unknown'	Read data from the Unknown extension.

### index

Numeric value specifying which extension to read, if more than one exists in the file.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'info'

`info` structure returned by `fitsinfo` specifying the location of data to read.

---

**Note** Using the `info` structure returned by `fitsinfo` to specify the location of data in a FITS file can significantly improve performance, especially when reading multiple images from the file.

---

### 'PixelRegion'

Cell array {rows, cols, ...} specifying the boundaries of a subimage region to read from the file. Each dimension (rows, cols) is a vector of 1-based indices given either as START, [START STOP], or [START INCREMENT STOP]. This parameter is valid only for primary or image extensions.

## **'raw'**

Specifies that fitsread should not scale the data read from the file or replace undefined values with NaN. Data read from the file is the same class as it is stored in the file.

## **'TableColumns'**

Vector of 1-based indices specifying the columns to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

## **'TableRows'**

Vector of 1-based indices specifying the rows to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

## **Output Arguments**

### **data**

Data returned from the FITS file.

## **Definitions**

### **extension**

A FITS file contains primary data and can optionally contain any number of optional components, called *extensions* in FITS terminology.

## **Examples**

Read primary data from FITS file

```
data = fitsread('tst0012.fits');
```

---

Name	Size	Bytes	Class	Attributes
data	109x102	88944	double	

---

Inspect available extensions, read 'image' extension using the extname option.

```
info = fitsinfo('tst0012.fits');
% List of contents, includes any extensions if present.
disp(info.Contents);
imageData = fitsread('tst0012.fits','image');
```

---

Subsample the fifth plane of 'image' extension by 2.

```
info      = fitsinfo('tst0012.fits');
rowend    = info.Image.Size(1);
colend    = info.Image.Size(2);
primaryData = fitsread('tst0012.fits','image',...
                      'Info',info,...
                      'PixelRegion',{[1 2 rowend], [1 2 colend], 5 });
```

---

Read every other row from an ASCII table.

```
info      = fitsinfo('tst0012.fits');
rowend    = info.AsciiTable.Rows;
tableData = fitsread('tst0012.fits','asciitable',...
                    'Info',info,...
                    'TableRows',[1:2:rowend]);
```

---

Read all data for the first, second and fifth columns of the Binary table.

```
info      = fitsinfo('tst0012.fits');
```

# fitsread

---

```
rowend      = info.BinaryTable.Rows;  
tableData = fitsread('tst0012.fits', 'binarytable', ...  
                    'Info', info, ...  
                    'TableColumns', [1 2 5]);
```

## Tutorials

- “Importing Flexible Image Transport System (FITS) Files”

---

<b>Purpose</b>	Write image to FITS file
<b>Syntax</b>	<code>fitswrite(imagedata,filename)</code> <code>fitswrite(imagedata,filename,Name,Value)</code>
<b>Description</b>	<p><code>fitswrite(imagedata,filename)</code> writes <code>imagedata</code> to the FITS file specified by <code>filename</code>. If <code>filename</code> does not exist, <code>fitswrite</code> creates the file as a simple FITS file. If <code>filename</code> exists, <code>fitswrite</code> overwrites the file or appends the image to the end of the file, depending on the value of the <code>writemode</code> argument.</p> <p><code>fitswrite(imagedata,filename,Name,Value)</code> writes <code>imagedata</code> to the FITS file specified by <code>filename</code> with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>imagedata</b> Image array.</p> <p><b>filename</b> Text string specifying the name of an existing FITS file or the name you want to assign to a new FITS file.</p> <p><b>Name-Value Pair Arguments</b> Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>'WriteMode'</b> One of these strings:</p> <ul style="list-style-type: none"><li>• <code>overwrite</code></li><li>• <code>append</code></li></ul>

# fitswrite

---

**Default:** overwrite

## **'Compression'**

One of these strings:

- none
- gzip
- rice
- hcompress
- plio

**Default:** none

## **Examples**

Create a FITS file containing the red channel of an RGB image.

```
X = imread('ngc6543a.jpg');
R = X(:,:,1);
fitswrite(R,'myfile.fits');
fitsdisp('myfile.fits');
```

Create a FITS file with three images constructed from the channels of an RGB image.

```
X = imread('ngc6543a.jpg');
R = X(:,:,1); G = X(:,:,2); B = X(:,:,3);
fitswrite(R,'myfile.fits');
fitswrite(G,'myfile.fits','writemode','append');
fitswrite(B,'myfile.fits','writemode','append');
fitsdisp('myfile.fits');
```

**Purpose** Round toward zero

**Syntax**  $B = \text{fix}(A)$

**Description**  $B = \text{fix}(A)$  rounds the elements of  $A$  toward zero, resulting in an array of integers. For complex  $A$ , the imaginary and real parts are rounded independently.

**Examples**  $a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]$

```
a =  
Columns 1 through 4  
-1.9000      -0.2000      3.4000      5.6000  
  
Columns 5 through 6  
7.0000      2.4000 + 3.6000i
```

```
fix(a)
```

```
ans =  
Columns 1 through 4  
-1.0000      0      3.0000      5.0000  
  
Columns 5 through 6  
7.0000      2.0000 + 3.0000i
```

# matlab.unittest.fixtures

---

## Purpose

Summary of classes in MATLAB Fixtures Interface

## Description

Fixtures ease creation of setup and teardown code. The matlab.unittest.fixtures package consists of the following customized MATLAB fixtures.

matlab.unittest.fixtures.CurrentFolderFixture for changing current working folder

matlab.unittest.fixtures.PathFixture Fixture for adding a folder to the MATLAB path

matlab.unittest.fixtures.SuppressedWarningsFixture Suppress display of warnings

matlab.unittest.fixtures.TemporaryFolderFixture creating a temporary folder

## See Also

“Write Tests Using Shared Fixtures”

# matlab.unittest.fixtures.CurrentFolderFixture

---

<b>Purpose</b>	Fixture for changing current working folder
<b>Description</b>	The <code>CurrentFolderFixture</code> class provides a fixture for changing the current working folder. When the test framework sets up the fixture, it changes the working folder. When the test framework tears down the fixture, it restores the working folder to its previous state.
<b>Construction</b>	<code>matlab.unittest.fixtures.CurrentFolderFixture(folder)</code> constructs a fixture for changing the current working folder to <code>folder</code> .
	<b>Input Arguments</b>
	<b>folder - Folder to make the current working folder</b> string  Folder to make the current working folder, specified as a string. MATLAB throws an error if <code>folder</code> does not exist.
<b>Properties</b>	<b>Folder</b>  Folder to make the current working folder, specified as a string in the <code>folder</code> input argument.
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see <a href="#">Copying Objects</a> in the MATLAB documentation.
<b>Examples</b>	<b>Create Fixture to Change Current Working Folder</b>  Create the following <code>changeFolderFixtureTest</code> class definition on your MATLAB path. This example assumes that the subfolder <code>helperFiles</code> exists in your working folder. Create the <code>changeToFolder</code> in your working folder if it does not exist.  The <code>test1</code> function includes a call to <code>pwd</code> to demonstrate the current path changed to the <code>helperFiles</code> folder.  <pre>classdef changeFolderFixtureTest &lt; matlab.unittest.TestCase     methods(Test)</pre>

