Set the display format to longEng and view the same values of A.

```
format longEng
```

```

A = 5.123456789;
for k=1:10
    disp(A)
    A = A * 10;
end

```

```

5.123456789000000e+000
51.23456789000000e+000
512.3456789000000e+000
5.123456789000000e+003
51.23456789000000e+003
512.3456789000000e+003
5.123456789000000e+006
51.23456789000000e+006
512.3456789000000e+006
5.123456789000000e+009

```

The values for A display with 15 digits, and an exponent that is a multiple of 3.

### **Display Large Data Range in short and shortg Formats**

View the difference between the short and shortg formats when the values in a matrix span a wide range.

Define variable x and display the output in the short format.

# format

---

```
x = [25 56 255 9876899999];
format short
x

x =
    1.0e+09 *
    0.0000    0.0000    0.0000    9.8769
```

The display indicates each value is multiplied by 1.0e+09.

Set the format to `shortg` and redisplay `x`.

```
format shortg
x

x =
           25           56           255    9.8769e+09
```

## Algorithms

MATLAB always displays integer variables to the appropriate number of digits for the class. For example, MATLAB uses 3 digits to display numbers of type `int8` (for example, `-128:127`). Setting `format` to `short` or `long` does not affect the display of integer variables.

If the largest element of a matrix is larger than  $10^3$  or smaller than  $10^{-3}$ , then MATLAB applies a common scale factor for the `short` and `long` formats.

## Tips

- The specified format applies only to the current MATLAB session. To maintain a format across sessions, choose a **Numeric format** or **Numeric display** option in the Command Window Preferences.
- To see which Style is currently in use, type

```
get(0, 'Format')
```

To see if `compact` or `loose` formatting is currently selected, type

```
get(0, 'FormatSpacing')
```

`sprintf` | `fprintf` | `num2str` | `rat` | `spy`

**Concepts**

- “Format Output in Command Window”

# fplot

---

**Purpose** Plot function between specified limits

**Syntax**

```
fplot(fun,limits)
fplot(fun,limits,LineStyle)
fplot(fun,limits,tol)
fplot(fun,limits,tol,LineStyle)
fplot(fun,limits,n)
fplot(fun,lims,...)
fplot(axes_handle,...)
[X,Y] = fplot(fun,limits,...)
```

**Description** fplot plots a function between specified limits. The function must be of the form  $y = f(x)$ , where  $x$  is a vector whose range specifies the limits, and  $y$  is a vector the same size as  $x$  and contains the function's value at the points in  $x$  (see the first example). If the function returns more than one value for a given  $x$ , then  $y$  is a matrix whose columns contain each component of  $f(x)$  (see the second example).

fplot(fun,limits) plots fun between the limits specified by limits. limits is a vector specifying the  $x$ -axis limits ([xmin xmax]), or the  $x$ - and  $y$ -axes limits, ([xmin xmax ymin ymax]).

fun must be

- The name of a function
- A string with variable  $x$  that may be passed to eval, such as 'sin(x)', 'diric(x,10)', or '[sin(x),cos(x)]'
- A function handle

The function  $f(x)$  must return a row vector for each element of vector  $x$ . For example, if  $f(x)$  returns  $[f_1(x), f_2(x), f_3(x)]$  then for input  $[x_1; x_2]$  the function should return the matrix

```
f1(x1) f2(x1) f3(x1)
f1(x2) f2(x2) f3(x2)
```

fplot(fun,limits,LineStyle) plots fun using the line specification LineSpec.

`fplot(fun,limits,tol)` plots `fun` using the relative error tolerance `tol` (the default is  $2e-3$ , i.e., 0.2 percent accuracy).

`fplot(fun,limits,tol,LineStyle)` plots `fun` using the relative error tolerance `tol` and a line specification that determines line type, marker symbol, and color. See `LineStyle` for more information.

`fplot(fun,limits,n)` with  $n \geq 1$  plots the function with a minimum of  $n+1$  points. The default  $n$  is 1. The maximum step size is restricted to be  $(1/n) * (xmax-xmin)$ .

`fplot(fun,lims,...)` accepts combinations of the optional arguments `tol`, `n`, and `LineStyle`, in any order.

`fplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`[X,Y] = fplot(fun,limits,...)` returns the abscissas and ordinates for `fun` in `X` and `Y`. No plot is drawn on the screen; however, you can plot the function using `plot(X,Y)`.

## Tips

`fplot` uses adaptive step control to produce a representative graph, concentrating its evaluation in regions where the function's rate of change is the greatest.

## Examples

Plot the hyperbolic tangent function from -2 to 2:

```
fnch = @tanh;  
fplot(fnch,[-2 2])
```

# fplot

---

For this example, you must create a file named `myfun.m` that returns a two-column matrix:

```
function Y = myfun(x)
Y(:,1) = 200*sin(x(:))./x(:);
Y(:,2) = x(:).^2;
```

Create a function handle pointing to `myfun`:

```
fh = @myfun;
```

Plot the function with the statement

```
fplot(fh,[-20 20])
```

### Additional Example

This example passes function handles to `fplot`, one created from a MATLAB function and the other created from an anonymous function.

```
hmp = @humps;  
subplot(2,1,1);fplot(hmp,[0 1])  
sn = @(x) sin(1./x);  
subplot(2,1,2);fplot(sn,[.01 .1])
```

# fplot

---

## How To

- [Anonymous Functions](#)

## Purpose

Write data to text file

## Syntax

```
fprintf(fileID,formatSpec,A1,...,An)
fprintf(formatSpec,A1,...,An)
```

```
nbytes = fprintf( ___ )
```

## Description

`fprintf(fileID,formatSpec,A1,...,An)` applies the `formatSpec` to all elements of arrays `A1,...,An` in column order, and writes the data to a text file. `fprintf` uses the encoding scheme specified in the call to `fopen`.

`fprintf(formatSpec,A1,...,An)` formats data and displays the results on the screen.

`nbytes = fprintf( ___ )` returns the number of bytes that `fprintf` writes, using any of the input arguments in the preceding syntaxes.

## Input Arguments

### **fileID - File identifier**

1 (default) | 2 | scalar

File identifier, specified as one of the following:

- A file identifier obtained from `fopen`.
- 1 for standard output (the screen).
- 2 for standard error.

### **Data Types**

double

### **formatSpec - Format of the output fields**

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F
Floating-point number	%f	Fixed-point notation
	%e	Exponential notation, such as 3.141593e+00
	%E	Same as %e, but uppercase, such as 3.141593E+00
	%g	The more compact of %e or %f, with no trailing zeros
	%G	The more compact of %E or %f, with no trailing zeros
	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value Example: %bx prints pi as 400921fb54442d18
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value Example: %tx prints pi as 40490fdb
Characters	%c	Single character
	%s	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Identifier

Order for processing inputs. Use the syntax `n$`, where `n` represents the position of the value in the input list.

For example, `'%3$s %2$s %1$s %2$s'` prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

' '	Left-justify. Example: <code>%-5.2f</code>
'+'	Print sign character (+) for positive values. Example: <code> %+5.2f</code>
' '	Pad to field width with spaces before the value. Example: <code> % 5.2f</code>

# fprintf

---

'0' Pad to field width with zeros. Example: `%05.2f`

'#' Modify selected numeric conversions:

- For `%o`, `%x`, or `%X`, print `0`, `0x`, or `0X` prefix.
- For `%f`, `%e`, or `%E`, print decimal point even when precision is `0`.
- For `%g` or `%G`, do not remove trailing zeros or decimal point.

Example:  `%#5.0f`

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list (`'%12d'`, `intmax`) is equivalent to (`'%*d'`, `12`, `intmax`).

- Precision

For `%f`, `%e`, or `%E`: Number of digits to the right of the decimal point.

Example: `'%6.4f'` prints `pi` as `'3.1416'`

For `%g` or `%G`: Number of significant digits.

Example: `'%6.4g'` prints `pi` as `' 3.142'`

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list (`'%6.4f'`, `pi`) is equivalent to (`'%*.4f'`, `6`, `4`, `pi`).

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include `' '` in `formatSpec`.
- Control characters, including:

<code>%%</code>	Percent character
<code>\\</code>	Backslash
<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\xN</code>	Character whose ASCII code is the hexadecimal number, <i>N</i>
<code>\W</code>	Character whose ASCII code is the octal number, <i>N</i>

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.
- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, `'%s'` converts `[65 66 67]` to `ABC`.

### **A1,...,An - Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

# fprintf

---

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

## Output Arguments

### nbytes - Number of bytes

scalar

Number of bytes that `fprintf` writes, returned as a scalar. When writing to a file, `nbytes` is determined by the character encoding. When printing data to the screen, `nbytes` is the number of characters displayed on the screen.

## Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

## Examples

### Print Literal Text and Array Values

Print multiple numeric values and literal text to the screen.

```
A1 = [9.9, 9900];  
A2 = [8.8, 7.7 ; ...  
      8800, 7700];  
formatSpec = 'X is %4.2f meters or %8.3f mm\n';  
fprintf(formatSpec,A1,A2)
```

```
X is 9.90 meters or 9900.000 mm  
X is 8.80 meters or 8800.000 mm  
X is 7.70 meters or 7700.000 mm
```

`%4.2f` in the `formatSpec` input specifies that the first value in each line of output is a floating-point number with a field width of four digits, including two digits after the decimal point. `%8.3f` in the `formatSpec` input specifies that the second value in each line of output is a floating-point number with a field width of eight digits, including three digits after the decimal point. `\n` is a control character that starts a new line.

## Print Double-Precision Values as Integers

Explicitly convert double-precision values with fractions to integer values.

```
a = [1.02, 3.04, 5.06];  
fprintf('%d\n',round(a));
```

```
1  
3  
5
```

`%d` in the `formatSpec` input prints each value in the vector, `round(a)`, as a signed integer. `\n` is a control character that starts a new line.

## Write Table to Text File

Write a short table of the exponential function to a text file called `exp.txt`.

```
x = 0:.1:1;  
A = [x; exp(x)];  
  
fileID = fopen('exp.txt','w');  
fprintf(fileID,'%6s %12s\n','x','exp(x)');  
fprintf(fileID,'%6.2f %12.8f\n',A);  
fclose(fileID);
```

The first call to `fprintf` prints header text `x` and `exp(x)`, and the second call prints the values from variable `A`.

If you plan to read the file with Microsoft Notepad, use `\r\n` instead of `\n` to move to a new line. For example, replace the calls to `fprintf` with the following:

```
fprintf(fileID,'%6s %12s\r\n','x','exp(x)');  
fprintf(fileID,'%6.2f %12.8f\r\n',A);
```

MATLAB import functions, all UNIX applications, and Microsoft Word and WordPad recognize `\n` as a newline indicator.

# fprintf

---

View the contents of the file with the `type` command.

```
type exp.txt

    x      exp(x)
0.00  1.00000000
0.10  1.10517092
0.20  1.22140276
0.30  1.34985881
0.40  1.49182470
0.50  1.64872127
0.60  1.82211880
0.70  2.01375271
0.80  2.22554093
0.90  2.45960311
1.00  2.71828183
```

## Get Number of Bytes Written to File

Write data to a file and return the number of bytes written.

Write an array of data, `A`, to a file and get the number of bytes that `fprintf` writes.

```
A = magic(4);

fileID = fopen('myfile.txt','w');
nbytes = fprintf(fileID,'%5d %5d %5d %5d\n',A)

nbytes =

    96
```

The `fprintf` function wrote 96 bytes to the file.

Close the file.

```
fclose(fileID);
```

View the contents of the file with the `type` command.

```
type('myfile.txt')  
  
16     5     9     4  
 2    11     7    14  
 3    10     6    15  
13     8    12     1
```

## Display Hyperlinks in Command Window

Display a hyperlink (The MathWorks Web Site) on the screen.

```
site = 'http://www.mathworks.com';  
title = 'The MathWorks Web Site';  
  
fprintf('<a href = "%s">%s</a>\n',site,title)
```

%s in the formatSpec input indicates that the values of the variables site and title, should be printed as strings.

# fprintf (serial)

---

**Purpose** Write text to device

**Syntax**

```
fprintf(obj, 'cmd')  
fprintf(obj, 'format', 'cmd')  
fprintf(obj, 'cmd', 'mode')  
fprintf(obj, 'format', 'cmd', 'mode')
```

**Description** fprintf(obj, 'cmd') writes the string cmd to the device connected to the serial port object, obj. The default format is %s\n. The write operation is synchronous and blocks the command-line until execution completes.

fprintf(obj, 'format', 'cmd') writes the string using the format specified by format.

fprintf(obj, 'cmd', 'mode') writes the string with command line access specified by mode. mode specifies if cmd is written synchronously or asynchronously.

fprintf(obj, 'format', 'cmd', 'mode') writes the string using the specified format. format is a C language conversion specification.

You need an open connection from the serial port object, obj, to the device before performing read or write operations.

Use the fopen function to open a connection to the device. When obj has an open connection to the device it has a Status property value of open. Refer to “Troubleshooting Common Errors” for fprintf errors.

To understand the use of fprintf refer to “Completing a Write Operation with fprintf” and “Rules for Writing the Terminator”.

## Input Arguments

### format

ANSI C conversion specification includes these conversion characters.

Specifier	Description
%c	Single character
%d or %i	Decimal notation (signed)

Specifier	Description
%e	Exponential notation (using lowercase e as in 3.1415e+00)
%E	Exponential notation (using uppercase E as in 3.1415E+00)
%f	Fixed-point notation
%g	The more compact of %e or %f, as defined above. Insignificant zeros do not print.
%G	Same as %g, but using uppercase E
%o	Octal notation (unsigned)
%s	String of characters
%u	Decimal notation (unsigned)
%x	Hexadecimal notation (using lowercase letters a–f)
%X	Hexadecimal notation (using uppercase letters A–F)

## mode

Specifies whether the string `cmd` is written synchronously or asynchronously:

- `sync`: `cmd` is written synchronously and the command line is blocked.
- `async`: `cmd` is written asynchronously and the command line is not blocked.

If `mode` is not specified, the write operation is synchronous.

If you specify asynchronous `mode`, when the write operation occurs:

- The `BytesToOutput` property value continuously updates to reflect the number of bytes in the output buffer.
- The MATLAB file callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

# fprintf (serial)

---

Use the `TransferStatus` property to determine whether an asynchronous write operation is in progress.

For more information on synchronous and asynchronous write operations, see [Controlling Access to the MATLAB Command Line](#).

## Examples

Create a serial port object `s` and connect it to a Tektronix TDS 210 oscilloscope. Write the `RS232?` command with `fprintf`. `RS232?` instructs the scope to return serial port communications settings. This example works on a Windows platform.

```
s = serial('COM1');  
fopen(s)  
fprintf(s, 'RS232?')
```

Specify a format for the data that does not include the terminator, or configure the terminator to empty.

```
s = serial('COM1');  
fopen(s)  
fprintf(s, '%s', 'RS232?')
```

The default format for `fprintf` is `%s\n`. Therefore, the terminator specified by the `Terminator` property is automatically written. However, in some cases you might want to suppress writing the terminator.

Specify an array of formats and commands:

```
s = serial('COM1');  
fopen(s)  
fprintf(s, ['ch:%d scale:%d'], [1 20e-3], 'sync');
```

## Tutorials

- [Writing and Reading Data](#)
- [Controlling Access to the MATLAB Command Line](#)

**Purpose** Return image data associated with movie frame

**Syntax** [X,Map] = frame2im(F)

**Description** [X,Map] = frame2im(F) returns the indexed image X and associated colormap Map from the single movie frame F. If the frame contains true-color data, the *m*-by-*n*-3 matrix Map is empty. The functions getframe and im2frame create a movie frame.

**Examples** Create and capture an image using getframe and frame2im:

```
peaks                                %Make figure
f = getframe;                         %Capture screen shot
[im,map] = frame2im(f);               %Return associated image data
if isempty(map)                       %Truecolor system
    rgb = im;
else                                   %Indexed system
    rgb = ind2rgb(im,map);            %Convert image data
end
```

**See Also** getframe | im2frame | movie

# fread

---

## Purpose

Read data from binary file

## Syntax

```
A = fread(fileID)
A = fread(fileID, sizeA)
A = fread(fileID, sizeA, precision)
A = fread(fileID, sizeA, precision, skip)
A = fread(fileID, sizeA, precision, skip, machineformat)
[A, count] = fread( ___ )
```

## Description

`A = fread(fileID)` reads data from a binary file into column vector *A* and positions the file pointer at the end-of-file marker.

`A = fread(fileID, sizeA)` reads *sizeA* elements into *A* and positions the file pointer after the last element read. *sizeA* can be an integer, or can have the form  $[m,n]$ .

`A = fread(fileID, sizeA, precision)` interprets values in the file according to the form and size described by the *precision*. The *sizeA* parameter is optional.

`A = fread(fileID, sizeA, precision, skip)` skips *skip* bytes after reading each value. If *precision* is *bitn* or *ubitn*, specify *skip* in bits. The *sizeA* parameter is optional.

`A = fread(fileID, sizeA, precision, skip, machineformat)` reads data with the specified *machineformat*. The *sizeA* and *skip* parameters are optional.

`[A, count] = fread( ___ )` returns the number of elements `fread` reads into *A*.

## Input Arguments

### **fileID**

An integer file identifier obtained from `fopen`.

### **sizeA**

Dimensions of the output array *A*. Specify in one of the following forms:

<code>inf</code>	Column vector with the number of elements in the file. (default)
<code>n</code>	Column vector with $n$ elements.
<code>[m,n]</code>	$m$ -by- $n$ matrix, filled in column order. $n$ can be <code>inf</code> , but $m$ cannot.

**precision**

String that specifies the form and size of the values to read. Optionally includes the class for the output matrix  $A$ .

Use one of the following forms:

<code>'source'</code>	Specifies class of input values. Output matrix $A$ is class <code>double</code> . Example: <code>'int16'</code>
<code>'source=&gt;output'</code>	Specifies classes of input and output. Example: <code>'int8=&gt;char'</code>
<code>'*source'</code>	Output has the same class as input. Example: <code>'*uint8'</code> For <code>'bitn'</code> or <code>'ubitn'</code> precisions, output has the smallest class that can contain the input. Example: <code>'*ubit18'</code> is equivalent to <code>'ubit18=&gt;uint32'</code>
<code>'N*source'</code> OR <code>'N*source=&gt;output'</code>	Valid if you specify a <code>skip</code> parameter. Read $N$ values before each skip. Example: <code>'4*int8'</code>

The following table shows possible values for `source` and `output`.

# fread

---

<b>Value Type</b>	<b>Precision</b>	<b>Bits (Bytes)</b>
Integers, unsigned	uint	32 (4)
	uint8	8 (1)
	uint16	16 (2)
	uint32	32 (4)
	uint64	64 (8)
	uchar	8 (1)
	unsigned char	8 (1)
	ushort	16 (2)
	ulong	32 (4)
	ubit $n$	$1 \leq n \leq 64$
Integers, signed	int	32 (4)
	int8	8 (1)
	int16	16 (2)
	int32	32 (4)
	int64	64 (8)
	integer*1	8 (1)
	integer*2	16 (2)
	integer*4	32 (4)
	integer*8	64 (8)
	schar	8 (1)
	signed char	8 (1)
	short	16 (2)
	long	32 (4)
	bit $n$	$1 \leq n \leq 64$

Value Type	Precision	Bits (Bytes)
Floating-point numbers	single	32 (4)
	double	64 (8)
	float	32 (4)
	float32	32 (4)
	float64	64 (8)
	real*4	32 (4)
	real*8	64 (8)
Characters	char*1	8 (1)
	char	Depends on the encoding scheme associated with the file. Set encoding with <code>fopen</code> .

For most *source* precisions, if `fread` reaches the end of the file before reading a complete element, `fread` does not return a value for the final element. However, if *source* is *bitn* or *ubitn*, then `fread` returns a partial result for the final element.

**Default:** 'uint8=>double'

### **skip**

Number of bytes to skip after reading each value. If you specify a *precision* of *bitn* or *ubitn*, specify *skip* in bits. Use this parameter to read data from noncontiguous fields in fixed-length records.

**Default:** 0

### **machineformat**

String that specifies the order for reading bytes within the file. For *bitn* and *ubitn* precisions, specifies the order for reading bits within a byte.

# fread

---

'n' or 'native'	Your system byte ordering (default)
'b' or 'ieee-be'	Big-endian ordering
'l' or 'ieee-le'	Little-endian ordering
's' or 'ieee-be.164'	Big-endian ordering, 64-bit long data type
'a' or 'ieee-le.164'	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

## Output Arguments

### A

A column vector, unless you specify *sizeA* with the form  $[m,n]$ . Data in A is class double unless you specify a different class in the *precision* argument.

### count

The number of elements that `fread` successfully reads.

## Examples

Read the contents of a file:

```
% Create the file
fid = fopen('magic5.bin', 'w');
fwrite(fid, magic(5));
fclose(fid);

% Read the contents back into an array
fid = fopen('magic5.bin');
m5 = fread(fid, [5, 5], '*uint8');
fclose(fid);
```

---

Simulate the type function with `fread`, to display the contents of a text file:

```
fid = fopen('fread.m');

% read the entire file as characters
% transpose so that F is a row vector
F = fread(fid, '*char')';

fclose(fid);
```

If you do not specify the precision, `fread` applies the default `uint8=>double`:

```
fid = fopen('fread.m');
F_nums = fread(fid, 6) % read the first 6 bytes ('%FREAD')
fclose(fid);
```

This code returns

```
F_nums =
    37    70    82    69    65    68
```

---

Read selected rows or columns from a file:

```
% Create a file with values from 1 to 9
fid = fopen('nine.bin', 'w');
alldata = reshape([1:9],3,3);
fwrite(fid, alldata);
fclose(fid);

% Read the first six values into two columns
fid = fopen('nine.bin');
two_cols = fread(fid, [3, 2]);

% Return to the beginning of the file
```

# fread

---

```
frewind(fid);

% Read two values at a time, skip one
% Returns six values into two rows
% (first two rows of 'alldata')

two_rows = fread(fid, [2, 3], '2*uint8', 1);

% Close the file
fclose(fid);
```

---

Specify *machineformat* to read separate digits of binary coded decimal (BCD) values correctly:

```
% Create a file with BCD values
str = ['AB'; 'CD'; 'EF'; 'FA'];

fid = fopen('bcd.bin', 'w');
fwrite(fid, hex2dec(str), 'ubit8');
fclose(fid);

% If you read one byte at a time,
% no need to specify machine format
fid = fopen('bcd.bin');

onebyte = fread(fid, 4, '*ubit8');
disp('Correct data, read with ubit8:')
disp(dec2hex(onebyte))

% However, if you read 4 bits on a little-endian
% system, your results appear in the wrong order
frewind(fid);      % return to beginning of file

part_err = fread(fid, 8, '*ubit4');
disp('Incorrect data on little-endian systems, ubit4:')
disp(dec2hex(part_err))
```

```
% Specify a big-endian format for correct results
frewind(fid);

part_corr = fread(fid, 8, '*ubit4', 'ieee-be');
disp('Correct result, ubit4:')
disp(dec2hex(part_corr))

fclose(fid);
```

**How To**

- “Reading Portions of a File”
- “Reading Files Created on Other Systems”

# fread (serial)

---

**Purpose** Read binary data from device

**Syntax**  
`A = fread(obj)`  
`A = fread(obj,size,'precision')`  
`[A,count] = fread(...)`  
`[A,count,msg] = fread(...)`

**Description** `A = fread(obj)` and `A = fread(obj,size)` read binary data from the device connected to the serial port object, `obj`, and returns the data to `A`. The maximum number of values to read is specified by `size`. If `size` is not specified, the maximum number of values to read is determined by the object's `InputBufferSize` property. Valid options for `size` are:

<code>n</code>	Read at most <code>n</code> values into a column vector.
<code>[m,n]</code>	Read at most <code>m</code> -by- <code>n</code> values filling an <code>m</code> -by- <code>n</code> matrix in column order.

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. A value is defined as a byte multiplied by the *precision* (see below).

`A = fread(obj,size,'precision')` reads binary data with precision specified by *precision*.

*precision* controls the number of bits read for each value and the interpretation of those bits as integer, floating-point, or character values. If *precision* is not specified, `uchar` (an 8-bit unsigned character) is used. By default, numeric values are returned in double-precision arrays. The supported values for *precision* are listed below in Tips.

`[A,count] = fread(...)` returns the number of values read to `count`.

`[A,count,msg] = fread(...)` returns a warning message to `msg` if the read operation was unsuccessful.

## Tips

Before you can read data from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read, each time `fread` is issued.

If you use the `help` command to display help for `fread`, then you need to supply the pathname shown below.

```
help serial/fread
```

## Rules for Completing a Binary Read Operation

A read operation with `fread` blocks access to the MATLAB command line until:

- The specified number of values are read.
- The time specified by the `Timeout` property passes.

---

**Note** The `Terminator` property is not used for binary read operations.

---

## Supported Precisions

The supported values for *precision* are listed below.

Data Type	Precision	Interpretation
Character	<code>uchar</code>	8-bit unsigned character
	<code>schar</code>	8-bit signed character
	<code>char</code>	8-bit signed or unsigned character

# fread (serial)

---

Data Type	Precision	Interpretation
Integer	int8	8-bit integer
	int16	16-bit integer
	int32	32-bit integer
	uint8	8-bit unsigned integer
	uint16	16-bit unsigned integer
	uint32	32-bit unsigned integer
	short	16-bit integer
	int	32-bit integer
	long	32- or 64-bit integer
	ushort	16-bit unsigned integer
	uint	32-bit unsigned integer
	ulong	32- or 64-bit unsigned integer
Floating-point	single	32-bit floating point
	float32	32-bit floating point
	float	32-bit floating point
	double	64-bit floating point
	float64	64-bit floating point

## Purpose

(Will be removed) Facets referenced by only one simplex

---

**Note** `freeBoundary(TriRep)` will be removed in a future release. Use `freeBoundary(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

## Syntax

`FF = freeBoundary(TR)`  
`[FF XF] = freeBoundary(TR)`

## Description

`FF = freeBoundary(TR)` returns a matrix `FF` that represents the free boundary facets of the triangulation. A facet is on the free boundary if it is referenced by only one simplex (triangle/tetrahedron, etc). `FF` is of size `m`-by-`n`, where `m` is the number of boundary facets and `n` is the number of vertices per facet. The vertices of the facets index into the array of points representing the vertex coordinates `TR.X`. The array `FF` could be empty as in the case of a triangular mesh representing the surface of a sphere.

`[FF XF] = freeBoundary(TR)` returns a matrix of free boundary facets

## Input Arguments

`TR`                      Triangulation representation.

## Output Arguments

`FF`                        `FF` that has vertices defined in terms of a compact array of coordinates `XF`.

`XF`                        `XF` is of size `m`-by-`ndim` where `m` is the number of free facets, and `ndim` is the dimension of the space where the triangulation resides

## Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

# TriRep.freeBoundary

---

## Examples

### Example 1

Use TriRep to compute the boundary triangulation of an imported triangulation.

Load a 3-D triangulation:

```
load tetmesh;  
trep = TriRep(tet, X);
```

Compute the boundary triangulation:

```
[tri xf] = freeBoundary(trep);
```

Plot the boundary triangulation:

```
trisurf(tri, xf(:,1),xf(:,2),xf(:,3), ...  
        'FaceColor','cyan', 'FaceAlpha', 0.8);
```

## Example 2

Perform a direct query of a 2-D triangulation created with `DelaunayTri`.

Plot the mesh:

```
x = rand(20,1);  
y = rand(20,1);  
dt = DelaunayTri(x,y);  
fe = freeBoundary(dt)';  
triplot(dt);  
hold on;
```

Display the free boundary edges in red:

```
plot(x(fe), y(fe), '-r', 'LineWidth',2) ;  
hold off;
```

In this instance the free edges correspond to the convex hull of  $(x, y)$ .

# TriRep.freeBoundary

---

| [triangulation](#)

**Purpose** Frequency spacing for frequency response

**Syntax**

```
[f1,f2] = freqspace(n)
[f1,f2] = freqspace([m n])
[x1,y1] = freqspace(...,'meshgrid')
f = freqspace(N)
f = freqspace(N,'whole')
```

**Description** `freqspace` returns the implied frequency range for equally spaced frequency responses. `freqspace` is useful when creating desired frequency responses for various one- and two-dimensional applications.

`[f1,f2] = freqspace(n)` returns the two-dimensional frequency vectors `f1` and `f2` for an `n`-by-`n` matrix.

For `n` odd, both `f1` and `f2` are `[-n+1:2:n-1]/n`.

For `n` even, both `f1` and `f2` are `[-n:2:n-2]/n`.

`[f1,f2] = freqspace([m n])` returns the two-dimensional frequency vectors `f1` and `f2` for an `m`-by-`n` matrix.

`[x1,y1] = freqspace(...,'meshgrid')` is equivalent to

```
[f1,f2] = freqspace(...);
[x1,y1] = meshgrid(f1,f2);
```

`f = freqspace(N)` returns the one-dimensional frequency vector `f` assuming `N` evenly spaced points around the unit circle. For `N` even or odd, `f` is `(0:2/N:1)`. For `N` even, `freqspace` therefore returns  $(N+2)/2$  points. For `N` odd, it returns  $(N+1)/2$  points.

`f = freqspace(N,'whole')` returns `N` evenly spaced points around the whole unit circle. In this case, `f` is `0:2/N:2*(N-1)/N`.

**See Also** `meshgrid`

# frewind

---

**Purpose** Move file position indicator to beginning of open file

**Syntax** `frewind(fileID)`

**Description** `frewind(fileID)` sets the file position indicator to the beginning of a file. *fileID* is an integer file identifier obtained from `fopen`.

If the file is on a tape device and the rewind operation fails, `frewind` does not return an error message.

**Alternatives** `frewind(fileID)` is equivalent to:

```
fseek(fileID, 0, 'bof');
```

**See Also** `fclose` | `feof` | `ferror` | `fopen` | `fseek` | `ftell` | `fscanf` | `fprintf` | `fread` | `fwrite`

---

<b>Purpose</b>	Read data from text file
<b>Syntax</b>	<pre>A = fscanf(<i>fileID</i>, <i>format</i>) A = fscanf(<i>fileID</i>, <i>format</i>, <i>sizeA</i>) [A, <i>count</i>] = fscanf(...)</pre>
<b>Description</b>	<p><code>A = fscanf(<i>fileID</i>, <i>format</i>)</code> reads and converts data from a text file into array <i>A</i> in column order. To convert, <code>fscanf</code> uses the <i>format</i> and the encoding scheme associated with the file. To set the encoding scheme, use <code>fopen</code>. The <code>fscanf</code> function reapplies the <i>format</i> throughout the entire file, and positions the file pointer at the end-of-file marker. If <code>fscanf</code> cannot match the <i>format</i> to the data, it reads only the portion that matches into <i>A</i> and stops processing.</p> <p><code>A = fscanf(<i>fileID</i>, <i>format</i>, <i>sizeA</i>)</code> reads <i>sizeA</i> elements into <i>A</i>, and positions the file pointer after the last element read. <i>sizeA</i> can be an integer, or can have the form <math>[m,n]</math>.</p> <p><code>[A, <i>count</i>] = fscanf(...)</code> returns the number of elements that <code>fscanf</code> successfully reads.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• Format specifiers for the reading functions <code>sscanf</code> and <code>fscanf</code> differ from the formats for the writing functions <code>sprintf</code> and <code>fprintf</code>. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.</li></ul>
<b>Input Arguments</b>	<p><b>fileID</b> Integer file identifier obtained from <code>fopen</code>.</p> <p><b>format</b> String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.</p>

Field Type	Specifier	Details
Integer, signed	%d	Base 10
	%i	Base determined from the values. Defaults to base 10. If initial digits are 0x or 0X, it is base 16. If initial digit is 0, it is base 8.
	%ld or %li	64-bit values, base 10, 8, or 16
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal)
	%lu, %lo, %lx	64-bit values, base 10, 8, or 16
Floating-point number	%f	Floating-point fields can contain any of the following (not case sensitive): Inf, -Inf, NaN, or -NaN.
	%e	
	%g	
Character string	%s	Read series of characters, until find white space.
	%c	Read any single character, including white space. (To read multiple characters, specify field length.)
	%[...]	Read only characters in the brackets, until the first nonmatching character or white space.

Optionally:

- To skip fields, insert an asterisk (\*) after the percent sign (%). For example, to skip integers, specify %\*d.

- To specify the maximum width of a field, insert a number. For example, `%10c` reads exactly 10 characters at a time, including white space.
- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from `'pi=3.14159'`, specify a *format* of `'pi=%f'`.

### sizeA

Dimensions of the output array *A*. Specify in one of the following forms:

<code>inf</code>	Read to the end of the file. (default)
<code>n</code>	Read at most <i>n</i> elements.
<code>[m,n]</code>	Read at most <i>m*n</i> elements in column order. <i>n</i> can be <code>inf</code> , but <i>m</i> cannot.

When the *format* includes `%s`, *A* can contain more than *n* columns. *n* refers to elements, not characters.

## Output Arguments

### A

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class `int64`. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class `uint64`. Otherwise, *A* is of class `double`. If *sizeA* is `inf` or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (`%c` or `%s`), *A* is a character array. If *sizeA* is `inf` or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with `char(0)`.
- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of `'%*d %s'`).

# fscanf

---

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

## count

The number of elements *fscanf* reads into *A*.

## Examples

Read the contents of a file. *fscanf* reuses the *format* throughout the file, so you do not need a control loop:

```
% Create a file with an exponential table
x = 0:.1:1;
y = [x; exp(x)];

fid = fopen('exp.txt', 'w');
fprintf(fid, '%6.2f %12.8f\n', y);
fclose(fid);

% Read the data, filling A in column order
% First line of the file:
%    0.00    1.00000000

fid = fopen('exp.txt');
A = fscanf(fid, '%g %g', [2 inf]);
fclose(fid);

% Transpose so that A matches
% the orientation of the file
A = A';
```

---

Skip specific characters in a file, and return only numeric values:

```
% Create a file with temperatures
tempstr = '78 F 72 F 64 F 66 F 49 F';
```

```
fid = fopen('temperature.dat', 'w+');
fprintf(fid, '%s', tempstr);

% Return to the beginning of the file
frewind(fid);

% Read the numbers in the file, skipping the units
% num_temps is a numeric column vector

degrees = char(176);
num_temps = fscanf(fid, ['%d' degrees 'F']);

fclose(fid);
```

**See Also**

[fclose](#) | [ferror](#) | [fgetl](#) | [fgets](#) | [fopen](#) | [fprintf](#) | [fread](#) | [fwrite](#)  
| [sscanf](#) | [textscan](#)

**How To**

- “Reading Data in a Formatted Pattern”
- “Opening Files with Different Character Encodings”

# fscanf (serial)

---

**Purpose** Read data from device, and format as text

**Syntax**

```
A = fscanf(obj)
A = fscanf(obj,'format')
A = fscanf(obj,'format',size)
[A,count] = fscanf(...)
[A,count,msg] = fscanf(...)
```

**Description** `A = fscanf(obj)` reads data from the device connected to the serial port object, `obj`, and returns it to `A`. The data is converted to text using the `%c` format.

`A = fscanf(obj,'format')` reads data and converts it according to `format`. `format` is a C language conversion specification. Conversion specifications involve the `%` character and the conversion characters `d`, `i`, `o`, `u`, `x`, `X`, `f`, `e`, `E`, `g`, `G`, `c`, and `s`. Refer to the `sscanf` file I/O format specifications or a C manual for more information.

`A = fscanf(obj,'format',size)` reads the number of values specified by `size`. Valid options for `size` are:

<code>n</code>	Read at most <code>n</code> values into a column vector.
<code>[m,n]</code>	Read at most <code>m</code> -by- <code>n</code> values filling an <code>m</code> -by- <code>n</code> matrix in column order.

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. If `size` is not of the form `[m,n]`, and a character conversion is specified, then `A` is returned as a row vector. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. An ASCII value is one byte.

`[A,count] = fscanf(...)` returns the number of values read to `count`.

`[A,count,msg] = fscanf(...)` returns a warning message to `msg` if the read operation did not complete successfully.

## Tips

Before you can read data from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fscanf` is issued.

If you use the `help` command to display help for `fscanf`, then you need to supply the pathname shown below.

```
help serial/fscanf
```

## Rules for Completing a Read Operation with fscanf

A read operation with `fscanf` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is read.
- The time specified by the `Timeout` property passes.
- The number of values specified by `size` is read.
- The input buffer is filled (unless `size` is specified)

## Examples

Create the serial port object `s` and connect `s` to a Tektronix TDS 210 oscilloscope, which is displaying sine wave. This example works on a Windows platform.

```
s = serial('COM1');  
fopen(s)
```

Use the `fprintf` function to configure the scope to measure the peak-to-peak voltage of the sine wave, return the measurement type, and return the peak-to-peak voltage.

```
fprintf(s, 'MEASUREMENT:IMMED:TYPE PK2PK')
```

## fscanf (serial)

---

```
fprintf(s, 'MEASUREMENT:IMMED:TYPE?')
fprintf(s, 'MEASUREMENT:IMMED:VALUE?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data associated with the two query commands is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
    21
```

Use `fscanf` to read the measurement type. The operation will complete when the first terminator is read.

```
meas = fscanf(s)
meas =
PK2PK
```

Use `fscanf` to read the peak-to-peak voltage as a floating-point number, and exclude the terminator.

```
pk2pk = fscanf(s, '%e', 14)
pk2pk =
    2.0200
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

---

<b>Purpose</b>	Move to specified position in file						
<b>Syntax</b>	<pre>fseek(<i>fileID</i>, <i>offset</i>, <i>origin</i>) status = fseek(<i>fileID</i>, <i>offset</i>, <i>origin</i>)</pre>						
<b>Description</b>	<p><code>fseek(<i>fileID</i>, <i>offset</i>, <i>origin</i>)</code> sets the file position indicator <i>offset</i> bytes from <i>origin</i> in the specified file.</p> <p><code>status = fseek(<i>fileID</i>, <i>offset</i>, <i>origin</i>)</code> returns 0 when the operation is successful. Otherwise, it returns -1.</p>						
<b>Input Arguments</b>	<p><b>fileID</b> Integer file identifier obtained from <code>fopen</code>.</p> <p><b>offset</b> Number of bytes to move from <code>origin</code>. Can be positive, negative, or zero. The <i>n</i> bytes of a given file are in positions 0 through <i>n</i>-1.</p> <p><b>origin</b> Starting location in the file:</p> <table><tr><td>'bof' or -1</td><td>Beginning of file</td></tr><tr><td>'cof' or 0</td><td>Current position in file</td></tr><tr><td>'eof' or 1</td><td>End of file</td></tr></table>	'bof' or -1	Beginning of file	'cof' or 0	Current position in file	'eof' or 1	End of file
'bof' or -1	Beginning of file						
'cof' or 0	Current position in file						
'eof' or 1	End of file						
<b>Examples</b>	<p>Copy 5 bytes from the file <code>test1.dat</code>, starting at the tenth byte, and append to the end of <code>test2.dat</code>:</p> <pre>% Create files test1.dat and test2.dat % Each character uses 8 bits (1 byte)  fid1 = fopen('test1.dat', 'w+'); fwrite(fid1, 'ABCDEFGHIJKLMNOPQRSTUVWXYZ');</pre>						

# fseek

---

```
fid2 = fopen('test2.dat', 'w+');
fwrite(fid2, 'Second File');

% Seek to the 10th byte ('J'), read 5
fseek(fid1, 9, 'bof');
A = fread(fid1, 5, 'uint8=>char');
fclose(fid1);

% Append to test2.dat
fseek(fid2, 0, 'eof');
fwrite(fid2, A);
fclose(fid2);
```

## Alternatives

To move to the beginning of a file, call

```
frewind(fileID)
```

This call is identical to

```
fseek(fileID, 0, 'bof')
```

## See Also

`fclose` | `feof` | `ferror` | `fopen` | `frewind` | `ftell` | `fscanf` | `fprintf`  
| `fread` | `fwrite`

## How To

- “Reading Portions of a File”

**Purpose** Position in open file

**Syntax** `position = ftell(fileID)`

**Description** `position = ftell(fileID)` returns the current position in the specified file. `position` is a zero-based integer that indicates the number of bytes from the beginning of the file. If the query is unsuccessful, `position` is `-1`. `fileID` is an integer file identifier obtained from `fopen`.

**See Also** `fclose` | `feof` | `ferror` | `fopen` | `frewind` | `fseek` | `fscanf` | `fprintf` | `fread` | `fwrite`

# FTP

---

**Purpose** Connect to FTP server

**Description** Connect to an FTP server by calling the `ftp` function, which creates an FTP object. Perform file operations using methods on the FTP object, such as `mput` and `mget`. When you finish accessing the server, call the `close` method to close the connection.

**Construction** `f = ftp(host,username,password)` connects to the FTP server `host` and creates FTP object `f`. If the host supports anonymous connections, you can use the `host` argument alone. To specify an alternate port, separate it from `host` with a colon (:).

## Input Arguments

### **host**

String enclosed in single quotation marks that specifies the FTP server.

### **username**

String enclosed in single quotation marks that specifies your user name for the FTP server.

### **password**

String enclosed in single quotation marks that specifies your password for the FTP server. Because FTP is not a secure protocol, others can see your user name and password.

## Methods

<code>ascii</code>	Set FTP transfer type to ASCII
<code>binary</code>	Set FTP transfer type to binary
<code>cd</code>	Change or view current folder on FTP server
<code>close</code>	Close connection to FTP server
<code>delete</code>	Remove file on FTP server

---

<code>dir</code>	View contents of folder on FTP server
<code>mget</code>	Download files from FTP server
<code>mkdir</code>	Create folder on FTP server
<code>mput</code>	Upload file or folder to FTP server
<code>rename</code>	Rename file on FTP server
<code>rmdir</code>	Remove folder on FTP server

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Connect to the MathWorks FTP server, and display the FTP object:

```
mw=ftp('ftp.mathworks.com');  
disp(mw)
```

MATLAB returns:

```
FTP Object  
  host: ftp.mathworks.com  
  user: anonymous  
  dir: /  
  mode: binary
```

---

Connect to port 34 (not supported at `ftp.mathworks.com`, so this code returns an error):

```
mw=ftp('ftp.mathworks.com:34')
```

---

Modify the following code to connect to a host that requires a password:

```
test=ftp('ftp.testsite.com','myname','mypassword')
```

# FTP

---

**Algorithms**      The ftp function is based on code from the Apache Jakarta Project.

**See Also**        `urlwrite`

**How To**         • “Specify Proxy Server Settings for Connecting to the Internet”

**Purpose** Convert sparse matrix to full matrix

**Syntax** `A = full(S)`

**Description** `A = full(S)` converts a sparse matrix `S` to full storage organization. If `S` is a full matrix, it is left unchanged. If `A` is full, `issparse(A)` is 0.

**Tips** If `X` is an  $m$ -by- $n$  matrix with  $nz$  nonzero elements then `full(X)` requires space to store  $m*n$  elements. On the other hand, `sparse(X)` requires space to store  $nz$  elements and  $(nz+n+1)$  integers.

The density of a matrix ( $nnz(X)/numel(X)$ ) determines whether or not it is more efficient to store the matrix as sparse or full. The exact crossover point depends on the matrix class as well as the platform. For example, in 32-bit MATLAB, a double sparse matrix with less than about 2/3 density will require less space than the same matrix in full storage. In 64-bit MATLAB, however, double matrices with less than half of their elements nonzero are more efficient to store as sparse matrices.

**Examples** Here is an example of a sparse matrix with a density of about two-thirds. `sparse(S)` and `full(S)` require about the same number of bytes of storage.