# matlab.unittest.fixtures.CurrentFolderFixture

---

```
function test1(testCase)
    import matlab.unittest.fixtures.CurrentFolderFixture;

    changeToFolder = 'helperFiles';
    testCase.applyFixture(CurrentFolderFixture(changeToFolder));
    pwd
end
end
end
```

At the command prompt, run the test. For the purposes of this example, call `pwd` before and after `run` to show the fixture was properly torn down and the path returned to the pre-test state.

```
currentFolderBeforeTest = pwd
run(changeFolderFixtureTest);
currentFolderAfterTest = pwd

currentFolderBeforeTest =
H:\Documents\doc_examples

Running changeFolderFixtureTest

ans =

H:\Documents\doc_examples\helperFiles

.
Done changeFolderFixtureTest
_____

currentFolderAfterTest =
H:\Documents\doc_examples
```

## Concepts

# matlab.unittest.fixtures.PathFixture

---

**Purpose** Fixture for adding a folder to the MATLAB path

**Description** The `PathFixture` class provides a fixture for adding a folder to the MATLAB path. When the test framework sets up the fixture, it adds the specified folder to the path. When the test framework tears down the fixture, it restores the MATLAB path to its previous state.

**Construction** `matlab.unittest.fixtures.PathFixture(folder)` constructs a fixture for adding a folder to the MATLAB path. When the test framework sets up the fixture, it adds `folder` to the path. When it tears down the fixture, it restores the MATLAB path to its previous state.

## Input Arguments

### **folder - Folder to add to the MATLAB path**

string

Folder to add to the MATLAB path, specified as a string. MATLAB throws an error if `folder` does not exist.

**Properties** **Folder**

Folder to add to the MATLAB path, specified as a string in the `folder` input argument.

**Copy Semantics** Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

**Examples** **Add Directory to MATLAB Path for Testing**

Create the following `addPathFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder, `helperFiles`, exists in your working folder. If it does not, define `addFolder` to be a directory that exists within your current folder.

```
classdef addPathFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
```

```
import matlab.unittest.fixtures.PathFixture;

addFolder = 'helperFiles';
f = testCase.applyFixture(PathFixture(addFolder));
disp(['Added to path: ' f.Folder])
end
end
end
```

At the command prompt, run the test.

```
run(addPathFixtureTest);
```

```
Running addPathFixtureTest
Added to path: H:\Documents\doc_examples\helperFiles
.
Done addPathFixtureTest
```

---

After the tests finish running, the framework removes the folder from the path.

## Add Directory to Path Using Shared Test Fixture

Create the following `sharedAddPathFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder, `helperFiles`, exists in your working folder.

```
classdef (SharedTestFixtures={ ...
    matlab.unittest.fixtures.PathFixture('helperFiles')}) ...
    sharedAddPathFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            f = testCase.getSharedTestFixtures;
            disp(['Added to path: ' f.Folder])
        end
    end
end
end
```

# matlab.unittest.fixtures.PathFixture

---

At the command prompt, run the test.

```
run(sharedAddPathFixtureTest);
```

Setting up PathFixture.

Description: Adds 'H:\Documents\doc\_examples\helperFiles' to the path.

---

```
Running sharedAddPathFixtureTest
```

```
Added to path: H:\Documents\doc_examples\helperFiles
```

```
.
```

```
Done sharedAddPathFixtureTest
```

---

Tearing down PathFixture.

Description: Restores the path to its previous state.

---

After the tests finish running, the framework removes the folder from the path.

## Concepts

# matlab.unittest.fixtures.SuppresseWarningsFixture

---

**Purpose** Fixture to suppress display of warnings

**Description** The SuppresseWarningsFixture class provides a fixture to suppress the display of warnings. When set up, SuppresseWarningsFixture disables one or more specified warnings. When torn down, the fixture restores the states of warnings to their previous values.

**Construction** `matlab.unittest.fixtures.SuppresseWarningsFixture(warnIDs)` constructs a fixture to suppress the display of one or more warnings.

## Input Arguments

**warnIDs - Identifier for warnings disabled when the fixture is set up**

string | cell array of strings

Warning identifiers for the warnings to be suppressed, specified as a string or cell array of strings.

**Properties** **Warnings**

Warning identifiers describing warnings to suppress specified as a cell array of strings in the warnings input argument.

**Copy Semantics** Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

**Examples** **Create Fixture to Suppress Warnings**

Suppress the warning that occurs when you try to remove a folder from the search path that is not on the search path.

Remove the folder, `folderthatisonpath` from your path, assuming it does not exist.

```
rmpath('folderthatisonpath');
```

```
Warning: "folderthatisonpath" not found in path.  
> In rmpath at 58
```

# matlab.unittest.fixtures.SuppresseWarningsFixture

---

A warning appears because `rmpath` cannot find the folder.

Suppress the warning during testing by creating the following `suppressWarningsTest` class definition on your MATLAB path.

```
classdef suppressWarningsTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            import matlab.unittest.fixtures.SuppresseWarningsFixture;

            testCase.applyFixture(SuppresseWarningsFixture('MATLAB:rmpath'));

            rmpath('folderthatisnotonpath'); % would otherwise cause warning
        end
    end
end
```

At the command prompt, run the test. For the purposes of this example, call `rmpath` before and after running the test to show the warning is not suppressed outside execution of the test.

```
rmpath('folderthatisnotonpath');
run(suppressWarningsTest);
rmpath('folderthatisnotonpath');
```

```
Warning: "folderthatisnotonpath" not found in path.
> In rmpath at 58
Running suppressWarningsTest
.
Done suppressWarningsTest
```

```
Warning: "folderthatisnotonpath" not found in path.
> In rmpath at 58
```

Note that the call to `rmpath` within `suppressWarningsTest` does not result in a warning.

# matlab.unittest.fixtures.SuppresseWarningsFixture

---

## See Also

`matlab.unittest.fixtures`

## Concepts

# matlab.unittest.fixtures.TemporaryFolderFixture

---

**Purpose** Fixture for creating a temporary folder

**Description** The `matlab.unittest.fixtures.TemporaryFolderFixture` provides a fixture to create a temporary folder. When the testing framework sets up the fixture, it creates the temporary folder. When it tears down the fixture, it deletes the folder and all its contents. Before it deletes the folder, the fixture clears from memory the definitions of any MATLAB-files, P-files, and MEX-files that are defined in the temporary folder.

**Construction** `matlab.unittest.fixtures.TemporaryFolderFixture` constructs a fixture for creating a temporary folder.

`matlab.unittest.fixtures.TemporaryFolderFixture(Name,Value)` constructs a fixture for creating a temporary folder with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### PreservingOnFailure - Preservation state of temporary folder and contents after test failure

`true`

Indicator of whether the temporary folder and its contents are preserved in the event of a test failure, specified as logical `true`. This property is `false` by default. You can specify it as `true` during fixture construction.

### Data Types

logical

### WithSuffix - Suffix for temporary folder name

string (default)

# matlab.unittest.fixtures.TemporaryFolderFixture

---

Suffix for temporary folder name, specified as a string.

## Properties

### Folder

Absolute path of the folder created by the fixture, specified as a string.

### PreserveOnFailure

Indicator of whether the temporary folder and its contents are preserved in the event of a test failure. This property is `logical(0)` or `logical(1)`. It is `logical(0)` by default but is set to `logical(1)` if the 'PreservingOnFailure' input value is set to true during fixture construction.

### Suffix

Suffix used for temporary folder, specified as a string in the Name, Value pair argument, 'WithSuffix'.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create Temporary Folder Fixture

Create the following `tempFolderFixtureTest` class definition on your MATLAB path.

```
classdef tempFolderFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            import matlab.unittest.fixtures.TemporaryFolderFixture;

            tempFolder = testCase.applyFixture(TemporaryFolderFixture);

            disp(['The temporary folder: ' tempFolder.Folder])
        end
    end
end
```

# matlab.unittest.fixtures.TemporaryFolderFixture

---

At the command prompt, run the test.

```
run(tempFolderFixtureTest);
```

```
Running tempFolderFixtureTest
```

```
The temporary folder: C:\Temp\tpfb1ae2cf_c9de_4de3_9557_00d52bfcc1b2
```

```
.
```

```
Done tempFolderFixtureTest
```

---

The name of the temporary folder varies.

## Create Temporary Folder Fixture Persisting Through Test Failure

Create the following `anotherTempFolderFixtureTest` class definition on your MATLAB path. For the purposes of this example, the `test1` function contains an assertion that causes test failure.

```
classdef anotherTempFolderFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            import matlab.unittest.fixtures.TemporaryFolderFixture;

            testCase.applyFixture(TemporaryFolderFixture('PreservingOnFailure'));

            % Failed assertion, perserved temporary folder
            testCase.assertEqual(1,2);
        end
    end
end
```

At the command prompt, run the test.

```
run(anotherTempFolderFixtureTest);
```

```
Running anotherTempFolderFixtureTest
```

```
=====
```

# matlab.unittest.fixtures.TemporaryFolderFixture

---

```
Assertion failed in anotherTempFolderFixtureTest/test1.  
The remainder of the test method will not run to completion.
```

```
-----  
Framework Diagnostic:  
-----
```

```
assertEqual failed.  
--> NumericComparator failed.  
    --> The values are not equal using "isequaln".
```

```
Actual Value:
```

```
    1
```

```
Expected Value:
```

```
    2
```

```
-----  
Stack Information:  
-----
```

```
In H:\Documents\doc_examples\anotherTempFolderFixtureTest.m (anotherTempFolderFixtureTest)
```

```
=====
```

Because of a failure in the test using the TemporaryFolderFixture, the test was aborted. The temporary folder created for this test is located at C:\Temp\tp70976704\_7e39\_48b8\_90ae\_f121bbfaf877TestData

```
.  
Done anotherTempFolderFixtureTest
```

-----

Failure Summary:

Name	Failed	Incomplete	Reason(s)
anotherTempFolderFixtureTest/test1	X	X	Failed by

The test failed and the temporary folder persists.

You can open the temporary folder, shown here as

C:\Temp\tp70976704\_7e39\_48b8\_90ae\_f121bbfaf877TestData, and examine any contents.

# matlab.unittest.fixtures.TemporaryFolderFixture

## Concepts

<b>Purpose</b>	Largest consecutive integer in floating-point format
<b>Syntax</b>	<pre>f = flintmax f = flintmax(precision)</pre>
<b>Description</b>	<p>f = flintmax returns the largest consecutive integer in IEEE® double precision, which is 2<sup>53</sup>. Above this value, double-precision format does not have integer precision, and not all integers can be represented exactly.</p> <p>f = flintmax(precision) returns the largest consecutive integer in IEEE single or double precision. flintmax returns single(2<sup>24</sup>) for single precision and 2<sup>53</sup> for double precision.</p>
<b>Input Arguments</b>	<p><b>precision - Floating-point precision type</b> 'double' (default)   'single'</p> <p>Floating-point precision type, specified as 'double' or 'single'.</p> <p><b>Data Types</b> char</p>
<b>Output Arguments</b>	<p><b>f - Largest consecutive integer in floating-point format</b> scalar constant</p> <p>Largest consecutive integer in floating-point format returned as a scalar constant. This constant is 2<sup>53</sup> for double precision and single(2<sup>24</sup>) for single precision.</p>
<b>Examples</b>	<p><b>Double Precision</b></p> <p>Return the largest consecutive integer in IEEE double precision.</p> <pre>format long e f = flintmax  f =</pre>

```
9.007199254740992e+15
```

This is  $2^{53}$ .

## Single Precision

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')
```

```
f =
```

```
16777216
```

This is `single(224)`.

Check the class of `f`.

```
class(f)
```

```
ans =
```

```
single
```

## Limit of Integer Single Precision

Above the value returned by `flintmax('single')`, not all integers can be represented exactly with single precision.

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')
```

```
f =
```

```
16777216
```

This is `single(224)`.

Add 1 to the value returned from `flintmax`.

```
f1 = f + 1
```

```
f1 =
```

```
16777216
```

f1 is the same as f.

```
isequal(f,f1)
```

```
ans =
```

```
1
```

Add 2 to the value returned from flintmax.

```
f2 = f + 2
```

```
f2 =
```

```
16777218
```

16777218 is represented exactly in single precision while 16777217 is not.

## Concepts

- “Floating-Point Numbers”

# flip

---

**Purpose** Flip order of elements

**Syntax**  
`B = flip(A)`  
`B = flip(A,dim)`

**Description** `B = flip(A)` returns array `B` the same size as `A`, but with the order of the elements reversed. The dimension that is reordered in `B` depends on the shape of `A`:

- If `A` is vector, then `flip(A)` reverses the order of the elements along the length of the vector.
- If `A` is a matrix, then `flip(A)` reverses the elements in each column.
- If `A` is an N-D array, then `flip(A)` operates on the first dimension of `A` in which the size value is not 1.