```
S = sparse+(rand(200,200) < 2/3);
A = full(S);
whos
Name      Size      Bytes      Class
   A      200X200  320000  double array
   S      200X200  318432  double array (sparse)
```

**See Also** `issparse` | `sparse`

# fullfile

---

<b>Purpose</b>	Build full file name from parts
<b>Syntax</b>	<code>f = fullfile(filepart1,...,filepartN)</code>
<b>Description</b>	<code>f = fullfile(filepart1,...,filepartN)</code> builds a full file specification, <code>f</code> , from the folders and file names specified. <code>fullfile</code> inserts platform-dependent file separators where necessary, and does not add a trailing file separator. The output of <code>fullfile</code> is conceptually equivalent to <code>f = [filepart1 filesep filepart2 filesep ... filesep filepartN]</code>

## Input Arguments

### **filepart1,...,filepartN - Folder and file names**

strings | cell arrays of strings

Folder and file names, specified as strings and cell arrays of strings. Any nonscalar cell arrays must be of the same size.

**Example:** `'folder1','folder2','myfile.m'`

**Example:**

`{'folder1';'folder2'},{'subfolder1';'subfolder2'},'myfile.m'`

## Examples

### **Create a Full File Name**

```
f = fullfile('myfolder','mysubfolder','myfile.m')
```

```
f =  
myfolder\mysubfolder\myfile.m
```

`fullfile` returns a string containing the full path to the file. On Windows platforms, the file separator character is a backslash, \. On other platforms, the file separator might be a different character.

### **Create Paths to Multiple Files**

```
f = fullfile(toolboxdir('matlab'),'iofun',{'filesep.m';'fullfile.m'});
```

`fullfile` returns a cell array containing a path to the file `filesep.m`, and a path to the file `fullfile.m`.

## Create a Path to a Folder

```
f = fullfile(matlabroot,'toolbox','matlab',filesep);
```

fullfile does not trim a leading or trailing filesep.

# func2str

---

**Purpose** Construct function name string from function handle

**Syntax** `func2str(fhandle)`

**Description** `func2str(fhandle)` constructs a string `s` that holds the name of the function to which the function handle `fhandle` belongs.

When you need to perform a string operation, such as compare or display, on a function handle, you can use `func2str` to construct a string bearing the function name.

The `func2str` command does not operate on nonscalar function handles. Passing a nonscalar function handle to `func2str` results in an error.

**Tips** Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

## Examples

### Example 1

Convert a `sin` function handle to a string:

```
fhandle = @sin;

func2str(fhandle)
ans =
    sin
```

### Example 2

The `catcherr` function shown here accepts function handle and data arguments and attempts to evaluate the function through its handle. If the function fails to execute, `catcherr` uses `sprintf` to display an error message giving the name of the failing function. The function name must be a string for `sprintf` to display it. The code derives the function name from the function handle using `func2str`:

```
function catcherr(func, data)
try
```

```
        ans = func(data);
        disp('Answer is:');
        ans
    catch
        disp(sprintf('Error executing function '%s'\n', ...
            func2str(func)))
    end
```

The first call to `catcherr` passes a handle to the `round` function and a valid data argument. This call succeeds and returns the expected answer. The second call passes the same function handle and an improper data type (a MATLAB structure). This time, `round` fails, causing `catcherr` to display an error message that includes the failing function name:

```
catcherr(@round, 5.432)
ans =
Answer is 5

xstruct.value = 5.432;
catcherr(@round, xstruct)
Error executing function "round"
```

**See Also**

[function\\_handle](#) | [str2func](#) | [functions](#)

# function

---

**Purpose**            Declare function name, inputs, and outputs

**Syntax**            `function [y1,...,yN] = myfun(x1,...,xM)`

**Description**      `function [y1,...,yN] = myfun(x1,...,xM)` declares a function named `myfun` that accepts inputs `x1,...,xM` and returns outputs `y1,...,yN`. This declaration statement must be the first executable line of the function.

Save the function code in a text file with a `.m` extension. The name of the file should match the name of the first function in the file. Valid function names begin with an alphabetic character, and can contain letters, numbers, or underscores.

You can declare multiple local functions within the same file, or nest functions. If any function in a file contains a nested function, all functions in the file must use the `end` keyword to indicate the end of the function. Otherwise, the `end` keyword is optional.

## Examples            **Function with One Output**

Define a function in a file named `average.m` that accepts an input vector, calculates the average of the values, and returns a single result.

```
function y = average(x)
if ~isvector(x)
    error('Input must be a vector')
end
y = sum(x)/length(x);
end
```

Call the function from the command line.

```
z = 1:99;
average(z)
```

```
ans =
    50
```

### Function with Multiple Outputs

Define a function in a file named `stat.m` that returns the mean and standard deviation of an input vector.

```
function [m,s] = stat(x)
n = length(x);
m = sum(x)/n;
s = sqrt(sum((x-m).^2/n));
end
```

Call the function from the command line.

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];
[ave,stdev] = stat(values)
```

```
ave =
    47.3400
stdev =
    29.4124
```

### Multiple Functions in a File

Define two functions in a file named `stat2.m`, where the first function calls the second.

```
function [m,s] = stat2(x)
n = length(x);
m = avg(x,n);
s = sqrt(sum((x-m).^2/n));
end
```

```
function m = avg(x,n)
m = sum(x)/n;
end
```

Function `avg` is a *local function*. Local functions are only available to other functions within the same file.

Call function `stat2` from the command line.

# function

---

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];  
[ave,stdev] = stat2(values)
```

```
ave =  
    47.3400  
stdev =  
    29.4124
```

- “Function Precedence Order”

**Purpose** Handle used in calling functions indirectly

**Syntax**  
`handle = @functionname`  
`handle = @(arglist)anonymous_function`

**Description** `handle = @functionname` returns a handle to the specified MATLAB function.

A function handle is a MATLAB value that provides a means of calling a function indirectly. You can pass function handles in calls to other functions (often called *function functions*). You can also store function handles in data structures for later use (for example, as Handle Graphics callbacks). A function handle is one of the standard MATLAB data types.

At the time you create a function handle, the function you specify must be on the MATLAB path and in the current scope of the code creating the handle. For example, you can create a handle to a local function as long as you do so from within the file that defines that local function. This condition does not apply when you evaluate the function handle. You can, for example, execute a local function from a separate (out-of-scope) file using a function handle. This requires that the handle was created by the local function (in-scope).

`handle = @(arglist)anonymous_function` constructs an anonymous function and returns a `handle` to that function. The body of the function, to the right of the parentheses, is a single MATLAB statement or command. `arglist` is a comma-separated list of input arguments. Execute the function by calling it by means of the function handle, `handle`.

**Tips** The function handle is a standard MATLAB data type. As such, you can manipulate and operate on function handles in the same manner as on other MATLAB data types. This includes using function handles in structures and cell arrays:

```
S.a = @sin; S.b = @cos; S.c = @tan;  
C = {@sin, @cos, @tan};
```

# function\_handle (@)

---

However, standard matrices or arrays of function handles are not supported:

```
A = [@sin, @cos, @tan];           % This is not supported
```

For nonoverloaded functions, local functions, and private functions, a function handle references just the one function specified in the `@functionname` syntax. When you evaluate an overloaded function by means of its handle, the arguments the handle is evaluated with determine the actual function that MATLAB dispatches to.

Use `isa(h, 'function_handle')` to see if variable `h` is a function handle.

## Examples

### Example 1 – Constructing a Handle to a Named Function

The following example creates a function handle for the `humps` function and assigns it to the variable `fhandle`.

```
fhandle = @humps;
```

Pass the handle to another function in the same way you would pass any argument. This example passes the function handle just created to `fminbnd`, which then minimizes over the interval `[0.3, 1]`.

```
x = fminbnd(fhandle, 0.3, 1)
x =
    0.6370
```

The `fminbnd` function evaluates the `@humps` function handle. A small portion of the `fminbnd` file is shown below. In line 1, the `funfcn` input parameter receives the function handle `@humps` that was passed in. The statement, in line 113, evaluates the handle.

```
1 function [xf,fval,exitflag,output] = ...
    fminbnd(funfcn,ax,bx,options,varargin)
    .
    .
    .
```

```
113 fx = funfcn(x,varargin{:});
```

## **Example 2 – Constructing a Handle to an Anonymous Function**

The statement below creates an anonymous function that finds the square of a number. When you call this function, MATLAB assigns the value you pass in to variable `x`, and then uses `x` in the equation `x.^2`:

```
sqr = @(x) x.^2;
```

The `@` operator constructs a function handle for this function, and assigns the handle to the output variable `sqr`. As with any function handle, you execute the function associated with it by specifying the variable that contains the handle, followed by a comma-separated argument list in parentheses. The syntax is

```
fhandle(arg1, arg2, ..., argN)
```

To execute the `sqr` function defined above, type

```
a = sqr(5)
a =
    25
```

Because `sqr` is a function handle, you can pass it in an argument list to other functions. The code shown here passes the `sqr` anonymous function to the MATLAB `integral` function to compute its integral from zero to one:

```
integral(sqr, 0, 1)
ans =
    0.3333
```

## **Example 3 – Using an Array of Function Handles**

This example creates a structure array of function handles `S` and then applies each handle in the array to the output of a `linspace` calculation in one operation using `structfun`:

```
S.a = @sin; S.b = @cos; S.c = @tan;
```

## function\_handle (@)

---

```
structfun(@(x)x(linspace(1,4,3)), S, 'UniformOutput', false)
ans =
    a: [0.8415 0.5985 -0.7568]
    b: [0.5403 -0.8011 -0.6536]
    c: [1.5574 -0.7470 1.1578]
```

### See Also

**Purpose** Information about function handle

**Syntax** `S = functions(funhandle)`

**Description** `S = functions(funhandle)` returns, in MATLAB structure `S`, the function name, type, filename, and other information for the function handle stored in the variable `funhandle`.

`functions` does not operate on nonscalar function handles. Passing a nonscalar function handle to `functions` results in an error.

---

**Caution** The `functions` function is provided for querying and debugging purposes. Because its behavior may change in subsequent releases, you should not rely upon it for programming purposes.

---

This table lists the standard fields of the return structure.

Field Name	Field Description
<code>function</code>	Function name
<code>type</code>	Function type (e.g., simple, overloaded)
<code>file</code>	The file to be executed when the function handle is evaluated with a nonoverloaded data type

## Examples

### Example 1

To obtain information on a function handle for the `poly` function, type

```
f = functions(@poly)
f =
    function: 'poly'
         type: 'simple'
         file: '$matlabroot\toolbox\matlab\polyfun\poly.m'
```

(The term `$matlabroot` used in this example stands for the file specification of the directory in which MATLAB software is installed for your system. Your output will display this file specification.)

Access individual fields of the returned structure using dot selection notation:

```
f.type
ans =
    simple
```

## Example 2

The function `get_handles` returns function handles for a local function and private function in output arguments `l` and `p` respectively:

```
function [l, p] = get_handles
l = @mylocfun;
p = @myprivatefun;
%
function mylocfun
disp 'Executing local function mylocfun'
```

Call `get_handles` to obtain the two function handles, and then pass each to the `functions` function. MATLAB returns information in a structure having the fields `function`, `type`, `file`, and `parentage`. The `file` field contains the file specification for the local or private function:

```
[floc fprv] = get_handles;

functions(floc)
ans =
    function: 'mylocfun'
           type: 'scopedfunction'
           file: 'c:\matlab\get_handles.m'
    parentage: {'mylocfun' 'get_handles'}
```

```
functions(fprv)
ans =
```

```

function: 'myprivatefun'
type: 'scopedfunction'
file: 'c:\matlab\private\myprivatefun.m'
parentage: {'myprivatefun'}

```

### Example 3

In this example, the function `get_handles_nested.m` contains a nested function `nestfun`. This function has a single output which is a function handle to the nested function:

```

function handle = get_handles_nested(A)
    nestfun(A);

    function y = nestfun(x)
        y = x + 1;
    end

```

```

handle = @nestfun;
end

```

Call this function to get the handle to the nested function. Use this handle as the input to `functions` to return the information shown here. Note that the `function` field of the return structure contains the names of the nested function and the function in which it is nested in the format. Also note that `functions` returns a `workspace` field containing the variables that are in context at the time you call this function by its handle:

```

fh = get_handles_nested(5);

finfo = functions(fh)
finfo =
    function: 'get_handles_nested/nestfun'
           type: 'nested'
           file: 'c:\matlab\get_handles_nested.m'
    workspace: [1x1 struct]

```

```

finfo.workspace

```

# functions

---

```
ans =  
  handle: @get_handles_nested/nestfun  
  A: 5
```

## **See Also**

`function_handle`

## Purpose

Create array of tests from handles to local functions

## Syntax

```
tests = functiontests(f)
```

## Description

`tests = functiontests(f)` creates an array of tests, `tests`, from a cell array of handles to local functions, `f`. To apply defined setup and teardown functions, include their function handles in `f`.

Local test functions must include 'test' at the beginning or end of the function name. `functiontests` must be called from within a test file.

## Input Arguments

### **f - Handles to local test functions**

cell array of function handles

Handles to local test functions, specified as a cell array. Use `f=localfunctions` in your working file to automatically generate a cell array of function handles for that file. If you want explicit test enumeration, construct `f` by listing individual functions. `f` must include any setup or teardown functions necessary for your test.

**Example:** `f = localfunctions;`

**Example:** `f = {@setup,@exampleOneTest,@teardown};`

## Examples

### **Create Test Array**

Create the file `exampleTest.m` in your MATLAB path. In the main function, create a test array. Use local functions to define setup, teardown, and two function tests. Your file should look like this.

```
function tests = exampleTest
tests = functiontests(localfunctions);
```

```
function setup(testCase)
function teardown(testCase)
function exampleOneTest(testCase)
function testExampleTwo(testCase)
```

From the command line, call the `exampleTest` function.

# functiontests

---

```
tests = exampleTest
```

```
tests =
```

```
1x2 Test array with properties:
```

```
    Name
```

```
    SharedTestFixtures
```

Access the test suite to verify the names of the two function tests.

```
tests.Name
```

```
ans =
```

```
exampleTest/exampleOneTest
```

```
ans =
```

```
exampleTest/testExampleTwo
```

## Related Examples

- “Write Function-Based Unit Tests”
- “Write Simple Test Case Using Functions”
- “Write Test Using Setup and Teardown Functions”

**Purpose** Evaluate general matrix function

**Syntax**

```
F = funm(A,fun)
F = funm(A,fun,options)
F = funm(A,fun,options,p1,p2,...)
[F,exitflag] = funm(...)
[F,exitflag,output] = funm(...)
```

**Description** `F = funm(A, fun)` evaluates the user-defined function `fun` at the square matrix argument `A`. `F = fun(x,k)` must accept a vector `x` and an integer `k`, and return a vector `f` of the same size of `x`, where `f(i)` is the `k`th derivative of the function `fun` evaluated at `x(i)`. The function represented by `fun` must have a Taylor series with an infinite radius of convergence, except for `fun = @log`, which is treated as a special case.

You can also use `funm` to evaluate the special functions listed in the following table at the matrix `A`.

Function	Syntax for Evaluating Function at Matrix A
<code>exp</code>	<code>funm(A, @exp)</code>
<code>log</code>	<code>funm(A, @log)</code>
<code>sin</code>	<code>funm(A, @sin)</code>
<code>cos</code>	<code>funm(A, @cos)</code>
<code>sinh</code>	<code>funm(A, @sinh)</code>
<code>cosh</code>	<code>funm(A, @cosh)</code>

For matrix square roots, use `sqrtn(A)` instead. For matrix exponentials, which of `expm(A)` or `funm(A, @exp)` is the more accurate depends on the matrix `A`.

The function represented by `fun` must have a Taylor series with an infinite radius of convergence. The exception is `@log`, which is treated as a special case. “Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

# funm

$F = \text{funm}(A, \text{fun}, \text{options})$  sets the algorithm's parameters to the values in the structure `options`.

The following table lists the fields of options.

Field	Description	Values
<code>options.Display</code>	Level of display	'off' (default), 'on', 'verbose'
<code>options.TolBlk</code>	Tolerance for blocking Schur form	Positive scalar. The default is 0.1.
<code>options.TolTay</code>	Termination tolerance for evaluating the Taylor series of diagonal blocks	Positive scalar. The default is <code>eps</code> .
<code>options.MaxTerms</code>	Maximum number of Taylor series terms	Positive integer. The default is 250.
<code>options.MaxSqrt</code>	When computing a logarithm, maximum number of square roots computed in inverse scaling and squaring method.	Positive integer. The default is 100.
<code>options.Ord</code>	Specifies the ordering of the Schur form $T$ .	A vector of length <code>length(A)</code> . <code>options.Ord(i)</code> is the index of the block into which $T(i, i)$ is placed. The default is <code>[]</code> .

$F = \text{funm}(A, \text{fun}, \text{options}, p1, p2, \dots)$  passes extra inputs `p1, p2, ...` to the function.

$[F, \text{exitflag}] = \text{funm}(\dots)$  returns a scalar `exitflag` that describes the exit condition of `funm`. `exitflag` can have the following values:

- 0 — The algorithm was successful.

- 1 — One or more Taylor series evaluations did not converge, or, in the case of a logarithm, too many square roots are needed. However, the computed value of F might still be accurate.

[F,exitflag,output] = funm(...) returns a structure output with the following fields:

Field	Description
output.terms	Vector for which output.terms(i) is the number of Taylor series terms used when evaluating the <i>i</i> th block, or, in the case of the logarithm, the number of square roots of matrices of dimension greater than 2.
output.ind	Cell array for which the (i,j) block of the reordered Schur factor T is T(output.ind{i}, output.ind{j}).
output.ord	Ordering of the Schur form, as passed to ordschur
output.T	Reordered Schur form

If the Schur form is diagonal then output = struct('terms',ones(n,1),'ind',{1:n}).

## Examples

### Example 1

The following command computes the matrix sine of the 3-by-3 magic matrix.

```
F=funm(magic(3), @sin)
```

F =

```
-0.3850    1.0191    0.0162
 0.6179    0.2168   -0.1844
 0.4173   -0.5856    0.8185
```

## Example 2

The statements

```
S = funm(X,@sin);  
C = funm(X,@cos);
```

produce the same results to within roundoff error as

```
E = expm(i*X);  
C = real(E);  
S = imag(E);
```

In either case, the results satisfy  $S*S+C*C = I$ , where  $I = \text{eye}(\text{size}(X))$ .

## Example 3

To compute the function  $\exp(x) + \cos(x)$  at  $A$  with one call to `funm`, use

```
F = funm(A,@fun_expcos)
```

where `fun_expcos` is the following function.

```
function f = fun_expcos(x, k)  
% Return kth derivative of exp + cos at X.  
    g = mod(ceil(k/2),2);  
    if mod(k,2)  
        f = exp(x) + sin(x)*(-1)^g;  
    else  
        f = exp(x) + cos(x)*(-1)^g;  
    end
```

## Algorithms

The algorithm `funm` uses is described in [1].

# fwrite

---

## Purpose

Write data to binary file

## Syntax

```
fwrite(fileID, A)  
fwrite(fileID, A, precision)  
fwrite(fileID, A, precision, skip)  
fwrite(fileID, A, precision, skip, machineformat)  
count = fwrite(...)
```

## Description

`fwrite(fileID, A)` writes the elements of array *A* to a binary file in column order.

`fwrite(fileID, A, precision)` translates the values of *A* according to the form and size described by the *precision*.

`fwrite(fileID, A, precision, skip)` skips *skip* bytes before writing each value. If *precision* is *bitn* or *ubitn*, specify *skip* in bits.

`fwrite(fileID, A, precision, skip, machineformat)` writes data with the specified *machineformat*. The *skip* parameter is optional.

`count = fwrite(...)` returns the number of elements of *A* that `fwrite` successfully writes to the file.

## Input Arguments

### **fileID**

File identifier, specified as one of the following:

- A file identifier obtained from `fopen`.
- 1 for standard output (the screen).
- 2 for standard error.

### **A**

Numeric or character array.

### **precision**

String in single quotation marks that controls the form and size of the output. The following table shows possible values for *precision*.

Value Type	Precision	Bits (Bytes)
Integers, unsigned	uint	32 (4)
	uint8	8 (1)
	uint16	16 (2)
	uint32	32 (4)
	uint64	64 (8)
	uchar	8 (1)
	unsigned char	8 (1)
	ushort	16 (2)
	ulong	32 (4)
	ubit <i>n</i>	$1 \leq n \leq 64$
Integers, signed	int	32 (4)
	int8	8 (1)
	int16	16 (2)
	int32	32 (4)
	int64	64 (8)
	integer*1	8 (1)
	integer*2	16 (2)
	integer*4	32 (4)
	integer*8	64 (8)
	schar	8 (1)
	signed char	8 (1)
	short	16 (2)
	long	32 (4)
	bit <i>n</i>	$1 \leq n \leq 64$

Value Type	Precision	Bits (Bytes)
Floating-point numbers	single	32 (4)
	double	64 (8)
	float	32 (4)
	float32	32 (4)
	float64	64 (8)
	real*4	32 (4)
	real*8	64 (8)
Characters	char*1	8 (1)
	char	Depends on the encoding scheme associated with the file. Set encoding with fopen.

If you specify a precision of `bitn` or `ubitn`, and a value is out of range, `fwrite` sets all bits for that value.

**Default:** `uint8`

## **skip**

Number of bytes to skip before writing each value. If you specify a *precision* of `bitn` or `ubitn`, specify *skip* in bits. Use this parameter to insert data into noncontiguous fields in fixed-length records.

**Default:** 0

## **machineformat**

String that specifies the order for writing bytes within the file. For `bitn` and `ubitn` precisions, specifies the order for writing bits within a byte.

'n' or 'native'	Your system byte ordering (default)
'b' or 'ieee-be'	Big-endian ordering
'l' or 'ieee-le'	Little-endian ordering
's' or 'ieee-be.l64'	Big-endian ordering, 64-bit long data type
'a' or 'ieee-le.l64'	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

## Examples

Create a 100-byte binary file containing the 25 elements of the 5-by-5 magic square, stored as 4-byte integers:

```
fid = fopen('magic5.bin', 'w');
fwrite(fid, magic(5), 'integer*4');
fclose(fid);
```

## How To

- “Overwriting or Appending to an Existing File”
- “Creating a File for Use on a Different System”
- “Writing and Reading Complex Numbers”

# fwrite (serial)

---

**Purpose** Write binary data to device

**Syntax**

```
fwrite(obj,A)
fwrite(obj,A,'precision')
fwrite(obj,A,'mode')
fwrite(obj,A,'precision','mode')
```

**Description** `fwrite(obj,A)` writes the binary data *A* to the device connected to the serial port object, *obj*.

`fwrite(obj,A,'precision')` writes binary data with precision specified by *precision*.

*precision* controls the number of bits written for each value and the interpretation of those bits as integer, floating-point, or character values. If *precision* is not specified, uchar (an 8-bit unsigned character) is used. The supported values for *precision* are listed below in Tips.

`fwrite(obj,A,'mode')` writes binary data with command line access specified by *mode*. If *mode* is *sync*, *A* is written synchronously and the command line is blocked. If *mode* is *async*, *A* is written asynchronously and the command line is not blocked. If *mode* is not specified, the write operation is synchronous.

`fwrite(obj,A,'precision','mode')` writes binary data with precision specified by *precision* and command line access specified by *mode*.

**Tips**

Before you can write data to the device, it must be connected to *obj* with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a write operation while *obj* is not connected to the device.

The `ValuesSent` property value is increased by the number of values written each time `fwrite` is issued.

An error occurs if the output buffer cannot hold all the data to be written. You can specify the size of the output buffer with the `OutputBufferSize` property.

If you use the `help` command to display help for `fwrite`, then you need to supply the pathname shown below.

```
help serial/fwrite
```

`fwrite` will return an error message if you set the `FlowControl` property to `hardware` on a serial object, and a hardware connection is not detected. This occurs if a device is not connected, or a connected device is not asserting that it is ready to receive data. Check your remote device's status and flow control settings to see if hardware flow control is causing errors in MATLAB.

---

**Note** If you want to check to see if the device is asserting that it is ready to receive data, set the `FlowControl` to `none`. Once you connect to the device check the `PinStatus` structure for `ClearToSend`. If `ClearToSend` is `off`, there is a problem on the remote device side. If `ClearToSend` is `on`, there is a hardware `FlowControl` device prepared to receive data and you can execute `fwrite`.

---

## Synchronous Versus Asynchronous Write Operations

By default, data is written to the device synchronously and the command line is blocked until the operation completes. You can perform an asynchronous write by configuring the `mode` input argument to be `async`. For asynchronous writes:

- The `BytesToOutput` property value is continuously updated to reflect the number of bytes in the output buffer.
- The callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

You can determine whether an asynchronous write operation is in progress with the `TransferStatus` property.

Synchronous and asynchronous write operations are discussed in more detail in [Writing Data](#).

# fwrite (serial)

---

## Rules for Completing a Write Operation with fwrite

A binary write operation using `fwrite` completes when:

- The specified data is written.
- The time specified by the `Timeout` property passes.

---

**Note** The `Terminator` property is not used with binary write operations.

---

## Supported Precisions

The supported values for *precision* are listed below.

Data Type	Precision	Interpretation
Character	uchar	8-bit unsigned character
	schar	8-bit signed character
	char	8-bit signed or unsigned character
Integer	int8	8-bit integer
	int16	16-bit integer
	int32	32-bit integer
	uint8	8-bit unsigned integer
	uint16	16-bit unsigned integer
	uint32	32-bit unsigned integer
	short	16-bit integer
	int	32-bit integer
	long	32- or 64-bit integer
	ushort	16-bit unsigned integer
	uint	32-bit unsigned integer

Data Type	Precision	Interpretation
	ulong	32- or 64-bit unsigned integer
Floating-point	single	32-bit floating point
	float32	32-bit floating point
	float	32-bit floating point
	double	64-bit floating point
	float64	64-bit floating point

# fzero

---

## Purpose

Root of nonlinear function

## Syntax

```
x = fzero(fun,x0)
x = fzero(fun,x0,options)
```

```
x = fzero(problem)
```

```
[x,fval,exitflag,output] = fzero( __ )
```

## Description

`x = fzero(fun,x0)` tries to find a point  $x$  where  $\text{fun}(x) = 0$ . This solution is where  $\text{fun}(x)$  changes sign—`fzero` cannot find a root of a function such as  $x^2$ .

`x = fzero(fun,x0,options)` uses options to modify the solution process.

`x = fzero(problem)` solves a root-finding problem specified by `problem`.

`[x,fval,exitflag,output] = fzero( __ )` returns  $\text{fun}(x)$  in the `fval` output, `exitflag` encoding the reason `fzero` stopped, and an output structure containing information on the solution process.

## Input Arguments

### **fun** - Function to solve

function handle

Function to solve, specified as a handle to a scalar-valued function. `fun` accepts a scalar  $x$  and returns a scalar  $\text{fun}(x)$ .

`fzero` solves  $\text{fun}(x) = 0$ . To solve an equation  $\text{fun}(x) = c(x)$ , instead solve  $\text{fun2}(x) = \text{fun}(x) - c(x) = 0$ .

To include extra parameters in your function, see the example “Root of Function with Extra Parameter” on page 1-2178 and the section “Parameterizing Functions”.

**Example:** @sin

**Example:** @myFunction

**Example:** @(x)(x-a)^5 - 3\*x + a - 1

### Data Types

function\_handle

### **x0 - Initial value**

scalar | 2-element vector

Initial value, specified as a real scalar or a 2-element real vector.

- Scalar — fzero begins at  $x_0$  and tries to locate a point  $x_1$  where  $\text{fun}(x_1)$  has the opposite sign of  $\text{fun}(x_0)$ . Then fzero iteratively shrinks the interval where fun changes sign to reach a solution.
- 2-element vector — fzero checks that  $\text{fun}(x_0(1))$  and  $\text{fun}(x_0(2))$  have opposite signs, and errors if they do not. It then iteratively shrinks the interval where fun changes sign to reach a solution. An interval  $x_0$  must be finite; it cannot contain  $\pm\text{Inf}$ .

---

**Tip** Calling fzero with an interval ( $x_0$  with two elements) is often faster than calling it with a scalar  $x_0$ .

---

**Example:** 3

**Example:** [2,17]

### Data Types

double

### **options - Options for solution process**

Structure, typically created using optimset

Options for solution process, specified as a structure. Create or modify the options structure using optimset. fzero uses these options structure fields.

Display	Level of display: <ul style="list-style-type: none"><li>• 'off' displays no output.</li><li>• 'iter' displays output at each iteration.</li><li>• 'final' displays just the final output.</li><li>• 'notify' (default) displays output only if the function does not converge.</li></ul>
FunValCheck	Check whether objective function values are valid. <ul style="list-style-type: none"><li>• 'on' displays an error when the objective function returns a value that is complex, Inf, or NaN.</li><li>• The default, 'off', displays no error.</li></ul>
OutputFcn	Specify one or more user-defined functions that an optimization function calls at each iteration, either as a function handle or as a cell array of function handles. The default is none ( []). See “Output Functions”.
PlotFcns	Plot various measures of progress while the algorithm executes. Select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none ( []). <ul style="list-style-type: none"><li>• @optimplotx plots the current point.</li><li>• @optimplotfval plots the function value.</li></ul> For information on writing a custom plot function, see “Plot Functions”.
TolX	Termination tolerance on x, a positive scalar. The default is eps, 2.2204e–16.

**Example:** `options = optimset('FunValCheck','on')`

## Data Types

struct

**problem - Root-finding problem**

Structure

Root-finding problem, specified as a structure with all of the following fields.

<code>objective</code>	Objective function
<code>x0</code>	Initial point for <code>x</code> , real scalar or 2-element vector
<code>solver</code>	'fzero'
<code>options</code>	Options structure, typically created using <code>optimset</code>

For an example, see “Solve Problem Structure” on page 1-2179.

**Data Types**

struct

**Output Arguments****`x` - Location of root or sign change**

Real scalar

Location of root or sign change, returned as a scalar.

**`fval` - Function value at `x`**

Real scalar

Function value at `x`, returned as a scalar.

**`exitflag` - Integer encoding the exit condition**

Integer

Integer encoding the exit condition, meaning the reason `fsolve` stopped its iterations.

1	Function converged to a solution <code>x</code> .
-1	Algorithm was terminated by the output function or plot function.

- 3 NaN or Inf function value was encountered while searching for an interval containing a sign change.
- 4 Complex function value was encountered while searching for an interval containing a sign change.
- 5 Algorithm might have converged to a singular point.
- 6 fzero did not detect a sign change.

## **output - Information about root-finding process**

### Structure

Information about root-finding process, returned as a structure. The fields of the structure are:

interval	Number of iterations taken to find an interval containing a root
iterations	Number of zero-finding iterations
funcCount	Number of function evaluations
algorithm	'bisection, interpolation'
message	Exit message

## **Examples**

### **Root Starting From One Point**

Calculate  $\pi$  by finding the zero of the sine function near 3.

```
fun = @sin; % function
x0 = 3; % initial point
x = fzero(fun,x0)
```

```
x =
    3.1416
```

### **Root Starting From an Interval**

Find the zero of cosine between 1 and 2.

```
fun = @cos; % function
x0 = [1 2]; % initial interval
x = fzero(fun,x0)
```

```
x =
    1.5708
```

Note that  $\cos(1)$  and  $\cos(2)$  differ in sign.

### Root of a Function Defined by a File

Find a zero of the function  $f(x) = x^3 - 2x - 5$ .

First, write a file called `f.m`.

```
function y = f(x)
y = x.^3 - 2*x - 5;
```

Save `f.m` on your MATLAB path.

Find the zero of  $f(x)$  near 2.

```
fun = @f; % function
x0 = 2; % initial point
z = fzero(fun,x0)
```

```
z =
    2.0946
```

Since  $f(x)$  is a polynomial, you can find the same real zero, and a complex conjugate pair of zeros, using the `roots` command.

```
roots([1 0 -2 -5])
```

```
ans =
    2.0946
   -1.0473 + 1.1359i
   -1.0473 - 1.1359i
```

## Root of Function with Extra Parameter

Find the root of a function that has an extra parameter.

```
myfun = @(x,c) cos(c*x); % parameterized function
c = 2; % parameter
fun = @(x) myfun(x,c); % function of x alone
x = fzero(fun,0.1)
```

x =

0.7854

## Nondefault Options

Plot the solution process by setting some plot functions.

Define the function and initial point.

```
fun = @(x)sin(cosh(x));
x0 = 1;
```

Examine the solution process by setting options that include plot functions.

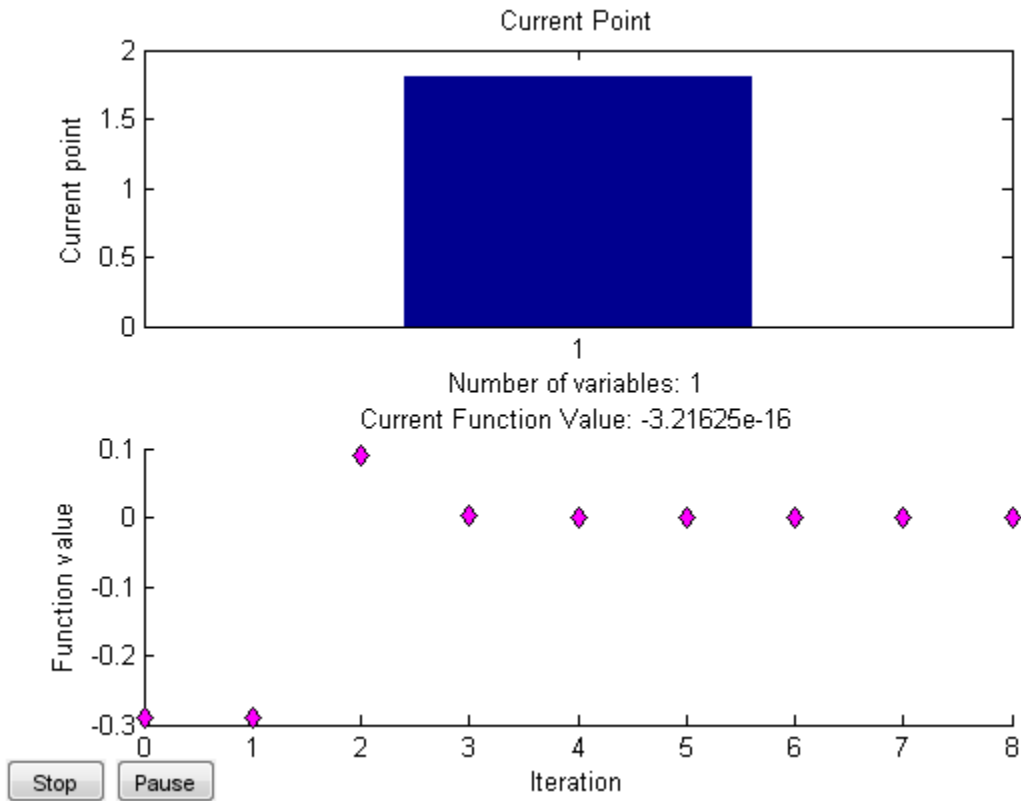

```
options = optimset('PlotFcns',{@optimplotx,@optimplotfval});
```

Run fzero including the options.

```
x = fzero(fun,x0,options)
```

x =

1.8115

### Solve Problem Structure

Solve a problem that is defined by a problem structure.

Define a structure that encodes a root-finding problem.

```
problem.objective = @(x)sin(cosh(x));
problem.x0 = 1;
problem.solver = 'fzero'; % a required part of the structure
problem.options = optimset(@fzero); % default options
```

Solve the problem.

```
x = fzero(problem)
```

```
x =
```

```
1.8115
```

## More Information from Solution

Find the point where  $\exp(-\exp(-x)) = x$ , and display information about the solution process.

```
fun = @(x) exp(-exp(-x)) - x; % function
x0 = [0 1]; % initial interval
options = optimset('Display','iter'); % show iterations
[x fval exitflag output] = fzero(fun,x0,options)
```

Func-count	x	f(x)	Procedure
2	1	-0.307799	initial
3	0.544459	0.0153522	interpolation
4	0.566101	0.00070708	interpolation
5	0.567143	-1.40255e-08	interpolation
6	0.567143	1.50013e-12	interpolation
7	0.567143	0	interpolation

```
Zero found in the interval [0, 1]
```

```
x =
```

```
0.5671
```

```
fval =
```

```
0
```

```
exitflag =
```

```
1
```

```
output =
```

```
intervaliterations: 0
```

```
iterations: 5
```

```
funcCount: 7
```

```
algorithm: 'bisection, interpolation'
```

```
message: 'Zero found in the interval [0, 1]'
```

`fval = 0` means  $\text{fun}(x) = 0$ , as desired.

## Algorithms

The `fzero` command is a function file. The algorithm, created by T. Dekker, uses a combination of bisection, secant, and inverse quadratic interpolation methods. An Algol 60 version, with some improvements, is given in [1]. A Fortran version, upon which `fzero` is based, is in [2].

# gallery

---

**Purpose** Test matrices

**Syntax**  
`[A,B,C,...] = gallery(matname,P1,P2,...)`  
`[A,B,C,...] = gallery(matname,P1,P2,...,classname)`  
`gallery(3)`  
`gallery(5)`

**Description** `[A,B,C,...] = gallery(matname,P1,P2,...)` returns the test matrices specified by the quoted string `matname`. The `matname` input is the name of a matrix family selected from the table below. `P1,P2,...` are input parameters required by the individual matrix family. The number of optional parameters `P1,P2,...` used in the calling syntax varies from matrix to matrix. The exact calling syntaxes are detailed in the individual matrix descriptions below.

`[A,B,C,...] = gallery(matname,P1,P2,...,classname)` produces a matrix of class `classname`. The `classname` input is a quoted string that must be either `'single'` or `'double'` (unless `matname` is `'integerdata'`, in which case `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, and `'uint32'` are also allowed). If `classname` is not specified, then the class of the matrix is determined from those arguments among `P1,P2,...` that do not specify dimensions or select an option. If any of these arguments is of class `single` then the matrix is `single`; otherwise the matrix is `double`.

`gallery(3)` is a badly conditioned 3-by-3 matrix and `gallery(5)` is an interesting eigenvalue problem.

The gallery holds over fifty different test matrix functions useful for testing algorithms and other purposes.

### **binomial – Multiple of involutory matrix**

$A = \text{gallery}('binomial', n)$  returns an  $n$ -by- $n$  matrix, with integer entries such that  $A^2 = 2^{n-1} \cdot \text{eye}(n)$ .

Thus,  $B = A \cdot 2^{-(n-1)/2}$  is involutory, that is,  $B^2 = \text{eye}(n)$ .

### **cauchy – Cauchy matrix**

$C = \text{gallery}('cauchy', x, y)$  returns an  $n$ -by- $n$  matrix,  $C(i, j) = 1/(x(i)+y(j))$ . Arguments  $x$  and  $y$  are vectors of length  $n$ . If you pass in scalars for  $x$  and  $y$ , they are interpreted as vectors  $1:x$  and  $1:y$ .

$C = \text{gallery}('cauchy', x)$  returns the same as above with  $y = x$ . That is, the command returns  $C(i, j) = 1/(x(i)+x(j))$ .

Explicit formulas are known for the inverse and determinant of a Cauchy matrix. The determinant  $\det(C)$  is nonzero if  $x$  and  $y$  both have distinct elements.  $C$  is totally positive if  $0 < x(1) < \dots < x(n)$  and  $0 < y(1) < \dots < y(n)$ .

### **chebspec – Chebyshev spectral differentiation matrix**

$C = \text{gallery}('chebspec', n, \text{switch})$  returns a Chebyshev spectral differentiation matrix of order  $n$ . Argument  $\text{switch}$  is a variable that determines the character of the output matrix. By default,  $\text{switch} = 0$ .

For  $\text{switch} = 0$  (“no boundary conditions”),  $C$  is nilpotent ( $C^n = 0$ ) and has the null vector  $\text{ones}(n, 1)$ . The matrix  $C$  is similar to a Jordan block of size  $n$  with eigenvalue zero.

For  $\text{switch} = 1$ ,  $C$  is nonsingular and well-conditioned, and its eigenvalues have negative real parts.

The eigenvector matrix of the Chebyshev spectral differentiation matrix is ill-conditioned.

## **chebvand – Vandermonde-like matrix for the Chebyshev polynomials**

`C = gallery('chebvand', p)` produces the (primal) Chebyshev Vandermonde matrix based on the vector of points `p`, which define where the Chebyshev polynomial is calculated.

`C = gallery('chebvand', m, p)` where `m` is scalar, produces a rectangular version of the above, with `m` rows.

If `p` is a vector, then  $C(i,j) = T_{i-1}(p(j))$  where  $T_{i-1}$  is the Chebyshev polynomial of degree  $i - 1$ . If `p` is a scalar, then `p` equally spaced points on the interval `[0, 1]` are used to calculate `C`.

## **chow – Singular Toeplitz lower Hessenberg matrix**

`A = gallery('chow', n, alpha, delta)` returns `A` such that  $A = H(\alpha) + \delta \cdot \text{eye}(n)$ , where  $H_{i,j}(\alpha) = \alpha^{(i-j+1)}$  and argument `n` is the order of the Chow matrix. Default value for scalars `alpha` and `delta` are 1 and 0, respectively.

$H(\alpha)$  has `p = floor(n/2)` eigenvalues that are equal to zero. The rest of the eigenvalues are equal to  $4 \cdot \alpha \cdot \cos(k \cdot \pi / (n+2))^2$ , `k=1:n-p`.

## **circul – Circulant matrix**

`C = gallery('circul', v)` returns the circulant matrix whose first row is the vector `v`.

A circulant matrix has the property that each row is obtained from the previous one by cyclically permuting the entries one step forward. It is a special Toeplitz matrix in which the diagonals “wrap around.”

If `v` is a scalar, then `C = gallery('circul', 1, v)`.

The eigensystem of `C` (`n`-by-`n`) is known explicitly: If `t` is an `n`th root of unity, then the inner product of `v` and  $w = [1 \ t \ t^2 \ \dots \ t^{(n-1)}]$  is an eigenvalue of `C` and  $w(n:-1:1)$  is an eigenvector.

**clement – Tridiagonal matrix with zero diagonal entries**

`A = gallery('clement',n,k)` returns an  $n$ -by- $n$  tridiagonal matrix with zeros on its main diagonal and known eigenvalues. It is singular if  $n$  is odd. About 64 percent of the entries of the inverse are zero. The eigenvalues include plus and minus the numbers  $n-1, n-3, n-5, \dots, (1 \text{ or } 0)$ .

For  $k=0$  (the default),  $A$  is nonsymmetric. For  $k=1$ ,  $A$  is symmetric.

`gallery('clement',n,1)` is diagonally similar to `gallery('clement',n)`.

For odd  $N = 2*M+1$ ,  $M+1$  of the singular values are the integers  $\sqrt{(2*M+1)^2 - (2*K+1)^2}$ ,  $K = 0:M$ .

---

**Note** Similar properties hold for `gallery('tridiag',x,y,z)` where  $y = \text{zeros}(n,1)$ . The eigenvalues still come in plus/minus pairs but they are not known explicitly.

---

**compar – Comparison matrices**

`A = gallery('compar',A,1)` returns  $A$  with each diagonal element replaced by its absolute value, and each off-diagonal element replaced by minus the absolute value of the largest element in absolute value in its row. However, if  $A$  is triangular `compar(A,1)` is too.

`gallery('compar',A)` is  $\text{diag}(B) - \text{tril}(B,-1) - \text{triu}(B,1)$ , where  $B = \text{abs}(A)$ . `compar(A)` is often denoted by  $M(A)$  in the literature.

`gallery('compar',A,0)` is the same as `gallery('compar',A)`.

**condex – Counter-examples to matrix condition number estimators**

`A = gallery('condex',n,k,theta)` returns a “counter-example” matrix to a condition estimator. It has order  $n$  and scalar parameter  $\theta$  (default 100).

The matrix, its natural size, and the estimator to which it applies are specified by  $k$ :

$k = 1$	4-by-4	LINPACK
$k = 2$	3-by-3	LINPACK
$k = 3$	arbitrary	LINPACK (rcond) (independent of $\theta$ )
$k = 4$	$n \geq 4$	LAPACK (RCOND) (default). It is the inverse of this matrix that is a counter-example.

If  $n$  is not equal to the natural size of the matrix, then the matrix is padded out with an identity matrix to order  $n$ .

## **cycol – Matrix whose columns repeat cyclically**

$A = \text{gallery}('cycol', [m \ n], k)$  returns an  $m$ -by- $n$  matrix with cyclically repeating columns, where one “cycle” consists of  $\text{randn}(m, k)$ . Thus, the rank of matrix  $A$  cannot exceed  $k$ , and  $k$  must be a scalar.

Argument  $k$  defaults to  $\text{round}(n/4)$ , and need not evenly divide  $n$ .

$A = \text{gallery}('cycol', n, k)$ , where  $n$  is a scalar, is the same as  $\text{gallery}('cycol', [n \ n], k)$ .

## **dorr – Diagonally dominant, ill-conditioned, tridiagonal matrix**

$[c, d, e] = \text{gallery}('dorr', n, \theta)$  returns the vectors defining an  $n$ -by- $n$ , row diagonally dominant, tridiagonal matrix that is ill-conditioned for small nonnegative values of  $\theta$ . The default value of  $\theta$  is 0.01. The Dorr matrix itself is the same as  $\text{gallery}('tridiag', c, d, e)$ .

$A = \text{gallery}('dorr', n, \theta)$  returns the matrix itself, rather than the defining vectors.

### dramadah – Matrix of zeros and ones whose inverse has large integer entries

`A = gallery('dramadah', n, k)` returns an  $n$ -by- $n$  matrix of 0's and 1's for which  $\mu(A) = \text{norm}(\text{inv}(A), 'fro')$  is relatively large, although not necessarily maximal. An anti-Hadamard matrix  $A$  is a matrix with elements 0 or 1 for which  $\mu(A)$  is maximal.

$n$  and  $k$  must both be scalars. Argument  $k$  determines the character of the output matrix:

- $k = 1$       Default.  $A$  is Toeplitz, with  $\text{abs}(\det(A)) = 1$ , and  $\mu(A) > c(1.75)^n$ , where  $c$  is a constant. The inverse of  $A$  has integer entries.
- $k = 2$        $A$  is upper triangular and Toeplitz. The inverse of  $A$  has integer entries.
- $k = 3$        $A$  has maximal determinant among lower Hessenberg (0,1) matrices.  $\det(A) =$  the  $n$ th Fibonacci number.  $A$  is Toeplitz. The eigenvalues have an interesting distribution in the complex plane.

### fiedler – Symmetric matrix

`A = gallery('fiedler', c)`, where  $c$  is a length  $n$  vector, returns the  $n$ -by- $n$  symmetric matrix with elements  $\text{abs}(n(i) - n(j))$ . For scalar  $c$ , `A = gallery('fiedler', 1:c)`.

Matrix  $A$  has a dominant positive eigenvalue and all the other eigenvalues are negative.

Explicit formulas for  $\text{inv}(A)$  and  $\det(A)$  are given in [Todd, J., *Basic Numerical Mathematics*, Vol. 2: Numerical Algebra, Birkhauser, Basel, and Academic Press, New York, 1977, p. 159] and attributed to Fiedler. These indicate that  $\text{inv}(A)$  is tridiagonal except for nonzero  $(1, n)$  and  $(n, 1)$  elements.

### forsythe – Perturbed Jordan block

`A = gallery('forsythe', n, alpha, lambda)` returns the  $n$ -by- $n$  matrix equal to the Jordan block with eigenvalue  $\lambda$ , excepting that

$A(n,1) = \alpha$ . The default values of scalars  $\alpha$  and  $\lambda$  are  $\sqrt{\epsilon}$  and 0, respectively.

The characteristic polynomial of  $A$  is given by:

$$\det(A-tI) = (\lambda-t)^N - \alpha(-1)^n.$$

## **frank – Matrix with ill-conditioned eigenvalues**

$F = \text{gallery}('frank', n, k)$  returns the Frank matrix of order  $n$ . It is upper Hessenberg with determinant 1. If  $k = 1$ , the elements are reflected about the anti-diagonal  $(1, n) \text{ — } (n, 1)$ . The eigenvalues of  $F$  may be obtained in terms of the zeros of the Hermite polynomials. They are positive and occur in reciprocal pairs; thus if  $n$  is odd, 1 is an eigenvalue.  $F$  has  $\text{floor}(n/2)$  ill-conditioned eigenvalues — the smaller ones.

## **gcdmat – Greatest common divisor matrix**

$A = \text{gallery}('gcdmat', n)$  returns the  $n$ -by- $n$  matrix with  $(i, j)$  entry  $\text{gcd}(i, j)$ . Matrix  $A$  is symmetric positive definite, and  $A.^r$  is symmetric positive semidefinite for all nonnegative  $r$ .

## **gearmat – Gear matrix**

$A = \text{gallery}('gearmat', n, i, j)$  returns the  $n$ -by- $n$  matrix with ones on the sub- and super-diagonals,  $\text{sign}(i)$  in the  $(1, \text{abs}(i))$  position,  $\text{sign}(j)$  in the  $(n, n+1-\text{abs}(j))$  position, and zeros everywhere else. Arguments  $i$  and  $j$  default to  $n$  and  $-n$ , respectively.

Matrix  $A$  is singular, can have double and triple eigenvalues, and can be defective.

All eigenvalues are of the form  $2\cos(a)$  and the eigenvectors are of the form  $[\sin(w+a), \sin(w+2a), \dots, \sin(w+n*a)]$ , where  $a$  and  $w$  are given in Gear, C. W., “A Simple Set of Test Matrices for Eigenvalue Programs,” *Math. Comp.*, Vol. 23 (1969), pp. 119-125.

## **grcar – Toeplitz matrix with sensitive eigenvalues**

$A = \text{gallery}('grcar', n, k)$  returns an  $n$ -by- $n$  Toeplitz matrix with  $-1$ s on the subdiagonal,  $1$ s on the diagonal, and  $k$  superdiagonals of  $1$ s. The default is  $k = 3$ . The eigenvalues are sensitive.

### hanowa – Matrix whose eigenvalues lie on a vertical line in the complex plane

`A = gallery('hanowa',n,d)` returns an  $n$ -by- $n$  block 2-by-2 matrix of the form:

```
[d*eye(m) -diag(1:m)
diag(1:m) d*eye(m)]
```

Argument  $n$  is an even integer  $n=2*m$ . Matrix  $A$  has complex eigenvalues of the form  $d \pm k*i$ , for  $1 \leq k \leq m$ . The default value of  $d$  is  $-1$ .

### house – Householder matrix

`[v,beta,s] = gallery('house',x,k)` takes  $x$ , an  $n$ -element column vector, and returns  $V$  and  $\beta$  such that  $H*x = s*e1$ . In this expression,  $e1$  is the first column of `eye(n)`, `abs(s) = norm(x)`, and  $H = eye(n) - \beta*V*V'$  is a Householder matrix.

$k$  determines the sign of  $s$ :

```
k = 0      sign(s) = -sign(x(1)) (default)
k = 1      sign(s) = sign(x(1))
k = 2      sign(s) = 1 (x must be real)
```

If  $x$  is complex, then `sign(x) = x./abs(x)` when  $x$  is nonzero.

If  $x = 0$ , or if  $x = \alpha*e1$  ( $\alpha \geq 0$ ) and either  $k = 1$  or  $k = 2$ , then  $V = 0$ ,  $\beta = 1$ , and  $s = x(1)$ . In this case,  $H$  is the identity matrix, which is not strictly a Householder matrix.

-----  
`[v, beta] = gallery('house',x)` takes  $x$ , a scalar or  $n$ -element column vector, and returns  $v$  and  $\beta$  such that `eye(n,n) - beta*v*v'` is a Householder matrix. A Householder matrix  $H$  satisfies the relationship

```
H*x = -sign(x(1))*norm(x)*e1
```

where  $e_1$  is the first column of  $\text{eye}(n,n)$ . Note that if  $x$  is complex, then  $\text{sign}(x) = \exp(i \cdot \arg(x))$  (which equals  $x./\text{abs}(x)$  when  $x$  is nonzero).

If  $x = 0$ , then  $v = 0$  and  $\text{beta} = 1$ .

## **integerdata – Array of arbitrary data from uniform distribution on specified range of integers**

`A = gallery('integerdata',imax,[m,n,...],j)` returns an  $m$ -by- $n$ -by-... array  $A$  whose values are a sample from the uniform distribution on the integers  $1:\text{imax}$ .  $j$  must be an integer value in the interval  $[0, 2^{32}-1]$ . Calling `gallery('integerdata', ...)` with different values of  $J$  will return different arrays. Repeated calls to `gallery('integerdata', ...)` with the same  $\text{imax}$ , size vector and  $j$  inputs will always return the same array.

In any call to `gallery('integerdata', ...)` you can substitute individual inputs  $m,n,\dots$  for the size vector input  $[m,n,\dots]$ . For example, `gallery('integerdata',7,[1,2,3,4],5)` is equivalent to `gallery('integerdata',7,1,2,3,4,5)`.

`A = gallery('integerdata',[imin imax],[m,n,...],j)` returns an  $m$ -by- $n$ -by-... array  $A$  whose values are a sample from the uniform distribution on the integers  $\text{imin}:\text{imax}$ .

`[A,B,...] = gallery('integerdata',[imin imax],[m,n,...],j)` returns multiple  $m$ -by- $n$ -by-... arrays  $A, B, \dots$ , containing different values.

`A = gallery('integerdata',[imin imax],[m,n,...],j,classname)` produces an array of class `classname`. `classname` must be `'uint8'`, `'uint16'`, `'uint32'`, `'int8'`, `'int16'`, `'int32'`, `'single'` or `'double'`.

## **invhess – Inverse of an upper Hessenberg matrix**

`A = gallery('invhess',x,y)`, where  $x$  is a length  $n$  vector and  $y$  is a length  $n-1$  vector, returns the matrix whose lower triangle agrees with that of  $\text{ones}(n,1) \cdot x'$  and whose strict upper triangle agrees with that of  $[1 \ y] \cdot \text{ones}(1,n)$ .

The matrix is nonsingular if  $x(1) \neq 0$  and  $x(i+1) \neq y(i)$  for all  $i$ , and its inverse is an upper Hessenberg matrix. Argument  $y$  defaults to  $-x(1:n-1)$ .

If  $x$  is a scalar, `invhess(x)` is the same as `invhess(1:x)`.

### **invol – Involutory matrix**

`A = gallery('invol',n)` returns an  $n$ -by- $n$  involutory ( $A^*A = \text{eye}(n)$ ) and ill-conditioned matrix. It is a diagonally scaled version of `hilb(n)`.

$B = (\text{eye}(n) - A)/2$  and  $B = (\text{eye}(n) + A)/2$  are idempotent ( $B^*B = B$ ).

### **ipjfact – Hankel matrix with factorial elements**

`[A,d] = gallery('ipjfact',n,k)` returns  $A$ , an  $n$ -by- $n$  Hankel matrix, and  $d$ , the determinant of  $A$ , which is known explicitly. If  $k = 0$  (the default), then the elements of  $A$  are  $A(i,j) = (i+j)!$ . If  $k = 1$ , then the elements of  $A$  are  $A(i,j) = 1/(i+j)$ .

Note that the inverse of  $A$  is also known explicitly.

### **jordbloc – Jordan block**

`A = gallery('jordbloc',n,lambda)` returns the  $n$ -by- $n$  Jordan block with eigenvalue  $\lambda$ . The default value for  $\lambda$  is 1.

### **kahan – Upper trapezoidal matrix**

`A = gallery('kahan',n,theta,pert)` returns an upper trapezoidal matrix that has interesting properties regarding estimation of condition and rank.

If  $n$  is a two-element vector, then  $A$  is  $n(1)$ -by- $n(2)$ ; otherwise,  $A$  is  $n$ -by- $n$ . The useful range of  $\theta$  is  $0 < \theta < \pi$ , with a default value of 1.2.

To ensure that the QR factorization with column pivoting does not interchange columns in the presence of rounding errors, the diagonal is perturbed by `pert*eps*diag([n:-1:1])`. The default `pert` is 25, which ensures no interchanges for `gallery('kahan',n)` up to at least  $n = 90$  in IEEE arithmetic.

## **kms – Kac-Murdock-Szego Toeplitz matrix**

`A = gallery('kms',n,rho)` returns the  $n$ -by- $n$  Kac-Murdock-Szego Toeplitz matrix such that  $A(i,j) = \rho^{(|i-j|)}$ , for real  $\rho$ .

For complex  $\rho$ , the same formula holds except that elements below the diagonal are conjugated.  $\rho$  defaults to 0.5.

The KMS matrix  $A$  has these properties:

- An LDL' factorization with  $L = \text{inv}(\text{gallery('trilw',n,-rho,1)})'$ , and  $D(i,i) = (1 - \text{abs}(\rho)^2)^{\text{eye}(n)}$ , except  $D(1,1) = 1$ .
- Positive definite if and only if  $0 < \text{abs}(\rho) < 1$ .
- The inverse  $\text{inv}(A)$  is tridiagonal.

## **krylov – Krylov matrix**

`B = gallery('krylov',A,x,j)` returns the Krylov matrix

$[x, Ax, A^2x, \dots, A^{(j-1)}x]$

where  $A$  is an  $n$ -by- $n$  matrix and  $x$  is a length  $n$  vector. The defaults are  $x = \text{ones}(n,1)$ , and  $j = n$ .

`B = gallery('krylov',n)` is the same as `gallery('krylov',(randn(n)))`.

## **lauchli – Rectangular matrix**

`A = gallery('lauchli',n,mu)` returns the  $(n+1)$ -by- $n$  matrix

$[\text{ones}(1,n); \mu * \text{eye}(n)]$

The Lauchli matrix is a well-known example in least squares and other problems that indicates the dangers of forming  $A' * A$ . Argument  $\mu$  defaults to  $\text{sqrt}(\text{eps})$ .

## **lehmer – Symmetric positive definite matrix**

`A = gallery('lehmer',n)` returns the symmetric positive definite  $n$ -by- $n$  matrix such that  $A(i,j) = i/j$  for  $j \geq i$ .

The Lehmer matrix  $A$  has these properties:

- A is totally nonnegative.
- The inverse  $\text{inv}(A)$  is tridiagonal and explicitly known.
- The order  $n \leq \text{cond}(A) \leq 4*n*n$ .

### **leslie – Matrix of birth numbers and survival rates**

$L = \text{gallery}('leslie', a, b)$  is the  $n$ -by- $n$  matrix from the Leslie population model with average birth numbers  $a(1:n)$  and survival rates  $b(1:n-1)$ . It is zero, apart from the first row (which contains the  $a(i)$ ) and the first subdiagonal (which contains the  $b(i)$ ). For a valid model, the  $a(i)$  are nonnegative and the  $b(i)$  are positive and bounded by 1, i.e.,  $0 < b(i) \leq 1$ .

$L = \text{gallery}('leslie', n)$  generates the Leslie matrix with  $a = \text{ones}(n, 1)$ ,  $b = \text{ones}(n-1, 1)$ .

### **lesp – Tridiagonal matrix with real, sensitive eigenvalues**

$A = \text{gallery}('lesp', n)$  returns an  $n$ -by- $n$  matrix whose eigenvalues are real and smoothly distributed in the interval approximately  $[-2*N-3.5, -4.5]$ .

The sensitivities of the eigenvalues increase exponentially as the eigenvalues grow more negative. The matrix is similar to the symmetric tridiagonal matrix with the same diagonal entries and with off-diagonal entries 1, via a similarity transformation with  $D = \text{diag}(1!, 2!, \dots, n!)$ .

### **lotkin – Lotkin matrix**

$A = \text{gallery}('lotkin', n)$  returns the Hilbert matrix with its first row altered to all ones. The Lotkin matrix  $A$  is nonsymmetric, ill-conditioned, and has many negative eigenvalues of small magnitude. Its inverse has integer entries and is known explicitly.

### **minij – Symmetric positive definite matrix**

$A = \text{gallery}('minij', n)$  returns the  $n$ -by- $n$  symmetric positive definite matrix with  $A(i, j) = \min(i, j)$ .

The  $\text{minij}$  matrix has these properties:

- The inverse `inv(A)` is tridiagonal and equal to -1 times the second difference matrix, except its  $(n,n)$  element is 1.
- Givens' matrix, `2*A-ones(size(A))`, has tridiagonal inverse and eigenvalues  $0.5*\sec((2*r-1)*\pi/(4*n))^2$ , where  $r=1:n$ .
- $(n+1)*\text{ones}(\text{size}(A))-A$  has elements that are  $\max(i,j)$  and a tridiagonal inverse.

## **moler – Symmetric positive definite matrix**

`A = gallery('moler',n,alpha)` returns the symmetric positive definite  $n$ -by- $n$  matrix  $U' * U$ , where `U = gallery('triw',n,alpha)`.

For the default `alpha = -1`,  $A(i,j) = \min(i,j)-2$ , and  $A(i,i) = i$ . One of the eigenvalues of  $A$  is small.

## **neumann – Singular matrix from the discrete Neumann problem (sparse)**

`C = gallery('neumann',n)` returns the sparse  $n$ -by- $n$  singular, row diagonally dominant matrix resulting from discretizing the Neumann problem with the usual five-point operator on a regular mesh. Argument  $n$  is a perfect square integer  $n = m^2$  or a two-element vector.  $C$  is sparse and has a one-dimensional null space with null vector `ones(n,1)`.

## **normaldata – Array of arbitrary data from standard normal distribution**

`A = gallery('normaldata',[m,n,...],j)` returns an  $m$ -by- $n$ -by-... array  $A$ . The values of  $A$  are a random sample from the standard normal distribution.  $j$  must be an integer value in the interval  $[0, 2^{32}-1]$ . Calling `gallery('normaldata',...)` with different values of  $j$  will return different arrays. Repeated calls to `gallery('normaldata',...)` with the same size vector and  $j$  inputs will always return the same array.

In any call to `gallery('normaldata',...)` you can substitute individual inputs  $m,n,...$  for the size vector input `[m,n,...]`. For example, `gallery('normaldata',[1,2,3,4],5)` is equivalent to `gallery('normaldata',1,2,3,4,5)`.

`[A,B,...] = gallery('normaldata',[m,n,...],j)` returns multiple m-by-n-by-... arrays A, B, ..., containing different values.

`A = gallery('normaldata',[m,n,...],j,classname)` produces a matrix of class `classname`. `classname` must be either 'single' or 'double'.

Generate the arbitrary 6-by-4 matrix of data from the standard normal distribution  $N(0, 1)$  corresponding to `j = 2`:

```
x = gallery('normaldata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the standard normal distribution  $N(0, 1)$  corresponding to `j = 17`:

```
y = gallery('normaldata', 1, 2, 3, 17, 'single');
```

### **orthog – Orthogonal and nearly orthogonal matrices**

`Q = gallery('orthog',n,k)` returns the `k`th type of matrix of order `n`, where `k > 0` selects exactly orthogonal matrices, and `k < 0` selects diagonal scalings of orthogonal matrices. Available types are:

$$k = 1 \quad Q(i,j) = \sqrt{2/(n+1)} * \sin(i*j*\pi/(n+1))$$

Symmetric eigenvector matrix for second difference matrix. This is the default.

$$k = 2 \quad Q(i,j) = 2/(\sqrt{2*n+1}) * \sin(2*i*j*\pi/(2*n+1))$$

Symmetric.

$$k = 3 \quad Q(r,s) = \exp(2*\pi*i*(r-1)*(s-1)/n) / \sqrt{n}$$

Unitary, the Fourier matrix.  $Q^4$  is the identity. This is essentially the same matrix as `fft(eye(n))/sqrt(n)!`

$$k = 4 \quad \text{Helmert matrix: a permutation of a lower Hessenberg matrix, whose first row is ones}(1:n)/\sqrt{n}.$$

$k = 5$       $Q(i, j) = \sin(2\pi(i-1)(j-1)/n) + \cos(2\pi(i-1)(j-1)/n)$

Symmetric matrix arising in the Hartley transform.

$k = 6$       $Q(i, j) = \sqrt{2/n} \cos((i-1/2)(j-1/2)\pi/n)$

Symmetric matrix arising as a discrete cosine transform.

$k = -1$      $Q(i, j) = \cos((i-1)(j-1)\pi/(n-1))$

Chebyshev Vandermonde-like matrix, based on extrema of  $T(n-1)$ .

$k = -2$      $Q(i, j) = \cos((i-1)(j-1/2)\pi/n)$

Chebyshev Vandermonde-like matrix, based on zeros of  $T(n)$ .

## **parter** – Toeplitz matrix with singular values near $\pi$

$C = \text{gallery}('parter', n)$  returns the matrix  $C$  such that  $C(i, j) = 1/(i-j+0.5)$ .

$C$  is a Cauchy matrix and a Toeplitz matrix. Most of the singular values of  $C$  are very close to  $\pi$ .

## **pei** – Pei matrix

$A = \text{gallery}('pei', n, \alpha)$ , where  $\alpha$  is a scalar, returns the symmetric matrix  $\alpha \text{eye}(n) + \text{ones}(n)$ . The default for  $\alpha$  is 1. The matrix is singular for  $\alpha$  equal to either 0 or  $-n$ .

## **poisson** – Block tridiagonal matrix from Poisson's equation (sparse)

$A = \text{gallery}('poisson', n)$  returns the block tridiagonal (sparse) matrix of order  $n^2$  resulting from discretizing Poisson's equation with the 5-point operator on an  $n$ -by- $n$  mesh.

## **prolate** – Symmetric, ill-conditioned Toeplitz matrix

$A = \text{gallery}('prolate', n, w)$  returns the  $n$ -by- $n$  prolate matrix with parameter  $w$ . It is a symmetric Toeplitz matrix.

If  $0 < w < 0.5$  then  $A$  is positive definite

- The eigenvalues of  $A$  are distinct, lie in  $(0, 1)$ , and tend to cluster around 0 and 1.
- The default value of  $w$  is 0.25.

### **randcolu – Random matrix with normalized cols and specified singular values**

$A = \text{gallery}('randcolu', n)$  is a random  $n$ -by- $n$  matrix with columns of unit 2-norm, with random singular values whose squares are from a uniform distribution.

$A^*A$  is a correlation matrix of the form produced by  $\text{gallery}('randcorr', n)$ .

$\text{gallery}('randcolu', x)$  where  $x$  is an  $n$ -vector ( $n > 1$ ), produces a random  $n$ -by- $n$  matrix having singular values given by the vector  $x$ . The vector  $x$  must have nonnegative elements whose sum of squares is  $n$ .

$\text{gallery}('randcolu', x, m)$  where  $m \geq n$ , produces an  $m$ -by- $n$  matrix.

$\text{gallery}('randcolu', x, m, k)$  provides a further option:

- |         |  |
|---------|--|
| $k = 0$ | $\text{diag}(x)$ is initially subjected to a random two-sided orthogonal transformation, and then a sequence of Givens rotations is applied (default). |
| $k = 1$ | The initial transformation is omitted. This is much faster, but the resulting matrix may have zero entries.  |

For more information, see:

## References

[1] Davies, P. I. and N. J. Higham, “Numerically Stable Generation of Correlation Matrices and Their Factors,” *BIT*, Vol. 40, 2000, pp. 640-651.

### **randcorr – Random correlation matrix with specified eigenvalues**

`gallery('randcorr',n)` is a random  $n$ -by- $n$  correlation matrix with random eigenvalues from a uniform distribution. A correlation matrix is a symmetric positive semidefinite matrix with 1s on the diagonal (see `corrcoef`).

`gallery('randcorr',x)` produces a random correlation matrix having eigenvalues given by the vector  $x$ , where  $\text{length}(x) > 1$ . The vector  $x$  must have nonnegative elements summing to  $\text{length}(x)$ .

`gallery('randcorr',x,k)` provides a further option:

- |         |   |
|---------|---|
| $k = 0$ | The diagonal matrix of eigenvalues is initially subjected to a random orthogonal similarity transformation, and then a sequence of Givens rotations is applied (default). |
| $k = 1$ | The initial transformation is omitted. This is much faster, but the resulting matrix may have some zero entries.  |

For more information, see:

### **randhess — Random, orthogonal upper Hessenberg matrix**

`H = gallery('randhess', n)` returns an  $n$ -by- $n$  real, random, orthogonal upper Hessenberg matrix.

`H = gallery('randhess', x)` if  $x$  is an arbitrary, real, length  $n$  vector with  $n > 1$ , constructs  $H$  nonrandomly using the elements of  $x$  as parameters.

Matrix  $H$  is constructed via a product of  $n-1$  Givens rotations.

### **randjorth — Random J-orthogonal matrix**

`A = gallery('randjorth', n)`, for a positive integer  $n$ , produces a random  $n$ -by- $n$  J-orthogonal matrix  $A$ , where

- `J = blkdiag(eye(ceil(n/2)), -eye(floor(n/2)))`
- `cond(A) = sqrt(1/eps)`

J-orthogonality means that  $A^*JA = J$ . Such matrices are sometimes called *hyperbolic*.

`A = gallery('randjorth', n, m)`, for positive integers  $n$  and  $m$ , produces a random  $(n+m)$ -by- $(n+m)$  J-orthogonal matrix  $A$ , where

- `J = blkdiag(eye(n), -eye(m))`
- `cond(A) = sqrt(1/eps)`

`A = gallery('randjorth', n, m, c, symm, method)`

uses the following optional input arguments:

- `c` — Specifies `cond(A)` to be the scalar `c`.
- `symm` — Enforces symmetry if the scalar `symm` is nonzero.
- `method` — calls `qr` to perform the underlying orthogonal transformations if the scalar `method` is nonzero. A call to `qr` is much faster than the default method for large dimensions

## **rando – Random matrix composed of elements -1, 0 or 1**

`A = gallery('rando', n, k)` returns a random  $n$ -by- $n$  matrix with elements from one of the following discrete distributions:

- `k = 1`             $A(i, j) = 0$  or  $1$  with equal probability (default).
- `k = 2`             $A(i, j) = -1$  or  $1$  with equal probability.
- `k = 3`             $A(i, j) = -1, 0$  or  $1$  with equal probability.

Argument  $n$  may be a two-element vector, in which case the matrix is  $n(1)$ -by- $n(2)$ .

## **randsvd – Random matrix with preassigned singular values**

`A = gallery('randsvd', n, kappa, mode, k1, ku)` returns a banded (multidiagonal) random matrix of order  $n$  with  $\text{cond}(A) = \text{kappa}$  and singular values from the distribution `mode`. If  $n$  is a two-element vector,  $A$  is  $n(1)$ -by- $n(2)$ .

Arguments `k1` and `ku` specify the number of lower and upper off-diagonals, respectively, in  $A$ . If they are omitted, a full matrix is produced. If only `k1` is present, `ku` defaults to `k1`.

Distribution `mode` can be:

- `1`            One large singular value.
- `2`            One small singular value.
- `3`            Geometrically distributed singular values (default).
- `4`            Arithmetically distributed singular values.
- `5`            Random singular values with uniformly distributed logarithm.
- `< 0`        If `mode` is `-1, -2, -3, -4, or -5`, then `randsvd` treats `mode` as `abs(mode)`, except that in the original matrix of singular values the order of the diagonal entries is reversed: small to large instead of large to small.

Condition number kappa defaults to  $\sqrt{1/\text{eps}}$ . In the special case where  $\text{kappa} < 0$ , A is a random, full, symmetric, positive definite matrix with  $\text{cond}(A) = -\text{kappa}$  and eigenvalues distributed according to mode. Arguments k1 and ku, if present, are ignored.

`A = gallery('randsvd', n, kappa, mode, k1, ku, method)` specifies how the computations are carried out. `method = 0` is the default, while `method = 1` uses an alternative method that is much faster for large dimensions, even though it uses more flops.

### **redheff – Redheffer’s matrix of 1s and 0s**

`A = gallery('redheff', n)` returns an n-by-n matrix of 0’s and 1’s defined by  $A(i, j) = 1$ , if  $j = 1$  or if  $i$  divides  $j$ , and  $A(i, j) = 0$  otherwise.

The Redheffer matrix has these properties:

- $(n - \text{floor}(\log_2(n))) - 1$  eigenvalues equal to 1
- A real eigenvalue (the spectral radius) approximately  $\sqrt{n}$
- A negative eigenvalue approximately  $-\sqrt{n}$
- The remaining eigenvalues are provably “small.”
- The Riemann hypothesis is true if and only if  $\det(A) = O(n^{1/2+\varepsilon})$  for every  $\varepsilon > 0$ .

Barrett and Jarvis conjecture that “the small eigenvalues all lie inside the unit circle  $\text{abs}(Z) = 1$ ,” and a proof of this conjecture, together with a proof that some eigenvalue tends to zero as  $n$  tends to infinity, would yield a new proof of the prime number theorem.

### **riemann – Matrix associated with the Riemann hypothesis**

`A = gallery('riemann', n)` returns an n-by-n matrix for which the Riemann hypothesis is true if and only if

$$\det(A) = O(n!n^{-1/2+\varepsilon})$$

for every  $\varepsilon > 0$ .

The Riemann matrix is defined by:

$$A = B(2:n+1,2:n+1)$$

where  $B(i, j) = i^{-1}$  if  $i$  divides  $j$ , and  $B(i, j) = -1$  otherwise.

The Riemann matrix has these properties:

- Each eigenvalue  $e(i)$  satisfies  $\text{abs}(e(i)) \leq m^{-1}/m$ , where  $m = n+1$ .
- $i \leq e(i) \leq i+1$  with at most  $m - \text{sqrt}(m)$  exceptions.
- All integers in the interval  $(m/3, m/2]$  are eigenvalues.

### **ris – Symmetric Hankel matrix**

`A = gallery('ris',n)` returns a symmetric  $n$ -by- $n$  Hankel matrix with elements

$$A(i, j) = 0.5 / (n - i - j + 1.5)$$

The eigenvalues of  $A$  cluster around  $\pi/2$  and  $-\pi/2$ . This matrix was invented by F.N. Ris.

### **sampling – Nonsymmetric matrix with ill-conditioned integer eigenvalues.**

`A = gallery('sampling',x)`, where  $x$  is an  $n$ -vector, is the  $n$ -by- $n$  matrix with  $A(i, j) = X(i)/(X(i)-X(j))$  for  $i \neq j$  and  $A(j, j)$  the sum of the off-diagonal elements in column  $j$ .  $A$  has eigenvalues  $0:n-1$ . For the eigenvalues  $0$  and  $n-1$ , corresponding eigenvectors are  $X$  and  $\text{ones}(n,1)$ , respectively.

The eigenvalues are ill-conditioned.  $A$  has the property that  $A(i, j) + A(j, i) = 1$  for  $i \neq j$ .

Explicit formulas are available for the left eigenvectors of  $A$ . For scalar  $n$ , `sampling(n)` is the same as `sampling(1:n)`. A special case of this matrix arises in sampling theory.

### **smoke – Complex matrix with a ‘smoke ring’ pseudospectrum**

`A = gallery('smoke', n)` returns an  $n$ -by- $n$  matrix with 1's on the superdiagonal, 1 in the  $(n, 1)$  position, and powers of roots of unity along the diagonal.

`A = gallery('smoke', n, 1)` returns the same except that element  $A(n, 1)$  is zero.

The eigenvalues of `gallery('smoke', n, 1)` are the  $n$ th roots of unity; those of `gallery('smoke', n)` are the  $n$ th roots of unity times  $2^{(1/n)}$ .

### **toeppd – Symmetric positive definite Toeplitz matrix**

`A = gallery('toeppd', n, m, w, theta)` returns an  $n$ -by- $n$  symmetric, positive semi-definite (SPD) Toeplitz matrix composed of the sum of  $m$  rank 2 (or, for certain  $\theta$ , rank 1) SPD Toeplitz matrices. Specifically,

$$T = w(1)*T(\theta(1)) + \dots + w(m)*T(\theta(m))$$

where  $T(\theta(k))$  has  $(i, j)$  element  $\cos(2*\pi*\theta(k)*(i-j))$ .

By default:  $m = n$ ,  $w = \text{rand}(m, 1)$ , and  $\theta = \text{rand}(m, 1)$ .

### **toeppen – Pentadiagonal Toeplitz matrix (sparse)**

`P = gallery('toeppen', n, a, b, c, d, e)` returns the  $n$ -by- $n$  sparse, pentadiagonal Toeplitz matrix with the diagonals:  $P(3, 1) = a$ ,  $P(2, 1) = b$ ,  $P(1, 1) = c$ ,  $P(1, 2) = d$ , and  $P(1, 3) = e$ , where  $a$ ,  $b$ ,  $c$ ,  $d$ , and  $e$  are scalars.

By default,  $(a, b, c, d, e) = (1, -10, 0, 10, 1)$ , yielding a matrix of Rutishauser. This matrix has eigenvalues lying approximately on the line segment  $2*\cos(2*t) + 20*i*\sin(t)$ .

### **tridiag – Tridiagonal matrix (sparse)**

`A = gallery('tridiag', c, d, e)` returns the tridiagonal matrix with subdiagonal  $c$ , diagonal  $d$ , and superdiagonal  $e$ . Vectors  $c$  and  $e$  must have  $\text{length}(d) - 1$ .

`A = gallery('tridiag',n,c,d,e)`, where `c`, `d`, and `e` are all scalars, yields the Toeplitz tridiagonal matrix of order `n` with subdiagonal elements `c`, diagonal elements `d`, and superdiagonal elements `e`. This matrix has eigenvalues

$$d + 2*\sqrt{c*e}*\cos(k*pi/(n+1))$$

where `k = 1:n`. (see [1].)

`A = gallery('tridiag',n)` is the same as `A = gallery('tridiag',n,-1,2,-1)`, which is a symmetric positive definite M-matrix (the negative of the second difference matrix).

## **triw – Upper triangular matrix discussed by Wilkinson and others**

`A = gallery('triw',n,alpha,k)` returns the upper triangular matrix with ones on the diagonal and alphas on the first `k >= 0` superdiagonals.

Order `n` may be a 2-element vector, in which case the matrix is `n(1)`-by-`n(2)` and upper trapezoidal.

Ostrowski [“On the Spectrum of a One-parametric Family of Matrices,” *J. Reine Angew. Math.*, 1954] shows that

$$\text{cond}(\text{gallery}('triw',n,2)) = \cot(\pi/(4*n))^2,$$

and, for large `abs(alpha)`, `cond(gallery('triw',n,alpha))` is approximately `abs(alpha)^n*sin(pi/(4*n-2))`.

Adding `-2^(2-n)` to the `(n,1)` element makes `triw(n)` singular, as does adding `-2^(1-n)` to all the elements in the first column.

## **uniformdata – Array of arbitrary data from standard uniform distribution**

`A = gallery('uniformdata',[m,n,...],j)` returns an `m`-by-`n`-by-... array `A`. The values of `A` are a random sample from the standard uniform distribution. `j` must be an integer value in the interval `[0, 2^32-1]`. Calling `gallery('uniformdata',...)` with different values of `j` will return different arrays. Repeated calls to

`gallery('uniformdata', ...)` with the same size vector and `j` inputs will always return the same array.

In any call to `gallery('uniformdata', ...)` you can substitute individual inputs `m,n,...` for the size vector input `[m,n,...]`. For example, `gallery('uniformdata',[1,2,3,4],5)` is equivalent to `gallery('uniformdata',1,2,3,4,5)`.

`[A,B,...] = gallery('uniformdata',[m,n,...],j)` returns multiple `m-by-n-by-...` arrays `A, B, ...`, containing different values.

`A = gallery('uniformdata',[m,n,...],j, classname)` produces a matrix of class `classname`. `classname` must be either `'single'` or `'double'`.

Generate the arbitrary 6-by-4 matrix of data from the uniform distribution on `[0, 1]` corresponding to `j = 2`.

```
x = gallery('uniformdata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the uniform distribution on `[0, 1]` corresponding to `j = 17`.

```
y = gallery('uniformdata', 1, 2, 3, 17, 'single');
```

## **wathen – Finite element matrix (sparse, random entries)**

`A = gallery('wathen',nx,ny)` returns a sparse, random, `n-by-n` finite element matrix where  $n = 3 \cdot nx \cdot ny + 2 \cdot nx + 2 \cdot ny + 1$ .

Matrix `A` is precisely the “consistent mass matrix” for a regular `nx-by-ny` grid of 8-node (serendipity) elements in two dimensions. `A` is symmetric, positive definite for any (positive) values of the “density,” `rho(nx,ny)`, which is chosen randomly in this routine.

`A = gallery('wathen',nx,ny,1)` returns a diagonally scaled matrix such that

$$0.25 \leq \text{eig}(\text{inv}(D) \cdot A) \leq 4.5$$

where `D = diag(diag(A))` for any positive integers `nx` and `ny` and any densities `rho(nx,ny)`.

## wilk – Various matrices devised or discussed by Wilkinson

`gallery('wilk',n)` returns a different matrix or linear system depending on the value of `n`.

<code>n = 3</code>	Upper triangular system $Ux=b$ illustrating inaccurate solution.
<code>n = 4</code>	Lower triangular system $Lx=b$ , ill-conditioned.
<code>n = 5</code>	<code>hilb(6)(1:5,2:6)*1.8144</code> . A symmetric positive definite matrix.
<code>n = 21</code>	W21+, a tridiagonal matrix. eigenvalue problem. For more detail, see [2].

**Purpose** Gamma function

**Syntax** `Y = gamma(X)`

**Definitions** The gamma function is defined by the integral:

$$\Gamma(x) = \int_0^{\infty} e^{-t} t^{x-1} dt$$

The gamma function interpolates the factorial function. For integer  $n$ :

$$\text{gamma}(n+1) = n! = \text{prod}(1:n)$$

**Description** `Y = gamma(X)` returns the gamma function at the elements of  $X$ .  $X$  must be real.

**Algorithms** The computation of `gamma` is based on algorithms outlined in [1]. Several different minimax rational approximations are used depending upon the value of  $A$ .

**See Also** `gammainc` | `gammaincinv` | `gammaaln` | `psi`

# gammainc

---

**Purpose** Incomplete gamma function

**Syntax**  
Y = gammainc(X,A)  
Y = gammainc(X,A,tail)  
Y = gammainc(X,A,'scaledlower')  
Y = gammainc(X,A,'scaledupper')

**Definitions** The incomplete gamma function is:

$$P(a,x) = \frac{1}{\Gamma(a)} \int_0^x e^{-t} t^{a-1} dt$$

---

**Note** The syntax `gammainc(X,A)` is equivalent to the function `P(A,X)` defined above, where `X` is the limit of integration in each case.

---

For any  $A \geq 0$ , `gammainc(X,A)` approaches 1 as `X` approaches infinity. For small `X` and `A`, `gammainc(X,A)` is approximately equal to  $X^A$ , so `gammainc(0,0) = 1`.

**Description** `Y = gammainc(X,A)` returns the incomplete gamma function of corresponding elements of `X` and `A`. The elements of `A` must be nonnegative. Furthermore, `X` and `A` must be real and the same size (or either can be scalar).

`Y = gammainc(X,A,tail)` specifies the tail of the incomplete gamma function. The choices for `tail` are 'lower' (the default) and 'upper'. The upper incomplete gamma function is defined as:

$$Q(a,x) = \frac{1}{\Gamma(a)} \int_x^\infty e^{-t} t^{a-1} dt = 1 - P(a,x).$$

When the upper tail value is close to 0, the 'upper' option provides a way to compute that value more accurately than by subtracting the lower tail value from 1.

`Y = gammainc(X,A,'scaledlower')` and `Y = gammainc(X,A,'scaledupper')` return the incomplete gamma function, scaled by

$$\Gamma(a+1) \left( \frac{e^x}{x^a} \right).$$

These functions are unbounded above, but are useful for values of `X` and `A` where `gammainc(X,A,'lower')` or `gammainc(X,A,'upper')` underflow to zero.

---

**Note** When `X` is negative, `Y` can be inaccurate for `abs(X)>A+1`. This applies to all syntaxes.

---

`gamma` | `gammaincinv` | `gammaIn` | `psi`

# gammaincinv

---

**Purpose** Inverse incomplete gamma function

**Syntax**  
`x = gammaincinv(y,a)`  
`y = gammaincinv(x,a,tail)`

**Description** `x = gammaincinv(y,a)` evaluates the inverse incomplete gamma function for corresponding elements of `y` and `a`, such that `y = gammainc(x,a)`. The elements of `y` must be in the closed interval  $[0, 1]$ , and those of `a` must be nonnegative. `y` and `a` must be real and the same size (or either can be a scalar).

`y = gammaincinv(x,a,tail)` specifies the tail of the incomplete gamma function. Choices are `lower` (the default) to use the integral from 0 to `x`, or `upper` to use the integral from `x` to infinity.

These two choices are related as:

`gammaincinv(y,a,'upper') = gammaincinv(1-y,a,'lower')`.

When `y` is close to 0, the `upper` option provides a way to compute `x` more accurately than by subtracting `y` from 1.

**Definitions** The lower incomplete gamma function is defined as:

$$\text{gammainc}(x,a) = \frac{1}{\Gamma(a)} \int_0^x e^{-t} t^{(a-1)} dt$$

The upper incomplete gamma function is defined as:

$$\text{gammainc}(x,a) = \frac{1}{\Gamma(a)} \int_x^\infty e^{-t} t^{(a-1)} dt$$

`gammaincinv` computes the inverse of the incomplete gamma function with respect to the integration limit `x` using Newton's method.

For any  $a > 0$ , as `y` approaches 1, `gammaincinv(y,a)` approaches infinity.

For small `x` and `a`, `gammainc(x,a)  $\cong x^a$` , so `gammaincinv(1,0) = 0`.

gamma | gammainc | gammaIn | psi

# gammaln

---

**Purpose**            Logarithm of gamma function

**Syntax**             $Y = \text{gammaln}(A)$

**Description**         $Y = \text{gammaln}(A)$  returns the logarithm of the gamma function,  $\text{gammaln}(A) = \log(\text{gamma}(A))$ . Input  $A$  must be nonnegative and real. The `gammaln` command avoids the underflow and overflow that may occur if it is computed directly using  $\log(\text{gamma}(A))$ .

**See Also**            `gammainc` | `gammaincinv` | `gamma` | `psi`

**Purpose** Current axes handle

**Syntax** `h = gca`

**Description** `h = gca` returns the handle to the current axes for the current figure. When multiple axes are present, `h` is the handle to the last axes created or clicked with the mouse. If an axes does not exist, then `gca` creates an axes and returns its handle.

**Examples** **Specify Properties for Current Axes**

Create a plot of a sine wave. Set the font size, tick direction, tick length, and *y*-axis limits for the current axes using the `gca` command.

```
x = linspace(0,10);
y = sin(4*x);
figure;
plot(x,y);
set(gca, 'FontSize', 12, ...
        'TickDir', 'out', ...
        'TickLength', [.02, .02], ...
        'YLim', [-2, 2])
```

**Tips**

- To view a list of all the axes properties, execute `get(gca)` or see the Axes Properties help page. Set axes properties after plotting since some plotting functions reset axes properties.
- To get the handle of the current axes without forcing the creation of an axes if one does not exist, query the figure `CurrentAxes` property.

```
h = get(gcf, 'CurrentAxes')
```

MATLAB returns `h` as an empty array if there is no current axes.

- User interaction can change the current axes. To be sure you are accessing the correct axes, store the axes handle in your program code and use this handle instead of `gca`.

**Definitions****Current Axes**

The current axes is the target for graphics output. It is the axes in which graphics commands such as `plot`, `text`, and `surf` draw their results. It is typically the last axes created or the last axes clicked with the mouse. Changing the current figure also changes the current axes.

**Concepts**

- “The Current Figure, Axes, and Object”
- “Accessing Object Handles”

# gcbf

---

**Purpose** Handle of figure containing object whose callback is executing

**Syntax** `fig = gcbf`

**Description** `fig = gcbf` returns the handle of the figure that contains the object whose callback is currently executing. This object can be the figure itself, in which case, `gcbf` returns the figure's handle.

When no callback is executing, `gcbf` returns the empty matrix, `[]`.

The value returned by `gcbf` is identical to the figure output argument returned by `gcbo`.

**See Also** `gcbo` | `gco` | `gcf` | `gca`

---

<b>Purpose</b>	Handle of object whose callback is executing
<b>Syntax</b>	<pre>h = gcbo [h,figure] = gcbo</pre>
<b>Description</b>	<p><code>h = gcbo</code> returns the handle of the graphics object whose callback is executing.</p> <p><code>[h,figure] = gcbo</code> returns the handle of the current callback object and the handle of the figure containing this object.</p>
<b>Tips</b>	<p>The MATLAB software stores the handle of the object whose callback is executing in the root <code>CallbackObject</code> property. If a callback interrupts another callback, MATLAB replaces the <code>CallbackObject</code> value with the handle of the object whose callback is interrupting. When that callback completes, MATLAB restores the handle of the object whose callback was interrupted.</p> <p>The root <code>CallbackObject</code> property is read only, so its value is always valid at any time during callback execution. The root <code>CurrentFigure</code> property, and the figure <code>CurrentAxes</code> and <code>CurrentObject</code> properties (returned by <code>gcf</code>, <code>gca</code>, and <code>gco</code>, respectively) are user settable, so they can change during the execution of a callback, especially if that callback is interrupted by another callback. Therefore, those functions are not reliable indicators of which object's callback is executing.</p> <p>When you write callback routines for the <code>CreateFcn</code> and <code>DeleteFcn</code> of any object and the figure <code>ResizeFcn</code>, you must use <code>gcbo</code> since those callbacks do not update the root's <code>CurrentFigure</code> property, or the figure's <code>CurrentObject</code> or <code>CurrentAxes</code> properties; they only update the root's <code>CurrentFigure</code> property.</p> <p>When no callbacks are executing, <code>gcbo</code> returns <code>[]</code> (an empty matrix).</p>

# gcd

---

**Purpose** Greatest common divisor

**Syntax**  $G = \text{gcd}(A,B)$   
 $[G,U,V] = \text{gcd}(A,B)$

**Description**  $G = \text{gcd}(A,B)$  returns the greatest common divisors of the elements of A and B. The elements in G are always nonnegative, and  $\text{gcd}(0,0)$  returns 0. This syntax supports inputs of any numeric type.

$[G,U,V] = \text{gcd}(A,B)$  also returns the Bézout coefficients, U and V, which satisfy:  $A.*U + B.*V = G$ . The Bézout coefficients are useful for solving Diophantine equations. This syntax supports double, single, and signed integer inputs.

## Input Arguments

**A,B - Input values**  
scalars, vectors, or arrays of real integer values

Input values, specified as scalars, vectors, or arrays of real integer values. A and B can be any numeric type, and they can be of different types within certain limitations:

- If A or B is of type `single`, then the other can be of type `single` or `double`.
- If A or B belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

A and B must be the same size or one must be a scalar.

**Example:** `[20 -3 13],[10 6 7]`

**Example:** `int16([100 -30 200]),int16([20 15 9])`

**Example:** `int16([100 -30 200]),20`

### Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |  
`uint16` | `uint32` | `uint64`

## Output Arguments

### **G - Greatest common divisor**

real, nonnegative integer values

Greatest common divisor, returned as an array of real nonnegative integer values. **G** is the same size as **A** and **B**, and the values in **G** are always real and nonnegative. **G** is returned as the same type as **A** and **B**. If **A** and **B** are of different types, then **G** is returned as the nondouble type.

### **U,V - Bézout coefficients**

real integer values

Bézout coefficients, returned as arrays of real integer values that satisfy the equation,  $A.*U + B.*V = G$ . The data type of **U** and **V** is the same type as that of **A** and **B**. If **A** and **B** are of different types, then **U** and **V** are returned as the nondouble type.

## Algorithms

$g = \text{gcd}(A,B)$  is calculated using the Euclidian algorithm.[1]

$[g,u,v] = \text{gcd}(A,B)$  is calculated using the extended Euclidian algorithm.[1]

## Examples

### **Greatest Common Divisors of Double Values**

```
A = [-5 17; 10 0];
B = [-15 3; 100 0];
G = gcd(A,B)
```

```
G =
```

```
     5     1
    10     0
```

gcd returns positive values, even when the inputs are negative.

### **Greatest Common Divisors of Unsigned Integers**

```
A = uint16([255 511 15]);
B = uint16([15 127 1023]);
```

$$G = \gcd(A, B)$$

$$G =$$

$$15 \quad 1 \quad 3$$

## Solution to Diophantine Equation

Solve the Diophantine equation,  $30x + 56y = 8$  for  $x$  and  $y$ .

Find the greatest common divisor and a pair of Bézout coefficients for 30 and 56.

$$[g, u, v] = \gcd(30, 56)$$

$$g =$$

$$2$$

$$u =$$

$$-13$$

$$v =$$

$$7$$

$u$  and  $v$  satisfy the Bézout's identity,  $(30 \cdot u) + (56 \cdot v) = g$ .

Rewrite Bézout's identity so that it looks more like the original equation. Do this by multiplying by 4. Use  $==$  to verify that both sides of the equation are equal.

$$(30 \cdot u \cdot 4) + (56 \cdot v \cdot 4) == g \cdot 4$$

$$\text{ans} =$$

$$1$$

---

Calculate the values of  $x$  and  $y$  that solve the problem.

$$x = u^4$$

$$y = v^4$$

$$x =$$

$$-52$$

$$y =$$

$$28$$

**Purpose** Current figure handle

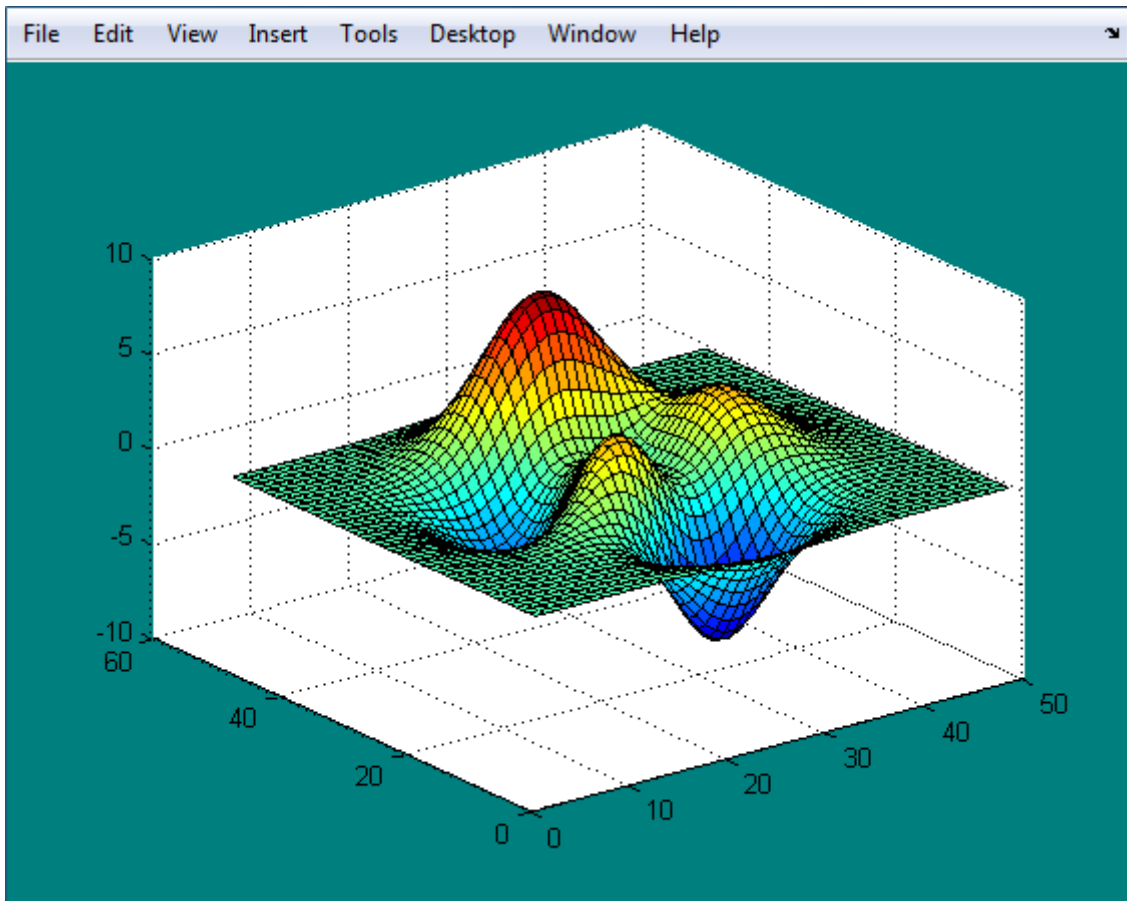

**Syntax** `h = gcf`

**Description** `h = gcf` returns the handle to the current figure. When multiple figures are present, `h` is the handle to the last figure created or clicked with the mouse. If no figure exists, then `gcf` creates a figure and returns its handle.

**Examples**      **Specify Properties for Current Figure**

Set the background color and remove the toolbar for the current figure using the `gcf` command.