`B = flip(A,dim)` reverses the order of the elements in `A` along dimension `dim`. For example, if `A` is a matrix, then `flip(A,1)` reverses the elements in each column, and `flip(A,2)` reverses the elements in each row.

## Input Arguments

**A - Input array**  
vector | matrix | array | cell array | table

Input array, specified as a vector, matrix, array, cell array, or table.

**Example:** `[1 2 3 4]`

**Example:** `['abcde']`

**Example:** `[1 2; 3 4]`

**Example:** `{'abcde',[1 2 3]}`

**Example:** `table(rand(1,5),rand(1,5))`

**dim - Dimension to operate along**  
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

The following illustration shows the difference between `dim=1` and `dim=2` when `A` is a matrix.

1	2	3
4	5	6

A

4	5	6
1	2	3

flip(A,1)

3	2	1
6	5	4

flip(A,2)

## Examples

### Flip String of Characters

```
A = 'no word, no bond, row on.'
```

```
B = flip(A)
```

```
B =
```

```
.no wor ,dnob on ,drow on
```

### Flip Column Vector

```
A = [1;2;3];
```

```
B = flip(A)
```

```
B =
```

```
3
```

```
2
```

```
1
```

### Flip Matrix

Create a diagonal matrix, `A`.

# flip

---

```
A = diag([100 200 300])
```

```
A =
```

```
    100     0     0
         0    200     0
         0     0    300
```

Flip A without specifying the dim argument.

```
B = flip(A)
```

```
B =
```

```
         0     0    300
         0    200     0
    100     0     0
```

Now, flip A along the second dimension.

```
B = flip(A,2)
```

```
B =
```

```
         0     0    100
         0    200     0
    300     0     0
```

## Flip N-D Array

Create a 1-by-3-by-2 array.

```
A = zeros(1,3,2);
A(:,:,1) = [1 2 3];
A(:,:,2) = [4 5 6];
A
```

```
A(:,:,1) =
```

```
1 2 3
```

```
A(:,:,2) =
```

```
4 5 6
```

Flip A without specifying the `dim` argument.

```
B = flip(A)
```

```
B(:,:,1) =
```

```
3 2 1
```

```
B(:,:,2) =
```

```
6 5 4
```

Now, flip A along the third dimension.

```
B = flip(A,3)
```

```
B(:,:,1) =
```

```
4 5 6
```

```
B(:,:,2) =
```

```
1 2 3
```

### Flip Cell Array

Create a 3-by-2 cell array.

```
A = {'foo',1000; 999,true; 'aaa','bbb'}
```

# flip

---

```
A =  
  
    'foo'    [1000]  
    [999]    [  1]  
    'aaa'    'bbb'
```

Flip A without specifying the `dim` argument.

```
B = flip(A)  
  
B =  
  
    'aaa'    'bbb'  
    [999]    [  1]  
    'foo'    [1000]
```

Now, flip A along the second dimension.

```
B = flip(A,2)  
  
B =  
  
    [1000]    'foo'  
    [  1]    [999]  
    'bbb'    'aaa'
```

## See Also

`flipplr` | `flipud` | `permute` | `rot90` | `transpose`

**Purpose** Flip array along specified dimension

**Syntax** `B = flipdim(A,dim)`

**Description** `B = flipdim(A,dim)` returns `A` with dimension `dim` flipped.

When the value of `dim` is 1, the array is flipped row-wise down. When `dim` is 2, the array is flipped columnwise left to right. `flipdim(A,1)` is the same as `flipud(A)`, and `flipdim(A,2)` is the same as `fliplr(A)`.

**Examples** `flipdim(A,1)` where

`A =`

```
1    4
2    5
3    6
```

produces

```
3    6
2    5
1    4
```

**See Also** `fliplr` | `flipud` | `permute` | `rot90`

# fliplr

---

**Purpose** Flip matrix left to right

**Syntax** `B = fliplr(A)`

**Description** `B = fliplr(A)` returns `A` with columns flipped in the left-right direction, that is, about a vertical axis.

If `A` is a row vector, then `fliplr(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a column vector, then `fliplr(A)` simply returns `A`.

**Examples** If `A` is the 3-by-2 matrix,

```
A =  
    1    4  
    2    5  
    3    6
```

then `fliplr(A)` produces

```
    4    1  
    5    2  
    6    3
```

If `A` is a row vector,

```
A =  
    1    3    5    7    9
```

then `fliplr(A)` produces

```
    9    7    5    3    1
```

**Limitations** The array being operated on cannot have more than two dimensions. This limitation exists because the axis upon which to flip a multidimensional array would be undefined.

**See Also** `flipdim` | `flipud` | `rot90`

**Purpose** Flip matrix up to down

**Syntax** `B = flipud(A)`

**Description** `B = flipud(A)` returns `A` with rows flipped in the up-down direction, that is, about a horizontal axis.

If `A` is a column vector, then `flipud(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a row vector, then `flipud(A)` simply returns `A`.

**Examples** If `A` is the 3-by-2 matrix,

```
A =  
    1    4  
    2    5  
    3    6
```

then `flipud(A)` produces

```
    3    6  
    2    5  
    1    4
```

If `A` is a column vector,

```
A =  
    3  
    5  
    7
```

then `flipud(A)` produces

```
A =  
    7  
    5  
    3
```

# flipud

---

## **Limitations**

The array being operated on cannot have more than two dimensions. This limitation exists because the axis upon which to flip a multidimensional array would be undefined.

## **See Also**

`flipdim` | `flip1r` | `rot90`

**Purpose** Round toward negative infinity

**Syntax** `B = floor(A)`

**Description** `B = floor(A)` rounds the elements of `A` to the nearest integers less than or equal to `A`. For complex `A`, the imaginary and real parts are rounded independently.

**Examples**

```
a = [-1.9 -0.2 3.4 5.6 7.0 2.4+3.6i];  
  
floor(a)  
  
ans =  
-2.0000 -1.0000 3.0000 5.0000 7.0000 2.0000 + 3.0000i
```

**See Also** `ceil` | `fix` | `round`

# flow

---

**Purpose** Simple function of three variables

**Syntax**

```
v = flow
v = flow(n)
v = flow(x,y,z)
[x,y,z,v] = flow(...)
```

**Description** `flow`, a function of three variables, generates fluid-flow data that is useful for demonstrating `slice`, `interp3`, and other functions that visualize scalar volume data.

`v = flow` produces a 50-by-25-by-25 array.

`v = flow(n)` produces a n-by-2n-by-n array.

`v = flow(x,y,z)` evaluates the speed profile at the points `x`, `y`, and `z`.

`[x,y,z,v] = flow(...)` returns the coordinates as well as the volume data.