```
figure
surf(peaks);
set(gcf, 'Color', [0,0.5,0.5], ...
        'Toolbar', 'none')
```

## Definitions

### Current Figure

The current figure is the target for graphics output. It is the figure window in which graphics commands such as `plot`, `title`, and `surf` draw their results. It is typically the last figure created or the last figure clicked with the mouse.

## Tips

- To view a list of all figure properties, execute `get(gcf)` or see [Figure Properties](#).
- To get the handle of the current figure without forcing the creation of a figure if one does not exist, query the `CurrentFigure` property on the root object.

```
h = get(0, 'CurrentFigure')
```

MATLAB returns `h` as an empty array if there is no current figure.

- User interaction can change the current figure. To be sure you are accessing the correct figure, store the figure handle in your program code and use this handle instead of `gcf`.

- “Accessing Object Handles”

---

<b>Purpose</b>	Handle of current object
<b>Syntax</b>	<pre>h = gco h = gco(<i>figure_handle</i>)</pre>
<b>Description</b>	<p><code>h = gco</code> returns the handle of the current object.</p> <p><code>h = gco(<i>figure_handle</i>)</code> returns the handle of the current object in the figure specified by <i>figure_handle</i>.</p>
<b>Tips</b>	<p>The current object is the last object clicked on, excluding <code>uimenu</code>. If the mouse click did not occur over a figure child object, the figure becomes the current object. The MATLAB software stores the handle of the current object in the figure's <code>CurrentObject</code> property.</p> <p>The <code>CurrentObject</code> of the <code>CurrentFigure</code> does not always indicate the object whose callback is being executed. Interruptions of callbacks by other callbacks can change the <code>CurrentObject</code> or even the <code>CurrentFigure</code>. Some callbacks, such as <code>CreateFcn</code> and <code>DeleteFcn</code>, and <code>uimenu Callback</code>, intentionally do not update <code>CurrentFigure</code> or <code>CurrentObject</code>.</p> <p><code>gcbo</code> provides the only completely reliable way to retrieve the handle to the object whose callback is executing, at any point in the callback function, regardless of the type of callback or of any previous interruptions.</p>
<b>See Also</b>	<code>gca</code>   <code>gcbo</code>   <code>gcf</code>

**Purpose** Determine greater than or equal to

**Syntax** A >= B  
ge(A,B)

**Description** A >= B returns a logical array with elements set to logical 1 (true) where A is greater than or equal to B; otherwise, it returns logical 0 (false). The test compares only the real part of numeric arrays. ge returns logical 0 (false) where A or B have NaN or undefined categorical elements.

ge(A,B) is an alternate way to execute A >= B, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Left array

numeric array | logical array | character array | ordinal categorical array

Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

### B - Right array

numeric array | logical array | character array | ordinal categorical array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one

is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

## Examples

### Test Vector Elements

Find which vector elements are greater than or equal to a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are greater than or equal to 11.

```
A >= 11
```

```
ans =
```

```
0     1     1     0     0     1     0     1
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are greater than or equal to 11.

```
A(A >= 11)
```

```
ans =
```

```
12    18    11    15
```

The result is a subset of the elements in A.

### **Replace Elements of Matrix**

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values greater than or equal to 9 with the value 10.

```
A(A >= 9) = 10
```

```
A =
```

```
    10     2     3    10
     5    10    10     8
    10     7     6    10
     4    10    10     1
```

The result is a new matrix whose largest element is 10.

### **Compare Values in Categorical Array**

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
 'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
    large    medium    small
    medium    small    large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values greater than or equal to the category 'medium'.

```
A >= 'medium'
```

```
ans =
```

```
     1     1     0
     1     0     1
```

A value of logical 1 (true) indicates a value greater than or equal to the category 'medium'.

Compare the rows of A.

```
A(1,:) >= A(2,:)
```

```
ans =
```

```
     1     1     0
```

The function returns logical 1 (true) where the first row has a category value greater than or equal to the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are greater than or equal to 2.

```
A(A >= 2)
```

```
ans =
```

```
2.0000 - 2.0000i  5.0000 - 1.0000i
```

ge compares only the real part of the elements in A.

Use abs to find which elements are outside a radius of 2 from the origin.

```
A(abs(A) >= 2)
```

```
ans =
```

```
2.0000 - 2.0000i  1.0000 + 3.0000i  1.0000 - 2.0000i  5.0000 - 1.0000i
```

The result has more elements since `abs` accounts for the imaginary part of the numbers.

## Tips

- Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `>=` operator reflects. For more information, see “Avoiding Common Problems with Floating-Point Arithmetic”.

## Concepts

- “Ordinal Categorical Arrays”

<b>Purpose</b>	Generate path string
<b>Syntax</b>	<pre>p = genpath p = genpath(folderName)</pre>
<b>Description</b>	<p>p = genpath returns a path string, p, that includes all the folders and subfolders below <i>matlabroot/toolbox</i>, including empty subfolders.</p> <p>p = genpath(folderName) returns a path string that includes folderName and multiple levels of subfolders below folderName. The path string does not include folders named private, folders that begin with the @ character (class folders), folders that begin with the + character (package folders), or subfolders within any of these.</p>
<b>Input Arguments</b>	<p><b>folderName - Folder name</b> string</p> <p>Folder name, specified as a string.</p> <p><b>Example:</b> 'c:/matlab/myfiles'</p>
<b>Examples</b>	<p><b>Add Folder and Subfolders to Search Path</b></p> <p>Use genpath in conjunction with addpath to add a folder and its subfolders to the search path.</p> <p>Generate a path that includes <i>matlabroot/toolbox/images/colorspaces</i> and all folders below it.</p> <pre>folderName = fullfile(matlabroot,'toolbox','images','colorspaces'); p = genpath(folderName);</pre> <p>Add the folder and its subfolders to the search path.</p> <pre>addpath(p)</pre>
<b>See Also</b>	<a href="#">addpath</a>   <a href="#">path</a>   <a href="#">rmpath</a>

# genpath

---

## **Concepts**

- “What Is the MATLAB Search Path?”

**Purpose** Construct valid variable name from string

**Syntax**  
varname = genvarname(str)  
varname = genvarname(str, exclusions)

**Description** varname = genvarname(str) constructs a string varname that is similar to or the same as the str input, and can be used as a valid variable name. str can be a single character array or a cell array of strings. If str is a cell array of strings, genvarname returns a cell array of strings in varname. The strings in a cell array returned by genvarname are guaranteed to be different from each other.

varname = genvarname(str, exclusions) returns a valid variable name that is different from any name listed in the exclusions input. The exclusions input can be a single character array or a cell array of strings. Specify the function who in the exclusions character array to create a variable name that will be unique in the current MATLAB workspace (see “Example 4” on page 1-2237, below).

---

**Note** genvarname returns a string that can be used as a variable name. It does not create a variable in the MATLAB workspace. You cannot, therefore, assign a value to the output of genvarname.

---

**Tips** A valid MATLAB variable name is a character string of letters, digits, and underscores, such that the first character is a letter, and the length of the string is less than or equal to the value returned by the namelengthmax function. Any string that exceeds namelengthmax is truncated in the varname output. See “Example 6” on page 1-2238, below.

The variable name returned by genvarname is not guaranteed to be different from other variable names currently in the MATLAB workspace unless you use the exclusions input in the manner shown in “Example 4” on page 1-2237, below.

If you use `genvarname` to generate a field name for a structure, MATLAB does create a variable for the structure and field in the MATLAB workspace. See “Example 3” on page 1-2236, below.

If the `str` input contains any whitespace characters, `genvarname` removes them and capitalizes the next alphabetic character in `str`. If `str` contains any nonalphanumeric characters, `genvarname` translates these characters into their hexadecimal value.

## Examples

### Example 1

Create four similar variable name strings that do not conflict with each other:

```
v = genvarname({'A', 'A', 'A', 'A'})
v =
    'A'    'A1'    'A2'    'A3'
```

### Example 2

Read a column header `hdr` from worksheet `trial2` in Excel spreadsheet `myproj_apr23`:

```
[data hdr] = xlsread('myproj_apr23.xls', 'trial2');
```

Make a variable name from the text of the column header that will not conflict with other names:

```
v = genvarname(['Column ' hdr{1,3}]);
```

Assign data taken from the spreadsheet to the variable in the MATLAB workspace:

```
eval([v '= data(1:7, 3);']);
```

### Example 3

Collect readings from an instrument once every minute over the period of an hour into different fields of a structure. Simulate instrument readings using a random number. `genvarname` not only generates

unique fieldname strings, but also creates the structure and fields in the MATLAB workspace:

```
for k = 1:60
record.(genvarname(['reading' datestr(clock, 'HHMMSS')])) = rand(1);
pause(60)
end
```

After the program ends, display the recorded data from the workspace:

```
record
record =
    reading092610: 0.6541
    reading092710: 0.6892
    reading092811: 0.7482
    reading092911: 0.4505
    reading093011: 0.0838
    .
    .
    .
```

## Example 4

Generate variable names that are unique in the MATLAB workspace by putting the output from the who function in the exclusions list.

```
for k = 1:5
    t = clock;
    pause(uint8(rand * 10));
    v = genvarname('time_elapsed', who);
    eval([v ' = etime(clock,t)'])
end
```

As this code runs, you can see that the variables created by genvarname are unique in the workspace:

```
time_elapsed =
```

# genvarname

---

```
5.0070
time_elapsed1 =
2.0030
time_elapsed2 =
7.0010
time_elapsed3 =
8.0010
time_elapsed4 =
3.0040
```

After the program completes, use the `who` function to view the workspace variables:

```
who

k          time_elapsed  time_elapsed2  time_elapsed4
t          time_elapsed1 time_elapsed3  v
```

## Example 5

If you try to make a variable name from a MATLAB keyword, `genvarname` creates a variable name string that capitalizes the keyword and precedes it with the letter `x`:

```
v = genvarname('global')
v =
    xGlobal
```

## Example 6

If you enter a string that is longer than the value returned by the `namelengthmax` function, `genvarname` truncates the resulting variable name string:

```
namelengthmax
ans =
    63

vstr = genvarname(sprintf('%s%s', ...
    'This name truncates because it contains ', ...
```

```
'more than the maximum number of characters'))  
vstr =  
ThisNameTruncatesBecauseItContainsMoreThanTheMaximumNumberOfCha
```

# get

---

**Purpose** Query Handle Graphics object properties

**Syntax**

```
get(h)
get(h,'PropertyName')
<m-by-n value cell array> = get(H,pn)
a = get(h)
a = get(0)
a = get(0,'Factory')
a = get(0,'FactoryObjectTypePropertyName')
a = get(h,'Default')
a = get(h,'DefaultObjectTypePropertyName')
```

## Description

---

**Note** Do not use the `get` function on Java objects as it will cause a memory leak. For more information, see “Accessing Private and Public Data”

---

`get(h)` returns all properties of the graphics object identified by the handle `h` and their current values. For this syntax, `h` must be a scalar.

`get(h,'PropertyName')` returns the value of the property `'PropertyName'` of the graphics object identified by `h`.

`<m-by-n value cell array> = get(H,pn)` returns  $n$  property values for  $m$  graphics objects in the  $m$ -by- $n$  cell array, where  $m = \text{length}(H)$  and  $n$  is equal to the number of property names contained in `pn`.

`a = get(h)` returns a structure whose field names are the object's property names and whose values are the current values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen. For this syntax, `h` may be a scalar or a  $m$ -by- $n$  array of handles. If `h` is a vector, `a` will be a  $(m*n)$ -by-1 struct array.

`a = get(0)` returns the current values of all user-settable properties. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties.

If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(0, 'Factory')` returns the factory-defined values of all user-settable properties. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(0, 'FactoryObjectTypePropertyName')` returns the factory-defined value of the named property for the specified object type. The argument *FactoryObjectTypePropertyName* is the word `Factory` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`)`FactoryFigureColor`.

`a = get(h, 'Default')` returns all default values currently defined on object `h`. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(h, 'DefaultObjectTypePropertyName')` returns the factory-defined value of the named property for the specified object type. The argument *DefaultObjectTypePropertyName* is the word `Default` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`).

`DefaultFigureColor`

## Examples

You can obtain the default value of the `LineWidth` property for line graphics objects defined on the root level with the statement

```
get(0, 'DefaultLineLineWidth')
ans =
    0.5000
```

To query a set of properties on all axes children, define a cell array of property names:

```
props = {'HandleVisibility', 'Interruptible';
```

# get

---

```
'SelectionHighlight', 'Type'}];  
output = get(get(gca,'Children'),props);
```

The variable `output` is a cell array of dimension `length(get(gca,'Children'))-by-4`.

For example, type

```
patch;surface;text;line  
output = get(get(gca,'Children'),props)  
output =  
    'on'    'on'    'on'    'line'  
    'on'    'off'   'on'    'text'  
    'on'    'on'    'on'    'surface'  
    'on'    'on'    'on'    'patch'
```

```

## See Also

[audiorecorder](#) | [set](#)

**Purpose** Get property value from interface, or display properties

**Syntax**

```
V = h.get  
V = h.get('propertyname')  
V = get(h,...)
```

**Description** V = h.get returns a list of all properties and their values for the object or interface, h.

If V is empty, either there are no properties in the object, or the MATLAB software cannot read the object's type library. Refer to the COM vendor's documentation. For Automation objects, if the vendor provides documentation for a specific property, use the V = get(h,...) syntax to call it.

V = h.get('propertyname') returns the value of the property specified in the string, propertyname.

V = get(h,...) is an alternate syntax for the same operation.

**Tips** The meaning and type of the return value is dependent upon the specific property being retrieved. The object's documentation should describe the specific meaning of the return value. MATLAB may convert the data type of the return value. For a description of how MATLAB converts COM data types, see "Handling COM Data in MATLAB Software".

COM functions are available on Microsoft Windows systems only.

**Examples** Create a COM server running Microsoft Excel software:

```
e = actxserver('Excel.Application');
```

Retrieve a single property value:

```
e.Path
```

Depending on your spreadsheet program, MATLAB software displays:

```
ans =
```

## get (COM)

---

```
C:\Program Files\MSOffice\OFFICE11
```

Retrieve a list of all properties for the CommandBars interface:

```
c = e.CommandBars.get
```

MATLAB displays information similar to the following:

```
c =
      Application: [1x1
Interface.Microsoft_Excel_11.0_Object_Library._Application]
      Creator: 1.4808e+009
      ActionControl: []
      ActiveMenuBar: [1x1
Interface.Microsoft_Office_12.0_Object_Library.CommandBar]
      Count: 129
      DisplayTooltips: 1
      DisplayKeysInTooltips: 0
      LargeButtons: 0
      MenuAnimationStyle: 'msoMenuAnimationNone'
      Parent: [1x1
Interface.Microsoft_Excel_11.0_Object_Library._Application]
      AdaptiveMenus: 0
      DisplayFonts: 1
      DisableCustomize: 0
      DisableAskAQuestionDropdown: 0
```

### See Also

```
set (COM) | inspect | isprop | addproperty | deleteproperty
```

**Purpose** Query property values of handle objects derived from hgsetget class

**Syntax**

```
CV = get(H, 'PropertyName')  
SV = get(h)  
get(h)
```

**Description** `CV = get(H, 'PropertyName')` returns the value of the named property from the objects in the handle array H. If H is scalar, `get` returns a single value; if H is an array, `get` returns a cell array of property values. If you specify a cell array of property names, then `get` returns a cell array of values, where each row in the cell corresponds to an element in H and each column in the cell corresponds to an element in the property name cell array.

If H is nonscalar and `PropertyName` is the name of a dynamic property, `get` returns a value only if the property exists in all objects referenced in H.

`SV = get(h)` returns a struct array in which the field names are the object's property names and the values are the current values of the corresponding properties. If h is an array, then SV is a `numel(h)-by-1` array of structs.

`get(h)` displays all property names and their current values for the MATLAB objects with handle h.

Your subclass can override the hgsetget `getdisp` method to control how MATLAB displays this information.

**See Also** `get` | `handle` | `hgsetget` | `set` (`hgsetget`)

**How To**

- “Implementing a Set/Get Interface for Properties”

# get (memmapfile)

---

**Purpose** Memory map properties

**Syntax**  
`s = get(m)`  
`val = get(m,prop)`

**Description** `s = get(m)` returns the values of all properties of the memory map, `m`, in structure array `s`. Each property is represented by a field in the output structure. The name and contents of each field are the same as the name and value of the property it represents.

---

**Note** Although property names of a memory map are not case sensitive, field names of the output structure returned by `get` (named the same as the properties they represent) are case sensitive.

---

`val = get(m,prop)` returns the value(s) of one or more properties specified by `prop`. The `prop` input can be a quoted string or a cell array of quoted strings, each containing a property name. If the latter is true, `get` returns the property values in a cell array.

## Examples

You can call `get` to return information on any or all of the memory map's properties. Specify one or more property names to get the values of specific properties.

This example returns the values of the `Offset`, `Repeat`, and `Format` properties for a memory map. Start by creating the memory map:

```
m = memmapfile('records.dat', ...
              'Offset', 2048, ...
              'Format', { ...
                  'int16' [2 2] 'model'; ...
                  'uint32' [1 1] 'serialno'; ...
                  'single' [1 3] 'expenses'});
```

Call `get` to return the specified property values in a 1-by-3 cell array `m_props`:

```
m_props = get(m, {'Offset', 'Repeat', 'Format'})
m_props =
    [2048]    [Inf]    {3x3 cell}

m_props{3}
ans =
    'int16'    [1x2 double]    'model'
    'uint32'   [1x2 double]    'serialno'
    'single'   [1x2 double]    'expenses'
```

Another way to return the same information is to use the `objname.property` syntax:

```
m_props = {m.Offset, m.Repeat, m.Format}
m_props =
    [2048]    [Inf]    {3x3 cell}
```

To return the values for all properties with `get`, pass just the name of the memory map:

```
s = get(m)
Filename: 'd:\matlab\records.dat'
Writable: 0
Offset: 2048
Format: {3x3 cell}
Repeat: Inf
Data: [753 1]
```

To see just the `Format` field of the returned structure, type

```
s.Format
ans =
    'int16'    [1x2 double]    'model'
    'uint32'   [1x2 double]    'serialno'
    'single'   [1x2 double]    'expenses'
```

## See Also

`memmapfile` | `disp (memmapfile)`

# VideoReader.get

---

**Purpose** Query property values for video reader object

**Syntax**  
Value = get(obj,Name)  
Values = get(obj,{Name1,...,NameN})  
allValues = get(obj)  
get(obj)

**Description**  
Value = get(obj,Name) returns the value of the property with the specified Name for object obj.  
Values = get(obj,{Name1,...,NameN}) returns the values of the specified properties in a 1-by-N cell array.  
allValues = get(obj) returns a scalar structure that contains the values of all properties of Obj. Each field name corresponds to a property name.  
get(obj) displays all property names and their current values.

**Input Arguments**

**obj**  
VideoReader object created by the VideoReader function.

**Name**  
String enclosed in single quotation marks that specifies a VideoReader property.

**Output Arguments**

**Value**  
String containing the value associated with the specified VideoReader property.

**Values**  
Cell array containing the values associated with the specified VideoReader properties. Values is a row vector, with one column for each property.

**allValues**

Scalar (1-by-1) structure array that contains the values of all properties of VideoReader object Obj.

## Examples

### Display All Object Properties

Display all properties of an object associated with the example file, xylophone.mp4.

```
xyloObj = VideoReader('xylophone.mp4');  
get(xyloObj)
```

General Settings:

```
Duration = 4.7000  
Name = xylophone.mp4  
Path = matlabroot\toolbox\matlab\audiovideo  
Tag =  
Type = VideoReader  
UserData = []
```

Video Settings:

```
BitsPerPixel = 24  
FrameRate = 30  
Height = 240  
NumberOfFrames = 141  
VideoFormat = RGB24  
Width = 320
```

### Store Specific Object Properties

Create a 1-by-3 cell array that contains the values of the Height, Width, and NumberOfFrames properties of an object associated with xylophone.mp4.

```
xyloObj = VideoReader('xylophone.mp4');  
xyloSize = get(xyloObj, {'Height', 'Width', 'NumberOfFrames'})
```

```
xyloSize =
```

```
[240] [320] [141]
```

# VideoReader.get

---

## Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `NumberOfFrames` property for object `xyloObj` (as created in the Examples):

```
numFrames = xyloObj.NumberOfFrames;
```

This command is exactly equivalent to:

```
numFrames = get(xyloObj, 'NumberOfFrames');
```

## See Also

[VideoReader](#) | [set](#)

**Purpose** Random stream properties

**Class** @RandStream

**Syntax**  
`get(s)`  
`P = get(s)`  
`P = get(s, 'PropertyName')`

**Description** `get(s)` prints the list of properties for the random stream `s`.  
`P = get(s)` returns all properties of `s` in a scalar structure.  
`P = get(s, 'PropertyName')` returns the property `'PropertyName'`.

**See Also** `RandStream` | `set (RandStream)`

# get (serial)

---

**Purpose** Serial port object properties

**Syntax**

```
get(obj)
out = get(obj)
out = get(obj, 'PropertyName')
```

**Description**

`get(obj)` returns all property names and their current values to the command line for the serial port object, `obj`.

`out = get(obj)` returns the structure `out` where each field name is the name of a property of `obj`, and each field contains the value of that property.

`out = get(obj, 'PropertyName')` returns the value `out` of the property specified by *PropertyName* for `obj`. If *PropertyName* is replaced by a 1-by-`n` or `n`-by-1 cell array of strings containing property names, then `get` returns a 1-by-`n` cell array of values to `out`. If `obj` is an array of serial port objects, then `out` will be a `m`-by-`n` cell array of property values where `m` is equal to the length of `obj` and `n` is equal to the number of properties specified.

**Tips**

Refer to [Displaying Property Names and Property Values](#) for a list of serial port object properties that you can return with `get`.

When you specify a property name, you can do so without regard to case, and you can make use of property name completion. For example, if `s` is a serial port object, then these commands are all valid.

```
out = get(s, 'BaudRate');
out = get(s, 'baudrate');
out = get(s, 'BAUD');
```

If you use the `help` command to display help for `get`, then you need to supply the pathname shown below.

```
help serial/get
```

## Examples

This example illustrates some of the ways you can use `get` to return property values for the serial port object `s` on a Windows platform.

```
s = serial('COM1');
out1 = get(s);
out2 = get(s,{'BaudRate','DataBits'});
get(s,'Parity')
ans =
none
```

## See Also

`set`

# get (tscollection)

---

**Purpose** Query tscollection object property values

**Syntax** `value = get(tsc, 'PropertyName')`

**Description** `value = get(tsc, 'PropertyName')` returns the value of the specified property of the tscollection object tsc. The following syntax is equivalent:

`value = tsc.PropertyName`

`get(tsc)` displays all properties and values of the tscollection object tsc.

**See Also** `set (tscollection) | timeseries`

**Purpose** Extract date-string time vector into cell array

**Syntax** `getabstime(tsc)`

**Description** `getabstime(tsc)` extracts the time vector from the `tscollection` object `tsc` as a cell array of date strings. To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the time-series collection. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

**Examples** **1** Create a `tscollection` object.

```
tsc = tscollection(timeseries([3 6 8 0 10]));
```

**2** Set the `StartDate` property.

```
tsc.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

**3** Extract a vector of absolute time values.

```
getabstime(tsc)
```

```
ans =
```

```
    '27-Oct-2005 07:05:36'
```

```
    '27-Oct-2005 07:05:37'
```

```
    '27-Oct-2005 07:05:38'
```

```
    '27-Oct-2005 07:05:39'
```

```
    '27-Oct-2005 07:05:40'
```

**4** Change the date-string format of the time vector.

```
tsc.TimeInfo.Format = 'mm/dd/yy';
```

**5** Extract the time vector with the new date-string format.

```
getabstime(tsc)
```

# getabstime (tscollection)

---

```
ans =  
      '10/27/05'  
      '10/27/05'  
      '10/27/05'  
      '10/27/05'  
      '10/27/05'
```

## See Also

`datestr` | `tscollection` | `setabstime (tscollection)`

**Purpose** Value of application-defined data

**Syntax**  
`value = getappdata(h, 'name')`  
`values = getappdata(h)`

**Description**  
`value = getappdata(h, 'name')` gets the value of the application-defined data with the name specified by `name`, in the object with handle `h`. If the application-defined data does not exist, the MATLAB software returns an empty matrix in `value`.  
`values = getappdata(h)` returns all application-defined data for the object with handle `h`.

**Definitions**  
Application-defined data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

**See Also** `setappdata` | `rmappdata` | `isappdata`

# audiorecorder.getaudiodata

---

**Purpose** Store recorded audio signal in numeric array

**Syntax**  
`y = getaudiodata(recorder)`  
`y = getaudiodata(recorder, dataType)`

**Description** `y = getaudiodata(recorder)` returns recorded audio data associated with audiorecorder object `recorder` to double array `y`.

`y = getaudiodata(recorder, dataType)` converts the signal data to the specified data type: 'double', 'single', 'int16', 'int8', or 'uint8'.

**Output Arguments**

**y**  
Audio signal data `y` contains the same number of columns as the number of channels in the recording: one for mono, two for stereo. The range of values depends on the data type, as shown in the following table.

Data Type	Sample Value Range
int8	-128 to 127
uint8	0 to 255
int16	-32768 to 32767
single	-1 to 1
double	-1 to 1

**Examples** Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.  
recObj = audiorecorder;  
disp('Start speaking.')
```

```
recordblocking(recObj, 5);  
disp('End of Recording.');
```

```
% Play back the recording.  
play(recObj);  
  
% Store data in double-precision array.  
myRecording = getaudiodata(recObj);  
  
% Plot the waveform.  
plot(myRecording);
```

- “Record Audio”

# GetCharArray

---

**Purpose** Character array from Automation server

**Syntax**

**MATLAB Client**

```
str = h.GetCharArray('varname', 'workspace')  
str = GetCharArray(h, 'varname', 'workspace')
```

**IDL Method Signature**

```
HRESULT GetCharArray([in] BSTR varName, [in] BSTR Workspace, [out, retval]
```

**Microsoft Visual Basic Client**

```
GetCharArray(varname As String, workspace As String) As String
```

**Description** `str = h.GetCharArray('varname', 'workspace')` gets the character array stored in `varname` from the specified workspace of the server attached to handle `h` and returns it in `str`. The values for `workspace` are `base` or `global`.

`str = GetCharArray(h, 'varname', 'workspace')` is an alternate syntax.

**Examples** This example uses a MATLAB client.

```
h = actxserver('matlab.application');  
%Assign a string to variable 'str' in the base workspace of the server  
h.PutCharArray('str', 'base', ...  
    'He jests at scars that never felt a wound.');
```

---

```
%Read 'str' back in the client  
S = h.GetCharArray('str', 'base')
```

This example uses a Visual Basic .NET client.

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application.

```
Dim Matlab As Object  
Dim S As String
```

```
Matlab = CreateObject("matlab.application")
MsgBox("In MATLAB, type" & vbCrLf _
    & "str='new string';")
```

**2** Open the MATLAB window, then type:

```
str='new string';
```

**3** Click **Ok**.

Try

```
S = Matlab.GetCharArray("str", "base")
MsgBox("str = " & S)
Catch ex As Exception
    MsgBox("You did not set 'str' in MATLAB")
End Try
```

The Visual Basic MsgBox displays what you typed in MATLAB.

## See Also

[PutCharArray](#) | [GetWorkspaceData](#) | [GetVariable](#)

# RandStream.getDefaultStream

---

**Purpose** Random number stream

---

**Note** RandStream.getDefaultStream has been removed. Use RandStream.getGlobalStream instead. The shared global stream used by rand, randi, and randn, referred to in former versions of MATLAB as the *default stream* is now referred to as the *global stream*.

---

**Class** RandStream

**Syntax** stream = RandStream.getDefaultStream

**Description** stream = RandStream.getDefaultStream returns the global random number stream. The MATLAB functions rand, randi, and randn use the global stream to generate values.

<b>Purpose</b>	Override to change command window display
<b>Syntax</b>	getdisp(H)
<b>Description</b>	getdisp(H) called by get when get is called with no output arguments and a single input argument that is a handle array. Override this hgsetget class method in a subclass to change how property information is displayed in the command window.
<b>See Also</b>	hgsetget   get (hgsetget)
<b>How To</b>	<ul style="list-style-type: none"><li>• “Implementing a Set/Get Interface for Properties”</li></ul>

# getenv

---

**Purpose** Environment variable

**Syntax** `getenv 'name'`  
`N = getenv('name')`

**Description** `getenv 'name'` searches the underlying operating system's environment list for a string of the form `name=value`, where `name` is the input string. If found, the MATLAB software returns the string value. If the specified name cannot be found, an empty matrix is returned.

`N = getenv('name')` returns value to the variable `N`.

**Examples** `os = getenv('OS')`

```
os =  
Windows_NT
```

**See Also** `setenv` | `computer` | `pwd` | `ver` | `path`

<b>Purpose</b>	Field of structure array
<b>Syntax</b>	<pre>value = getfield(struct, 'field') value = getfield(struct, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN})</pre>
<b>Description</b>	<p><code>value = getfield(struct, 'field')</code>, where <code>struct</code> is a 1-by-1 structure, returns the contents of the specified field, equivalent to <code>value = struct.field</code>. Pass field references as strings.</p> <p><code>value = getfield(struct, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN})</code> returns the contents of the specified field, equivalent to <code>value = struct(sIndx1, ..., sIndxM).field(fIndx1, ..., fIndxN)</code>. The <code>getfield</code> function supports multiple sets of <code>field</code> and <code>fIndx</code> inputs, and all <code>Indx</code> inputs are optional. If structure <code>struct</code> or any of the fields is a nonscalar structure, and you do not specify an <code>Indx</code>, the <code>getfield</code> function returns the values associated with the first index. If you specify a single colon operator for an <code>fIndx</code> input, enclose it in single quotation marks: <code>' : '</code>.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• For most cases, retrieve data from a structure array by indexing rather than using the <code>getfield</code> function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.</li><li>• Call <code>getfield</code> to simplify references to structure arrays with nested fields, or to avoid creating unnecessary temporary variables, as shown in the Examples section.</li></ul>
<b>Examples</b>	<p>The <code>what</code> function returns a structure array that describes the MATLAB files in the current folder. Find the files with the <code>.m</code> extension:</p> <pre>files = getfield(what, 'm');</pre> <p>To perform the same task by indexing requires that you create a temporary variable:</p>

```
templist = what;  
files = templist.m;
```

---

Find values within a structure that contains nested fields:

```
level = 5;  
semester = 'Fall';  
subject = 'Math';  
student = 'John_Doe';  
fieldnames = {semester subject student};  
  
% Add data to a structure named grades.  
grades(level).(semester).(subject).(student)(10,21:30) = ...  
    [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];  
  
% Retrieve the data added.  
getfield(grades, {level}, fieldnames{:}, {10,21:30})
```

---

Using the structure defined in the previous example, find all values in the tenth row of the specified field:

```
getfield(grades, {level}, fieldnames{:}, {10,':'})
```

## See Also

## How To

- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

**Purpose** File formats that VideoReader supports

**Syntax** `formats = VideoReader.getFileFormats()`

**Description** `formats = VideoReader.getFileFormats()` returns an array of `audiovideo.FileFormatInfo` objects that indicate which formats VideoReader can read on the current system. Each object has the following properties: `Extension`, `Description`, `ContainsVideo`, and `ContainsAudio`.

- Tips**
- On Windows and UNIX systems, the list of file formats does not always contain all the formats that VideoReader can read on your system. `getFileFormats` returns a platform-dependent, static list of formats that VideoReader can read on most systems.
  - On all systems, VideoReader cannot always read a particular video file even if `getFileFormats` lists its format. For more information, see Supported Video File Formats.

## Output Arguments

### **formats**

Array of `audiovideo.FileFormatInfo` objects, which have the following properties:

<code>Extension</code>	File extension.
<code>Description</code>	Text description of the file format.
<code>ContainsVideo</code>	Whether VideoReader can read video from this format.
<code>ContainsAudio</code>	Whether VideoReader can read audio from this format.

To convert this array to a filter list for dialog boxes generated with `uigetfile`, use the `getFilterSpec` method with the following syntax:

# VideoReader.getFileFormats

---

```
filterSpec = getFilterSpec(formats)
```

The filter list includes 'All Video Files' in the first row of the cell array, and 'All Files (\*.\*)' in the last row.

## Examples

View the list of file formats that VideoReader supports on your system:

```
VideoReader.getFileFormats()
```

On a Windows system, this list appears as follows:

```
Video File Formats:  
  .asf - ASF File  
  .asx - ASX File  
  .avi - AVI File  
  .mj2 - Motion JPEG2000  
  .mpg - MPEG-1  
  .wmv - Windows Media Video
```

---

Create a dialog box to select a video file:

```
% Get the supported file formats.  
formats = VideoReader.getFileFormats();  
  
% Convert to a filter list.  
filterSpec = getFilterSpec(formats);  
  
% Create the dialog box.  
[filename, pathname] = uigetfile(filterSpec);
```

---

Check whether VideoReader can read an .avi file on the current system:

```
fmtList = VideoReader.getFileFormats();
```

```
if any(ismember({fmtList.Extension},'avi'))
    disp('VideoReader can read AVI files on this system.');
```

else

```
    disp('VideoReader cannot read AVI files on this system.');
```

end

## See Also

VideoReader

# getframe

---

**Purpose** Capture movie frame

**Syntax**

```
getframe
F = getframe
F = getframe(h)
F = getframe(h,rect)
```

**Description** `getframe` returns a movie frame. The frame is a snapshot (pixmap) of the current axes or figure.

`F = getframe` gets a frame from the current axes.

`F = getframe(h)` gets a frame from the figure or axes identified by handle `h`.

`F = getframe(h,rect)` specifies a rectangular area from which to copy the pixmap. `rect` is relative to the lower left corner of the figure or axes `h`, in pixel units. `rect` is a four-element vector in the form `[left bottom width height]`, where `width` and `height` define the dimensions of the rectangle.

`getframe` returns a movie frame, which is a structure having two fields:

- `cdata` — The image data stored as a matrix of `uint8` values. The dimensions of `F.cdata` are height-by-width-by-3.
- `colormap` — The colormap stored as an n-by-3 matrix of doubles. `F.colormap` is empty on true color systems.

To capture an image, use this approach:

```
F = getframe(gcf);
image(F.cdata)
colormap(F.colormap)
```

**Tips** `getframe` is usually used in a `for` loop to assemble an array of movie frames for playback using `movie`. For example,

```
for j = 1:n
    plotting commands
    F(j) = getframe;
```

```
end  
movie(F)
```

If you are capturing frames of a plot that takes a long time to generate or are repeatedly calling `getframe` in a loop, make sure that your computer's screen saver does not activate and that your monitor does not turn off for the duration of the capture; otherwise one or more of the captured frames can contain graphics from your screen saver or nothing at all.

---

**Note** In situations where MATLAB software is running on a virtual desktop that is not currently visible on your monitor, calls to `getframe` will complete, but will capture a region on your monitor that corresponds to the position occupied by the figure or axes on the hidden desktop. Therefore, make sure that the window to be captured by `getframe` exists on the currently active desktop.

---

### Capture Regions

`F = getframe` returns the contents of the current axes, exclusive of the axis labels, title, or tick labels.

`F = getframe(gcf)` captures the entire interior of the current figure window.

To capture the figure window menu, use `F = getframe(h,rect)` with a rectangle sized to include the menu.

### Resolution of Captured Frames

The resolution of the framed image depends on the size of the axes in pixels when `getframe` is called. As the `getframe` command takes a snapshot of the screen, if the axes is small in size (e.g., because you have restricted the view to a window within the axes), `getframe` captures fewer screen pixels, and the captured image might have poor resolution if enlarged for display.

## Capturing UIControls

To capture uicontrols along with the axes and any annotations displayed on the plot, specify the figure handle:

```
F = getframe(figure_handle);
```

To exclude uicontrols outside of the current axes, do not specify the figure handle:

```
F = getframe;
```

## Limitations with Renderer on Windows Systems

Setting the figure `Renderer` property to `zbuffer` or `painters` works around limitations of using `getframe` with the OpenGL renderer on some Windows systems.

## Examples

Make the peaks function vibrate.

```
Z = peaks;
figure('Renderer','zbuffer');
surf(Z);
axis tight manual;
set(gca,'NextPlot','replaceChildren');
for j = 1:20
    surf(sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
end
movie(F,20) % Play the movie twenty times
```

The fifth frame of the sequence looks like this.

**See Also**

[axis](#) | [frame2im](#) | [gcf](#) | [image](#) | [im2frame](#) | [movie](#)

# GetFullMatrix

---

**Purpose** Matrix from Automation server workspace

**Syntax** **MATLAB Client**  
[xreal ximag] =  
h.GetFullMatrix('varname', 'workspace', zreal,  
zimag)  
[xreal ximag] =  
GetFullMatrix(h, 'varname', 'workspace', zreal,  
zimag)

## IDL Method Signature

```
GetFullMatrix([in] BSTR varname, [in] BSTR  
workspace, [in, out] SAFEARRAY(double) *pr, [in,  
out] SAFEARRAY(double) *pi)
```

## Microsoft Visual Basic Client

```
GetFullMatrix(varname As String, workspace As String,  
[out] XReal As Double, [out] XImag As Double)
```

**Description** [xreal ximag] =  
h.GetFullMatrix('varname', 'workspace', zreal, zimag) gets  
matrix stored in variable varname from the specified workspace of the  
server attached to handle h. The function returns the real  
part in xreal and the imaginary part in ximag. The values  
for *workspace* are base or global.

[xreal ximag] =  
GetFullMatrix(h, 'varname', 'workspace', zreal, zimag) is an  
alternate syntax.

The zreal and zimag arguments are matrices of the same size as the  
real and imaginary matrices (xreal and ximag) returned from the  
server. The zreal and zimag matrices are commonly set to zero.

Use GetFullMatrix for values of type double only. Use GetVariable or  
GetWorkspaceData for other types.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the `variant` data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

## Examples

This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create variable M in the base workspace of the server
h.PutFullMatrix('M','base',rand(5),zeros(5));
MReal = h.GetFullMatrix('M','base',zeros(5),zeros(5))
```

---

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application.

```
Dim MatLab As Object
Dim Result As String
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim i, j As Integer

MatLab = CreateObject("matlab.application")
Result = MatLab.Execute("M = rand(5);")
MsgBox("In MATLAB, type" & vbCrLf _
    & "M(3,4)")
```

- 2 Open the MATLAB window and type:

```
M(3,4)
```

# GetFullMatrix

---

**3** Click **Ok**.

**4** In the Visual Basic application:

```
MatLab.GetFullMatrix("M", "base", XReal, XImag)
i = 2    %0-based array
j = 3
```

```
MsgBox("XReal(" & i + 1 & ", " & j + 1 & ") " & _
      " = " & XReal(i, j))
```

**5** Click **Ok** to close and terminate MATLAB.

## See Also

## How To

- “Exchanging Data with the Server”
- “MATLAB COM Automation Server Interface”

**Purpose** Get component position in pixels

**Syntax**  
`position = getpixelposition(handle)`  
`position = getpixelposition(handle,recursive)`

**Description** `position = getpixelposition(handle)` gets the position, in pixel units, of the component with handle `handle`. The `position` is returned as a four-element vector that specifies the location and size of the component: [distance from left, distance from bottom, width, height].

`position = getpixelposition(handle,recursive)` gets the position as above. If `recursive` is true, the returned position is relative to the parent figure of `handle`.

Use the `getpixelposition` function only to obtain coordinates for children of figures and container components (uipanel, or uibuttongroups). Results are not reliable for children of axes or other Handle Graphics objects.

**Examples** This example creates a push button within a panel, and then retrieves its position, in pixels, relative to the panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton','Units','Normalized',...
              'String','Push Button','Position',[.1 .1 .5 .2]);
pos1 = getpixelposition(h1)
```

```
pos1 =
    18.6000    12.6000    88.0000    23.2000
```

# getpixelposition

---

The following statement retrieves the position of the push button, in pixels, relative to the figure.

```
pos1 = getpixelposition(h1,true)

pos1 =
    79.6000    53.6000    88.0000    23.2000
```

## See Also

**Purpose**

Preference

**Syntax**

```
getpref('group','pref')
getpref('group','pref',default)
getpref('group',{'pref1','pref2',... 'prefn'})
getpref('group',{'pref1',... 'prefn'},{default1,...defaultn})
getpref('group')
getpref
```

**Description**

`getpref('group','pref')` returns the value for the preference specified by `group` and `pref`. It is an error to get a preference that does not exist.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. 'ApplicationOnePrefs'. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`getpref('group','pref',default)` returns the current value if the preference specified by `group` and `pref` exists. Otherwise creates the preference with the specified default value and returns that value.

`getpref('group',{'pref1','pref2',... 'prefn'})` returns a cell array containing the values for the preferences specified by `group` and the cell array of preference names. The return value is the same size as the input cell array. It is an error if any of the preferences do not exist.

`getpref('group',{'pref1',... 'prefn'},{default1,...defaultn})` returns a cell array with the current values of the preferences specified by `group` and the cell array of preference names. Any preference that does not exist is created with the specified default value and returned.

`getpref('group')` returns the names and values of all preferences in the group as a structure.

`getpref` returns all groups and preferences as a structure.

# getpref

---

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

## Examples

### Example 1

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')
```

```
ans =
     1.0
```

### Example 2

```
rmpref('mytoolbox','version')
getpref('mytoolbox','version','1.0');
getpref('mytoolbox','version')
```

```
ans =
     1.0
```

## See Also

`addpref` | `ispref` | `rmpref` | `setpref` | `uigetpref` | `uisetpref`

**Purpose** List profiles and file formats supported by VideoWriter

**Syntax** `profiles = VideoWriter.getProfiles()`

**Description** `profiles = VideoWriter.getProfiles()` returns an array of `audiovideo.writer.ProfileInfo` objects that indicate the types of files VideoWriter can create.

**Output Arguments**

**profiles**

An array of `audiovideo.writer.ProfileInfo` objects, which have the following read-only properties:

<code>Name</code>	String profile name, such as 'Uncompressed AVI'.
<code>Description</code>	String description of the profile.
<code>FileExtensions</code>	Cell array of strings containing file extensions supported by the file format.
<code>ColorChannels</code>	Number of color channels in each output video frame.
<code>CompressionRatio</code>	Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. Only applies to objects associated with Motion JPEG 2000 files. Default: 10.
<code>FrameRate</code>	Rate of playback for the video in frames per second. Default: 30.

# VideoWriter.getProfiles

---

LosslessCompression	Boolean value (logical true or false) that specifies whether to use reversible mode, so that the decompressed data is identical to the input data. When true, VideoWriter ignores values for CompressionRatio. Only applies to objects associated with Motion JPEG 2000 files.
MJ2BitDepth	Number of least significant bits in the input image data, from 1 to 16. Only applies to objects associated with Motion JPEG 2000 files.
Quality	Number from 0 through 100. Higher values correspond to higher quality video and larger files. Only applies to objects associated with the MPEG-4 or Motion JPEG AVI profile. Default: 75.
VideoBitsPerPixel	Number of bits per pixel in each output video frame.
VideoCompressionMethod	String indicating the type of video compression, such as 'None' or 'Motion JPEG'.
VideoFormat	String indicating the MATLAB representation of the video format, such as 'RGB24'.

## Examples

### Profile Information

View the list of available profiles and specific information about the 'Uncompressed AVI' profile.

```
profiles = VideoWriter.getProfiles()

uncompAVI = find(ismember({profiles.Name}, 'Uncompressed AVI'));
profiles(uncompAVI)
```

`profiles(uncompAVI).FileExtensions`

`VideoWriter`

# getReport (MException)

---

**Purpose** Get error message for exception

**Syntax**

```
msgString = getReport(exception)
msgString = getReport(exception, type)
msgString = getReport(exception, type, 'hyperlinks', value)
```

**Description** `msgString = getReport(exception)` returns a formatted message string, `msgString`, from an exception. This exception is represented by the `exception` input which is a scalar object of the `MException` class. The message string returned by `getReport` is the same as the error message displayed by MATLAB when it throws this exception.

`msgString = getReport(exception, type)` returns a message string that either describes just the error (**basic** type), or shows the error and the stack as well (**extended** type). The `type` argument, when used, must be the second argument in the input argument list. See “Examples” on page 1-2289 , below.

type Option	Displayed Text
'extended'	Display line number, error message, and cause and stack summary (default)
'basic'	Display line number and error message

`msgString = getReport(exception, type, 'hyperlinks', value)` returns a message string that either does or does not include active hyperlinks to the failing lines in the code. See the table below for the valid choices for `value`. The **hyperlinks** and `value` arguments, when used, must be the third and fourth arguments in the input argument list.

value Option	Action
'on'	Display hyperlinks to failing lines (default)
'off'	Do not display hyperlinks to failing lines
'default'	Use the default for the Command Window to determine whether or not to use hyperlinks in the error message

## Examples

This function attempts to read from a file that does not exist. When you call it, pass either 'basic' or 'extended' to specify the type of report you want to see displayed:

```
function line = test_getreport(file, rpttype)
try
    line = read_file(file);
catch exc
    getReport(exc, rpttype)
end

function line = read_file(file)
    fid = fopen(file, 'r');
    line = fread(fid);
```

The basic option displays only the error message:

```
test_getreport('filethatdoesnotexist.txt', 'basic')
ans =
```

Error using fread

Invalid file identifier. Use fopen to generate a valid file identifier

The extended option displays the error message and error call stack:

```
test_getreport('filethatdoesnotexist.txt', 'extended')
ans =
```

## getReport (MException)

---

Error using fread

Invalid file identifier. Use fopen to generate a valid file identifier.

Error in test\_getreport>read\_file (line 10)

```
line = fread(fid);
```

Error in test\_getreport (line 3)

```
line = read_file(file);
```

# getsampleusingtime (tscollection)

---

## Purpose

Extract data samples into new tscollection object

## Syntax

```
tsc2 = getsampleusingtime(tsc1,Time)
tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)
```

## Description

tsc2 = getsampleusingtime(tsc1,Time) returns a new tscollection tsc2 with a single sample corresponding to Time in tsc1.

tsc2 = getsampleusingtime(tsc1,StartTime,EndTime) returns a new tscollection tsc2 with samples between the times StartTime and EndTime in tsc1.

## Tips

When the time vector in ts1 is numeric, StartTime and EndTime must also be numeric. When the times in ts1 are date strings and the StartTime and EndTime values are numeric, then the StartTime and EndTime values are treated as datenum values.

## See Also

tscollection

# Tiff.getTag

---

**Purpose** Value of specified tag

**Syntax** `tagValue = getTag(tagId)`

**Description** `tagValue = getTag(tagId)` retrieves the value of the TIFF tag specified by `tagId`. You can specify `tagId` as a character string ('ImageWidth') or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

## Examples **Get Value of Tag**

Open a Tiff object and get the value of a tag. Specify the tag by name.

```
t = Tiff('example.tif', 'r');
tagval = t.getTag('ImageWidth')
```

```
tagval =
```

```
600
```

Alternatively, specify the tag by numeric identifier.

```
tagval1 = t.getTag(256)
```

```
tagval1 =
```

```
600
```

Another way to specify the numeric identifier is to use the `TagID` property.

```
tagval2 = t.getTag(Tiff.TagID.ImageWidth)
```

```
tagval2 =
```

600

Close the Tiff object.

```
t.close();
```

## References

This method corresponds to the `TIFFGetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

# Tiff.getTagNames

---

**Purpose** List of recognized TIFF tags

**Syntax** `tagNames = Tiff.getTagNames()`

**Description** `tagNames = Tiff.getTagNames()` returns a cell array of TIFF tags recognized by the `Tiff` object.

**Examples** Retrieve a list of TIFF tags recognized by the `Tiff` object.

```
Tiff.getTagNames

ans =

    'SubFileType'
    'ImageWidth'
    'ImageLength'
    'BitsPerSample'
    'Compression'
    'Photometric'
    'Thresholding'
    'FillOrder'
    'DocumentName'
    'ImageDescription'
    .
    .
    .
```

**See Also** `Tiff.getTag`

**Purpose** Cell array of names of timeseries objects in tscollection object

**Syntax** `names = gettimeseriesnames(tsc)`

**Description** `names = gettimeseriesnames(tsc)` returns names of timeseries objects in a tscollection object tsc. names is a cell array of strings.

**Examples** **1** Create timeseries objects a and b.

```
a = timeseries(rand(1000,1), 'name', 'position');  
b = timeseries(rand(1000,1), 'name', 'response');
```

**2** Create a tscollection object that includes these two time series.

```
tsc = tscollection({a,b});
```

**3** Get the names of the timeseries objects in tsc.

```
names = gettimeseriesnames(tsc)
```

```
names =
```

```
    'position'    'response'
```

**See Also** `timeseries` | `tscollection`

# gettsafteratevent

---

**Purpose** New timeseries object with samples occurring at or after event

**Syntax**  
`ts1 = gettsafteratevent(ts,event)`  
`ts1 = gettsafteratevent(ts,event,n)`

**Description** `ts1 = gettsafteratevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and after an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of the time series `ts` that matches the event name specifies the time.

`ts1 = gettsafteratevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples at and after an event in `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsbeforeevent` | `gettsbetweenevents` | `tsdata.event` | `timeseries`

**Purpose** New timeseries object with samples occurring after event

**Syntax**

```
ts1 = gettsafterevent(ts,event)
ts1 = ttsafterevent(ts,event,n)
```

**Description** `ts1 = gettsafterevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring after an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = ttsafterevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring after an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the event is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the event is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafteratevent` | `gettsbeforeevent` | `gettsbetweenevents` | `timeseries` | `tsdata.event`

# gettsatevent

---

**Purpose** New timeseries object with samples occurring at event

**Syntax**  
`ts1 = gettsatevent(ts,event)`  
`ts1 = gettsatevent(ts,event,n)`

**Description** `ts1 = gettsatevent(ts,event)` returns a new timeseries object `ts1` with samples occurring at an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsatevent(ts,event,n)` returns a new time series `ts1` with samples occurring at an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the timeseries object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in the `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsafteratevent` | `gettsbeforeevent` | `gettsbetweenevents` | `timeseries`

**Purpose** New `timeseries` object with samples occurring before or at event

**Syntax**

```
ts1 = gettsbeforeatevent(ts,event)
ts1 = gettsbeforeatevent(ts,event,n)
```

**Description** `ts1 = gettsbeforeatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeatevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the event is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the event is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsbeforeevent` | `gettsbetweenevents` | `tsdata.event`

# gettsbeforeevent

---

**Purpose** New timeseries object with samples occurring before event

**Syntax**  
`ts1 = gettsbeforeevent(ts,event)`  
`ts1 = gettsbeforeevent(ts,event,n)`

**Description** `ts1 = gettsbeforeevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsbeforeatevent` | `gettsbetweenevents` | `tsdata.event`

**Purpose** New timeseries object with samples occurring between events

**Syntax**

```
ts1 = gettsbetweenevents(ts,event1,event2)
ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)
```

**Description** `ts1 = gettsbetweenevents(ts,event1,event2)` returns a new timeseries object `ts1` with samples occurring between events in `ts`, where `event1` and `event2` can be either a `tsdata.event` object or a string. When `event1` and `event2` are `tsdata.event` objects, the time defined by the events is used. When `event1` and `event2` are strings, the first `tsdata.event` object in the `Events` property of `ts` that matches the event names specifies the time.

`ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)` returns a new timeseries object `ts1` with samples occurring between events in `ts`, where `n1` and `n2` are the `n`th occurrences of the events with matching event names.

**Tips** When the timeseries object `ts` contains date strings and `event` uses numeric time, the time selected by the event is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the event is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsbeforeevent` | `tsdata.event`

# GetVariable

---

**Purpose** Data from variable in Automation server workspace

**Syntax**

**MATLAB Client**

```
D = h.GetVariable('varname','workspace')
D = GetVariable(h,'varname','workspace')
```

**IDL Method Signature**

```
HRESULT GetVariable([in] BSTR varname, [in] BSTR
workspace, [out, retval] VARIANT* pdata)
```

**Microsoft Visual Basic Client**

```
GetVariable(varname As String, workspace As
String) As Object
```

**Description** `D = h.GetVariable('varname','workspace')` gets data stored in variable `varname` from the specified workspace of the server attached to handle `h` and returns it in output argument `D`. The values for `workspace` are `base` or `global`.

`D = GetVariable(h,'varname','workspace')` is an alternate syntax.

Do *not* use `GetVariable` on sparse arrays, structures, or function handles.

If your scripting language requires a result be returned explicitly, use the `GetVariable` function in place of `GetWorkspaceData`, `GetFullMatrix` or `GetCharArray`.

**Examples** This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create variable C1 in the base workspace of the server
h.PutWorkspaceData('C1', 'base', {25.72, 'hello', rand(4)});
%The client reads the data
C2 = h.GetVariable('C1','base')
```

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
Dim Result As String
Dim C2 As Variant
Matlab = CreateObject("matlab.application")
Result = Matlab.Execute("C1 = {25.72, 'hello', rand(4)};")
C2 = Matlab.GetVariable("C1", "base")
MsgBox("Second item in cell array: " & C2(0, 1))
```

## See Also

# Tiff.getVersion

---

**Purpose** LibTIFF library version

**Syntax** `versionString = Tiff.getVersion()`

**Description** `versionString = Tiff.getVersion()` returns the version number and other information about the LibTIFF library.

**Examples** Display version of LibTIFF library:

```
Tiff.getVersion
```

```
ans =
```

```
LIBTIFF, Version 3.9.5  
Copyright (c) 1988-1996 Sam Leffler  
Copyright (c) 1991-1996 Silicon Graphics, Inc.
```

**References** This method corresponds to the `TIFFGetVersion` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**Purpose** Data from Automation server workspace

**Syntax**

**MATLAB Client**

```
D = h.GetWorkspaceData('varname','workspace')
D = GetWorkspaceData(h,'varname','workspace')
```

### IDL Method Signature

```
HRESULT GetWorkspaceData([in] BSTR varname, [in] BSTR
workspace, [out] VARIANT* pdata)
```

### Microsoft Visual Basic Client

```
GetWorkspaceData(varname As String, workspace
As String) As Object
```

**Description**

`D = h.GetWorkspaceData('varname','workspace')` gets data stored in variable `varname` from the specified workspace of the server attached to handle `h` and returns it in output argument `D`. The values for `workspace` are `base` or `global`.

`D = GetWorkspaceData(h,'varname','workspace')` is an alternate syntax.

Use `GetWorkspaceData` instead of `GetFullMatrix` and `GetCharArray` to get numeric and character array data, respectively. Do *not* use `GetWorkspaceData` on sparse arrays, structures, or function handles.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

**Examples**

This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create cell array C1 in the base workspace of the server
```

# GetWorkspaceData

---

```
h.PutWorkspaceData('C1', 'base', ...  
    {25.72, 'hello', rand(4)});  
C2 = h.GetWorkspaceData('C1', 'base')
```

---

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object  
Dim C2 As Variant  
Dim Result As String  
Matlab = CreateObject("matlab.application")  
Result = MatLab.Execute("C1 = {25.72, 'hello', rand(4)};")  
MsgBox("In MATLAB, type" & vbCrLf & "C1")  
Matlab.GetWorkspaceData("C1", "base", C2)  
MsgBox("second value of C1 = " & C2(0, 1))
```

## See Also

| [Execute](#)

## How To

- “MATLAB COM Automation Server Interface”
- “Exchanging Data with the Server”

**Purpose**

Graphical input from mouse or cursor

**Syntax**

```
[x,y] = ginput(n)
[x,y] = ginput
[x,y,button] = ginput(...)
```

**Description**

`ginput` raises crosshairs in the current axes to for you to identify points in the figure, positioning the cursor with the mouse. The figure must have focus before `ginput` can receive input. If it has no axes, one is created upon the first click or keypress.

`[x,y] = ginput(n)` enables you to identify `n` points from the current axes and returns their  $x$ - and  $y$ -coordinates in the `x` and `y` column vectors. Press the **Return** key to terminate the input before entering `n` points.

`[x,y] = ginput` gathers an unlimited number of points until you press the **Return** key.

`[x,y,button] = ginput(...)` returns the  $x$ -coordinates, the  $y$ -coordinates, and the button or key designation. `button` is a vector of integers indicating which mouse buttons you pressed (1 for left, 2 for middle, 3 for right), or ASCII numbers indicating which keys on the keyboard you pressed.

Clicking an axes makes that axes the current axes. Even if you set the current axes before calling `ginput`, whichever axes you click becomes the current axes and `ginput` returns points relative to that axes. If you select points from multiple axes, the results returned are relative to the coordinate system of the axes they come from.

---

**Note** MATLAB returns errors such as the following if you start MATLAB with the `noFigureWindows` or `nodisplay` flag and then run `ginput`:

```
Error using ginput (line 31)
Terminal mode is no longer supported
```

---

## Definitions

Coordinates returned by `ginput` are scaled to the `XLim` and `YLim` bounds of the axes you click (data units). Setting the axes or figure `Units` property has no effect on the output from `ginput`. You can click anywhere within the figure canvas to obtain coordinates. If you click outside the axes limits, `ginput` extrapolates coordinate values so they are still relative to the axes origin.

The figure `CurrentPoint` property, by contrast, is always returned in figure `Units`, irrespective of axes `Units` or limits.

## Examples

Pick 4 two-dimensional points from the figure window.

```
[x,y] = ginput(4)
```

Position the cursor with the mouse. Enter data points by pressing a mouse button or a key on the keyboard. To terminate input before entering 4 points, press the **Return** key.

```
x =
    0.2362
    0.5749
    0.5680
    0.2707
```

```
y =
    0.6711
    0.6769
    0.4313
```

```
0.4401
```

```
plot(x,y)
```

In this example, `plot` rescaled the axes *x*-limits and *y*-limits from `[0 1]` and `[0 1]` to `[0.20 0.65]` and `[0.40 0.75]`. The rescaling occurred because the axes `XLimMode` and `YLimMode` are set to `'auto'` (the default). Consider setting `XLimMode` and `YLimMode` to `'manual'` if you want to maintain consistency when you gather results from `ginput` and plot them together.

# global

---

**Purpose**            Declare global variables

**Syntax**            `global X Y Z`

**Description**      `global X Y Z` defines X, Y, and Z as global in scope.

Ordinarily, each MATLAB function has its own local variables, which are separate from those of other functions, and from those of the base workspace. However, if several functions, and possibly the base workspace, all declare a particular name as global, they all share a single copy of that variable. Any assignment to that variable, in any function, is available to all the functions declaring it global.

If the global variable does not exist the first time you issue the `global` statement, it is initialized to the empty matrix.

If a variable with the same name as the global variable already exists in the current workspace, MATLAB issues a warning and changes the value of that variable to match the global.

**Tips**                Use `clear global variable` to clear a global variable from the global workspace. Use `clear variable` to clear the global link from the current workspace without affecting the value of the global.

To use a global within a callback, declare the global, use it, then clear the global link from the workspace. This avoids declaring the global after it has been referenced. For example,

```
cbstr = sprintf('%s, %s, %s, %s, %s', ...
    'global MY_GLOBAL', ...
    'MY_GLOBAL = 100', ...
    'disp(MY_GLOBAL)', ...
    'MY_GLOBAL = MY_GLOBAL+1', ...
    'clear MY_GLOBAL');
```

```
uicontrol('style', 'pushbutton', 'Callback', cbstr, ...
    'string', 'count')
```

There is no function form of the `global` command (i.e., you cannot use parentheses and quote the variable names).

## Examples

### Example 1

Type `edit global_demo1` at the command line and enter the following function definition in a new file named `global_demo1.m`.

```
function global_demo1(num)
global globalvar

if nargin > 0
    globalvar = num;
end

fprintf('Global variable in function %s is %d\n', ...
        mfilename, globalvar);
```

This function declares a global variable named `globalvar`. If you pass a value when calling the function, the function stores the value in `globalvar` and then displays it. If you call the function with no arguments, the function just displays the value last written to the global workspace.

Create another function `global_demo2` just like it. These two functions have separate function workspaces, but share a common global workspace:

```
copyfile global_demo1.m global_demo2.m
```

Call `global_demo1`, passing a numeric value. Then call `global_demo2` with no value. You can see that the latter function has global access to the value that was passed to `global_demo1`.

```
global_demo1(1357);
Global variable in function global_demo1 is 1357

global_demo2
Global variable in function global_demo2 is 1357
```

Now set the value in `global_demo2` and read it in `global_demo1`:

```
global_demo2(2468)
Global variable in function global_demo2 is 2468
```

```
global_demo1
Global variable in function global_demo1 is 2468
```

## Example 2

Call the function `global_demo1` that was defined in the previous example to assign a value to variable `globalvar` in the global workspace. Even though the variable is global, it is not accessible outside of the function workspace:

```
clear all
global_demo1(1357);
Global variable in function global_demo1 is 1357

if exist('globalvar', 'var')
    fprintf('Global variable is set to %d\n', globalvar);
else
    fprintf('Global variable is not available at the command line.\n');
end
```

Global variable is not available at the command line.

Now declare `globalvar` as a global variable at the MATLAB command line. Run the same statements to display the variable and this time you can see that the value assigned by the function is also available as a global variable in the base workspace:

```
global globalvar

if exist('globalvar', 'var')
    fprintf('Global variable is set to %d\n', globalvar);
else
```

```
    fprintf('Global variable is not available at the command line.\n')  
end
```

Global variable is set to 1357

### Example 3

Here is the code for the functions `tic` and `toc` (some comments abridged). These functions manipulate a stopwatch-like timer. The global variable `TICTOC` is shared by the two functions, but it is invisible in the base workspace or in any other functions that do not declare it.

```
function tic  
% TIC Start a stopwatch timer.  
% TIC; any stuff; TOC  
% prints the time required.  
% See also: TOC, CLOCK.  
global TICTOC  
TICTOC = clock;  
  
function t = toc  
% TOC Read the stopwatch timer.  
% TOC prints the elapsed time since TIC was used.  
% t = TOC; saves elapsed time in t, does not print.  
% See also: TIC, ETIME.  
global TICTOC  
if nargin < 1  
    elapsed_time = etime(clock, TICTOC)  
else  
    t = etime(clock, TICTOC);  
end
```

**Purpose** Generalized minimum residual method (with restarts)

**Syntax**

```
x = gmres(A,b)
gmres(A,b,restart)
gmres(A,b,restart,tol)
gmres(A,b,restart,tol,maxit)
gmres(A,b,restart,tol,maxit,M)
gmres(A,b,restart,tol,maxit,M1,M2)
gmres(A,b,restart,tol,maxit,M1,M2,x0)
[x,flag] = gmres(A,b,...)
[x,flag,relres] = gmres(A,b,...)
[x,flag,relres,iter] = gmres(A,b,...)
[x,flag,relres,iter,resvec] = gmres(A,b,...)
```

**Description** `x = gmres(A,b)` attempts to solve the system of linear equations  $A*x = b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ .  $A$  can be a function handle, `afun`, such that `afun(x)` returns  $A*x$ . For this syntax, `gmres` does not restart; the maximum number of iterations is  $\min(n,10)$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `gmres` converges, a message to that effect is displayed. If `gmres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`gmres(A,b,restart)` restarts the method every `restart` inner iterations. The maximum number of outer iterations is  $\min(n/\text{restart},10)$ . The maximum number of total iterations is  $\text{restart}*\min(n/\text{restart},10)$ . If `restart` is `n` or `[]`, then `gmres` does not restart and the maximum number of total iterations is  $\min(n,10)$ .

`gmres(A,b,restart,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `gmres` uses the default,  $1e-6$ .

`gmres(A,b,restart,tol,maxit)` specifies the maximum number of outer iterations, i.e., the total number of iterations does not exceed `restart*maxit`. If `maxit` is `[]` then `gmres` uses the default, `min(n/restart,10)`. If `restart` is `n` or `[]`, then the maximum number of total iterations is `maxit` (instead of `restart*maxit`).

`gmres(A,b,restart,tol,maxit,M)` and `gmres(A,b,restart,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for `x`. If `M` is `[]` then `gmres` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns  $M \setminus x$ .

`gmres(A,b,restart,tol,maxit,M1,M2,x0)` specifies the first initial guess. If `x0` is `[]`, then `gmres` uses the default, an all-zero vector.

`[x,flag] = gmres(A,b,...)` also returns a convergence flag:

- `flag = 0`    `gmres` converged to the desired tolerance `tol` within `maxit` outer iterations.
- `flag = 1`    `gmres` iterated `maxit` times but did not converge.
- `flag = 2`    Preconditioner `M` was ill-conditioned.
- `flag = 3`    `gmres` stagnated. (Two consecutive iterates were the same.)

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = gmres(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`. The third output, `relres`, is the relative residual of the preconditioned system.

`[x,flag,relres,iter] = gmres(A,b,...)` also returns both the outer and inner iteration numbers at which `x` was computed, where  $0 \leq \text{iter}(1) \leq \text{maxit}$  and  $0 \leq \text{iter}(2) \leq \text{restart}$ .

`[x,flag,relres,iter,resvec] = gmres(A,b,...)` also returns a vector of the residual norms at each inner iteration. These are the residual norms for the preconditioned system.

## Examples

### Using gmres with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = gmres(A,b,10,tol,maxit,M1);
```

displays the following message:

```
gmres(10) converged at outer iteration 2 (inner iteration 9) to
a solution with relative residual 3.3e-013
```

### Using gmres with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*, and the preconditioner *M1* with a handle to a backsolve function *mfun*. The example is contained in a function *run\_gmres* that

- Calls *gmres* with the function handle *@afun* as its first argument.
- Contains *afun* and *mfun* as nested functions, so that all variables in *run\_gmres* are available to *afun* and *mfun*.

The following shows the code for *run\_gmres*:

```
function x1 = run_gmres
n = 21;
b = afun(ones(n,1));
tol = 1e-12; maxit = 15;
x1 = gmres(@afun,b,10,tol,maxit,@mfun);

function y = afun(x)
    y = [0; x(1:n-1)] + ...
        [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
        [x(2:n); 0];
end
```

```
function y = mfun(r)
    y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
end
end
```

When you enter

```
x1 = run_gmres;
```

MATLAB software displays the message

```
gmres(10) converged at outer iteration 2 (inner iteration 10)
to a solution with relative residual 1.1e-013.
```

### Using a Preconditioner without Restart

This example demonstrates the use of a preconditioner without restarting gmres.

#### 1

Load west0479, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

#### 2

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

#### 3

Define **b** so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
[x0,f10,rr0,it0,rv0] = gmres(A,b,[],tol,maxit);
```

`f10` is 1 because `gmres` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. The best approximate solution that `gmres` returns is the last one (as indicated by `it0(2) = 20`). MATLAB stores the residual history in `rv0`.

## 4

Plot the behavior of `gmres`:

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution converges slowly. A preconditioner may improve the outcome.

**5**

Use `ilu` to form the preconditioner, since  $A$  is nonsymmetric :

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
Error using ilu
```

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

Note MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

**6**

As indicated by the error message, try again with a reduced drop tolerance:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = gmres(A,b,[],tol,maxit,L,U);
```

`f11` is 0 because `gmres` drives the relative residual to  $9.5436e-14$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of `it1(2)`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output, `rv1(1)`, is  $\text{norm}(M \setminus b)$ , where  $M = L * U$ . The output, `rv1(7)`, is  $\text{norm}(U \setminus (L \setminus (b - A * x1)))$ .

**7**

Follow the progress of `gmres` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1(2),rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

## Using a Preconditioner with Restart

This example demonstrates the use of a preconditioner with restarted gmres.

### 1

Load west0479, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;  
A = west0479;
```

### 2

Define **b** so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

**3**

Construct an incomplete LU preconditioner as in the previous example:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
```

The benefit to using restarted gmres is to limit the amount of memory required to execute the method. Without restart, gmres requires `maxit` vectors of storage to keep the basis of the Krylov subspace. Also, gmres must orthogonalize against all of the previous vectors at each step. Restarting limits the amount of workspace used and the amount of work done per outer iteration. Note that even though preconditioned gmres converged in six iterations above, the algorithm allowed for as many as twenty basis vectors and therefore, allocated all of that space up front.

**4**

Execute `gmres(3)`, `gmres(4)`, and `gmres(5)`:

```
tol = 1e-12; maxit = 20;
re3 = 3;
[x3,f13,rr3,it3,rv3] = gmres(A,b,re3,tol,maxit,L,U);
re4 = 4;
[x4,f14,rr4,it4,rv4] = gmres(A,b,re4,tol,maxit,L,U);
re5 = 5;
[x5,f15,rr5,it5,rv5] = gmres(A,b,re5,tol,maxit,L,U);
```

`f13`, `f14`, and `f15` are all 0 because in each case restarted gmres drives the relative residual to less than the prescribed tolerance of  $1e-12$ . The following plots show the convergence histories of each restarted gmres method. `gmres(3)` converges at outer iteration 5, inner iteration 3 (`it3 = [5, 3]`) which would be the same as outer iteration 6, inner iteration 0, hence the marking of 6 on the final tick mark.

# gmres

**Purpose** Create array of graphics handles

**Syntax**

```
H = gobjects(n)
H = gobjects(s1,...,sn)
H = gobjects(v)
```

```
H = gobjects
H = gobjects(0)
```

**Description** H = gobjects(n) returns an n-by-n array of graphics handles. Use the gobjects function instead of the ones or zeros functions to preallocate an array to store graphics handles.

H = gobjects(s1,...,sn) returns an s1-by-...-by-sn array of graphics handles, where the list of integers s1,...,sn defines the dimensions of the array. For example, gobjects(2,3) returns a 2-by-3 array.

H = gobjects(v) returns an array of graphics handles where the elements of the row vector, v, define the dimensions of the array. For example, gobjects([2,3,4]) returns a 2-by-3-by-4 array.

H = gobjects returns a 1-by-1 graphics handle array.

H = gobjects(0) returns empty.

## Input Arguments

### **n - Size of square matrix**

integer value

Size of the square matrix, specified as an integer value. Negative integers are treated as 0. The square matrix has dimensions n-by-n.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## **s1,...,sn - Size of each array dimension**

two or more integer values

Size of each array dimension, specified as a list of two or more integer values. Negative integers are treated as 0.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## **v - Size of each array dimension**

row vector of integer values

Size of each array dimension, specified as a row vector of integer values. Negative integers are treated as 0.

**Example:** [2,4,6,7]

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## **Examples**

### **Specifying Array Dimensions**

Preallocate a 4-by-1 array to store graphics handles.

```
H = gobjects(4,1);
```

You can assign axes handles to the array elements.

```
for k = 1:4  
    H(k) = subplot(2,2,k);  
end
```

### **Specifying Array Dimensions with Size of Existing Array**

Create an array to store graphics handles using the size of an existing array.

Define A as a 3-by-4 array.

```
A = [1,2,3,2; 4,5,6,6; 7,8,9,7];
```

Create an array of graphics handles using the size of A.

```
v = size(A);  
H = gobjects(v);
```

The dimensions of the graphics handle array are the same as the dimensions of A.

```
isequal(size(H),size(A))
```

```
ans =
```

```
1
```

## **Returning Empty Handle Array**

Use the `gobjects` function to return an empty array.

```
H = gobjects(0)
```

```
H =
```

```
[]
```

# gplot

---

## Purpose

Plot nodes and links representing adjacency matrix

## Syntax

```
gplot(A,Coordinates)
gplot(A,Coordinates,LineStyle)
```

## Description

The `gplot` function graphs a set of coordinates using an adjacency matrix.

`gplot(A,Coordinates)` plots a graph of the nodes defined in `Coordinates` according to the  $n$ -by- $n$  adjacency matrix `A`, where  $n$  is the number of nodes. `Coordinates` is an  $n$ -by-2 matrix, where  $n$  is the number of nodes and each coordinate pair represents one node.

`gplot(A,Coordinates,LineStyle)` plots the nodes using the line type, marker symbol, and color specified by `LineStyle`.

## Tips

For two-dimensional data, `Coordinates(i,:) = [x(i) y(i)]` denotes node  $i$ , and `Coordinates(j,:) = [x(j) y(j)]` denotes node  $j$ . If node  $i$  and node  $j$  are connected, `A(i,j)` or `A(j,i)` is nonzero; otherwise, `A(i,j)` and `A(j,i)` are zero.

## Examples

Plot half of a “Bucky ball” carbon molecule, placing asterisks at each node:

```
k = 1:30;
[B,XY] = bucky;
gplot(B(k,k),XY(k,:), '-*')
axis square
```

# grabcode

---

**Purpose** Extract MATLAB code from file published to HTML

**Syntax**

```
grabcode('name.html')
grabcode('urlname')
codeString = grabcode('name.html')
```

**Description** `grabcode('name.html')` copies MATLAB code from the file `name.html` and pastes it into an untitled document in the Editor. Use `grabcode` to get MATLAB code from published files when the source code is not readily available. The file `name.html` was created by publishing `name.m`, a MATLAB code file containing cells. The MATLAB code from `name.m` is included at the end of `name.html` as HTML comments.

`grabcode('urlname')` copies MATLAB code from the `urlname` location and pastes it into an untitled document in the Editor.

`codeString = grabcode('name.html')` gets MATLAB code from the file `name.html` and assigns it the variable `codeString`.

**Examples** This example illustrates how to use `grabcode` to get MATLAB code from an existing HTML file:

```
% Copy sine_wave_f.html and the images it includes
% from the MATLAB examples directory to your
% current folder:

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
    'examples','sine_wave_f.html'), 'my_sine_wave.html')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
    'examples','sine_wave_f_01.png'), 'sine_wave_f_01.png')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
    'examples','sine_wave_f_02.png'), 'sine_wave_f_02.png')

% If you want to view the file, double-click my_sine_wave.html
% in your current folder.
```

```
% Extract the MATLAB code from sine_wave_f.html:  
code = grabcode('my_sine_wave.html')
```

MATLAB returns:

```
code =
```

```
%% Plot Sine Wave  
% Calculate and plot a sine wave.  
  
%% Calculate and Plot Sine Wave  
% Calculate and plot |y = sin(x)|.
```

```
function sine_wave_f(x)
```

```
y = sin(x);  
plot(x,y)
```

```
%% Modify Plot Properties
```

```
title('Sine Wave', 'FontWeight','bold')  
xlabel('x')  
ylabel('sin(x)')  
set(gca, 'Color', 'w')  
set(gcf, 'MenuBar', 'none')
```

```
publish
```

# gradient

---

**Purpose** Numerical gradient

**Syntax**  
FX = gradient(F)  
[FX,FY] = gradient(F)  
[FX,FY,FZ,...] = gradient(F)  
[...] = gradient(F,h)  
[...] = gradient(F,h1,h2,...)

**Definitions** The *gradient* of a function of two variables,  $F(x,y)$ , is defined as

$$\nabla F = \frac{\partial F}{\partial x} \hat{i} + \frac{\partial F}{\partial y} \hat{j}$$

and can be thought of as a collection of vectors pointing in the direction of increasing values of  $F$ . In MATLAB software, numerical gradients (differences) can be computed for functions with any number of variables. For a function of  $N$  variables,  $F(x,y,z, \dots)$ ,

$$\nabla F = \frac{\partial F}{\partial x} \hat{i} + \frac{\partial F}{\partial y} \hat{j} + \frac{\partial F}{\partial z} \hat{k} + \dots$$

**Description** FX = gradient(F), where F is a vector, returns the one-dimensional numerical gradient of F. Here FX corresponds to  $\partial F/\partial x$ , the differences in x (horizontal) direction.

[FX,FY] = gradient(F), where F is a matrix, returns the  $x$  and  $y$  components of the two-dimensional numerical gradient. FX corresponds to  $\partial F/\partial x$ , the differences in  $x$  (horizontal) direction. FY corresponds to  $\partial F/\partial y$ , the differences in the  $y$  (vertical) direction. The spacing between points in each direction is assumed to be one.

[FX,FY,FZ,...] = gradient(F), where F has  $N$  dimensions, returns the  $N$  components of the gradient of F. There are two ways to control the spacing between values in F:

- A single spacing value, h, specifies the spacing between points in every direction.

- N spacing values ( $h_1, h_2, \dots$ ) specifies the spacing for each dimension of F. Scalar spacing parameters specify a constant spacing for each dimension. Vector parameters specify the coordinates of the values along corresponding dimensions of F. In this case, the length of the vector must match the size of the corresponding dimension.

---

**Note** The first output FX is always the gradient along the 2nd dimension of F, going across columns. The second output FY is always the gradient along the 1st dimension of F, going across rows. For the third output FZ and the outputs that follow, the Nth output is the gradient along the Nth dimension of F.

---

[...] = gradient(F,h), where h is a scalar, uses h as the spacing between points in each direction.

[...] = gradient(F,h1,h2,...) with N spacing parameters specifies the spacing for each dimension of F.

## Examples

The statements

```
v = -2:0.2:2;
[x,y] = meshgrid(v);
z = x .* exp(-x.^2 - y.^2);
[px,py] = gradient(z,.2,.2);
contour(v,v,z), hold on, quiver(v,v,px,py), hold off
```

produce

# gradient

Given,

```
F(:,:,1) = magic(3); F(:,:,2) = pascal(3);  
gradient(F)
```

takes  $dx = dy = dz = 1$ .

```
[PX,PY,PZ] = gradient(F,0.2,0.1,0.2)
```

takes  $dx = 0.2$ ,  $dy = 0.1$ , and  $dz = 0.2$ .

## Algorithms

`gradient` calculates the central difference between data points. For an array, matrix, or vector with  $N$  values in each row, the  $i$ th value is defined by

$$A_i = \frac{1}{2} \sum_{i=2}^{N-1} A_{i+1} - A_{i-1}.$$

The gradient at the end points, where  $i=1$  and  $i=N$ , is calculated with a single-sided difference between the endpoint value and the next adjacent value within the row. If two or more outputs are specified, `gradient` also calculates central differences along other dimensions. Unlike the `diff` function, `gradient` returns an array with the same number of elements as the input.

# graymon

---

<b>Purpose</b>	Set default figure properties for grayscale monitors
<b>Syntax</b>	<code>graymon</code>
<b>Description</b>	<code>graymon</code> sets defaults for graphics properties to produce more legible displays for grayscale monitors.
<b>See Also</b>	<code>axes</code>   <code>figure</code>

**Purpose**

Grid lines for 2-D and 3-D plots

**Syntax**

```
grid on
grid off
grid
grid minor
grid(axes_handle,...)
```

**Description**

`grid on` adds major grid lines to the current axes.

`grid off` removes all grid lines from the current axes.

`grid` toggles the visibility of the major grid lines of the current axes.

`grid minor` toggles the visibility of the minor grid lines of the current axes.

`grid(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

**Examples**

Use the `grid` function to display the major grid lines for a sine plot. By default, MATLAB does not display grid lines for a 2-D view.

```
figure
x = linspace(0,10);
y = sin(x);
plot(x,y);
grid on;
```

# grid

---

Reissuing the command `grid` toggles the visibility of the major grid lines.

---

Create a 3-D plot and turn off the display of the grid lines. By default, MATLAB displays grid lines for a 3-D view.

```
figure
surf(peaks);
grid off;
```

---

Use the `grid` function to display the major and minor grid lines.

Set up a vector of random numbers.

```
rng(0, 'twister');  
randnumbers = rand(1,20);
```

Create a figure and get the handle to the current axes. Display the grid lines and set the line style for the major grid lines using the axes handle.

# grid

```
figure
axh = gca;
plot(randnumbers);
grid on;
set(axh, 'GridLineStyle', '-');
grid minor;
```

## Algorithms

Some axes properties control the axes grid lines. For more information on axes properties see [Axes Properties](#).

`grid` sets the `XGrid`, `YGrid`, and `ZGrid` properties of the axes.

To control the major grid line visibility separately for each axis direction set the `XGrid`, `YGrid`, and `ZGrid` axes properties. These properties can be set to `on` or `off`.

```
axh = gca;  
set(axh, 'XGrid', 'on')  
set(axh, 'ZGrid', 'off')
```

`grid minor` sets the `XMinorGrid`, `YMinorGrid`, and `ZMinorGrid` properties of the axes.

To control the minor grid line visibility separately for each axis direction set the `XMinorGrid`, `YMinorGrid`, and `ZMinorGrid` axes properties. These properties can be set to `on` or `off`.

```
axh = gca;  
set(axh, 'XMinorGrid', 'on')
```

To change the grid line width, set the `LineWidth` axes property.

```
axh = gca;  
set(axh, 'LineWidth', 2);
```

By default, the number of grid lines changes when you resize a figure. To keep the same number of grid lines for any figure size, set the `XTickMode`, `YTickMode`, or `ZTickMode` axes properties to `'manual'`.

```
axh = gca;  
set(axh, 'XTickMode', 'manual');
```

To customize the locations of the tick marks along an axis, set the `XTick`, `YTick`, and `ZTick` axes properties.

```
axh = gca;  
set(axh, 'XTick', [0:5:50]);
```

To turn on and off the display of the minor tick marks along an axis, set the `XMinorTick`, `YMinorTick`, and `ZMinorTick` properties to `on` or `off`.

# grid

---

```
axh = gca;  
set(axh, 'XMinorTick', 'on')
```

**Purpose** Interpolate scattered data

---

**Note** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `griddata`.

In a future release, the following syntaxes will be removed:

```
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq)
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq, method)
```

In addition, `griddata` will not accept any input vectors of mixed orientation in a future release. To specify a grid of query points, construct a full grid with `ndgrid` or `meshgrid` before calling `griddata`.

---

**Syntax**

```
vq = griddata(x,y,v,xq,yq)
vq = griddata(x,y,z,v,xq,yq,zq)
vq = griddata(..., method)
```

**Description** `vq = griddata(x,y,v,xq,yq)` fits a surface of the form  $v = f(x,y)$  to the scattered data in the vectors  $(x,y,v)$ . The `griddata` function interpolates the surface at the query points specified by  $(xq,yq)$  and returns the interpolated values, `vq`. The surface always passes through the data points defined by `x` and `y`.

`vq = griddata(x,y,z,v,xq,yq,zq)` fits a hypersurface of the form  $v = f(x,y,z)$ .

`vq = griddata(..., method)` uses a specified interpolation method to compute `vq`.

**Input Arguments**

**x**  
Vector specifying the  $x$ - coordinates of the sample points.

**y**

Vector specifying the  $y$ - coordinates of the sample points.

## **z**

Vector specifying the  $z$ - coordinates of the sample points.

## **v**

Vector of sample values that correspond to the sample coordinates  $x$ ,  $y$  (and  $z$  for 3-D interpolation).

## **xq**

Vector or array that specifies  $x$ - coordinates of the query points to be evaluated.  $xq$  must be the same size as  $yq$  (and  $zq$  for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

## **yq**

Vector or array that specifies  $y$ - coordinates of the query points to be evaluated.  $yq$  must be the same size as  $xq$  (and  $zq$  for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

## **zq**

Vector or array that specifies  $z$ - coordinates of the query points to be evaluated.  $zq$  must be the same size as  $xq$  and  $yq$ .

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

## **method**

Keyword that specifies the interpolation method. Use one of the following:

'linear'	Linear interpolation (default)
'cubic'	Cubic interpolation
'natural'	Natural neighbor interpolation
'nearest'	Nearest neighbor interpolation
'v4'	MATLAB 4 griddata method

## Output Arguments

### **vq**

The interpolated values at the query points.

- For 2-D interpolation, where  $xq$  and  $yq$  specify an  $m$ -by- $n$  grid of query points,  $vq$  is an  $m$ -by- $n$  array.
- For 3-D interpolation, where  $xq$ ,  $yq$ , and  $zq$  specify an  $m$ -by- $n$ -by- $p$  grid of query points,  $vq$  is an  $m$ -by- $n$ -by- $p$  array.
- If  $xq$ ,  $yq$ , (and  $zq$  for 3-D interpolation) are vectors that specify scattered points,  $vq$  is a vector of the same length.

## Examples

### **Interpolate Scattered Data Over a Uniform Grid**

Sample a function at 200 random points between -2.5 and 2.5.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1); y = xy(:,2);
v = x.*exp(-x.^2-y.^2);
```

$x$ ,  $y$ , and  $v$  are vectors containing scattered (nonuniform) sample points and data.

Define a regular grid and interpolate the scattered data over the grid.

```
[xq,yq] = meshgrid(-2:.2:2, -2:.2:2);
vq = griddata(x,y,v,xq,yq);
```

Plot the gridded data as a mesh and the scattered data as dots.

```
figure
mesh(xq,yq,vq);
hold on
plot3(x,y,v,'o');
h = gca;
set(h,'XLim',[-2.7 2.7]);
set(h,'YLim',[-2.7 2.7]);
```

## Interpolate 3-D Data Set Over a Grid in the x-y Plane

Sample a function at 5000 random points between -1 and 1.

```
rng(0, 'twister')
x = 2*rand(5000,1)-1;
y = 2*rand(5000,1)-1;
z = 2*rand(5000,1)-1;
v = x.^2 + y.^2 + z.^2;
```

x, y, and z are now vectors containing nonuniformly sampled data. Define a regular grid with points in the range [-0.8, 0.8].

```
d = -0.8:0.05:0.8;
[xq,yq,zq] = meshgrid(d,d,0);
```

Interpolate the scattered data over a rectangular region at z=0. Then, plot the results.