**See Also** `slice` | `interp3`

**How To**

- “Slicing Fluid Flow Data”

**Purpose**

Find minimum of single-variable function on fixed interval

**Syntax**

```
x = fminbnd(fun,x1,x2)
x = fminbnd(fun,x1,x2,options)
[x,fval] = fminbnd(...)
[x,fval,exitflag] = fminbnd(...)
[x,fval,exitflag,output] = fminbnd(...)
```

**Description**

fminbnd finds the minimum of a function of one variable within a fixed interval.

`x = fminbnd(fun,x1,x2)` returns a value `x` that is a local minimizer of the function that is described in `fun` in the interval  $x_1 < x < x_2$ . `fun` is a `function_handle`.

“Parameterizing Functions” in the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective function `fun`.

`x = fminbnd(fun,x1,x2,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminbnd` uses these `options` structure fields:

<code>Display</code>	Level of display. 'off' displays no output; 'iter' displays output at each iteration; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge. See “Iterative Display” in MATLAB Mathematics for more information.
<code>FunValCheck</code>	Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is complex or NaN. 'off' displays no error.
<code>MaxFunEvals</code>	Maximum number of function evaluations allowed.
<code>MaxIter</code>	Maximum number of iterations allowed.

# fminbnd

---

OutputFcn	User-defined function that is called at each iteration. See “Output Functions” in MATLAB Mathematics for more information.
PlotFcns	Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none ( <code>[]</code> ). <ul style="list-style-type: none"><li>• <code>@optimplotx</code> plots the current point</li><li>• <code>@optimplotfval</code> plots the function value</li><li>• <code>@optimplotfunccount</code> plots the function count</li></ul> See “Plot Functions” in MATLAB Mathematics for more information.
TolX	Termination tolerance on $x$ .

`[x,fval] = fminbnd(...)` returns the value of the objective function computed in `fun` at  $x$ .

`[x,fval,exitflag] = fminbnd(...)` returns a value `exitflag` that describes the exit condition of `fminbnd`:

1	<code>fminbnd</code> converged to a solution $x$ based on <code>options.TolX</code> .
0	Maximum number of function evaluations or iterations was reached.
-1	Algorithm was terminated by the output function.
-2	Bounds are inconsistent ( $x_1 > x_2$ ).

`[x,fval,exitflag,output] = fminbnd(...)` returns a structure `output` that contains information about the optimization in the following fields:

algorithm	Algorithm used
funcCount	Number of function evaluations
iterations	Number of iterations
message	Exit message

## Arguments

`fun` is the function to be minimized. `fun` accepts a scalar `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for a function file

```
x = fminbnd(@myfun,x1,x2);
```

where `myfun.m` is a function file such as

```
function f = myfun(x)
f = ...           % Compute function value at x.
```

or as a function handle for an anonymous function:

```
x = fminbnd(@(x) sin(x*x),x1,x2);
```

Other arguments are described in the syntax descriptions above.

## Examples

`x = fminbnd(@cos,3,4)` computes  $\pi$  to a few decimal places and gives a message on termination.

```
[x,fval,exitflag] = ...
    fminbnd(@cos,3,4,optimset('TolX',1e-12,'Display','off'))
```

computes  $\pi$  to about 12 decimal places, suppresses output, returns the function value at `x`, and returns an `exitflag` of 1.

The argument `fun` can also be a function handle for an anonymous function. For example, to find the minimum of the function  $f(x) = x^3 - 2x - 5$  on the interval  $(0,2)$ , create an anonymous function `f`

```
f = @(x)x.^3-2*x-5;
```

# fminbnd

---

Then invoke `fminbnd` with

```
x = fminbnd(f, 0, 2)
```

The result is

```
x =  
    0.8165
```

The value of the function at the minimum is

```
y = f(x)  
  
y =  
   -6.0887
```

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following function file:

```
function f = myfun(x,a)  
f = (x - a)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminbnd`. To optimize for a specific value of `a`, such as `a = 1.5`.

**1** Assign the value to `a`.

```
a = 1.5; % define parameter first
```

**2** Call `fminbnd` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

```
x = fminbnd(@(x) myfun(x,a),0,1)
```

## Algorithms

`fminbnd` is a function file. Its algorithm is based on golden section search and parabolic interpolation. Unless the left endpoint  $x_1$  is very

close to the right endpoint  $x_2$ , `fminbnd` never evaluates `fun` at the endpoints, so `fun` need only be defined for  $x$  in the interval  $x_1 < x < x_2$ .

If the minimum actually occurs at  $x_1$  or  $x_2$ , `fminbnd` returns a point  $x$  in the interior of the interval  $(x_1, x_2)$  that is close to the minimizer. In this case, the distance of  $x$  from the minimizer is no more than  $2 * (\text{To1X} + 3 * \text{abs}(x) * \text{sqrt}(\text{eps}))$ . See [1] or [2] for details about the algorithm.

## Limitations

The function to be minimized must be continuous. `fminbnd` may only give local solutions.

`fminbnd` often exhibits slow convergence when the solution is on a boundary of the interval.

`fminbnd` only handles real variables.

## How To

- anonymous function

# fminsearch

---

**Purpose** Find minimum of unconstrained multivariable function using derivative-free method

**Syntax**

```
x = fminsearch(fun,x0)
x = fminsearch(fun,x0,options)
[x,fval] = fminsearch(...)
[x,fval,exitflag] = fminsearch(...)
[x,fval,exitflag,output] = fminsearch(...)
```

**Description** `fminsearch` finds the minimum of a scalar function of several variables, starting at an initial estimate. This is generally referred to as *unconstrained nonlinear optimization*.

`x = fminsearch(fun,x0)` starts at the point `x0` and returns a value `x` that is a local minimizer of the function described in `fun`. `x0` can be a scalar, vector, or matrix. `fun` is a `function_handle`.

“Parameterizing Functions” in the MATLAB Mathematics documentation explains how to pass additional parameters to your objective function `fun`. See also “Example 2” on page 1-2069 and “Example 3” on page 1-2069 below.

`x = fminsearch(fun,x0,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminsearch` uses these `options` structure fields:

<code>Display</code>	Level of display. 'off' displays no output; 'iter' displays output at each iteration; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge. See “Iterative Display” in MATLAB Mathematics for more information.
<code>FunValCheck</code>	Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is complex, Inf or NaN. 'off' (the default) displays no error.

MaxFunEvals	Maximum number of function evaluations allowed
MaxIter	Maximum number of iterations allowed
OutputFcn	User-defined function that is called at each iteration. See “Output Functions” in MATLAB Mathematics for more information.
PlotFcns	Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none ([ ]). <ul style="list-style-type: none"><li>• @optimplotx plots the current point</li><li>• @optimplotfval plots the function value</li><li>• @optimplotfunccount plots the function count</li></ul> See “Plot Functions” in MATLAB Mathematics for more information.
TolFun	Termination tolerance on the function value
TolX	Termination tolerance on x

`[x,fval] = fminsearch(...)` returns in `fval` the value of the objective function `fun` at the solution `x`.

`[x,fval,exitflag] = fminsearch(...)` returns a value `exitflag` that describes the exit condition of `fminsearch`:

1	<code>fminsearch</code> converged to a solution <code>x</code> .
0	Maximum number of function evaluations or iterations was reached.
-1	Algorithm was terminated by the output function.

`[x,fval,exitflag,output] = fminsearch(...)` returns a structure `output` that contains information about the optimization in the following fields:

# fminsearch

---

algorithm	'Nelder-Mead simplex direct search'
funcCount	Number of function evaluations
iterations	Number of iterations
message	Exit message

## Arguments

fun is the function to be minimized. It accepts an input  $x$  and returns a scalar  $f$ , the objective function evaluated at  $x$ . The function `fun` can be specified as a function handle for a function file