```
vq = griddata(x,y,z,v,xq,yq,zq);
surf(xq,yq,vq);
set(gca, 'XTick', [-1 -0.5 0 0.5 1]);
set(gca, 'YTick', [-1 -0.5 0 0.5 1]);
```

# griddata

---

## See Also

`scatteredInterpolant` | `delaunay` | `griddatan` | `interp` | `interp` | `meshgrid` | `ndgrid`

**Purpose**

Data gridding and hypersurface fitting (dimension  $\geq 2$ )

**Syntax**

```
yi = griddatan(x,y,xi)
yi = griddatan(x,y,xi,method)
yi = griddatan(x,y,xi,method,options)
```

**Description**

`yi = griddatan(x,y,xi)` fits a hyper-surface of the form  $y = f(x)$  to the data in the (usually) nonuniformly-spaced vectors  $(x, y)$ . `griddatan` interpolates this hyper-surface at the points specified by `xi` to produce `yi`. `xi` can be nonuniform.

`X` is of dimension  $m$ -by- $n$ , representing  $m$  points in  $n$ -dimensional space. `y` is of dimension  $m$ -by-1, representing  $m$  values of the hyper-surface  $f(X)$ . `xi` is a vector of size  $p$ -by- $n$ , representing  $p$  points in the  $n$ -dimensional space whose surface value is to be fitted. `yi` is a vector of length  $p$  approximating the values  $f(xi)$ . The hypersurface always goes through the data points  $(X,y)$ . `xi` is usually a uniform grid (as produced by `meshgrid`).

`yi = griddatan(x,y,xi,method)` defines the type of surface fit to the data, where 'method' is one of:

'linear'      Triangulation-based linear interpolation (default)

'nearest'     Nearest neighbor interpolation

All the methods are based on a Delaunay triangulation of the data.

If `method` is `[]`, the default 'linear' method is used.

`yi = griddatan(x,y,xi,method,options)` specifies a cell array of strings `options` to be used in `Qhull` via `delaunayn`.

If `options` is `[]`, the default options are used. If `options` is `{ ' ' }`, no options are used, not even the default.

**Examples**

```
X=2*gallery('uniformdata',[5000 3],0)-1;;
Y = sum(X.^2,2);
d = -0.8:0.05:0.8;
```

# griddatan

---

```
[y0,x0,z0] = ndgrid(d,d,d);  
XI = [x0(:) y0(:) z0(:)];  
YI = griddatan(X,Y,XI);
```

Since it is difficult to visualize 4-D data sets, use `isosurface` at 0.8:

```
YI = reshape(YI, size(x0));  
p = patch(isosurface(x0,y0,z0,YI,0.8));  
isonormals(x0,y0,z0,YI,p);  
set(p,'FaceColor','blue','EdgeColor','none');  
view(3), axis equal, axis off, camlight, lighting phong
```

## See Also

[delaunayn](#) | [griddata](#) | [meshgrid](#)

**Purpose** Gridded data interpolation

---

**Note** The behavior of `griddedInterpolant` has changed. All interpolation methods now support extrapolation by default. Set `F.ExtrapolationMethod` to 'none' to preserve the pre-R2013a behavior when `F.Method` is 'linear', 'cubic' or 'nearest'. Before R2013a, evaluation returned NaN values at query points outside the domain when `F.Method` was set to 'linear', 'cubic' or 'nearest'.

---

## Description

Use `griddedInterpolant` to perform interpolation on a 1-D, 2-D, 3-D, or N-D “Gridded Data” on page 1-2356 set. For example, you can pass a set of  $(x, y)$  points and values,  $v$ , to `griddedInterpolant`, and it returns a surface of the form  $v = F(x, y)$ . This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point,  $(xq, yq)$ , to produce an interpolated value,  $vq$ .

Use `griddedInterpolant` to create the “Interpolant” on page 1-2356, `F`. Then you can evaluate `F` at specific points using any of the following syntaxes:

- $Vq = F(Xq)$  evaluates `F` at a set of query points in matrix `Xq`. The points in `Xq` are scattered, and each row of `Xq` contains the coordinates of a query point.
- $Vq = F(xq1, xq2, \dots, xqn)$  specifies the query locations,  $xq1, xq2, \dots, xqn$ , as column vectors of length  $m$  representing  $m$  points scattered in  $n$ -dimensional space.
- $Vq = F(Xq1, Xq2, \dots, Xqn)$  specifies the query locations as  $n$   $n$ -dimensional arrays,  $Xq1, Xq2, \dots, Xqn$ , of equal size which define a “Full Grid” on page 1-2356 of points.
- $Vq = F(\{xgq1, xgq2, \dots, xgqn\})$  specifies the query locations as “Grid Vectors” on page 1-2356. Use this syntax to conserve memory when you want to query a large grid of points.

# griddedInterpolant

---

## Construction

`F = griddedInterpolant(x,v)` creates a 1-D interpolant from a vector of sample points, `x`, and corresponding values, `v`.

`F = griddedInterpolant(X1,X2,...,Xn,V)` creates a 2-D, 3-D, or N-D interpolant using a “Full Grid” on page 1-2356 of sample points passed as a set of `n`-dimensional arrays, `X1,X2,...,Xn`. The `V` array contains the sample values associated with the point locations in `X1,X2,...,Xn`. Each of the arrays, `X1,X2,...,Xn` must be the same size as `V`.

`F = griddedInterpolant(V)` uses the default grid to create the interpolant. When you use this syntax, `griddedInterpolant` defines the grid as set of points whose spacing is 1 and range is `[1, size(V,i)]` in the `i`th dimension. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`F = griddedInterpolant({xg1,xg2,...,xgn},V)` specifies `n` “Grid Vectors” on page 1-2356 to describe an `n`-dimensional grid of sample points. Use this syntax when you want to use a specific grid and also conserve memory.

`F = griddedInterpolant( __,Method)` specifies any of five strings that describe an interpolation method: 'linear', 'nearest', 'pchip', 'cubic', or 'spline'. You can specify `Method` as the last input argument in any of the first four syntaxes.

`F = griddedInterpolant( __,Method,ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `griddedInterpolant` uses `ExtrapolationMethod` to estimate the value when your query points fall outside the domain of your sample points. Specify `Method` and `ExtrapolationMethod` together as the last two input arguments in any of the first four syntaxes.

## Input Arguments

**x**

Sample points vector, specified as a vector of input coordinates the same size as `v`.

**v**

Sample values vector, specified as a vector of input values the same size as  $x$ .

## **$X_1, X_2, \dots, X_n$**

Sample points in “Full Grid” on page 1-2356 form, specified as a set of  $n$ -dimensional arrays. You can create the arrays,  $X_1, X_2, \dots, X_n$ , using the `ndgrid` function. These arrays are all the same size, and each one is the same size as  $V$ .

## **$\{xg_1, xg_2, \dots, xg_n\}$**

Sample points in grid vector form, specified as a cell array of grid vectors. These vectors must specify a grid that is the same size as  $V$ . In other words, `size(V) = [length(xg1) length(xg2) ... length(xgn)]`. Use this form as an alternative to the full grid to save memory when your grid is very large.

## **$V$**

Sample values, specified as an array. The elements of  $V$  are the values that correspond to the sample points. The size of  $V$  must be the size of the full grid of sample points.

- If you specify the sample points as a full grid consisting of  $N$ -D arrays, then  $V$  must be the same size as any one of:  $X_1, X_2, \dots, X_n$ .
- If you specify the sample points as grid vectors, then `size(V) = [length(xg1) length(xg2) ... length(xgn)]`.

## **Method**

Interpolation method, specified as a string from the table below.

# griddedInterpolant

(Continued)

Method	Description	Continuity	Comments
'linear' (default)	The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension.	$C^0$	<ul style="list-style-type: none"><li>• Requires at least 2 grid points in each dimension.</li><li>• Requires more memory than 'nearest'.</li></ul>
'nearest'	The interpolated value at a query point is the value at the nearest sample grid point.	Discontinuous	<ul style="list-style-type: none"><li>• Requires 2 grid points in each dimension.</li><li>• Fastest computation with modest memory requirements</li></ul>
'pchip'	Shape-preserving piecewise cubic interpolation (for 1-D only). The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points.	$C^1$	<ul style="list-style-type: none"><li>• Requires at least 4 points.</li><li>• Requires more memory and computation time than 'linear'.</li></ul>
'cubic'	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The	$C^1$	<ul style="list-style-type: none"><li>• Grid must have uniform spacing, though the spacing in each dimension does not have to be the same.</li></ul>

(Continued)

Method	Description	Continuity	Comments
	interpolation is based on a cubic convolution.		<ul style="list-style-type: none"> <li>• Requires at least 4 points in each dimension.</li> <li>• Requires more memory and computation time than 'linear'.</li> </ul>
'spline'	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline.	$C^2$	<ul style="list-style-type: none"> <li>• Requires 4 points in each dimension.</li> <li>• Requires more memory and computation time than 'cubic'.</li> </ul>

### ExtrapolationMethod

Extrapolation method, specified as any of the Method choices: 'linear', 'nearest', 'pchip', 'cubic', or 'spline'. In addition, you can specify 'none' if you want queries outside the domain of your grid return NaN values.

If you omit ExtrapolationMethod, the default value is the string you specify for Method. If you omit both the Method and ExtrapolationMethod arguments, both default to 'linear'.

### Properties

#### GridVectors

Cell array containing grid vectors, { $xg_1, xg_2, \dots, xg_n$ }. These vectors specify the grid points (locations) for the values in F.Values.

#### Values

Array of values associated with the grid points in F.GridVectors.

# griddedInterpolant

---

## Method

A string specifying the name of a method used to interpolate the data. Method is one of five strings: 'linear', 'nearest', 'pchip', 'cubic', or 'spline'. The default value is 'linear'.

## ExtrapolationMethod

A string specifying the name of a method used to extrapolate the data. ExtrapolationMethod is one of six strings: 'linear', 'nearest', 'pchip', 'cubic', 'spline', or 'none'. A value of 'none' indicates that extrapolation is disabled. The default value is the value of F.Method.

## Definitions

### Interpolant

Interpolating function that you can evaluate at query locations.

### Gridded Data

A set of points that are axis-aligned and ordered.

### Scattered Data

A set of points that have no structure among their relative locations.

### Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

### Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices X and Y. You can represent the same grid using the grid vectors, xg and yg.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Indexing

Index-based editing of the properties of `F` are not supported. Instead, wholly replace the `GridVectors` or `Values` arrays as necessary. See “Interpolation with the `griddedInterpolant` Class” in the MATLAB Mathematics documentation for more information.

## Examples

### 2-D Interpolation Over Finer Grid

Interpolate coarsely sampled data using a full grid with spacing of 0.5.

Define the sample points as a full grid with range [1, 10] in both dimensions.

```
[X,Y] = ndgrid(1:10,1:10);
```

Sample  $f(x,y) = x^2+y^2$  at the grid points.

```
V = X.^2 + Y.^2;
```

Create the interpolant, specifying cubic interpolation.

```
F = griddedInterpolant(X,Y,V, 'cubic');
```

Define a full grid of query points with 0.5 spacing and evaluate the interpolant at those points. Then plot the result.

```
[Xq,Yq] = ndgrid(1:0.5:10,1:0.5:10);  
Vq = F(Xq,Yq);  
mesh(Xq,Yq,Vq);
```

# griddedInterpolant

---

## 1-D Extrapolation

Compare results of querying the interpolant outside the domain of  $F$  using the 'pchip' and 'nearest' extrapolation methods.

Create the interpolant and specify 'pchip' as the interpolation method.

```
x = [1 2 3 4 5];  
v = [12 16 31 10 6];  
F = griddedInterpolant(x,v,'pchip')
```

```
F =
```

```
griddedInterpolant with properties:
```

```
GridVectors: {[1 2 3 4 5]}  
Values: [12 16 31 10 6]  
Method: 'pchip'
```

ExtrapolationMethod: 'pchip'

Query the interpolant, and include points outside the domain of F.

```
xq = 0:0.1:6;  
vq = F(xq);  
figure  
plot(x,v,'o',xq,vq,'-b');  
legend('v','vq')
```

# griddedInterpolant

Query the interpolant at the same points again, using the nearest neighbor extrapolation method.

```
F.ExtrapolationMethod = 'nearest';  
figure  
vq = F(xq);  
plot(x,v,'o',xq,vq,'-b');
```

legend ('v', 'vq')

## How To

- Class Attributes
- Property Attributes
- “Interpolating Gridded Data”

**Purpose**

Generalized singular value decomposition

**Syntax**

```
[U,V,X,C,S] = gsvd(A,B)
sigma = gsvd(A,B)
```

**Description**

`[U,V,X,C,S] = gsvd(A,B)` returns unitary matrices `U` and `V`, a (usually) square matrix `X`, and nonnegative diagonal matrices `C` and `S` so that

$$\begin{aligned} A &= U * C * X' \\ B &= V * S * X' \\ C' * C + S' * S &= I \end{aligned}$$

`A` and `B` must have the same number of columns, but may have different numbers of rows. If `A` is `m`-by-`p` and `B` is `n`-by-`p`, then `U` is `m`-by-`m`, `V` is `n`-by-`n` and `X` is `p`-by-`q` where `q = min(m+n, p)`.

`sigma = gsvd(A,B)` returns the vector of generalized singular values, `sqrt(diag(C' * C) ./ diag(S' * S))`.

The nonzero elements of `S` are always on its main diagonal. If `m >= p` the nonzero elements of `C` are also on its main diagonal. But if `m < p`, the nonzero diagonal of `C` is `diag(C, p-m)`. This allows the diagonal elements to be ordered so that the generalized singular values are nondecreasing.

`gsvd(A,B,0)`, with three input arguments and either `m` or `n >= p`, produces the “economy-sized” decomposition where the resulting `U` and `V` have at most `p` columns, and `C` and `S` have at most `p` rows. The generalized singular values are `diag(C) ./ diag(S)`.

When `B` is square and nonsingular, the generalized singular values, `gsvd(A,B)`, are equal to the ordinary singular values, `svd(A/B)`, but they are sorted in the opposite order. Their reciprocals are `gsvd(B,A)`.

In this formulation of the `gsvd`, no assumptions are made about the individual ranks of `A` or `B`. The matrix `X` has full rank if and only if the matrix `[A;B]` has full rank. In fact, `svd(X)` and `cond(X)` are equal to `svd([A;B])` and `cond([A;B])`. Other formulations, eg. G. Golub and

C. Van Loan [1], require that  $\text{null}(A)$  and  $\text{null}(B)$  do not overlap and replace  $X$  by  $\text{inv}(X)$  or  $\text{inv}(X')$ .

Note, however, that when  $\text{null}(A)$  and  $\text{null}(B)$  do overlap, the nonzero elements of  $C$  and  $S$  are not uniquely determined.

## Examples

### Example 1

The matrices have at least as many rows as columns.

```
A = reshape(1:15,5,3)
```

```
B = magic(3)
```

```
A =
```

```
    1    6   11
    2    7   12
    3    8   13
    4    9   14
    5   10   15
```

```
B =
```

```
    8    1    6
    3    5    7
    4    9    2
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 5-by-5 orthogonal  $U$ , a 3-by-3 orthogonal  $V$ , a 3-by-3 nonsingular  $X$ ,

```
X =
```

```
    2.8284   -9.3761   -6.9346
   -5.6569   -8.3071  -18.3301
    2.8284   -7.2381  -29.7256
```

and

```
C =
```

```
    0.0000         0         0
```

$$S = \begin{bmatrix} 0 & 0.3155 & 0 \\ 0 & 0 & 0.9807 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1.0000 & 0 & 0 \\ 0 & 0.9489 & 0 \\ 0 & 0 & 0.1957 \end{bmatrix}$$

Since A is rank deficient, the first diagonal element of C is zero.

The economy sized decomposition,

$$[U, V, X, C, S] = \text{gsvd}(A, B, 0)$$

produces a 5-by-3 matrix U and a 3-by-3 matrix C.

$$U = \begin{bmatrix} 0.5700 & -0.6457 & -0.4279 \\ -0.7455 & -0.3296 & -0.4375 \\ -0.1702 & -0.0135 & -0.4470 \\ 0.2966 & 0.3026 & -0.4566 \\ 0.0490 & 0.6187 & -0.4661 \end{bmatrix}$$

$$C = \begin{bmatrix} 0.0000 & 0 & 0 \\ 0 & 0.3155 & 0 \\ 0 & 0 & 0.9807 \end{bmatrix}$$

The other three matrices, V, X, and S are the same as those obtained with the full decomposition.

The generalized singular values are the ratios of the diagonal elements of C and S.

$$\begin{aligned} \text{sigma} &= \text{gsvd}(A, B) \\ \text{sigma} &= \\ &0.0000 \\ &0.3325 \end{aligned}$$

5.0123

These values are a reordering of the ordinary singular values

```
svd(A/B)
ans =
    5.0123
    0.3325
    0.0000
```

## Example 2

The matrices have at least as many columns as rows.

```
A = reshape(1:15,3,5)
B = magic(5)
A =
```

1	4	7	10	13
2	5	8	11	14
3	6	9	12	15

```
B =
```

17	24	1	8	15
23	5	7	14	16
4	6	13	20	22
10	12	19	21	3
11	18	25	2	9

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 3-by-3 orthogonal U, a 5-by-5 orthogonal V, a 5-by-5 nonsingular X and

```
C =
```

```

      0      0      0.0000      0      0
      0      0      0      0.0439      0
      0      0      0      0      0.7432

```

S =

```

      1.0000      0      0      0      0
      0      1.0000      0      0      0
      0      0      1.0000      0      0
      0      0      0      0.9990      0
      0      0      0      0      0.6690

```

In this situation, the nonzero diagonal of C is  $\text{diag}(C,2)$ . The generalized singular values include three zeros.

```

sigma = gsvd(A,B)
sigma =

```

```

      0
      0
      0.0000
      0.0439
      1.1109

```

Reversing the roles of A and B reciprocates these values, producing two infinities.

```

gsvd(B,A)
ans =

```

```

      1.0e+16 *
      0.0000
      0.0000
      8.8252
      Inf
      Inf

```

**Algorithms**

The generalized singular value decomposition uses the C-S decomposition described in [1], as well as the built-in `svd` and `qr` functions. The C-S decomposition is implemented in a local function in the `gsvd` program file.

**Diagnostics**

The only warning or error message produced by `gsvd` itself occurs when the two input arguments do not have the same number of columns.

<b>Purpose</b>	Determine greater than
<b>Syntax</b>	<code>A &gt; B</code> <code>gt(A,B)</code>
<b>Description</b>	<p><code>A &gt; B</code> returns a logical array with elements set to logical 1 (true) where <code>A</code> is greater than <code>B</code>; otherwise, it returns logical 0 (false). The test compares only the real part of numeric arrays. <code>gt</code> returns logical 0 (false) where <code>A</code> or <code>B</code> have NaN or undefined categorical elements.</p> <p><code>gt(A,B)</code> is an alternate way to execute <code>A &gt; B</code>, but is rarely used. It enables operator overloading for classes.</p>
<b>Input Arguments</b>	<p><b>A - Left array</b> numeric array   logical array   character array   ordinal categorical array</p> <p>Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs <code>A</code> and <code>B</code> must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.</p> <p>If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.</p> <p><b>B - Right array</b> numeric array   logical array   character array   ordinal categorical array</p> <p>Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs <code>A</code> and <code>B</code> must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.</p>

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

## Examples

### Test Vector Elements

Determine if vector elements are greater than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are greater than 10.

```
A > 10
```

```
ans =
```

```
0     1     1     0     0     1     0     1
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are greater than 10.

```
A(A > 10)
```

```
ans =
```

```
12    18    11    15
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values greater than 9 with the value 10.

```
A(A > 9) = 10
```

```
A =
```

```
    10     2     3    10
     5    10    10     8
     9     7     6    10
     4    10    10     1
```

The result is a new matrix whose largest element is 10.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
 'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
    large    medium    small
    medium    small    large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values greater than the category 'medium'.

```
A > 'medium'
```

```
ans =
```

```
     1     0     0
     0     0     1
```

A value of logical 1 (true) indicates a value greater than the category 'medium'.

Compare the rows of A.

```
A(1,:) > A(2,:)
```

```
ans =
```

```
     1     1     0
```

The function returns logical 1 (true) where the first row has a category value greater than the second row.

### **Test Complex Numbers**

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are greater than 2.

```
A(A > 2)
```

```
ans =
```

```
5.0000 - 1.0000i
```

gt compares only the real part of the elements in A.

Use abs to find which elements are outside a radius of 2 from the origin.

```
A(abs(A) > 2)
```

```
ans =
```

```
2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i 5.0000 - 1.0000i
```

The result has more elements since `abs` accounts for the imaginary part of the numbers.

# gtext

---

## Purpose

Mouse placement of text in 2-D view

## Syntax

```
gtext('string')
gtext({'string1','string2','string3',...})
gtext({'string1';'string2';'string3';...})
gtext(...,'PropertyName',PropertyValue,...)
h = gtext(...)
```

## Description

`gtext` displays a text string in the current figure window after you select a location with the mouse.

`gtext('string')` waits for you to press a mouse button or keyboard key while the pointer is within a figure window. Pressing a mouse button or any key places *string* on the plot at the selected location.

`gtext({'string1','string2','string3',...})` places all strings with one click, each on a separate line.

`gtext({'string1';'string2';'string3';...})` places one string per click, in the sequence specified.

`gtext(...,'PropertyName',PropertyValue,...)` sets the values of the specified text properties. For a list of properties, see [Text Properties](#).

`h = gtext(...)` returns the handle to a text graphics object that is placed on the plot at the location you select.

## Tips

As you move the pointer into a figure window, the pointer becomes crosshairs to indicate that `gtext` is waiting for you to select a location. `gtext` uses the functions `ginput` and `text`.

## Examples

Place a label on the current plot:

```
gtext('Note this divergence!')
```

## See Also

**Purpose** Store or retrieve GUI data

**Syntax** `guidata(object_handle,data)`  
`data = guidata(object_handle)`

**Description** `guidata(object_handle,data)` stores the variable `data` as GUI data. If `object_handle` is not a figure handle, then the object's parent figure is used. `data` can be any MATLAB variable, but is typically a structure, which enables you to add new fields as required.

`guidata` can manage only one variable at any time. Subsequent calls to `guidata(object_handle,data)` overwrite the previously created version of GUI data.

---

### **GUIDE Uses guidata**

GUIDE uses `guidata` to store and maintain the `handles` structure. In a GUIDE GUI code file, do not overwrite the `handles` structure or your GUI will no longer work. If you need to store data other than handles for your GUI, you can add new fields to the `handles` structure and safely place your data there. See GUI Data in the MATLAB documentation.

---

`data = guidata(object_handle)` returns previously stored data, or an empty matrix if nothing is stored.

To change the data managed by `guidata`:

- 1** Get a copy of the data with the command `data = guidata(object_handle)`.
- 2** Make the desired changes to `data`.
- 3** Save the changed version of `data` with the command `guidata(object_handle,data)`.

`guidata` provides application developers with a convenient interface to a figure's application data:

- You do not need to create and maintain a hard-coded property name for the application data throughout your source code.
- You can access the data from within a local function callback routine using the component's handle (which is returned by `gcb0`), without needing to find the figure's handle.

If you are not using GUIDE, `guidata` is particularly useful in conjunction with `guihandles`, which creates a structure containing the handles of all the components in a GUI.

## Examples

This example calls `guidata` to save a structure containing a GUI figure's application data from within the initialization section of the application code file. The first section shows how to do this within a GUI you create manually. The second section shows how the code differs when you use GUIDE to create a template code file. GUIDE provides a `handles` structure as an argument to all local function callbacks, so you do not need to call `guidata` to obtain it. You do, however, need to call `guidata` to save changes you make to the structure.

### Using guidata in a Programmed GUI

Calling the `guihandles` function creates the structure into which your code places additional data. It contains all handles used by the figure at the time it is called, generating field names based on each object's `Tag` property.

```
% Create figure to use as GUI in your main function or a local function
figure_handle = figure('Toolbar','none');
% create structure of handles
myhandles = guihandles(figure_handle);
% Add some additional data as a new field called numberOfErrors
myhandles.numberOfErrors = 0;
% Save the structure
guidata(figure_handle,myhandles)
```

You can recall the data from within a local callback function, modify it, and then replace the structure in the figure:

```
function My_Callback()
% ...
% Get the structure using guidata in the local function
myhandles = guidata(gcbo);
% Modify the value of your counter
myhandles.numberOfErrors = myhandles.numberOfErrors + 1;
% Save the change you made to the structure
guidata(gcbo,myhandles)
```

## Using guidata in a GUIDE GUI

If you use GUIDE, you do not need to call `guihandles` to create a structure, because GUIDE generates a `handles` structure that contains the GUI's handles. You can add your own data to it, for example from within the `OpeningFcn` template that GUIDE creates:

```
% --- Executes just before simple_gui_tab is made visible.
function my_GUIDE_GUI_OpeningFcn(hObject, eventdata, handles, varargin)
% This function has no output args, see OutputFcn.
% hObject    handle to figure
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
% varargin   command line arguments to simple_gui_tab (see VARARGIN)
% ...

% add some additional data as a new field called numberOfErrors
handles.numberOfErrors = 0;
% Save the change you made to the structure
guidata(hObject,handles)
```

Notice that you use the input argument `hObject` in place of `gcbo` to refer to the object whose callback is executing.

Suppose you needed to access the `numberOfErrors` field in a push button callback. Your callback code now looks something like this:

# guidata

---

```
% --- Executes on button press in pushbutton1.
function my_GUIDE_GUI_pushbutton1_Callback(hObject, eventdata, handles)
% hObject    handle to pushbutton1 (see GCBO)
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
% ...

% No need to call guidata to obtain a structure;
% it is provided by GUIDE via the handles argument
handles.numberOfErrors = handles.numberOfErrors + 1;
% save the changes to the structure
guidata(hObject,handles)
```

# guihandles

---

**Purpose** Create structure of handles

**Syntax** `handles = guihandles(object_handle)`  
`handles = guihandles`

**Description** `handles = guihandles(object_handle)` returns a structure containing the handles of the objects in a figure, using the value of their Tag properties as the field names, with the following caveats:

- Objects are excluded if their Tag properties are empty, or are not legal variable names.
- If several objects have the same Tag, that field in the structure contains a vector of handles.
- Objects with hidden handles are included in the structure.

`handles = guihandles` returns a structure of handles for the current figure.

<b>Purpose</b>	Uncompress GNU zip files
<b>Syntax</b>	<pre>gunzip(files) gunzip(files,outputdir) gunzip(url, ...) filenames = gunzip(...)</pre>
<b>Description</b>	<p><code>gunzip(files)</code> uncompresses GNU zip files from the list of files specified in <code>files</code>. Directories recursively <code>gunzip</code> all of their content. The output files have the same name, excluding the extension <code>.gz</code>, and are written to the same directory as the input files.</p> <p><code>files</code> is a string or cell array of strings containing a list of files or directories. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.</p> <p>Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with <code>~/</code> or <code>~username/</code>, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character <code>*</code> can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.</p> <p><code>gunzip(files,outputdir)</code> writes the gunzipped file into the directory <code>outputdir</code>. If <code>outputdir</code> does not exist, MATLAB creates it.</p> <p><code>gunzip(url, ...)</code> extracts the GNU zip contents from an Internet universal resource locator (URL). The URL must include the protocol type (for example, <code>'http://'</code>). MATLAB downloads the URL to the temp directory, and then deletes it.</p> <p><code>filenames = gunzip(...)</code> gunzips the files and returns the relative path names of the gunzipped files in the string cell array <code>filenames</code>.</p>
<b>Examples</b>	<p>To <code>gunzip</code> all <code>.gz</code> files in the current directory, type:</p> <pre>gunzip('*.*gz');</pre>

# gunzip

---

To `gunzip` Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`, type:

```
url = 'http://www.mathworks.com/moler/ncm.tar.gz';  
gunzip(url, 'ncm')  
untar('ncm/ncm.tar', 'ncm')
```

# h5create

---

**Purpose** Create HDF5 data set

**Syntax** `h5create(filename,datasetname,size,Name,Value)`

**Description** `h5create(filename,datasetname,size,Name,Value)` creates an HDF5 data set in the file specified by `filename`.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file. If `filename` does not already exist, `h5create` creates it, with additional options specified by one or more `Name,Value` pair arguments.

### **datasetname**

Text string specifying the name of the data set you want to create. If `datasetname` is a full path name, `h5create` creates all intermediate groups, if they don't already exist.

### **size**

Array specifying the extents of the dataset. To specify an unlimited extent, set the corresponding element of `size` to `Inf`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **Datatype**

Any of the following MATLAB datatypes.

double	uint64	uint32	uint16	uint8
single	int64	int32	int16	int8

**Default:** double

## **ChunkSize**

Defines chunking layout.

**Default:** Not chunked

## **Deflate**

Defines gzip compression level (0-9).

**Default:** 0

## **FillValue**

Defines the fill value for numeric data sets.

## **Fletcher32**

Turns on the Fletcher32 checksum filter.

**Default:** false

## **Shuffle**

Turns on the Shuffle filter.

**Default:** false

## **Examples**

Create a fixed-size 100-by-200 data set.

```
h5create('myfile.h5', '/myDataset1', [100 200]);  
h5disp('myfile.h5');
```

---

Create a single-precision 1000-by-2000 data set with a chunk size of 50-by-80. Apply the highest level of compression.

# h5create

---

```
h5create('myfile.h5', '/myDataset2', [1000 2000], 'Datatype', 'single', ...  
        'ChunkSize', [50 80], 'Deflate', 9);  
h5disp('myfile.h5');
```

---

Create a two-dimensional data set that is unlimited along the second extent.

```
h5create('myfile.h5', '/myDataset3', [200 Inf], 'ChunkSize', [20 20]);  
h5disp('myfile.h5');
```

## See Also

## Tutorials

- “Exporting to Hierarchical Data Format (HDF5) Files”

**Purpose** Display contents of HDF5 file

**Syntax**  
h5disp(filename)  
h5disp(filename,location)  
h5disp(filename,location,mode)

**Description**  
h5disp(filename) displays the structure (metadata) of the entire HDF5 file, filename.  
h5disp(filename,location) displays the metadata for the specified location.  
h5disp(filename,location,mode) displays the file metadata according to the value of mode.

## Input Arguments

### filename

Text string specifying the name of an HDF5 file.

### location

Text string specifying the full path to a location in an HDF5 file. To display the metadata for the entire file, specify '/' as the value of location. If location is a group, h5disp displays all objects below the group.

### mode

Either of the following text strings.

Value	Description
min	Minimal, display only group and data set names.
simple	Display data set metadata and attribute values, if the attribute is an integer, floating point, or a scalar string.

**Default:** simple

# h5disp

---

## Examples

Display the entire contents of an HDF5 file.

```
h5disp('example.h5')
```

---

Display metadata for one data set in an HDF5 file.

```
h5disp('example.h5', '/g4/world');
```

## See Also

`h5info`

## Tutorials

- “Using the High-Level HDF5 Functions to Import Data”

**Purpose**

Return information about HDF5 file

**Syntax**

```
info = h5info(filename)
info = h5info(filename,location)
```

**Description**

`info = h5info(filename)` returns information about the entire HDF5 file, specified by `filename`.

`info = h5info(filename,location)` returns information about the group, data set, or named datatype specified by `location` in the HDF5 file, `filename`.

**Input Arguments****filename**

Text string specifying the name of an HDF5 file.

**location**

Text string specifying the location of a group, data set, or named datatype in an HDF5 file.

**Output Arguments****info**

A structure containing information about the HDF5 file. The set of fields in the structure depends on the `location` parameter. The first field is always 'Filename'. Other fields that might be present in the `info` structure are as follows.

Location Type	Field	Description
Files and Groups		
	Name	Text string specifying name of the group. If you specify only a file name, this value is '/ '.

Location Type	Field	Description
	Groups	Array of structures describing subgroups.
	Datasets	Array of structures describing data sets.
	Datatypes	Array of structures describing named datatypes.
	Links	Array of structures describing soft, external, user-defined, and certain hard links.
	Attributes	Array of structures describing group attributes.
Data sets		
	Name	Text string specifying the name of the data set.
	Datatype	Structure describing the datatype.
	Dataspace	Structure describing the size of the dataset.
	ChunkSize	Extents of the data set's chunk size, if defined.
	FillValue	Data set's fill value, if defined.
	Filter	Array of structures describing any defined filters such as compression.
	Attributes	Array of structures describing data set attributes.
Named Datatypes		

Location Type	Field	Description
	Name	Text string specifying the name of the datatype object.
	Class	HDF5 class of the named datatype.
	Type	Text string or struct further describing the datatype.
	Size	Size of the named datatype in bytes.

## Examples

Return all information.

```
info = h5info('example.h5');
```

---

Return information about a group and all data sets contained within the group.

```
info = h5info('example.h5', '/g4');
```

---

Return information about a specific dataset.

```
info = h5info('example.h5', '/g4/time');
```

- “Using the High-Level HDF5 Functions to Import Data”

# h5read

---

**Purpose** Read data from HDF5 data set

**Syntax**

```
data = h5read(filename,datasetname)
data = h5read(filename,datasetname,start,count)
data = h5read(filename,datasetname,start,count,stride)
```

**Description** `data = h5read(filename,datasetname)` retrieves all of the data from the HDF5 data set `datasetname` in the file `filename`.

`data = h5read(filename,datasetname,start,count)` reads a subset of data from the data set `datasetname`. `start` is the one-based index of the first element to be read. `count` defines how many elements to read along each dimension. If a particular element of `count` is `Inf`, `h5read` reads data until the end of the corresponding dimension.

`data = h5read(filename,datasetname,start,count,stride)` reads a subset of data, where `stride` specifies the interelement spacing along each data set extent.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **datasetname**

Text string specifying the name of a data set in an HDF5 file.

### **start**

Numeric index value specifying the place to start reading data in the dataset in an HDF5 file. Indices are 1-based.

### **count**

Numeric value specifying the amount of data to read.

### **stride**

Numeric value specifying the interval spacing during the read operation. For example, a spacing of 2 indicates reading every other value.

## Output Arguments

### **data**

Data read from the data set.

## Examples

Read an entire data set.

```
h5disp('example.h5','/g4/lat');  
data = h5read('example.h5','/g4/lat');
```

---

Read the first 5-by-3 subset of a data set.

```
h5disp('example.h5','/g4/world');  
data = h5read('example.h5','/g4/world',[1 1],[5 3]);
```

---

Read a data set of references to other data sets.

```
h5disp('example.h5','/g3/reference');  
data = h5read('example.h5','/g3/reference');
```

- “Using the High-Level HDF5 Functions to Import Data”

# h5readatt

---

<b>Purpose</b>	Read attribute from HDF5 file
<b>Syntax</b>	<code>attval = h5readatt(filename,location,attr)</code>
<b>Description</b>	<code>attval = h5readatt(filename,location,attr)</code> retrieves the value for the named attribute <code>attr</code> from the given location in the HDF5 file <code>filename</code> .
<b>Input Arguments</b>	<b>filename</b> Text string specifying the name of an HDF5 file.
	<b>location</b> Text string specifying the full path of the attribute in an HDF5 file. <code>location</code> can refer to either a group or a data set.
	<b>attr</b> Text string specifying the name of an attribute in an HDF5 file.
<b>Output Arguments</b>	<b>attval</b> Value of the attribute.
<b>Examples</b>	Read a group attribute.  <code>attval = h5readatt('example.h5','/', 'attr2');</code>
	Read a data set attribute.  <code>attval = h5readatt('example.h5','/g4/lon', 'units');</code>
<b>See Also</b>	<code>h5writeatt</code>   <code>h5info</code>
<b>Tutorials</b>	<ul style="list-style-type: none"><li>• “Using the High-Level HDF5 Functions to Import Data”</li></ul>

**Purpose**

Write to HDF5 data set

**Syntax**

```
h5write(filename,datasetname,data)
h5write(filename,datasetname,data,start,count)
h5write(filename,datasetname,data,start,count,stride)
```

**Description**

`h5write(filename,datasetname,data)` writes data to an entire data set, `datasetname`, in the HDF5 file, `filename`.

`h5write(filename,datasetname,data,start,count)` writes a subset of the data to a data set, `datasetname`, in the HDF5 file, `filename`. `start` is a one-based index value that specifies the first element to be written. `count` specifies the number of elements to write along each dimension. `h5write` extends an extendable data set along any unlimited dimensions, if necessary.

`h5write(filename,datasetname,data,start,count,stride)` writes a hyperslab of data, where `stride` specifies the inter-element spacing along each dimension.

**Input Arguments****filename**

Text string specifying the name of an HDF5 file.

**datasetname**

Text string specifying the name of a data set in the HDF5 file.

**data**

Data to be written to the HDF5 file. You can specify only floating-point and integer data sets.

**start**

Numeric index value specifying where in the data set to start writing to the file.

**count**

# h5write

---

Numeric value specifying how much data to write to the file.

## **stride**

Numeric value specifying the interelement spacing of data to write to the file.

**Default:** Vector of ones.

## **Definitions**

### **Hyperslab**

A hyperslab is a collection of points in a data space. The points can be contiguous or form a regular pattern of points or blocks in a data space.

## **Examples**

Write to an entire data set.

```
h5create('myfile.h5','/DS1',[10 20]);
mydata = rand(10,20);
h5write('myfile.h5','/DS1', mydata);
```

---

Write a hyperslab of data to the last 5-by-7 block of a data set.

```
h5create('myfile.h5','/DS2',[10 20]);
mydata = rand(5,7);
h5write('myfile.h5','/DS2',mydata,[6 14],[5 7]);
```

---

Append data to an unlimited data set.

```
h5create('myfile.h5','/DS3',[20 Inf],'ChunkSize',[5 5]);
for j = 1:10
    data = j*ones(20,1);
    start = [1 j];
    count = [20 1];
    h5write('myfile.h5','/DS3',data,start,count);
end
```

```
h5disp('myfile.h5');
```

- `h5write` supports only floating point and integer data sets. To write to string data sets, you must use the `H5D` package.

## Tutorials

- “Exporting to Hierarchical Data Format (HDF5) Files”

# h5writeatt

---

**Purpose** Write HDF5 attribute

**Syntax** `h5writeatt(filename,location,attname,attvalue)`

**Description** `h5writeatt(filename,location,attname,attvalue)` writes the attribute named `attname` with the value `attvalue` to the HDF5 file `filename`. The parent object `location` can be either a group or variable. `location` is the complete path name of the group or variable to which you want to associate the attribute.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **location**

Text string specifying the full path identifying a group or variable in an HDF5 file.

### **attname**

Text string specifying the name of an attribute in an HDF5 file. If the attribute does not exist, `h5writeatt` creates the attribute with the name specified.

If the specified attribute already exists but does not have a datatype or dataspace consistent with `attvalue`, `h5writeatt` deletes the attribute and recreates it. String attributes are created with a scalar dataspace.

### **attvalue**

Value to be written to the attribute in an HDF5 file.

## Examples

Create a root group attribute whose value is the current time.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
h5writeatt('myfile.h5','/', 'creation_date',datestr(now));
```

Create a double-precision data set attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
attData = [0 1 2 3];
h5writeatt('myfile.h5','/g4/world','attr',attData);
h5disp('myfile.h5','/g4/world');
```

# H5.close

---

**Purpose** Close HDF5 library

**Syntax** `H5.close()`

**Description** `H5.close()` closes the HDF5 library.

**See Also** `H5.open`

**Purpose** Free unused memory in HDF5 library

**Syntax** H5.garbage\_collect()

**Description** H5.garbage\_collect() frees unused memory in the HDF5 library.

# H5.get\_libversion

---

**Purpose** Version of HDF5 library

**Syntax** [majnum,minnum,relnum] = H5.get\_libversion()

**Description** [majnum,minnum,relnum] = H5.get\_libversion() returns the version of the HDF5 library in use.

**Purpose** Open HDF5 library

**Syntax** `H5.open()`

**Description** `H5.open()` opens the HDF5 library.

**See Also** `H5.close`

## H5.set\_free\_list\_limits

---

**Purpose** Set size limits on free lists

**Syntax** `H5.set_free_list_limits(reg_global_lim,reg_list_lim,  
arr_global_lim,arr_list_lim,blk_global_lim,blk_list_lim)`

**Description** `H5.set_free_list_limits(reg_global_lim,reg_list_lim,  
arr_global_lim,arr_list_lim,blk_global_lim,blk_list_lim)` sets  
size limits on all types of free lists.

**Purpose** Close specified attribute

**Syntax** `H5A.close(attr_id)`

**Description** `H5A.close(attr_id)` terminates access to the attribute specified by `attr_id`, releasing the identifier.

**See Also** `H5A.open`

# H5A.create

---

## Purpose

Create attribute

## Syntax

```
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id,
    aapl_id)
```

## Description

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)` creates the attribute name that is attached to the object specified by `loc_id`. `loc_id` is a group, dataset, or named datatype identifier. The datatype and dataspace identifiers of the attribute, `type_id` and `space_id`, respectively, are created with the `H5T` and `H5S` interfaces. The attribute property list, `acpl_id`, is currently unused and should be set to `'H5P_DEFAULT'`. This interface corresponds to the 1.6.x version of `H5Acreate`.

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id, aapl_id)` creates the attribute with the additional attribute access property list identifier `aapl_id`. `aapl_id` should currently be set to `'H5P_DEFAULT'`. This interface corresponds to the 1.8.x version of `H5Acreate`.

## Examples

```
acpl_id = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl_id);
H5A.close(attr_id);
H5F.close(fid);
```

## See Also

`H5A.close` | `H5P.create`

**Purpose** Delete attribute

**Syntax** H5A.delete(loc\_id,name)

**Description** H5A.delete(loc\_id,name) removes the attribute specified by name from the dataset, group, or named datatype specified by loc\_id.

**Examples** Delete a root group attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
gid = H5G.open(fid,'/');
H5A.delete(gid,'attr1');
H5G.close(gid);
H5F.close(fid);
```

# H5A.get\_info

---

**Purpose** Information about attribute

**Syntax** `info = H5A.get_info(attr_id)`

**Description** `info = H5A.get_info(attr_id)` returns information about an attribute specified by `attr_id`.

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
attr_id = H5A.open(gid, 'attr1');
info = H5A.get_info(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

**See Also** `H5A.open`

**Purpose** Attribute name

**Syntax** `attr_name = H5A.get_name(attr_id)`

**Description** `attr_name = H5A.get_name(attr_id)` returns the name of the attribute specified by `attr_id`.

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g1/g1.1');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
attr_id = H5A.open_by_idx(gid, 'dset1.1.1', idx_type, order, 0);
name = H5A.get_name(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

**See Also** `H5A.open_by_idx`

# H5A.get\_space

---

**Purpose** Copy of attribute data space

**Syntax** `dspace_id = H5A.get_space(attr_id)`

**Description** `dspace_id = H5A.get_space(attr_id)` returns a copy of the data space for the attribute specified by `attr_id`.

**Examples** Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
attr_id = H5A.open(fid, 'attr2');
space = H5A.get_space(attr_id);
[~, dims] = H5S.get_simple_extent_dims(space);
H5A.close(attr_id);
H5F.close(fid);
```

**See Also** `H5A.open` | `H5S.close`

<b>Purpose</b>	Copy of attribute data type
<b>Syntax</b>	<code>type_id = H5A.get_type(attr_id)</code>
<b>Description</b>	<code>type_id = H5A.get_type(attr_id)</code> returns a copy of the data type for the attribute specified by <code>attr_id</code> .
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); gid = H5G.open(fid, '/'); attr_id = H5A.open(gid, 'attr1'); type_id = H5A.get_type(attr_id); H5T.close(type_id); H5A.close(attr_id); H5G.close(gid); H5F.close(fid);</pre>
<b>See Also</b>	<code>H5A.open</code>   <code>H5T.close</code>

# H5A.iterate

---

**Purpose** Execute function for attributes attached to object

**Syntax** `[status,idx_stop,cdata_out] = H5A.iterate(obj_id,idx_type,  
order,idx_start,iter_func,cdata_in)  
H5A.iterate(loc_id,attr_idx,iterator_func)`

**Description** `[status,idx_stop,cdata_out] = H5A.iterate(obj_id,idx_type,  
order,idx_start,iter_func,cdata_in)` executes the specified  
function `iter_func` for each attribute connected to an object. `obj_id`  
identifies the object to which attributes are attached. `idx_type` is the  
type of index and valid values include the following.

'H5\_INDEX\_NAME' An alpha-numeric index by  
attribute name

'H5\_INDEX\_CRT\_ORDER' An index by creation order

`order` specifies the index traversal order. Valid values include the  
following.

'H5\_ITER\_INC' Iteration from beginning to end

'H5\_ITER\_DEC' Iteration from end to beginning

'H5\_ITER\_NATIVE' Iteration in the fastest available  
order

`idx_start` specifies the starting point of the iteration. `idx_stop`  
returns the point at which iteration was stopped. This allows an  
interrupted iteration to be resumed.

The callback function, `iter_func`, must have the following signature:

```
[status,cdata_out] =  
iter_func(obj_id,attr_name,info,cdata_in)
```

`cdata_in` is a user-defined value or structure and is passed to the  
first step of the iteration in the `iter_func cdata_in` parameter. The  
`cdata_out` of an iteration step forms the `cdata_in` for the next iteration  
step. Then, the final `cdata_out` at the end of the iteration is returned

to the caller as `cdata_out`. This form of `H5A.iterate` corresponds to the `H5Aiterate2` function in the HDF5 C API.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

`H5A.iterate(loc_id, attr_idx, iterator_func)` executes the specified function for each attribute of the group, dataset, or named datatype specified by `loc_id`. The `attr_idx` argument specifies where the iteration begins. `iterator_func` must be a function handle.