```
x = fminsearch(@myfun, x0)
```

where `myfun` is a function file such as

```
function f = myfun(x)
f = ...           % Compute function value at x
```

or as a function handle for an anonymous function, such as

```
x = fminsearch(@(x)sin(x^2), x0);
```

Other arguments are described in the syntax descriptions above.

## Examples

### Example 1

The Rosenbrock banana function is a classic test example for multidimensional minimization:

$$f(x) = 100(x_2 - x_1^2)^2 + (1 - x_1)^2.$$

The minimum is at  $(1, 1)$  and has the value 0. The traditional starting point is  $(-1.2, 1)$ . The anonymous function shown here defines the function and returns a function handle called `banana`:

```
banana = @(x)100*(x(2)-x(1)^2)^2+(1-x(1))^2;
```

Pass the function handle to `fminsearch`:

```
[x,fval] = fminsearch(banana,[-1.2, 1])
```

This produces

```
x =
```

```
    1.0000    1.0000
```

```
fval =
```

```
    8.1777e-010
```

This indicates that the minimizer was found to at least four decimal places with a value near zero.

## Example 2

If fun is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function myfun defined by the following function file:

```
function f = myfun(x,a)
f = x(1)^2 + a*x(2)^2;
```

Note that myfun has an extra parameter a, so you cannot pass it directly to fminsearch. To optimize for a specific value of a, such as a = 1.5.

**1** Assign the value to a.

```
a = 1.5; % define parameter first
```

**2** Call fminsearch with a one-argument anonymous function that captures that value of a and calls myfun with two arguments:

```
x = fminsearch(@(x) myfun(x,a),[0,1])
```

## Example 3

You can modify the first example by adding a parameter a to the second term of the banana function:

$$f(x) = 100(x_2 - x_1^2)^2 + (a - x_1)^2.$$

This changes the location of the minimum to the point  $[a, a^2]$ . To minimize this function for a specific value of  $a$ , for example  $a = \sqrt{2}$ , create a one-argument anonymous function that captures the value of  $a$ .

```
a = sqrt(2);  
banana = @(x) 100*(x(2)-x(1)^2)^2+(a-x(1))^2;
```

Then the statement

```
[x,fval] = fminsearch(banana, [-1.2, 1], ...  
    optimset('TolX',1e-8));
```

seeks the minimum  $[\sqrt{2}, 2]$  to an accuracy higher than the default on  $x$ .

## Algorithms

`fminsearch` uses the simplex search method of Lagarias et al. [1]. This is a direct search method that does not use numerical or analytic gradients.

If  $n$  is the length of  $x$ , a simplex in  $n$ -dimensional space is characterized by the  $n+1$  distinct vectors that are its vertices. In two-space, a simplex is a triangle; in three-space, it is a pyramid. At each step of the search, a new point in or near the current simplex is generated. The function value at the new point is compared with the function's values at the vertices of the simplex and, usually, one of the vertices is replaced by the new point, giving a new simplex. This step is repeated until the diameter of the simplex is less than the specified tolerance.

For more information, see “`fminsearch` Algorithm”.

## Limitations

`fminsearch` can often handle discontinuity, particularly if it does not occur near the solution. `fminsearch` may only give local solutions.

`fminsearch` only minimizes over the real numbers, that is,  $x$  must only consist of real numbers and  $f(x)$  must only return real numbers. When  $x$  has complex variables, they must be split into real and imaginary parts.

## How To

- anonymous function

# fopen

---

**Purpose** Open file, or obtain information about open files

**Syntax**

```
fileID = fopen(filename)
fileID = fopen(filename,permission)
fileID = fopen(filename,permission,machinefmt,encodingIn)
[fileID,errmsg] = fopen( ___)
```