The iterator function must have the following signature:

```
status = iterator_func(loc_id, attr_name)
```

`loc_id` still specifies the group, dataset, or named data type passed into `H5A.iterate`, and `attr_name` specifies the current attribute. This form of `H5A.iterate` corresponds to `H5Aiterate1` function in the HDF5 C API.

# H5A.open

---

**Purpose** Open attribute

**Syntax**  
`attr_id = H5A.open(obj_id,attr_name)`  
`attr_id = H5A.open(obj_id,attr_name,aapl_id)`

**Description**  
`attr_id = H5A.open(obj_id,attr_name)` opens an attribute for an object specified by a parent object identifier and attribute name.  
`attr_id = H5A.open(obj_id,attr_name,aapl_id)` opens an attribute with an attribute access property list identifier, `aapl_id`. The only currently valid value for `aapl_id` is 'H5P\_DEFAULT'.

**Examples**

```
fid = H5F.open('example.h5');  
gid = H5G.open(fid,'/');  
attr_id = H5A.open(gid,'attr1');  
H5A.close(attr_id);  
H5G.close(gid);  
H5F.close(fid);
```

**See Also** [H5A.close](#) | [H5A.open\\_by\\_name](#) | [H5A.open\\_by\\_idx](#)

## Purpose

Open attribute specified by index

## Syntax

```
attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n)
attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n,
    aapl_id,lapl_id)
```

## Description

`attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n)` opens an existing attribute at index `n` attached to an object specified by its location, `loc_id`, and name, `obj_name`.

`idx_type` is the type of index and valid values include the following.

'H5_INDEX_NAME'	An alpha-numeric index by attribute name
'H5_INDEX_CRT_ORDER'	An index by creation order

`order` specifies the index traversal order. Valid values include the following.

'H5_ITER_INC'	Iteration from beginning to end
'H5_ITER_DEC'	Iteration from end to beginning
'H5_ITER_NATIVE'	Iteration in the fastest available order

`attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n, aapl_id,lapl_id)` opens an attribute with attribute access property list, `aapl_id`, and link access property list, `lapl_id`. The `aapl_id` argument must currently be specified as 'H5P\_DEFAULT'. Also, `lapl_id` can be specified by 'H5P\_DEFAULT'.

## Examples

Loop through a set of dataset attributes in reverse alphabetical order.

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g1/g1.1');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
info = H5O.get_info(dset_id);
```

## H5A.open\_by\_idx

---

```
for idx = 0:info.num_attrs-1
    attr_id =H5A.open_by_idx(gid,'dset1.1.1','H5_INDEX_NAME','H5_ITER_DEC',
    fprintf('attribute name:  %s\n',H5A.get_name(attr_id));
    H5A.close(attr_id);
end
H5G.close(gid);
H5F.close(fid);
```

### See Also

[H5A.open](#) | [H5A.open\\_by\\_name](#) | [H5A.close](#)

**Purpose**

Open attribute specified by name

**Syntax**

```
attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)
attr_id = H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,
    lapl_id)
```

**Description**

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)` opens an existing attribute `attr_name` attached to an object specified by its location `loc_id` and name `obj_name`.

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,lapl_id)` opens an existing attribute with the attribute access property list `aapl_id` and link access property list `lapl_id`. `aapl_id` must be specified as 'H5P\_DEFAULT'. `lapl_id` may also be specified by 'H5P\_DEFAULT'.

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
attr_id = H5A.open_by_name(gid,'dset1.1.1','attr1');
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

**See Also**

[H5A.close](#) | [H5A.open](#) | [H5A.open\\_by\\_idx](#)

# H5A.read

---

**Purpose** Read attribute

**Syntax**  
`attr = H5A.read(attr_id)`  
`attr = H5A.read(attr_id, mem_type_id)`

**Description** `attr = H5A.read(attr_id)` reads the attribute specified by `attr_id`. MATLAB will determine the appropriate memory datatype.

`attr = H5A.read(attr_id, mem_type_id)` reads the attribute specified by `attr_id`. `mem_type_id` specifies the attribute's memory datatype and should usually be given as `'H5ML_DEFAULT'`, which specifies that MATLAB will determine the appropriate memory datatype.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the HDF5 library reports the attribute size as 3-by-4-by-5, then the corresponding MATLAB array size is 5-by-4-by-3. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
attr_id = H5A.open(gid, 'attr1');
data = H5A.read(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

**See Also** `H5A.open` | `H5A.write`

**Purpose** Write attribute

**Syntax** `H5A.write(attr_id,type_id,buf)`

**Description** `H5A.write(attr_id,type_id,buf)` writes the data in `buf` into the attribute specified by `attr_id`. `type_id` specifies the attribute's memory datatype. The memory datatype should be `'H5ML_DEFAULT'`, which specifies that MATLAB should determine the appropriate memory datatype.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the MATLAB array size is 5-by-4-by-3, then the HDF5 library should be reporting the attribute size as 3-by-4-by-5. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples** Write a scalar double precision attribute.

```
acpl = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl);
H5A.write(attr_id,'H5ML_DEFAULT',10.0)
H5A.close(attr_id);
H5F.close(fid);
H5T.close(type_id);
```

**See Also** `H5A.read`

# H5D.close

---

<b>Purpose</b>	Close dataset
<b>Syntax</b>	<code>H5D.close(dataset_id)</code>
<b>Description</b>	<code>H5D.close(dataset_id)</code> ends access to a dataset specified by <code>dataset_id</code> and releases resources used by it.
<b>See Also</b>	<code>H5D.create</code>   <code>H5D.open</code>

## Purpose

Create new dataset

## Syntax

```
dataset_id = H5D.create(loc_id,name,type_id,space_id,  
    plist_id)  
dataset_id = H5D.create(loc_id,name,type_id,space_id,lcpl_id,  
    dcpl_id,dapl_id)
```

## Description

`dataset_id = H5D.create(loc_id,name,type_id,space_id,plist_id)` creates the data set specified by name in the file or in the group specified by `loc_id`. `type_id` and `space_id` identify the datatype and dataspace, respectively. `plist_id` identifies the dataset creation property list. This interface corresponds to the `H5Dcreate1` function in the HDF5 library C 1.6 API.

`dataset_id = H5D.create(loc_id,name,type_id,space_id,lcpl_id,dcpl_id,dapl_id)` creates the data set with three distinct property lists:

<code>lcpl_id</code>	link creation property list
<code>dcpl_id</code>	dataset creation property list
<code>dapl_id</code>	dataset access property list

This interface corresponds to the `H5Dcreate` function in the HDF5 library C 1.8 API.

## Examples

Create a 10x5 double precision dataset with default property list settings.

```
fid = H5F.create('myfile.h5');  
type_id = H5T.copy('H5T_NATIVE_DOUBLE');  
dims = [10 5];  
h5_dims = fliplr(dims);  
h5_maxdims = h5_dims;  
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);  
dcpl = 'H5P_DEFAULT';
```

## H5D.create

---

```
dset_id = H5D.create(fid, 'DS', type_id, space_id, dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile.h5');
```

---

Create a 6x3 fixed length string dataset. Each string will have a length of 4 characters.

```
fid = H5F.create('myfile_strings.h5');
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id, 4);
dims = [6 3];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2, h5_dims, h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid, 'DS', type_id, space_id, dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile_strings.h5');
```

### See Also

[H5D.close](#) | [H5S.create\\_simple](#) | [H5S.close](#) | [H5T.copy](#)

<b>Purpose</b>	Copy of dataset access property list
<b>Syntax</b>	<code>plist_id = H5D.get_access_plist(dataset_id)</code>
<b>Description</b>	<code>plist_id = H5D.get_access_plist(dataset_id)</code> returns a copy of the dataset access property list used to open the specified dataset.
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1'); dap1 = H5D.get_access_plist(dset_id); H5P.close(dap1); H5D.close(dset_id); H5F.close(fid);</pre>
<b>See Also</b>	<code>H5D.get_create_plist</code>   <code>H5P.close</code>

# H5D.get\_create\_plist

---

**Purpose** Copy of dataset creation property list

**Syntax** `plist_id = H5D.get_create_plist(dataset_id)`

**Description** `plist_id = H5D.get_create_plist(dataset_id)` returns the identifier to a copy of the dataset creation property list for the dataset specified by `dataset_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
dcpl = H5D.get_create_plist(dset_id);
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5D.get_access_plist` | `H5P.close`

**Purpose** Location of dataset in file

**Syntax** `offset = H5D.get_offset(dataset_id)`

**Description** `offset = H5D.get_offset(dataset_id)` returns the location in the file of the dataset specified by `dataset_id`. The location is expressed as an offset, in bytes, from the beginning of the file.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
offset = H5D.get_offset(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

# H5D.get\_space

---

**Purpose** Copy of dataset data space

**Syntax** `dspace_id = H5D.get_space(dataset_id)`

**Description** `dspace_id = H5D.get_space(dataset_id)` returns an identifier for a copy of the data space for a dataset.

**Examples** Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
space = H5D.get_space(dset_id);
[~, dims] = H5S.get_simple_extent_dims(space);
H5S.close(space);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5D.open` | `H5S.close`

**Purpose** Determine if space is allocated

**Syntax** `status = H5D.get_space_status(dataset_id)`

**Description** `status = H5D.get_space_status(dataset_id)` determines whether space has been allocated for the dataset specified by `dataset_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
status = H5D.get_space_status(dset_id);
switch(status)
    case H5ML.get_constant_value('H5D_SPACE_STATUS_NOT_ALLOCATED')
        fprintf('Not allocated.\n');
    case H5ML.get_constant_value('H5D_SPACE_STATUS_ALLOCATED')
        fprintf('Allocated.\n');
    case H5ML.get_constant_value('H5D_SPACE_STATUS_PART_ALLOCATED')
        fprintf('Part allocated.\n');
end
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5D.get_space`

# H5D.get\_storage\_size

---

**Purpose** Determine required storage size

**Syntax** `dataset_size = H5D.get_storage_size(dataset_id)`

**Description** `dataset_size = H5D.get_storage_size(dataset_id)` returns the amount of storage that is required for the dataset specified by `dataset_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
dataset_size = H5D.get_storage_size(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

**Purpose** Copy of datatype

**Syntax** `type_id = H5D.get_type(dataset_id)`

**Description** `type_id = H5D.get_type(dataset_id)` returns an identifier for a copy of the data type for the dataset specified by `dataset_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
type_id = H5D.get_type(dset_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5T.close`

# H5D.open

---

**Purpose** Open specified dataset

**Syntax**

```
dataset_id = H5D.open(loc_id,name)
dataset_id = H5D.open(loc_id,name,dapl_id)
```

**Description** `dataset_id = H5D.open(loc_id,name)` opens the dataset specified by name in the file or group specified by `loc_id`.

`dataset_id = H5D.open(loc_id,name,dapl_id)` opens the dataset specified by name in the file or group specified by `loc_id`. The dataset access property list, `dapl_id`, provides information regarding access to the dataset.

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
dset_id = H5D.open(gid,'dset2.2');
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5D.close`

**Purpose** Read data from HDF5 dataset

**Syntax**

```
data = H5D.read(dataset_id)
data = H5D.read(dataset_id,mem_type_id,mem_space_id,
    file_space_id,dxpl)
```

**Description**

`data = H5D.read(dataset_id)` reads the entire dataset specified by `dataset_id`.

`data = H5D.read(dataset_id,mem_type_id,mem_space_id, file_space_id,dxpl)` reads the dataset specified by `dataset_id`. The `mem_type_id` input specifies the memory data type and should usually be 'H5ML\_DEFAULT' to allow MATLAB to determine the appropriate value. `mem_space_id` describes how the data is to be arranged in memory and should usually be 'H5S\_ALL'. The `file_space_id` input describes how the data is to be selected from the file. It also can be given as 'H5S\_ALL', but this results in the entire dataset being read into memory. `dxpl` is the dataset transfer property list identifier and should usually be 'H5P\_DEFAULT'.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples** Read an entire dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
data = H5D.read(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

---

# H5D.read

---

Read the 2x3 hyperslab starting in the 4th row and 5th column of the example dataset.

```
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
dims = fliplr([2 3]);
mem_space_id = H5S.create_simple(2,dims,[]);
file_space_id = H5D.get_space(dset_id);
offset = fliplr([3 4]);
block = fliplr([2 3]);
H5S.select_hyperslab(file_space_id, 'H5S_SELECT_SET', offset, [], [], block);
data = H5D.read(dset_id, 'H5ML_DEFAULT', mem_space_id, file_space_id, plist);
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

[H5D.open](#) | [H5D.write](#) | [H5S.create\\_simple](#)

<b>Purpose</b>	Change size of dataset dimensions
<b>Syntax</b>	<code>H5D.set_extent(dset_id,h5_extents)</code>
<b>Description</b>	<code>H5D.set_extent(dset_id,h5_extents)</code> changes the dimensions of the dataset <code>dset_id</code> to the sizes specified in <code>h5_extents</code> .

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_extents` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples** Extend an unlimited one-dimensional dataset from a length of 10 to a length of 20.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
dset_id = H5D.open(fid,'/g4/time');
H5D.set_extent(dset_id,20);
H5D.close(dset_id);
H5F.close(fid);
```

# H5D.vlen\_get\_buf\_size

---

**Purpose** Determine variable length storage requirements

**Syntax** `size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)`

**Description** `size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)` determines the number of bytes required to store the VL data from the dataset, using the `space_id` for the selection in the dataset on disk and the `type_id` for the memory representation of the VL data in memory.

**Purpose** Write data to HDF5 dataset

**Syntax** `H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,plist_id,buf)`

**Description** `H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,plist_id,buf)` writes the dataset specified by `dataset_id` from the application memory buffer `buf` into the file. `plist_id` specifies the data transfer properties. `mem_type_id` identifies the memory datatype of the dataset. `mem_space_id` and `file_space_id` define the part of the dataset to write. The memory datatype should usually be 'H5ML\_DEFAULT', which specifies that MATLAB should determine the appropriate memory datatype.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples** Write to the entire 36-by-19 /g4/world example dataset.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g4/world');
dims = [36 19];
data = rand(dims);
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5D.close(dset_id);
H5F.close(fid);
```

---

## H5D.write

---

Write to the entire two-element /g3/VLstring dataset.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
h5disp('myfile.h5','/g3/VLstring');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g3/VLstring');
data = {'dogs'; 'dogs and cats'};
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5D.close(dset_id);
H5F.close(fid);
data_out = h5read('myfile.h5','/g3/VLstring');
```

---

Write a 10-by-5 block of data to the location starting at row index 15 and column index 5 of the same dataset. Recall that indexing is zero-based.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g4/world');
start = [15 5];
h5_start = fliplr(start);
block = [10 5];
h5_block = fliplr(block);
mem_space_id = H5S.create_simple(2,h5_block,[]);
file_space_id = H5D.get_space(dset_id);
H5S.select_hyperslab(file_space_id,'H5S_SELECT_SET',h5_start,[],[],h5_block);
data = rand(block);
H5D.write(dset_id,'H5ML_DEFAULT',mem_space_id,file_space_id,plist,data);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** [H5D.read](#)

# H5DS.attach\_scale

---

<b>Purpose</b>	Attach dimension scale to specific dataset dimension
<b>Syntax</b>	H5DS.attach_scale(dataset_id,dimscale_id,idx)
<b>Description</b>	H5DS.attach_scale(dataset_id,dimscale_id,idx) attaches a dimension scale dimscale_id to dimension idx of the dataset dataset_id.

---

**Note** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

**Examples** Add the 'lon' and 'lat' dimension scales to the 'world' dataset.

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
lat_dset_id = H5D.open(fid,'/g4/lat',plist);
lon_dset_id = H5D.open(fid,'/g4/lon',plist);
H5DS.attach_scale(world_dset_id,lat_dset_id,0);
H5DS.attach_scale(world_dset_id,lon_dset_id,1);
H5D.close(lat_dset_id);
H5D.close(lon_dset_id);
H5D.close(world_dset_id);
H5F.close(fid);
```

**See Also** H5DS.detach\_scale

**Purpose** Detach dimension scale from specific dataset dimension

**Syntax** `H5DS.detach_scale(dataset_id,dimscale_id,idx)`

**Description** `H5DS.detach_scale(dataset_id,dimscale_id,idx)` detaches dimension scale `dimscale_id` from dimension `idx` of the dataset `dataset_id`.

---

**Note** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

**See Also** `H5DS.attach_scale`

# H5DS.get\_label

---

**Purpose** Retrieve label from specific dataset dimension

**Syntax** `label = H5DS.get_label(dataset_id,idx)`

**Description** `label = H5DS.get_label(dataset_id,idx)` retrieves the label for dimension `idx` of the dataset `dataset_id`.

---

**Note** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

**Examples**

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid,'/g4/world');
label = H5DS.get_label(world_dset_id,0);
H5D.close(world_dset_id);
H5F.close(fid);
```

**See Also** `H5DS.set_label`

**Purpose** Number of scales attached to dataset dimension

**Syntax** `num_scales = H5DS.get_num_scales(dataset_id,idx)`

**Description** `num_scales = H5DS.get_num_scales(dataset_id,idx)` determines the number of dimension scales that are attached to dimension `idx` of the dataset `dataset_id`.

**Examples**

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid,'/g4/world');
num_scales = H5DS.get_num_scales(world_dset_id,0);
H5D.close(world_dset_id);
H5F.close(fid);
```

# H5DS.get\_scale\_name

---

**Purpose** Name of dimension scale

**Syntax** `name = H5DS.get_scale_name(dimscale_id)`

**Description** `name = H5DS.get_scale_name(dimscale_id)` retrieves the name of the dimension scale `dimscale_id`.

**Examples**

```
fid = H5F.open('example.h5');
lat_dset_id = H5D.open(fid, '/g4/lat');
scale_name = H5DS.get_scale_name(lat_dset_id);
H5D.close(lat_dset_id);
H5F.close(fid);
```

**See Also** `H5DS.set_scale`

<b>Purpose</b>	Determine if dataset is a dimension scale
<b>Syntax</b>	<code>bool = H5DS.is_scale(dataset_id)</code>
<b>Description</b>	<code>bool = H5DS.is_scale(dataset_id)</code> determines whether the dataset <code>dataset_id</code> is a dimension scale.
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); lat_dset_id = H5D.open(fid, '/g4/lat'); if H5DS.is_scale(lat_dset_id)     fprintf('/g4/lat is a dimension scale.\n'); else     fprintf('/g4/lat is not a dimension scale.\n'); end H5D.close(lat_dset_id); H5F.close(fid);</pre>

# H5DS.iterate\_scales

---

<b>Purpose</b>	Iterate on scales attached to dataset dimension
<b>Syntax</b>	<pre>[status,idx_out,opdata_out] = H5DS.iterate_scales(dset_id,dim,         idx_in,iter_func,opdata_in)</pre>
<b>Description</b>	<p><code>[status,idx_out,opdata_out] = H5DS.iterate_scales(dset_id,dim,idx_in,iter_func,opdata_in)</code> iterates over the scales attached to dimension <code>dim</code> of the dataset <code>dset_id</code> to perform a common operation whose function handle is <code>iter_func</code>.</p> <p><code>idx_in</code> specifies the starting point of the iteration. <code>idx_out</code> returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed. If <code>idx_in</code> is <code>[]</code>, then the iterator starts at the first member.</p> <p>The callback function <code>iter_func</code> must have the following signature:</p> <pre>function [status,opdata_out] = iter_func(dset_id,dim,dimscale_id,opdata_in)</pre> <p><code>opdata_in</code> is a user-defined value or structure and is passed to the first step of the iteration in the <code>iter_func</code> <code>opdata_in</code> parameter. The <code>opdata_out</code> of an iteration step forms the <code>opdata_in</code> for the next iteration step. The final <code>opdata_out</code> at the end of the iteration is then returned to the caller as <code>opdata_out</code>.</p> <p><code>dimscale_id</code> specifies the current dimension scale dataset identifier and <code>dim</code> is the associated dimension.</p> <p><code>status</code> value returned by <code>iter_func</code> is interpreted as follows:</p>

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

# H5DS.set\_label

---

**Purpose** Set label for dataset dimension

**Syntax** H5DS.set\_label(dataset\_id,idx,label)

**Description** H5DS.set\_label(dataset\_id,idx,label) sets a label for dimension idx of the dataset dataset\_id.

---

**Note** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

## Examples

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
H5DS.set_label(world_dset_id,0,'latitude');
H5DS.set_label(world_dset_id,1,'longitude');
H5D.close(world_dset_id);
H5F.close(fid);
```

**See Also** H5DS.get\_label

<b>Purpose</b>	Convert dataset to dimension scale
<b>Syntax</b>	<code>H5DS.set_scale(dataset_id,dim_name)</code>
<b>Description</b>	<code>H5DS.set_scale(dataset_id,dim_name)</code> converts the dataset, <code>dataset_id</code> , to a dimension scale with name <code>dim_name</code> .
<b>Examples</b>	<p>Create a dimension scale with name 'xdim'. The dataset has the name, 'x'.</p> <pre>fid = H5F.create('myfile.h5'); space_id = H5S.create_simple(1,10,10); dtype = 'H5T_NATIVE_INT'; dcpl = 'H5P_DEFAULT'; dset_id = H5D.create(fid,'x',dtype,space_id,dcpl); H5DS.set_scale(dset_id,'xdim'); H5S.close(space_id); H5D.close(dset_id); H5F.close(fid);</pre>
<b>See Also</b>	<code>H5DS.get_scale_name</code>

# H5E.clear

---

**Purpose** Clear error stack

**Syntax** `H5E.clear()`

**Description** `H5E.clear()` clears the error stack for the current thread.

**Purpose** Description of major error number

**Syntax** `err_string = H5E.get_major(major_number)`

**Description** `err_string = H5E.get_major(major_number)` returns a character string describing an error specified by the major error number, `major_number`.

The HDF5 group has deprecated the use of this function.

**See Also** `H5E.get_minor`

# H5E.get\_minor

---

**Purpose** Description of minor error number

**Syntax** `err_string = H5E.get_minor(minor_number)`

**Description** `err_string = H5E.get_minor(minor_number)` returns a character string describing an error specified by the minor error number, `minor_number`.

The HDF5 group has deprecated the use of this function.

**See Also** `H5E.get_major`

**Purpose** Walk error stack

**Syntax** `H5E.walk(direction,func)`

**Description** `H5E.walk(direction,func)` walks the error stack for the current thread and calls the specified function for each error along the way. `func` is a function handle. `direction` specifies how the error stack is traversed and can be given by one of the following strings or the numeric equivalent.

`'H5E_WALK_UPWARD'`

`'H5E_WALK_DOWNWARD'`

The specified function must have the following signature:

`status = func(n,error_struct)`

where `n` is the indexed position of the error in the stack and `error_struct` is a structure with the following fields:

<code>maj_num</code>	Major error number
<code>min_num</code>	Minor error number
<code>func_name</code>	Function in which the error occurred
<code>file_name</code>	File in which the error occurred
<code>line</code>	Line in file where error occurs
<code>desc</code>	Optional supplied description

This function corresponds to the `H5Ewalk1` function in the HDF5 library C API.

**See Also** `H5ML.get_constant_value`

# H5F.close

---

**Purpose** Close HDF5 file

**Syntax** `H5F.close(file_id)`

**Description** `H5F.close(file_id)` terminates access to HDF5 file identified by `file_id`, flushing all data to storage.

**See Also** `H5F.open`

**Purpose** Create HDF5 file

**Syntax**

```
file_id = H5F.create(filename)
file_id = H5F.create(name, flags, fcpl_id, fapl_id)
```

**Description**

`file_id = H5F.create(filename)` creates the file specified by `filename` with default library properties if the file does not already exist.

`file_id = H5F.create(name, flags, fcpl_id, fapl_id)` creates the file specified by `name`. `flags` specifies whether to truncate the file, if it already exists, or to fail if the file already exists. `flags` can be specified by one of the following strings or the numeric equivalent:

'H5F_ACC_TRUNC'	overwrite any existing file by the same name
-----------------	--

'H5F_ACC_EXCL'	do not overwrite an existing file
----------------	-----------------------------------

`fcpl_id` is the file creation property list identifier. `fapl_id` is the file access property list identifier. A value of 'H5P\_DEFAULT' for either property list indicates that the library should use default values for the appropriate property list.

**Examples** Create an HDF5 file called 'myfile.h5'.

```
fid = H5F.create('myfile.h5');
H5F.close(fid);
```

---

Create an HDF5 file called 'myfile.h5', overwriting any existing file by the same name. Default file access and file creation properties shall apply.

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

# H5F.create

---

## See Also

[H5F.close](#) | [H5P.create](#) | [H5ML.get\\_constant\\_value](#)

**Purpose** Flush buffers to disk

**Syntax** `H5F.flush(object_id,scope)`

**Description** `H5F.flush(object_id,scope)` causes all buffers associated with a file to be immediately flushed to disk without removing the data from the cache. `object_id` can be any object associated with the file, including the file itself, a dataset, a group, an attribute, or a named data type. `scope` specifies whether the scope of the flushing action is global or local. `scope` may be one of the following strings:

`'H5F_SCOPE_GLOBAL'`

`'H5F_SCOPE_LOCAL'`

# H5F.get\_access\_plist

---

**Purpose** File access property list

**Syntax** `fapl_id = H5F.get_access_plist(file_id)`

**Description** `fapl_id = H5F.get_access_plist(file_id)` returns the file access property list identifier of the file specified by `file_id`.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5F.get_create_plist`

**Purpose** File creation property list

**Syntax** `fcpl_id = H5F.get_create_plist(file_id)`

**Description** `fcpl_id = H5F.get_create_plist(file_id)` returns a file creation property list identifier identifying the creation properties used to create the file specified by `file_id`.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
H5P.close(fcpl);
H5F.close(fid);
```

**See Also** `H5F.get_access_plist`

# H5F.get\_filesize

---

**Purpose**            Size of HDF5 file

**Syntax**            `size = H5F.get_filesize(file_id)`

**Description**        `size = H5F.get_filesize(file_id)` returns the size of the HDF5 file specified by `file_id`.

**Purpose** Amount of free space in file

**Syntax** `free_space = H5F.get_freespace(file_id)`

**Description** `free_space = H5F.get_freespace(file_id)` returns the amount of space that is unused by any objects in the file specified by `file_id`.

# H5F.get\_info

---

**Purpose** Global information about file

**Syntax** `file_info = H5F.get_info(obj_id)`

**Description** `file_info = H5F.get_info(obj_id)` returns global information for the file associated with the object identifier `obj_id`. For details about the fields of the `file_info` structure, please refer to the HDF5 documentation.

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, 'g2');
info = H5F.get_info(gid);
H5G.close(gid);
H5F.close(fid);
```

**Purpose** Metadata cache configuration

**Syntax** `config_struct = H5F.get_mdc_config(file_id)`

**Description** `config_struct = H5F.get_mdc_config(file_id)` returns the current metadata cache configuration for the target file.

**Examples**

```
fid = H5F.open('example.h5');
config = H5F.get_mdc_config(fid);
H5F.close(fid);
```

**See Also** `H5F.set_mdc_config`

# H5F.get\_mdc\_hit\_rate

---

**Purpose** Metadata cache hit-rate

**Syntax** `hitRate = H5F.get_mdc_hit_rate(file_id)`

**Description** `hitRate = H5F.get_mdc_hit_rate(file_id)` queries the metadata cache of the target file to obtain its hit-rate since the last time hit-rate statistics were reset. If the cache has not been accessed since the last time the hit-rate statistics were reset, the hit-rate is defined to be 0.0. The hit-rate is calculated as

$$(\text{cache hits} / (\text{cache hits} + \text{cache misses}))$$

**Examples**

```
fid = H5F.open('example.h5');
hit_rate = H5F.get_mdc_hit_rate(fid);
H5F.close(fid);
```

**See Also** `H5F.get_mdc_config`

**Purpose** Metadata cache size data

**Syntax**

```
[max_sz,min_clean_sz,cursz,  
num_cur_entries] = H5F.get_mdc_size(fileId)
```

**Description**

```
[max_sz,min_clean_sz,cursz, num_cur_entries] =  
H5F.get_mdc_size(fileId)
```

 queries the metadata cache of the target file to obtain current metadata cache size information.

**Examples**

```
fid = H5F.open('example.h5');  
[maxsz,minsz,cursz,nent] = H5F.get_mdc_size(fid);  
H5F.close(fid);
```

**See Also** `H5F.get_mdc_config`

# H5F.get\_name

---

**Purpose** Name of HDF5 file

**Syntax** `name = H5F.get_name(obj_id)`

**Description** `name = H5F.get_name(obj_id)` returns the name of the file to which the object `obj_id` belongs. The object can be a group, dataset, attribute, or named data type.

**Examples**

```
fid = H5F.open('example.h5');
name = H5F.get_name(fid);
H5F.close(fid);
```

**See Also** [H5A.get\\_name](#) | [H5I.get\\_name](#)

**Purpose** Number of open objects in HDF5 file

**Syntax** `obj_count = H5F.get_obj_count(file_id,types)`

**Description** `obj_count = H5F.get_obj_count(file_id,types)` returns the number of open object identifiers for the file specified by `file_id` for the specified type. `types` can be one of the following strings.

```
'H5F_OBJ_FILE'  
'H5F_OBJ_DATASET'  
'H5F_OBJ_GROUP'  
'H5F_OBJ_DATATYPE'  
'H5F_OBJ_ATTR'  
'H5F_OBJ_ALL'  
'H5F_OBJ_LOCAL'
```

**Examples**

```
fid = H5F.open('example.h5');  
gid = H5G.open(fid, '/g2');  
obj_count = H5F.get_obj_count(fid, 'H5F_OBJ_GROUP');  
H5G.close(gid);  
H5F.close(fid);
```

**See Also** `H5F.get_obj_ids`

# H5F.get\_obj\_ids

---

**Purpose** List of open HDF5 file objects

**Syntax** `[num_obj_ids,obj_id_list] = H5F.get_obj_ids(file_id,types,  
max_objs)`

**Description** `[num_obj_ids,obj_id_list] = H5F.get_obj_ids(file_id,types,  
max_objs)` returns a list of all open identifiers for HDF5 objects of the type specified by `types` in the file specified by `file_id`. The `max_objs` input specifies the maximum number of object identifiers to return. `num_obj_ids` is the total number of objects in the list. `types` can be one of the following strings.

```
'H5F_OBJ_FILE'  
'H5F_OBJ_DATASET'  
'H5F_OBJ_GROUP'  
'H5F_OBJ_DATATYPE'  
'H5F_OBJ_ATTR'  
'H5F_OBJ_ALL'  
'H5F_OBJ_LOCAL'
```

**Examples**

```
fid = H5F.open('example.h5');  
gid1 = H5G.open(fid,'/g1');  
gid2 = H5G.open(fid,'/g2');  
gid3 = H5G.open(fid,'/g3');  
gid4 = H5G.open(fid,'/g4');  
[num_obj_ids,objs] = H5F.get_obj_ids(fid,'H5F_OBJ_GROUP',3);  
H5G.close(gid1);  
H5G.close(gid2);  
H5G.close(gid3);  
H5G.close(gid4);  
H5F.close(fid);
```

**See Also** `H5F.get_obj_count`

**Purpose** Determine if file is HDF5

**Syntax** `value = H5F.is_hdf5(name)`

**Description** `value = H5F.is_hdf5(name)` returns a positive number if the file specified by name is in the HDF5 format, and zero if it is not. A negative return value indicates failure.

**Examples**

```
value = H5F.is_hdf5('example.tif');
if value > 0
    fprintf('example.tif is an HDF5 file\n');
else
    fprintf('example.tif is not an HDF5 file\n');
end
```

# H5F.mount

---

**Purpose** Mount HDF5 file onto specified location

**Syntax** `H5F.mount(loc_id,name,child_id,plist_id)`

**Description** `H5F.mount(loc_id,name,child_id,plist_id)` mounts the file specified by `child_id` onto the group specified by `loc_id` and `name`, using the mount properties specified by `plist_id`.

**Examples** Mount one file with a dataset onto a group in a second file and access the dataset via the second file.

```
plist = 'H5P_DEFAULT';
fid2 = H5F.create('file2.h5', 'H5F_ACC_TRUNC', plist, plist);
gid2 = H5G.create(fid2, 'g2', plist, plist, plist);
fid1 = H5F.create('file1.h5', 'H5F_ACC_TRUNC', 'H5P_DEFAULT', ...
    'H5P_DEFAULT');
space_id = H5S.create('H5S_SCALAR');
dset_id = H5D.create(fid1, 'DS1', 'H5T_NATIVE_DOUBLE', space_id, plist);
H5S.close(space_id);
H5D.close(dset_id);
H5F.mount(fid2, 'g2', fid1, plist);
dset_id1 = H5D.open(fid1, '/g2/DS1', plist);
H5D.close(dset_id1);
H5F.unmount(fid1, 'g2');
H5G.close(gid2);
H5F.close(fid1);
H5F.close(fid2);
```

**See Also** `H5F.unmount`

**Purpose** Open HDF5 file

**Syntax**

```
file_id = H5F.open(filename)
file_id = H5F.open(name, flags, fapl_id)
```

**Description**

`file_id = H5F.open(filename)` opens the file specified by `filename` for read-only access and returns the file identifier, `file_id`.

`file_id = H5F.open(name, flags, fapl_id)` opens the file specified by `name`, returning the file identifier, `file_id`. `flags` specifies file access flags and can be specified by one of the following strings or their numeric equivalents:

'H5F_ACC_RDWR'	read-write mode
'H5F_ACC_RDONLY'	read-only mode

The file access property list, `fapl_id`, may be specified as 'H5P\_DEFAULT', in which case the default I/O settings are used.

**Examples** Open a file in read-only mode with default file access properties.

```
fid = H5F.open('example.h5');
H5F.close(fid);
```

---

Open a file in read-write mode.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.h5');
copyfile(srcFile, 'myfile.h5');
fileattrib('myfile.h5', '+w');
fid = H5F.open('myfile.h5', 'H5F_ACC_RDWR', 'H5P_DEFAULT');
H5F.close(fid);
```

**See Also** [H5F.close](#) | [H5ML.get\\_constant\\_value](#)

# H5F.reopen

---

**Purpose** Reopen HDF5 file

**Syntax** `new_file_id = H5F.reopen(file_id)`

**Description** `new_file_id = H5F.reopen(file_id)` returns a new file identifier for the already open HDF5 file specified by `file_id`.

**See Also** `H5F.open`

**Purpose** Configure HDF5 file metadata cache

**Syntax** `H5F.set_mdc_config(fileId,config)`

**Description** `H5F.set_mdc_config(fileId,config)` attempts to configure the file's metadata cache according to the supplied configuration structure. Before using this function, you should retrieve the current configuration using `H5F.get_mdc_config`.

**See Also** `H5F.get_mdc_config`

# H5F.unmount

---

**Purpose** Unmount file or group from mount point

**Syntax** `H5F.unmount(loc_id,name)`

**Description** `H5F.unmount(loc_id,name)` disassociates the file or group specified by `loc_id` from the mount point specified by `name`. `loc_id` can be a file or group identifier.

**See Also** `H5F.mount`

<b>Purpose</b>	Close group
<b>Syntax</b>	<code>H5G.close(group_id)</code>
<b>Description</b>	<code>H5G.close(group_id)</code> releases resources used by the group specified by <code>group_id</code> . <code>group_id</code> was returned by either <code>H5G.create</code> or <code>H5G.open</code> .
<b>See Also</b>	<code>H5G.create</code>   <code>H5G.open</code>

# H5G.create

---

<b>Purpose</b>	Create group
<b>Syntax</b>	<pre>group_id = H5G.create(loc_id,name,size_hint) group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)</pre>
<b>Description</b>	<p><code>group_id = H5G.create(loc_id,name,size_hint)</code> creates a new group with the name specified by <code>name</code> at the location specified by <code>loc_id</code>. <code>loc_id</code> can be a file or group identifier. <code>size_hint</code> specifies the number of bytes to reserve for the names that will appear in the group. This interface corresponds to the 1.6 version of <code>H5Gcreate</code>.</p> <p><code>group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)</code> creates a new group with link creation, group creation, and group access property lists <code>lcpl_id</code>, <code>gcpl_id</code>, and <code>gapl_id</code>. This interface corresponds to the 1.8 version of <code>H5Gcreate</code>.</p>
<b>Examples</b>	<p>Create an HDF5 file 'myfile.h5' with a group 'my_group' with default property list settings.</p> <pre>fid = H5F.create('myfile.h5'); plist = 'H5P_DEFAULT'; gid = H5G.create(fid,'my_group',plist,plist,plist); H5G.close(gid); H5F.close(fid);</pre>
<b>See Also</b>	<a href="#">H5G.open</a>   <a href="#">H5G.close</a>

<b>Purpose</b>	Information about group
<b>Syntax</b>	<code>info = H5G.get_info(group_id)</code>
<b>Description</b>	<code>info = H5G.get_info(group_id)</code> retrieves information about the group specified by <code>group_id</code> .
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); gid = H5G.open(fid, '/g2'); info = H5G.get_info(gid); H5G.close(gid); H5F.close(fid);</pre>
<b>See Also</b>	<code>H5G.open</code>   <code>H5G.create</code>

# H5G.open

---

**Purpose** Open specified group

**Syntax**  
`group_id = H5G.open(loc_id,name)`  
`group_id = H5G.open(loc_id,name,gapl_id)`

**Description**  
`group_id = H5G.open(loc_id,name)` opens the group specified by `name` at the location specified by `loc_id`. `loc_id` is a file or group identifier. This interface corresponds to the 1.6 version of H5Gopen.  
`group_id = H5G.open(loc_id,name,gapl_id)` opens the group with an additional group access property list, `gapl_id`. This interface corresponds to the 1.8 version of H5Gopen.

**Examples**  

```
fid = H5F.open('example.h5');  
gid = H5G.open(fid,'/g2');  
H5G.close(gid);  
H5F.close(fid);
```

**See Also** [H5G.close](#) | [H5P.create](#)

**Purpose** Decrement reference count

**Syntax** `ref_count = H5I.dec_ref(obj_id)`

**Description** `ref_count = H5I.dec_ref(obj_id)` decrements the reference count of the object identified by `obj_id` and returns the new count.

**See Also** `H5I.get_ref` | `H5I.inc_ref`

# H5I.get\_file\_id

---

**Purpose** File identifier for specified object

**Syntax** `file_id = H5I.get_file_id(obj_id)`

**Description** `file_id = H5I.get_file_id(obj_id)` returns the identifier of the file associated with the object referenced by `obj_id`.

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g4');
fid2 = H5I.get_file_id(gid);
name = H5F.get_name(fid2);
fprintf('The filename is %s.\n', name);
H5G.close(gid);
H5F.close(fid);
H5F.close(fid2);
```

**Purpose** Name of object

**Syntax** name = H5I.get\_name(obj\_id)

**Description** name = H5I.get\_name(obj\_id) returns the name of the object specified by obj\_id. If no name is attached to the object, the empty string is returned.

**Examples** Display the names of all the objects in the /g3 group in the example file by alphabetical order.

```
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g3');
info = H5G.get_info(gid);
for j = 1:info.nlinks
    obj_id = H5O.open_by_idx(fid, 'g3', idx_type, order, j-1, 'H5P_DEFAULT');
    name = H5I.get_name(obj_id);
    fprintf('Object %d: ''%s''.\n', j-1, name);
    H5O.close(obj_id);
end
H5G.close(gid);
H5F.close(fid);
```

**See Also** H5A.get\_name | H5F.get\_name

# H5I.get\_ref

---

<b>Purpose</b>	Reference count of object
<b>Syntax</b>	<code>refcount = H5I.get_ref(obj_id)</code>
<b>Description</b>	<code>refcount = H5I.get_ref(obj_id)</code> returns the reference count of the object specified by <code>obj_id</code> .
<b>See Also</b>	<code>H5I.dec_ref</code>   <code>H5I.inc_ref</code>

**Purpose**

Type of object

**Syntax**

```
obj_type = H5I.get_type(obj_id)
```

**Description**

`obj_type = H5I.get_type(obj_id)` returns the type of the object specified by `obj_id`. `obj_type` corresponds to one of the following enumerated values.

```
H5I_FILE  
H5I_GROUP  
H5I_DATATYPE  
H5I_DATASPACE  
H5I_DATASET  
H5I_ATTR  
H5I_BADID
```

**Examples**

```
fid = H5F.open('example.h5');  
gid = H5G.open(fid, '/g3');  
dset_id = H5D.open(fid, '/g4/world');  
[~,objs] = H5F.get_obj_ids(fid, 'H5F_OBJ_ALL', 3);  
for j = 1:numel(objs)  
    name = H5I.get_name(objs(j));  
    fprintf('object '%s': ==> ', name);  
    type = H5I.get_type(objs(j));  
    switch(type)  
        case H5ML.get_constant_value('H5I_FILE')  
            fprintf('FILE identifier.\n');  
        case H5ML.get_constant_value('H5I_GROUP')  
            fprintf('GROUP identifier.\n');  
        case H5ML.get_constant_value('H5I_DATASET')  
            fprintf('DATASET identifier.\n');  
        otherwise  
            fprintf('unknown identifier type.\n');  
    end  
end
```

# H5I.get\_type

---

```
end
H5G.close(gid);
H5F.close(fid);
```

**See Also** [H5ML.get\\_constant\\_value](#)

<b>Purpose</b>	Increment reference count of specified object
<b>Syntax</b>	<code>ref_count = H5I.inc_ref(obj_id)</code>
<b>Description</b>	<code>ref_count = H5I.inc_ref(obj_id)</code> increments the reference count of the object specified by <code>obj_id</code> and returns the new count.
<b>See Also</b>	<code>H5I.dec_ref</code>   <code>H5I.get_ref</code>

# H5I.is\_valid

---

**Purpose** Determine if specified identifier is valid

**Syntax** `tf = H5I.is_valid(obj_id)`

**Description** `tf = H5I.is_valid(obj_id)` determines whether the identifier `obj_id` is valid.

**Examples**

```
fap1 = H5P.create('H5P_FILE_ACCESS');
H5P.close(fap1);
if H5I.is_valid(fap1);
    fprintf('File access property list is valid.\n');
else
    fprintf('File access property list is not valid.\n');
end
```

<b>Purpose</b>	Copy link from source location to destination location
<b>Syntax</b>	<code>H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)</code>
<b>Description</b>	<p><code>H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)</code> copies the link specified by <code>src_name</code> from the file or group specified by <code>src_loc_id</code> to the destination <code>dest_loc_id</code>. The new copy of the link is created with the name <code>dest_name</code>.</p> <p><code>dest_loc_id</code> must refer to either the current file or a group in the current file. If <code>dest_loc_id</code> is the file identifier, the copy is placed in the file's root group.</p> <p>The new link is created with the creation and access property lists specified by <code>lcpl_id</code> and <code>lapl_id</code>.</p>
<b>Examples</b>	<pre>plist_id = 'H5P_DEFAULT'; fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', plist_id, plist_id); g1 = H5G.create(fid, 'g1', plist_id); g2 = H5G.create(fid, 'g2', plist_id); g11 = H5G.create(g1, 'g3', plist_id); H5L.copy(g1, 'g3', g2, 'g4', plist_id, plist_id);</pre>

# H5L.create\_external

---

**Purpose** Create soft link to external object

**Syntax** `H5L.create_external(filename,objname,link_loc_id,link_name,  
lcp1_id,lapl_id)`

**Description** `H5L.create_external(filename,objname,link_loc_id,link_name,  
lcp1_id,lapl_id)` creates a soft link to an object in a different file. `filename` identifies the target file containing the target object. `obj_name` specifies the path to the target object within that file. `obj_name` must start at the target file's root group but is not interpreted until lookup time.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcp1_id` and `lapl_id` are the link creation and access property lists associated with the new link.

## Examples

```
plist_id = 'H5P_DEFAULT';  
fid1 = H5F.create('myfile1.h5');  
g1 = H5G.create(fid1,'g1',plist_id,plist_id,plist_id);  
H5G.close(g1);  
H5F.close(fid1);  
fid2 = H5F.create('myfile2.h5');  
H5L.create_external('myfile1.h5','g1',fid2,'g2',plist_id,plist_id);
```

**Purpose** Create hard link

**Syntax** `H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,  
lcp1_id,lapl_id)`

**Description** `H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,  
lcp1_id,lapl_id)` creates a new hard link to a pre-existing object in an HDF5 file. The new link may be one of many that point to that object. `obj_loc_id` and `obj_name` specify the location and name, respectively, of the target object, i.e., the object to which the new hard link points.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcp1_id` and `lapl_id` are the link creation and access property lists associated with the new link.

**Examples**

```
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid, '/g1', 0);
gid2 = H5G.create(gid1, 'g2', 0);
gid3 = H5G.create(gid2, 'g3', 0);
lcp1 = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_hard(gid2, 'g3', gid1, 'g4', lcp1, lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```

**See Also** `H5L.create_soft`

# H5L.create\_soft

---

**Purpose** Create soft link

**Syntax** `H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,lapl_id)`

**Description** `H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,lapl_id)` creates a new soft link to an object in an HDF5 file. The new link may be one of many that point to that object. `target_path` specifies the path to the target object, i.e., the object that the new soft link points to. `target_path` can be anything and is interpreted at lookup time. This `target_path` may be absolute in the file or relative to `link_loc_id`.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

## Examples

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid, '/g1', 0);
gid3 = H5G.create(gid1, 'g3', 0);
gid2 = H5G.create(fid, '/g2', 0);
lcpl = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_soft('/g1/g3', gid2, 'g4', lcpl, lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```

**See Also** `H5L.create_hard`

**Purpose** Remove link

**Syntax** H5L.delete(loc\_id,name,lapl\_id)

**Description** H5L.delete(loc\_id,name,lapl\_id) removes the link specified by name from the location loc\_id. lapl\_id is a link access property list identifier.