```
fIDs = fopen('all')
```

```
filename = fopen(fileID)
[filename,permission,machinefmt,encodingOut]
= fopen(fileID)
```

**Description** `fileID = fopen(filename)` opens the file, `filename`, for binary read access, and returns an integer file identifier equal to or greater than 3. MATLAB reserves file identifiers 0, 1, and 2 for standard input, standard output (the screen), and standard error, respectively.

If `fopen` cannot open the file, then `fileID` is -1.

`fileID = fopen(filename,permission)` opens the file with the type of access specified by `permission`.

`fileID = fopen(filename,permission,machinefmt,encodingIn)` additionally specifies the order for reading or writing bytes or bits in the file using the `machinefmt` argument. The optional `encodingIn` argument specifies the character encoding scheme associated with the file.

`[fileID,errmsg] = fopen( ___)` additionally returns a system-dependent error message if `fopen` fails to open the file. Otherwise, `errmsg` is an empty string. You can use this syntax with any of the input arguments of the previous syntaxes.

`fIDs = fopen('all')` returns a row vector containing the file identifiers of all open files. The identifiers reserved for standard input, output, and error are not included. The number of elements in the vector is equal to the number of open files.

`filename = fopen(fileID)` returns the file name that a previous call to `fopen` used when it opened the file specified by `fileID`. The output `filename` is resolved to the full path. The `fopen` function does not read information from the file to determine the output value.

`[filename,permission,machinefmt,encodingOut] = fopen(fileID)` additionally returns the permission, machine format, and encoding that a previous call to `fopen` used when it opened the specified file. If the file was opened in binary mode, `permission` includes the letter 'b'. The `encodingOut` output is a standard encoding scheme name. `fopen` does not read information from the file to determine these output values. An invalid `fileID` returns empty strings for all output arguments.

## Input Arguments

### **filename - Name of file to open**

string

Name of the file to open, including the file extension, specified as a string. If the file is not in the current folder, `filename` must include a full or a relative path.

On UNIX systems, if `filename` begins with `'~/ '` or `'~username/ '`, the `fopen` function expands the path to the current or specified user's home directory, respectively.

- If you open a file with read access and the file is not in the current folder, then `fopen` searches along the MATLAB search path.
- If you open a file with write or append access and the file is not in the current folder, then `fopen` creates a file in the current directory.

**Example:** `'myFile.txt'`

## Data Types

char

### permission - File access type

'r' (default) | 'w' | 'a' | 'r+' | 'w+' | 'a+' | 'A' | 'W' | ...

File access type, specified as a string. You can open a file in binary mode or in text mode. On UNIX systems, both translation modes have the same effect. To open a file in binary mode, specify one of the following strings.

'r'	Open file for reading.
'w'	Open or create new file for writing. Discard existing contents, if any.
'a'	Open or create new file for writing. Append data to the end of the file.
'r+'	Open file for reading and writing.
'w+'	Open or create new file for reading and writing. Discard existing contents, if any.
'a+'	Open or create new file for reading and writing. Append data to the end of the file.
'A'	Append without automatic flushing of the current output buffer. (Used with tape drives.)
'W'	Write without automatic flushing of the current output buffer. (Used with tape drives.)

To open files in text mode, attach the letter 't' to the permission argument, such as 'rt' or 'wt+'.

On Windows systems, in text mode:

- Read operations that encounter a carriage return followed by a newline character ('\r\n') remove the carriage return from the input.

- Write operations insert a carriage return before any newline character in the output.

Open or create a new file in text mode if you want to write to it in MATLAB and then open it in Microsoft Notepad, or any text editor that does not recognize '\n' as a newline sequence. When writing to the file, end each line with '\r\n'. For an example, see `fprintf`. Otherwise, open files in binary mode for better performance.

To read and write to the same file:

- Open the file with a value for permission that includes a plus sign, '+'.  
 For example, `+'r'`.
- Call `fseek` or `frewind` between read and write operations. For example, do not call `fread` followed by `fwrite`, or `fwrite` followed by `fread`, unless you call `fseek` or `frewind` between them.

### **machinefmt - Order for reading or writing bytes or bits**

'n' (default) | 'b' | 'l' | 's' | 'a' | ...

Order for reading or writing bytes or bits in the file, specified as one of the following strings.

'n' or 'native'	Your system byte ordering (default)
'b' or 'ieee-be'	Big-endian ordering
'l' or 'ieee-le'	Little-endian ordering
's' or 'ieee-be.164'	Big-endian ordering, 64-bit long data type
'a' or 'ieee-le.164'	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

### **encodingIn - Character encoding**

'UTF-8' | 'ISO-8859-1' | 'windows-1251' | 'windows-1252' | ...

Character encoding to use for subsequent read and write operations, including `fscanf`, `fprintf`, `fgetl`, `fgets`, `fread`, and `fwrite`, specified as one of the following strings.

'Big5'	'ISO-8859-1'	'windows-932'
'EUC-JP'	'ISO-8859-2'	'windows-936'
'GBK'	'ISO-8859-3'	'windows-949'
'KSC_5601'	'ISO-8859-4'	'windows-950'
'Macintosh'	'ISO-8859-9'	'windows-1250'
'Shift_JIS'	'ISO-8859-13'	'windows-1251'
'US-ASCII'	'ISO-8859-15'	'windows-1252'
'UTF-8'		'windows-1253'
		'windows-1254'
		'windows-1257'

The default encoding is system-dependent.

If you specify a value for encoding that is not in the list of supported values, MATLAB issues a warning. Specifying other encoding names sometimes (but not always) produces correct results.

## Data Types

`char`

## **fileID** - File identifier of an open file

`integer`

File identifier of an open file, specified as an integer.

## Data Types

`double`

## Examples

### **Open File and Pass Identifier to File I/O Function**

Open a file and pass the file identifier to the `fgetl` function to read data.

Open the file, `airfoil.m`, and obtain the file identifier.

```
fileID = fopen('airfoil.m');
```

Pass the `fileID` to the `fgetl` function to read one line from the file. Then, close the file.

```
tline = fgetl(fileID);  
fclose(fileID)
```

### **Request Name of File to Open**

Create a prompt to request the name of a file to open. If `fopen` cannot open the file, display the relevant error message.

```
fileID = -1;  
errmsg = '';  
while fileID < 0  
    disp(errmsg);  
    filename = input('Open file: ', 's');  
    [fileID,errmsg] = fopen(filename);  
end
```

### **Open File for Writing and Specify Access Type, Writing Order, Character Encoding**

Open a file to write to a file using the Shift-JIS character encoding.

```
fileID = fopen('japanese_out.txt', 'w', 'n', 'Shift_JIS');
```

The `'w'` input specifies write access, the `'n'` input specifies native byte ordering, and `'Shift_JIS'` specifies the character encoding scheme.

### **Get Information About Open Files**

Suppose you previously opened a file using `fopen`.

```
fileID = fopen('airfoil.m');
```

Get the file identifiers of all open files.

# fopen

---

```
fIDs = fopen('all')
```

```
fIDs =
```

```
3
```

Get the file name and character encoding for the open file. Use ~ in place of output arguments you want to omit.

```
[filename,~,~,encoding] = fopen(3)
```

```
filename =
```

```
matlabroot\toolbox\matlab\demos\airfoil.m
```

```
encoding =
```

```
windows-1252
```

The output shown here is representative. Your results might differ.

## Tips

- In most cases, it is not necessary to open a file in text mode. MATLAB import functions, all UNIX applications, and Microsoft Word and WordPad recognize '\n' as a newline indicator.

fread | fwrite | frewind
```

**Purpose** Connect serial port object to device

**Syntax** `fopen(obj)`

**Description** `fopen(obj)` connects the serial port object, `obj` to the device.

**Tips** Before you can perform a read or write operation, `obj` must be connected to the device with the `fopen` function. When `obj` is connected to the device:

- Data remaining in the input buffer or the output buffer is flushed.
- The `Status` property is set to `open`.
- The `BytesAvailable`, `ValuesReceived`, `ValuesSent`, and `BytesToOutput` properties are set to 0.

An error is returned if you attempt to perform a read or write operation while `obj` is not connected to the device. You can connect only one serial port object to a given device.

Some properties are read-only while the serial port object is open (connected), and must be configured before using `fopen`. Examples include `InputBufferSize` and `OutputBufferSize`. Refer to the property reference pages to determine which properties have this constraint.

The values for some properties are verified only after `obj` is connected to the device. If any of these properties are incorrectly configured, then an error is returned when `fopen` is issued and `obj` is not connected to the device. Properties of this type include `BaudRate`, and are associated with device settings.

If you use the `help` command to display help for `fopen`, then you need to supply the pathname shown below.

```
help serial/fopen
```

**Examples** This example creates the serial port object `s`, connects `s` to the device using `fopen`, writes and reads text data, and then disconnects `s` from the device. This example works on a Windows platform.

# fopen (serial)

---

```
s = serial('COM1');  
fopen(s)  
fprintf(s, '*IDN?')  
idn = fscanf(s);  
fclose(s)
```

---

<b>Purpose</b>	Execute statements specified number of times
<b>Syntax</b>	<pre>for <i>index</i> = <i>values</i>     <i>program statements</i>     : end</pre>
<b>Description</b>	<p>for <i>index=values</i>, <i>program statements</i>, end repeatedly executes one or more MATLAB statements in a loop. <i>values</i> has one of the following forms:</p> <p><i>initval:endval</i> increments the <i>index</i> variable from <i>initval</i> to <i>endval</i> by 1, and repeats execution of <i>program statements</i> until <i>index</i> is greater than <i>endval</i>.</p> <p><i>initval:step:endval</i> increments <i>index</i> by the value <i>step</i> on each iteration, or decrements when <i>step</i> is negative.</p> <p><i>valArray</i> creates a column vector <i>index</i> from subsequent columns of array <i>valArray</i> on each iteration. For example, on the first iteration, <i>index</i> = <i>valArray</i>(:,1). The loop executes for a maximum of <i>n</i> times, where <i>n</i> is the number of columns of <i>valArray</i>, given by <code>numel(<i>valArray</i>, 1, :)</code>. The input <i>valArray</i> can be of any MATLAB data type, including a string, cell array, or struct.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• To force an immediate exit of the loop, use a <code>break</code> or <code>return</code> statement. To skip the rest of the instructions in the loop, increment the loop counter, and begin the next iteration, use a <code>continue</code> statement.</li><li>• Avoid assigning a value to the <i>index</i> variable within the body of a loop. The <code>for</code> statement overrides any changes made to the <i>index</i> within the loop.</li></ul>

# for

---

- To iterate over the values of a single column vector, first transpose it to create a row vector.

## Examples

Create a Hilbert matrix using nested for loops:

```
k = 10;
hilbert = zeros(k,k);      % Preallocate matrix

for m = 1:k
    for n = 1:k
        hilbert(m,n) = 1/(m+n -1);
    end
end
```

---

Step by increments of -0.1, and display the step values:

```
for s = 1.0: -0.1: 0.0
    disp(s)
end
```

---

Execute statements for a defined set of index values:

```
for s = [1,5,8,17]
    disp(s)
end
```

---

Successively set e to unit vectors:

```
for e = eye(5)
    disp('Current value of e:')
    disp(e)
end
```

**See Also**

end | while | break | continue | parfor | return | if | switch  
| colon

# format

---

**Purpose** Set display format for output

**Syntax** format  
format Style

**Description** format sets the display of floating-point numeric values to the default display format, which is the short fixed decimal format. This format displays 5-digit scaled, fixed-point values.

The format function affects only how numbers display in the Command Window, not how MATLAB computes or saves them.

format Style changes the display format to the specified Style.

## Input Arguments

**Style - Output display format**  
short (default) | long | shortE | longE | ...

Output display format, specified as one of the strings listed in the tables that follow.

Use these styles to switch between different output display formats for floating-point variables. Styles are case insensitive. You also can insert a space between short or long and the presentation type, for instance, format short E.

Style	Result	Example
short (default)	Short fixed decimal format, with 4 digits after the decimal point.  If you are displaying a matrix with a wide range of values, consider using shortG. See “Display Large Data Range in short and shortg Formats” on page 1-2089	3.1416
long	Long fixed decimal format, with 15 digits after the decimal point for double values, and 7 digits	3.141592653589793

Style	Result	Example
	after the decimal point for <code>single</code> values.	
<code>shortE</code>	Short scientific notation, with 4 digits after the decimal point. Integer-valued floating-point numbers with a maximum of 9 digits do not display in scientific notation.	3.1416e+00
<code>longE</code>	Long scientific notation, with 15 digits after the decimal point for <code>double</code> values, and 7 digits after the decimal point for <code>single</code> values. Integer-valued floating-point numbers with a maximum of 9 digits do not display in scientific notation.	3.141592653589793e+00
<code>shortG</code>	The more compact of short fixed decimal or scientific notation, with 5 digits.	3.1416
<code>longG</code>	The more compact of long fixed decimal or scientific notation, with 15 digits for <code>double</code> values, and 7 digits for <code>single</code> values.	3.14159265358979
<code>shortEng</code>	Short engineering notation, with 4 digits after the decimal point, and an exponent that is a multiple of 3.	3.1416e+000
<code>longEng</code>	Long engineering notation, with 15 significant digits, and an exponent that is a multiple of 3.	3.14159265358979e+000

# format

Use these format styles to switch between different output display formats for all numeric variables.

Style	Result	Example
+	Positive/Negative format, with +, -, and blank characters displayed for positive, negative, and zero elements.	+
bank	Currency format, with 2 digits after the decimal point.	3.14
hex	Hexadecimal representation of a binary double-precision number.	400921fb54442d18
rat	Ratio of small integers.	355/113

Use these format styles to affect the spacing in the display of all variables.

DispType	Result	Example
compact	Suppresses excess line feeds to show more output in a single screen. Contrast with loose.	theta = pi/2 theta = 1.5708
loose	Adds linefeeds to make output more readable. Contrast with compact.	theta = pi/2  theta =  1.5708

## Examples

### Change and View Current Format

Set the display format to long fixed decimal.

```
format long
```

View the result for the value of pi.

```
pi
```

```
ans =
```

```
3.141592653589793
```

View the current format.

```
get(0, 'format')
```

```
ans =
```

```
long
```

## Display Values in Default and Hexadecimal Format

Set the format to its default, and display the maximum values for integers and real numbers in MATLAB.

```
format
```

```
intmax('uint64')
```

```
ans =
```

```
18446744073709551615
```

```
realmax
```

```
ans =
```

```
1.7977e+308
```

Change the display format to hexadecimal, and then display the same values.

```
format hex
```

```
intmax('uint64')  
  
ans =  
  
    ffffffffffffffffff  
  
realmax  
  
ans =  
  
    7fefffffffffffffff
```

The hexadecimal display corresponds to the internal representation of the value. It is not the same as the hexadecimal notation in the C programming language.

## **View Output in Short and Long Engineering Notation**

View the difference between output displayed in the shortEng and longEng formats.

Set the display format to shortEng.

```
format shortEng
```

Create variable A and increase its value by a multiple of 10 each time through a for loop. Display each value of A.

```
A = 5.123456789;  
for k=1:10  
    disp(A)  
    A = A * 10;  
end
```

```
    5.1235e+000  
   51.2346e+000  
  512.3457e+000  
   5.1235e+003  
  51.2346e+003
```

```

512.3457e+003
  5.1235e+006
 51.2346e+006
512.3457e+006
  5.1235e+009

```

The values for A display with 4 digits after the decimal point, and an exponent that is a multiple of 3.