**Examples** Remove the only link to the '/g3' group in example.h5.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
H5L.delete(fid,'g3','H5P_DEFAULT');
H5F.close(fid);
```

**See Also** H5L.move

# H5L.exists

---

**Purpose** Determine if link exists

**Syntax** `bool = H5L.exists(loc_id,name,lapl_id)`

**Description** `bool = H5L.exists(loc_id,name,lapl_id)` checks if a link specified by the pairing of an object id and name exists within a group. `lapl_id` is a link access property list identifier.

**Examples**

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.2/g1.2.1');
if H5L.exists(gid,'slink','H5P_DEFAULT')
    fprintf('link exists\n');
else
    fprintf('link does not exist\n');
end
```

<b>Purpose</b>	Information about link
<b>Syntax</b>	<code>linkStruct = H5L.get_info(location_id,link_name,lapl_id)</code>
<b>Description</b>	<p><code>linkStruct = H5L.get_info(location_id,link_name,lapl_id)</code> returns information about a link.</p> <p>A file or group identifier, <code>location_id</code>, specifies the location of the link. <code>link_name</code>, interpreted relative to <code>link_id</code>, specifies the link being queried.</p>
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); info = H5L.get_info(fid,'g3','H5P_DEFAULT'); H5F.close(fid);</pre>

# H5L.get\_name\_by\_idx

---

**Purpose** Information about link specified by index

**Syntax** `name = H5L.get_name_by_idx(loc_id,group_name,idx_type,order,n,lapl_id)`

**Description** `name = H5L.get_name_by_idx(loc_id,group_name,idx_type,order,n,lapl_id)` retrieves information about a link at index `n`, present in group `group_name`, at location `loc_id`. The `lapl_id` input specifies the link access property list for querying the group.

`idx_type` is the type of index and valid values include the following.

'H5_INDEX_NAME'	Alpha-numeric index on name
'H5_INDEX_CRT_ORDER'	Index on creation order

`order` specifies the index traversal order. Valid values include the following.

'H5_ITER_INC'	Iteration from beginning to end
'H5_ITER_DEC'	Iteration from end to beginning
'H5_ITER_NATIVE'	Iteration in the fastest available order

**Examples**

```
fid = H5F.open('example.h5');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
lapl_id = 'H5P_DEFAULT';
name = H5L.get_name_by_idx(fid,'g3',idx_type,order,0,lapl_id);
H5F.close(fid);
```

<b>Purpose</b>	Value of symbolic link
<b>Syntax</b>	<code>linkval = H5L.get_val(link_loc_id,link_name,lapl_id)</code>
<b>Description</b>	<p><code>linkval = H5L.get_val(link_loc_id,link_name,lapl_id)</code> returns the value of a symbolic link.</p> <p><code>link_loc_id</code> is a file or group identifier. <code>link_name</code> identifies a symbolic link and is defined relative to <code>link_loc_id</code>. Symbolic links include soft and external links and some user-defined links.</p> <p>In the case of soft links, <code>linkval</code> is a cell array containing the path to which the link points.</p> <p>In the case of external links, <code>linkval</code> is a cell array consisting of the name of the target file and the object name.</p> <p>This function corresponds to the <code>H5L.get_val</code> and <code>H5Lunpack_elink_val</code> functions in the HDF5 1.8 C API.</p>
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); gid = H5G.open(fid, '/g1/g1.2/g1.2.1'); linkval = H5L.get_val(gid, 'slink', 'H5P_DEFAULT'); H5G.close(gid); H5F.close(fid);</pre>

# H5L.iterate

---

## Purpose

Iterate over links

## Syntax

```
[status,idx_out,opdata_out] = H5L.iterate(group_id,index_type,
    order,idx_in,iter_func,opdata_in)
```

## Description

```
[status,idx_out,opdata_out] =
H5L.iterate(group_id,index_type,
order,idx_in,iter_func,opdata_in) iterates through the links in a
group, specified by group_id, to perform a common function whose
function handle is iter_func. H5L.iterate does not recursively follow
links into subgroups of the specified group.
```

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they will first be sorted by that index then the iteration will begin. If the links have been so indexed, the sorting step will be unnecessary, so the iteration may begin more quickly. Valid values include the following:

'H5_INDEX_NAME'	Alpha-numeric index on name
'H5_INDEX_CRT_ORDER'	Index on creation order

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following:

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =
iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

status value returned by `iter_func` is interpreted as follows:

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

# H5L.iterate\_by\_name

---

**Purpose** Iterate through links in group specified by name

**Syntax** `[status,idx_out,opdata_out] = H5L.iterate_by_name(loc_id, group_name,index_type,order,idx_in,iter_func,opdata_in, lapl_id)`

**Description** `[status,idx_out,opdata_out] = H5L.iterate_by_name(loc_id, group_name,index_type,order,idx_in,iter_func,opdata_in, lapl_id)` iterates through the links in a group to perform a common function whose function handle is `iter_func`. The starting point of the iteration is pairing of a specified by the location id and a relative group name. `H5L.iterate_by_name` does not recursively follow links into subgroups of the specified group. A link access property list, `lapl_id`, may affect the outcome depending upon the type of link being traversed.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they will first be sorted by that index then the iteration will begin. If the links have been so indexed, the sorting step will be unnecessary, so the iteration may begin more quickly. Valid values include the following:

'H5_INDEX_NAME'	Alpha-numeric index on name
'H5_INDEX_CRT_ORDER'	Index on creation order

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following:

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =  
iter_func(group_id,name,opdata_in)
```

opdata\_in is a user-defined value or structure and is passed to the first step of the iteration in the iter\_func opdata\_in parameter. The opdata\_out of an iteration step forms the opdata\_in for the next iteration step. The final opdata\_out at the end of the iteration is then returned to the caller as opdata\_out.

status value returned by iter\_func is interpreted as follows:

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

# H5L.move

---

<b>Purpose</b>	Rename link
<b>Syntax</b>	<code>H5L.move(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)</code>
<b>Description</b>	<p><code>H5L.move(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)</code> renames a link within an HDF5 file. The original link, <code>src_name</code>, is removed from the group graph and the new link, <code>dest_name</code>, is inserted; this change is accomplished as an atomic operation.</p> <p><code>src_loc_id</code> and <code>src_name</code> identify the existing link. <code>src_loc_id</code> is either a file or group identifier; <code>src_name</code> is the path to the link and is interpreted relative to <code>src_loc_id</code>.</p> <p><code>dest_loc_id</code> and <code>dest_name</code> identify the new link. <code>dest_loc_id</code> is either a file or group identifier; <code>dest_name</code> is the path to the link and is interpreted relative to <code>dest_loc_id</code>.</p> <p><code>lcpl_id</code> and <code>lapl_id</code> are the link creation and link access property lists, respectively, associated with the new link, <code>dest_name</code>.</p>

## Examples

Rename the '/g2' group to '/g2/g3'.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
g2id = H5G.open(fid,'g2');
H5L.move(fid,'g3',g2id,'g3','H5P_DEFAULT','H5P_DEFAULT');
H5G.close(g2id);
H5F.close(fid);
```

**See Also** `H5L.delete`

**Purpose** Recursively iterate through links in group specified by group identifier

**Syntax** `[status opdata_out] = H5L.visit(group_id,index_type,order, iter_func,opdata_in)`

**Description** `[status opdata_out] = H5L.visit(group_id,index_type,order, iter_func,opdata_in)` recursively iterates through all links in and below a group, specified by `group_id`, to perform a common function whose function handle is `iter_func`.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

'H5_INDEX_NAME'	Alpha-numeric index on name
'H5_INDEX_CRT_ORDER'	Index on creation order

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.)

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =  
iter_func(group_id,name,opdata_in)
```

## H5L.visit

---

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

## Purpose

Recursively iterate through links in group specified by location and group name

## Syntax

```
[status,opdata_out] = H5L.visit_by_name(loc_id,group_name,  
index_type,order,iter_func,opdata_in,lapl_id)
```

## Description

[status,opdata\_out] = H5L.visit\_by\_name(loc\_id,group\_name, index\_type,order,iter\_func,opdata\_in,lapl\_id) recursively iterates through all links in and below a group to perform a common function whose function handle is iter\_func. The starting point of the iteration is specified by the pairing of a location id and a relative group name. A link access property list, lapl\_id, may affect the outcome depending upon the type of link being traversed.

index\_type and order establish the iteration. index\_type specifies the index to be used. If the links have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

'H5_INDEX_NAME'	Alpha-numeric index on name
'H5_INDEX_CRT_ORDER'	Index on creation order

Note that the index type passed in index\_type is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.)

order specifies the order in which objects are to be inspected along the index specified in index\_type. Valid values include the following.

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

## H5L.visit\_by\_name

---

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =  
iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

**Purpose** Numerically compare two HDF5 values

**Syntax** `bEqual = H5ML.compare_values(value1,value2)`

**Description** `bEqual = H5ML.compare_values(value1,value2)` compares two values, where either or both values may be represented as a string. The values are compared numerically.

Function parameters:

<code>bEqual</code>	A logical value indicating whether the two values are equal
<code>value1</code>	The first value to be compared
<code>value2</code>	The second value to be compared

**Examples**

```
val = H5ML.get_constant_value('H5T_NATIVE_INT');  
H5ML.compare_values(val, 'H5T_NATIVE_INT')
```

# H5ML.get\_constant\_names

---

**Purpose** Constants known by HDF5 library

**Syntax** `names = H5ML.get_constant_names()`

**Description** `names = H5ML.get_constant_names()` returns a list of known library constants, definitions, and enumerations. When these strings are supplied as actual parameters to HDF5 functions, they are automatically be converted to the appropriate numeric value.

Function parameters.

<code>names</code>	An alphabetized cell array of names
--------------------	-------------------------------------

**Purpose** Value corresponding to a string

**Syntax** `value = H5ML.get_constant_value(constant)`

**Description** `value = H5ML.get_constant_value(constant)` returns the value corresponding to a given string. The string should correspond to an enumeration (for example, 'H5\_ENUM\_T') or a predefined identifier (for example, 'H5T\_NATIVE\_INT'). Since the value corresponding to a given string is not guaranteed to remain the same, it is almost always preferable to use the `H5ML.compare_values()` function instead.

Function parameters:

<code>value</code>	The value corresponding to the supplied string
<code>constant</code>	A string that corresponds to a HDF5 enumeration or defined value.

**Examples** `a = H5ML.get_constant_value('H5T_NATIVE_INT');`

# H5ML.get\_function\_names

---

**Purpose** Functions provided by HDF5 library

**Syntax** `names = H5ML.get_function_names()`

**Description** `names = H5ML.get_function_names()` returns a list of supported library functions.

Function parameters:

<code>names</code>	An alphabetized cell array of names
--------------------	-------------------------------------

<b>Purpose</b>	Data type for dataset ID
<b>Syntax</b>	<code>DTYPE_ID = H5ML.get_mem_datatype(LOCATION_ID)</code>
<b>Description</b>	<p><code>DTYPE_ID = H5ML.get_mem_datatype(LOCATION_ID)</code> returns the ID of an HDF5 memory datatype for the dataset or attribute identified by <code>LOCATION_ID</code>. This HDF5 memory datatype is the default used by <code>H5D.read</code> or <code>H5D.write</code> when you specify <code>'H5ML_DEFAULT'</code> as a value of the memory data type parameter.</p> <p>The identifier returned by <code>H5ML.get_mem_datatype</code> should eventually be closed by calling <code>H5T.close</code> to release resources.</p>
<b>Examples</b>	<pre>file_id = H5F.open('example.h5', 'H5F_ACC_RDONLY', 'H5P_DEFAULT'); dset_id = H5D.open(file_id, '/g1/g1.1/dset1.1.1'); datatype_id = H5ML.get_mem_datatype(dset_id) H5T.close(datatype_id); H5D.close(dset_id); H5F.close(file_id);</pre>

# H5ML.hoffset

---

**Purpose** Determine the offset of a field within a structure

---

**Note** H5ML.hoffset is not recommended. Use H5T instead.

---

## Syntax

**Description** This function is used to determine the offset (in bytes) of a structure, `H5T.insert(file_type, 'a', offset(1), dtype(1));`, within a field. It is used when constructing an HDF5 COMPOUND type. It is designed to correspond to the HDF5 HOFFSET macro. For more details about the operation of the HOFFSET macro, please consult the HDF5 documentation.

Function parameters:

<code>offset</code>	The byte offset of the field within the structure.
<code>structure</code>	The structure which contains the specified fieldname.
<code>fieldname</code>	The field for which the offset is determined.

## Examples

This function is deprecated. It can only be used in workflows that do not include a field that is itself an HDF5 COMPOUND or of variable length. To handle these cases, the offsets should be computed directly. For example, in the case above, a file dataspace for such a compound could be created with:

```
dtype(1) = H5T.copy('H5T_NATIVE_INT');
dtype(2) = H5T.copy('H5T_NATIVE_DOUBLE');
dtype(3) = H5T.copy('H5T_NATIVE_FLOAT');

for j = 1:3, sz(j,1) = H5T.get_size(dtype(j)); end
```

```
% The first offset would always be zero and the size of the last
% field does not matter.
offset(1) = 0;
offset(2:3) = cumsum(sz(1:2));

file_type = H5T.create('H5T_COMPOUND',sum(sz));

H5T.insert(file_type,'a', offset(1), dtype(1));
H5T.insert(file_type,'b', offset(2), dtype(2));
H5T.insert(file_type,'c', offset(3), dtype(3));
```

**See Also** [H5T.get\\_size](#)

# H5ML.sizeof

---

## Purpose

Return the size (in bytes) of a variable as stored on disk

---

**Note** `H5ML.sizeof` is not recommended. Use `H5T` instead.

---

## Syntax

## Description

This function is used to determine the size (in bytes) of a structure or other (simple) variable. It is designed to correspond to the C `sizeof()` operator as it is used during the creation of HDF5 datatypes, especially the HDF5 COMPOUND type.

Function parameters:

<code>size</code>	The size (in bytes) of the variable as it would be stored on disk.
<code>arg</code>	The variable for which the size is being sought.

## Examples

This function is deprecated. It can only be used in workflows that do not include a field that is itself an HDF5 COMPOUND or of variable length. To handle these cases, the offsets should be computed directly. For example, in the case above, a file dataspace for such a compound could be created with:

```
dtype(1) = H5T.copy('H5T_NATIVE_INT');
dtype(2) = H5T.copy('H5T_NATIVE_DOUBLE');
dtype(3) = H5T.copy('H5T_NATIVE_FLOAT');

for j = 1:3, sz(j,1) = H5T.get_size(dtype(j)); end

% The first offset would always be zero and the size of the last
% field does not matter.
offset(1) = 0;
offset(2:3) = cumsum(sz(1:2));
```

```
file_type = H5T.create('H5T_COMPOUND', sum(sz));  
  
H5T.insert(file_type, 'a', offset(1), dtype(1));  
H5T.insert(file_type, 'b', offset(2), dtype(2));  
H5T.insert(file_type, 'c', offset(3), dtype(3));
```

**See Also** [H5T.get\\_size](#)

# H5O.close

---

**Purpose** Close object

**Syntax** `H5O.close(obj_id)`

**Description** `H5O.close(obj_id)` closes the object specified by `obj_id`. `obj_id` cannot be a dataspace, attribute, property list, or file.

<b>Purpose</b>	Copy object from source location to destination location
<b>Syntax</b>	<code>H5O.copy(src_loc_id,src_name,dst_loc_id,dst_name,ocpypl_id,lcpl_id)</code>
<b>Description</b>	<p><code>H5O.copy(src_loc_id,src_name,dst_loc_id,dst_name,ocpypl_id,lcpl_id)</code> copies the group, dataset or named datatype specified by <code>src_name</code> from the file or group specified by <code>src_loc_id</code> to the destination location <code>dst_loc_id</code>.</p> <p>The destination location, as specified in <code>dst_loc_id</code>, may be a group in the current file or a location in a different file. If <code>dst_loc_id</code> is a file identifier, the copy will be placed in that file's root group.</p> <p>The new copy will be created with the name <code>dst_name</code>. <code>dst_name</code> must not pre-exist in the destination location. If <code>dst_name</code> already exists at the location <code>dst_loc_id</code>, the operation will fail.</p> <p>The new copy of the object is created with the object creation property and link creation property lists <code>ocpypl_id</code> and <code>lcpl_id</code>, respectively.</p>
<b>Examples</b>	<p>Copy the group <code>'/g3'</code> and all its datasets to a new group <code>'/g3.5'</code>.</p> <pre>srcFile = [matlabroot '/toolbox/matlab/demos/example.h5']; copyfile(srcFile,'myfile.h5'); fileattrib('myfile.h5','+w'); ocpl = H5P.create('H5P_OBJECT_COPY'); lcpl = H5P.create('H5P_LINK_CREATE'); H5P.set_create_intermediate_group(lcpl,true); fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT'); gid = H5G.open(fid,'/'); H5O.copy(gid,'g3',gid,'g3.5',ocpl,lcpl); H5G.close(gid); H5P.close(ocpl); H5P.close(lcpl); H5F.close(fid);</pre>

# H5O.get\_comment

---

**Purpose** Get comment for object specified by object identifier

**Syntax** `comment = H5O.get_comment(obj_id)`

**Description** `comment = H5O.get_comment(obj_id)` retrieves the comment for the object specified by `obj_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, 'g4/world');
comment = H5O.get_comment(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5O.get_comment_by_name` | `H5O.set_comment` | `H5O.set_comment_by_name`

# H5O.get\_comment\_by\_name

---

<b>Purpose</b>	Get comment for object specified by location and object name
<b>Syntax</b>	<code>comment = H5O.get_comment_by_name(loc_id,name,lapl_id)</code>
<b>Description</b>	<code>comment = H5O.get_comment_by_name(loc_id,name,lapl_id)</code> retrieves a comment where a location id and name together specify the object. A link access property list can affect the outcome if a link is traversed to access the object.
<b>Examples</b>	<pre>fid = H5F.open('example.h5','H5F_ACC_RDONLY','H5P_DEFAULT'); comment = H5O.get_comment_by_name(fid,'g4/world','H5P_DEFAULT'); H5F.close(fid);</pre>
<b>See Also</b>	<code>H5O.get_comment</code>   <code>H5O.set_comment</code>   <code>H5O.set_comment_by_name</code>

# H5O.get\_info

---

**Purpose** Object metadata

**Syntax** `info = H5O.get_info(obj_id)`

**Description** `info = H5O.get_info(obj_id)` retrieves the metadata for an object specified by `obj_id`. For details about the object metadata, please refer to the HDF5 documentation.

**Examples** Determine the number of attributes for a dataset.

```
fid = H5F.open('example.h5', 'H5F_ACC_RDONLY', 'H5P_DEFAULT');
dsetId = H5D.open(fid, '/g1/g1.1/dset1.1.1');
info = H5O.get_info(dsetId);
info.num_attrs
```

---

Determine the type of objects in the root group.

```
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
root_info = H5G.get_info(gid);
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
for j = 0:root_info.nlinks-1
    obj_id = H5O.open_by_idx(fid, '/', idx_type, order, j, plist);
    obj_info = H5O.get_info(obj_id);
    switch(obj_info.type)
        case H5ML.get_constant_value('H5G_LINK')
            fprintf('Object #%d is a link.\n', j);
        case H5ML.get_constant_value('H5G_GROUP')
            fprintf('Object #%d is a group.\n', j);
        case H5ML.get_constant_value('H5G_DATASET')
            fprintf('Object #%d is a dataset.\n', j);
        case H5ML.get_constant_value('H5G_TYPE')
            fprintf('Object #%d is a named datatype.\n', j);
```

```
        end
    H5O.close(obj_id);
end
H5G.close(gid);
H5F.close(fid);
```

# H5O.link

---

**Purpose** Create hard link to specified object

**Syntax** `H5O.link(obj_id,new_loc_id,new_link_name,lcpl_id,lapl_id)`

**Description** `H5O.link(obj_id,new_loc_id,new_link_name,lcpl_id,lapl_id)` creates a hard link to an object, where `new_loc_id` and `new_link_name` specify the location. `lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

`H5O.link` is designed to add additional structure to an existing file so that, for example, an object can be shared among multiple groups.

**Examples** Create a hard link from group `'/g2'` to the dataset `'/g1/ds1'`.

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', plist_id, plist_id);
gid1 = H5G.create(fid, '/g1', plist_id);
space_id = H5S.create_simple(1, 10, []);
ds1 = H5D.create(gid1, 'ds1', 'H5T_NATIVE_INT', space_id, plist_id);
gid2 = H5G.create(fid, '/g2', plist_id);
H5O.link(ds1, gid2, 'ds2', plist_id, plist_id);
H5D.close(ds1);
H5S.close(space_id);
H5G.close(gid2); H5G.close(gid1);
H5F.close(fid);
```

**See Also** `H5L.create_hard` | `H5L.create_soft`

**Purpose** Open specified object

**Syntax** `obj_id = H5O.open(loc_id, relname, lapl_id)`

**Description** `obj_id = H5O.open(loc_id, relname, lapl_id)` opens an object specified by location identifier and relative path name. `lapl_id` is the link access property list associated with the link pointing to the object. If default link access properties are appropriate, this can be passed in as `'H5P_DEFAULT'`.

**Examples**

```
fid = H5F.open('example.h5');
obj_id = H5O.open(fid, 'g3', 'H5P_DEFAULT');
H5O.close(obj_id);
H5F.close(fid);
```

**See Also** `H5O.open_by_idx` | `H5O.close`

# H5O.open\_by\_idx

---

**Purpose** Open object specified by index

**Syntax** `obj_id = H5O.open_by_idx(loc_id, group_name, idx_type, order, n, lapl_id)`

**Description** `obj_id = H5O.open_by_idx(loc_id, group_name, idx_type, order, n, lapl_id)` opens the n-th object in the group specified by `loc_id` and `group_name`. `loc_id` specifies a file or group. `group_name` specifies the group relative to `loc_id` in which the object can be found.

Two parameters are used to establish the iteration: `index_type` and `order`. `index_type` specifies the type of index by which objects are ordered. Valid values include the following:

'H5_INDEX_NAME'	Alpha-numeric index on name
'H5_INDEX_CRT_ORDER'	Index on creation order

`order` specifies the order in which the links are to be referenced for the purposes of this function. Valid values include the following:

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

`n` specifies the zero-based position of the object within the index. `lapl_id` specifies the link access property list to be used in accessing the object.

**Examples**

```
fid = H5F.open('example.h5');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
obj_id = H5O.open_by_idx(fid, 'g3', idx_type, order, 0, 'H5P_DEFAULT');
H5O.close(obj_id);
H5F.close(fid);
```

**See Also** [H5O.open](#) | [H5O.close](#)

<b>Purpose</b>	Set comment for object specified by object identifier
<b>Syntax</b>	<code>H5O.set_comment(obj_id,comment)</code>
<b>Description</b>	<code>H5O.set_comment(obj_id,comment)</code> sets a comment for the object specified by <code>obj_id</code> .
<b>Examples</b>	<pre>plist = 'H5P_DEFAULT'; fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', plist, plist); gid = H5G.create(fid, '/g1', plist); H5O.set_comment(gid, 'This is a group comment. '); H5G.close(gid); H5F.close(fid);</pre>
<b>See Also</b>	<code>H5O.get_comment</code>   <code>H5O.get_comment_by_name</code>   <code>H5O.set_comment_by_name</code>

# H5O.set\_comment\_by\_name

---

**Purpose**

Set comment for object specified by location and object name

**Syntax**

```
H5O.set_comment_by_name(loc_id,rel_name,comment,lapl_id)
```

**Description**

H5O.set\_comment\_by\_name(loc\_id,rel\_name,comment,lapl\_id) sets a comment for an object specified by a location ID and a relative name. `lapl_id` is a link access property list identifier that can affect the outcome if links are traversed.

**Examples**

```
plist = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist,plist);
gid = H5G.create(fid,'/g1',plist);
H5O.set_comment_by_name(fid,'g1','This is a group comment.',plist);
H5G.close(gid);
H5F.close(fid);
```

**See Also**

H5O.get\_comment | H5O.get\_comment\_by\_name | H5O.set\_comment

**Purpose** Visit objects specified by object identifier

**Syntax** `[status,opdata_out] = H5O.visit(obj_id,index_type,order,iter_func,opdata_in)`

**Description** `[status,opdata_out] = H5O.visit(obj_id,index_type,order,iter_func,opdata_in)` is a recursive iteration function to visit the object `object_id` and, if `object_id` is a group, all objects in and below it in an HDF5 file. This provides a mechanism for an application to perform a common set of operations across all of those objects or a dynamically selected subset.

If `object_id` is a group identifier, that group serves as the root of a recursive iteration. If `object_id` is a file identifier, that file's root group serves as the root of the recursive iteration. If `object_id` is any other type of object, such as a dataset or named data type, there is no iteration.

Two parameters are used to establish the iteration: `index_type` and `order`. The `index_type` parameter specifies the index used. If the links in a group have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

<code>'H5_INDEX_NAME'</code>	Alpha-numeric index on name
<code>'H5_INDEX_CRT_ORDER'</code>	Index on creation order

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.) `order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

# H5O.visit

---

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =  
iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

**See Also** `H5O.visit_by_name`

## Purpose

Visit objects specified by location and object name

## Syntax

```
[status,opdata_out] = H5O.visit_by_name(loc_id,obj_name,  
index_type,order,iter_func,opdata_in,lapl_id)
```

## Description

[status,opdata\_out] = H5O.visit\_by\_name(loc\_id,obj\_name, index\_type,order,iter\_func,opdata\_in,lapl\_id) specifies the object by the pairing of the location identifier and object name. loc\_id specifies a file or an object in a file and obj\_name specifies an object in the file with either an absolute name or relative to loc\_id. A link access property list can affect the outcome if links are involved.

Two parameters are used to establish the iteration: index\_type and order. The index\_type parameter specifies the index to be used. If the links in a group have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin; if the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

'H5_INDEX_NAME'	Alpha-numeric index on name
'H5_INDEX_CRT_ORDER'	Index on creation order

Note that the index type passed in index\_type is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.) order specifies the order in which objects are to be inspected along the index specified in index\_type. Valid values include the following.

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

The callback function iter\_func must have the following signature:

## H5O.visit\_by\_name

---

```
function [status,opdata_out] =  
iter_func(group_id,name,opdata_in)
```

opdata\_in is a user-defined value or structure and is passed to the first step of the iteration in the iter\_func opdata\_in parameter. The opdata\_out of an iteration step forms the opdata\_in for the next iteration step. The final opdata\_out at the end of the iteration is then returned to the caller as opdata\_out.

lapl\_id is a link access property list. When default link access properties are acceptable, 'H5P\_DEFAULT' can be used.

status value returned by iter\_func is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

**See Also** H5O.visit

**Purpose** Close property list

**Syntax** `H5P.close(plist_id)`

**Description** `H5P.close(plist_id)` terminates access to the property list specified by `plist_id`.

**See Also** `H5P.create`

# H5P.copy

---

**Purpose** Copy of property list

**Syntax** `plist_copy = H5P.copy(plist_id)`

**Description** `plist_copy = H5P.copy(plist_id)` returns a copy of the property list specified by `plist_id`.

**Examples** Make a copy of the file creation property list for 'example.h5'.

```
fid = H5F.open('example.h5');  
fcpl = H5F.get_create_plist(fid);  
fcpl2 = H5P.copy(fcpl);
```

**Purpose** Create new property list

**Syntax** `plist = H5P.create(class_id)`

**Description** `plist = H5P.create(class_id)` creates a new property list as an instance of the property list class specified by `class_id`. The `class_id` input can be one of the following strings or the corresponding constant value.

```
'H5P_ATTRIBUTE_CREATE'  
'H5P_DATASET_ACCESS'  
'H5P_DATASET_CREATE'  
'H5P_DATASET_XFER'  
'H5P_DATATYPE_CREATE'  
'H5P_DATATYPE_ACCESS'  
'H5P_FILE_MOUNT'  
'H5P_FILE_CREATE'  
'H5P_FILE_ACCESS'  
'H5P_GROUP_CREATE'  
'H5P_GROUP_ACCESS'  
'H5P_LINK_CREATE'  
'H5P_LINK_ACCESS'  
'H5P_OBJECT_COPY'  
'H5P_OBJECT_CREATE'  
'H5P_STRING_CREATE'
```

`class_id` can also be an instance of a property list class.

## Examples

```
fap1 = H5P.create('H5P_FILE_ACCESS');  
fid = H5F.open('example.h5', 'H5F_ACC_RDONLY', fap1);
```

# H5P.create

---

## See Also

[H5P.close](#) | [H5P.get\\_class](#) | [H5ML.get\\_constant\\_value](#)

**Purpose** Property list class

**Syntax** `plist_class = H5P.get_class(plist_id)`

**Description** `plist_class = H5P.get_class(plist_id)` returns the property list class for the property list specified by `plist_id`.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
pclass = H5P.get_class(fcpl);
name = H5P.get_class_name(pclass);
```

**See Also** `H5P.get_class_name`

## H5P.close\_class

---

<b>Purpose</b>	Close property list class
<b>Syntax</b>	<code>H5P.close_class(class)</code>
<b>Description</b>	<code>H5P.close_class(class)</code> closes the property list class specified by <code>pclass_id</code> .

**Purpose** Determine equality of property lists

**Syntax** `value = H5P.equal(plist1_id, plist2_id)`

**Description** `value = H5P.equal(plist1_id, plist2_id)` returns a positive number if the two property lists specified are equal, and zero if they are not. A negative value indicates failure.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
fcpl = H5F.get_create_plist(fid);
if H5P.equal(fapl,fcpl)
    fprintf('property lists are equal\n');
else
    fprintf('property lists are not equal\n');
end
```

# H5P.exist

---

**Purpose** Determine if specified property exists in property list

**Syntax** `value = H5P.exist(prop_id, name)`

**Description** `value = H5P.exist(prop_id, name)` returns a positive value if the property specified by the text string `name` exists within the property list or class specified by `prop_id`.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
if H5P.exist(fapl,'sieve_buf_size')
    fprintf('sieve buffer size property exists\n');
else
    fprintf('sieve buffer size property does not exist\n');
end
```

**Purpose** Value of specified property in property list

**Syntax** `value = H5P.get(plist_id, name)`

**Description** `value = H5P.get(plist_id, name)` retrieves a copy of the value of the property specified by the text string `name` in the property list specified by `plist_id`. The `H5P.get` function returns the property as an array of `uint8` values. You might need to cast the value to an appropriate data type to get a meaningful result.

**Examples**

```
plist = H5P.create('H5P_FILE_ACCESS');  
val = H5P.get(plist, 'rdcc_w0');  
rdcc_w0 = typecast(val, 'double');
```

It is recommended to use alternative functions like `H5P.get_chunk`, `H5P.get_layout`, `H5P.get_size` etc., where available, to get values for the common property names.

**See Also** `H5P.set` | `typecast`

# H5P.get\_class\_name

---

**Purpose** Name of property list class

**Syntax** `classname = H5P.get_class_name(pclass_id)`

**Description** `classname = H5P.get_class_name(pclass_id)` retrieves the name of the generic property list class. `classname` is a text string. If no class is found, the empty string is returned.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
pclass = H5P.get_class(fcpl);
name = H5P.get_class_name(pclass);
```

**See Also** `H5P.get_class`

<b>Purpose</b>	Identifier for parent class
<b>Syntax</b>	<code>pclass_obj_id = H5P.get_class_parent(pclass_id)</code>
<b>Description</b>	<code>pclass_obj_id = H5P.get_class_parent(pclass_id)</code> returns an identifier to the parent class object of the property class specified by <code>pclass_id</code> .
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); fcpl = H5F.get_create_plist(fid); fcpl_class = H5P.get_class(fcpl); parent_class = H5P.get_class_parent(fcpl_class); name = H5P.get_class_name(parent_class);</pre>
<b>See Also</b>	<code>H5P.get_class</code>   <code>H5P.get_class_name</code>

# H5P.get\_nprops

---

**Purpose** Query number of properties in property list or class

**Syntax** `nprops = H5P.get_nprops(id)`

**Description** `nprops = H5P.get_nprops(id)` returns the number of properties in the property list or class specified by `id`.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
nprops = H5P.get_nprops(fcpl);
```

**Purpose** Query size of property value in bytes

**Syntax** `sz = H5P.get_size(id,name)`

**Description** `sz = H5P.get_size(id,name)` returns the size, in bytes, of the property specified by the text string name in the property list or property class specified by id.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_size(fapl,'sieve_buf_size');
```

# H5P.isa\_class

---

**Purpose** Determine if property list is member of class

**Syntax** `output = H5P.isa_class(plist_id, pclass_id)`

**Description** `output = H5P.isa_class(plist_id, pclass_id)` returns a positive number if the property list specified by `plist_id` is a member of the class specified by `pclass_id`, zero if it is not, and a negative value to indicate an error.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
if H5P.isa_class(fcpl, 'H5P_FILE_ACCESS')
    fprintf('fcpl is a file access property list\n');
else
    fprintf('fcpl is not a file access property list\n');
end
```

**See Also** `H5P.get_class`

**Purpose** Iterate over properties in property list

**Syntax** `[output,idx_out] = H5P.iterate(id,idx_in,iter_func)`

**Description** `[output,idx_out] = H5P.iterate(id,idx_in,iter_func)` executes the operation `iter_func` on each property in the property object specified in `id`. The `id` input can be a property list or a property class. `idx_in` specifies the index of the next property to be processed. `output` is the value returned by the last call to `iter_func`. `idx_out` is the index of the last property processed. `iter_func` is a function handle.

The iterator function must have the following signature:

```
status = iter_func(id,prop_name)
```

`id` still identifies the property object passed into `H5P.iterate`, but `name` identifies the name of the current property.

# H5P.set

---

**Purpose** Set property list value

**Syntax** `H5P.set(plist_id,name,value)`

**Description** `H5P.set(plist_id,name,value)` sets the value of the property specified by the text string name in the property list specified by `plist_id` to the value specified in `value`. The datatype of `value` must be `uint8`.

**Examples**

```
plist = H5P.create('H5P_FILE_ACCESS');
H5P.set(plist, 'rdcc_w0', typecast(0.8, 'uint8'));
```

It is recommended to use alternative functions like `H5P.set_chunk`, `H5P.set_layout`, `H5P.set_size`, etc., where available, to set values for the common property names.

**See Also** `typecast`

**Purpose** B-tree split ratios

**Syntax** `[left,middle,right] = H5P.get_btree_ratios(plist_id)`

**Description** `[left,middle,right] = H5P.get_btree_ratios(plist_id)` returns the B-tree split ratios for the dataset transfer property list specified by `plist_id`. The `left` output specifies the B-tree split ratio for left-most nodes. `right` corresponds to the right-most nodes and lone nodes, and `middle` corresponds to all other nodes.

**Examples**

```
dxpl = H5P.create('H5P_DATASET_XFER');  
[left,middle,right] = H5P.get_btree_ratios(dxpl);
```

**See Also** `H5P.set_btree_ratios`

# H5P.get\_chunk\_cache

---

**Purpose** Raw data chunk cache parameters

**Syntax** `[rdcc_nslots,rdcc_nbytes,  
rdcc_w0] = H5P.get_chunk_cache(dapl_id)`

**Description** `[rdcc_nslots,rdcc_nbytes, rdcc_w0] = H5P.get_chunk_cache(dapl_id)` retrieves the number of chunk slots in the raw data chunk cache hash table (`rdcc_nslots`), the maximum possible number of bytes in the raw data chunk cache (`rdcc_nbytes`), and the preemption policy value (`rdcc_w0`) on a dataset access property list.

**Examples**

```
fid = H5F.open('example.h5');  
dset_id = H5D.open(fid, '/g3/vlen3D');  
dapl = H5D.get_access_plist(dset_id);  
[rrdcc_nslots,rdcc_nbytes,rdcc_w0] = H5P.get_chunk_cache(dapl);  
H5P.close(dapl);  
H5D.close(dset_id);  
H5F.close(fid);
```

**See Also** `H5P.set_chunk_cache`

**Purpose** Data access property lists for multiple files

**Syntax** `memb_dxpl = H5P.get_dxpl_multi(dxpl_id)`

**Description** `memb_dxpl = H5P.get_dxpl_multi(dxpl_id)` returns an array of data access property lists for the multifile data transfer property list specified by `dxpl_id`.

**See Also** `H5P.set_dxpl_multi`

# H5P.get\_edc\_check

---

**Purpose** Determine if error detection is enabled

**Syntax** `check = H5P.get_edc_check(plist_id)`

**Description** `check = H5P.get_edc_check(plist_id)` queries the dataset transfer property list, specified by `plist_id`, to determine whether error detection is enabled for data read operations. Returns either `H5Z_ENABLE_EDC` or `H5Z_DISABLE_EDC`.

**Examples**

```
dxpl = H5P.create('H5P_DATASET_XFER');
check = H5P.get_edc_check(dxpl);
switch(check)
    case H5ML.get_constant_value('H5Z_ENABLE_EDC')
        fprintf('error detection enabled\n');
    case H5ML.get_constant_value('H5Z_DISABLE_EDC')
        fprintf('error detection disabled\n');
end
```

**See Also** `H5P.set_edc_check`

- Purpose** Number of I/O vectors
- Syntax** `sz = H5P.get_hyper_vector_size(dxpl_id)`
- Description** `sz = H5P.get_hyper_vector_size(dxpl_id)` returns the number of I/O vectors to be read/written in hyperslab I/O.
- Examples**
- ```
dxpl = H5P.create('H5P_DATASET_XFER');  
sz = H5P.get_hyper_vector_size(dxpl);
```
- See Also** `H5P.set_hyper_vector_size`

# H5P.set\_btree\_ratios

---

**Purpose** Set B-tree split ratios for dataset transfer

**Syntax** `H5P.set_btree_ratios(plist_id,left,middle,right)`

**Description** `H5P.set_btree_ratios(plist_id,left,middle,right)` sets the B-tree split ratios for the dataset transfer property list specified by `plist_id`. The `left` argument specifies the B-tree split ratio for left-most nodes. `right` specifies the B-tree split ratio for right-most nodes and lone nodes. `middle` specifies the B-tree split ratio for all other nodes.

**Examples**

```
dxpl = H5P.create('H5P_DATASET_XFER');
H5P.set_btree_ratios(dxpl, 0.2, 0.6, 0.95);
```

**See Also** `H5P.get_btree_ratios`

- Purpose** Set raw data chunk cache parameters
- Syntax** `H5P.set_chunk_cache(dapl_id, rdcc_nslots, rdcc_nbytes, rdcc_w0)`
- Description** `H5P.set_chunk_cache(dapl_id, rdcc_nslots, rdcc_nbytes, rdcc_w0)` sets the number of elements (`rdcc_nslots`), the total number of bytes (`rdcc_nbytes`), and the preemption policy value (`rdcc_w0`) in the raw data chunk cache.
- Examples**
- ```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/vlen3D');
dapl = H5D.get_access_plist(dset_id);
H5P.set_chunk_cache(dapl, 500, 1e6, 0.7);
H5P.close(dapl);
H5D.close(dset_id);
H5F.close(fid);
```
- See Also** `H5P.get_chunk_cache`

# H5P.set\_dxpl\_multi

---

**Purpose** Set data transfer property list for multifile driver

**Syntax** `H5P.set_dxpl_multi(dxpl_id, memb_dxpl)`

**Description** `H5P.set_dxpl_multi(dxpl_id, memb_dxpl)` sets the data transfer property list `dxpl_id` to use the multifile driver. `memb_dxpl` is an array of data access property lists.

**See Also** `H5P.get_dxpl_multi`

**Purpose** Enable error detection for dataset transfer

**Syntax** `H5P.set_edc_check(plist_id,check)`

**Description** `H5P.set_edc_check(plist_id,check)` sets the dataset transfer property list specified by `plist_id` to enable or disable error detection when reading data. `check` can have the value `H5Z_ENABLE_EDC` or `H5Z_DISABLE_EDC`.

**Examples** Disable error detection for a default dataset transfer property list.

```
dxpl = H5P.create('H5P_DATASET_XFER');  
H5P.set_edc_check(dxpl, 'H5Z_DISABLE_EDC');
```

**See Also** `H5P.get_edc_check`

# H5P.set\_hyper\_vector\_size

---

**Purpose** Set number of I/O vectors for hyperslab I/O

**Syntax** `H5P.set_hyper_vector_size(dxpl_id,size)`

**Description** `H5P.set_hyper_vector_size(dxpl_id,size)` sets the number of I/O vectors to be accumulated in memory before being issued to the lower levels of the HDF5 library for reading or writing the actual data. `dxpl_id` is a dataset transfer property list identifier. `size` specifies the number of I/O vectors to accumulate in memory for I/O operations.

**Examples**

```
dxpl = H5P.create('H5P_DATASET_XFER');  
H5P.set_hyper_vector_size(dxpl,2048);
```

**See Also** `H5P.get_hyper_vector_size`

**Purpose** Determine availability of all filters

**Syntax** `value = H5P.all_filters_avail(dcpl_id)`

**Description** `value = H5P.all_filters_avail(dcpl_id)` returns a positive value if all of the filters set in the dataset creation property list `dcpl_id` are currently available, and zero if they are not. A negative value indicates failure.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
dcpl = H5D.get_create_plist(dset_id);
if H5P.all_filters_avail(dcpl)
    fprintf('all filters available\n');
else
    fprintf('all filters not available\n');
end
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5P.set_filter`

# H5P.fill\_value\_defined

---

**Purpose** Determine if fill value is defined

**Syntax** `fvstatus = H5P.fill_value_defined(plist_id)`

**Description** `fvstatus = H5P.fill_value_defined(plist_id)` determines whether a fill value is defined in the dataset creation property list `plist_id`. The `fvstatus` output can have any of the following values: `H5D_FILL_VALUE_UNDEFINED`, `H5D_FILL_VALUE_DEFAULT`, or `H5D_FILL_VALUE_USER_DEFINED`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
dcpl = H5D.get_create_plist(dset_id);
fvstatus = H5P.fill_value_defined(dcpl);
switch(fvstatus)
    case H5ML.get_constant_value('H5D_FILL_VALUE_UNDEFINED')
        fprintf('fill value undefined\n');
    case H5ML.get_constant_value('H5D_FILL_VALUE_DEFAULT')
        fprintf('fill value set to default\n');
    case H5ML.get_constant_value('H5D_FILL_VALUE_USER_DEFINED')
        fprintf('fill value is user defined\n');
end
```

**See Also** `H5P.get_fill_value` | `H5P.set_fill_value`

**Purpose** Return timing of storage space allocation

**Syntax** `alloc_time = H5P.get_alloc_time(plist_id)`

**Description** `alloc_time = H5P.get_alloc_time(plist_id)` retrieves the timing for storage space allocation from the dataset creation property list specified by `plist_id`. The `alloc_time` output can have any of the following values: `H5D_ALLOC_TIME_DEFAULT`, `H5D_ALLOC_TIME_EARLY`, `H5D_ALLOC_TIME_INCR`, or `H5D_ALLOC_TIME_LATE`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
alloc_time = H5P.get_alloc_time(dcpl);
switch(alloc_time)
    case H5ML.get_constant_value('H5D_ALLOC_TIME_DEFAULT')
        fprintf('allocation time is default\n');
    case H5ML.get_constant_value('H5D_ALLOC_TIME_EARLY')
        fprintf('allocation time is dataset creation time\n');
    case H5ML.get_constant_value('H5D_ALLOC_TIME_INCR')
        fprintf('allocation time is incremental\n');
    case H5ML.get_constant_value('H5D_ALLOC_TIME_LATE')
        fprintf('allocation time is when data is first written\n');
end
```

# H5P.get\_chunk

---

**Purpose** Return size of chunks

**Syntax** `[rank,h5_chunk_dims] = H5P.get_chunk(plist_id)`

**Description** `[rank,h5_chunk_dims] = H5P.get_chunk(plist_id)` retrieves the size of chunks for the raw data of a chunked layout dataset for the dataset creation property list specified by `plist_id`.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_chunk_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g4/time');
dcpl = H5D.get_create_plist(dset_id);
[rank,chunk_dims] = H5P.get_chunk(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5P.set_chunk`

**Purpose** Return information about external file

**Syntax** `[name,offset,size] = H5P.get_external(plist_id,idx)`

**Description** `[name,offset,size] = H5P.get_external(plist_id,idx)` returns information about the external file specified by the dataset creation property list `plist_id`. The `idx` specifies the external file index, which is a number from zero to `N-1`, where `N` is the value returned by `H5P.get_external_count`. The `name` output returns the name of the external file (limited by 2048 characters). The `offset` output returns the location in bytes, from the beginning of the external file, where the data starts. The `size` output returns the size of the external data.

**See Also** `H5P.get_external_count`

# H5P.get\_external\_count

---

**Purpose** Return count of external files

**Syntax** `num_files = H5P.get_external_count(plist_id)`

**Description** `num_files = H5P.get_external_count(plist_id)` returns the number of external files for the dataset creation property list, `plist_id`.

**See Also** `H5P.get_external`

**Purpose** Return time when fill values are written to dataset

**Syntax** `fill_time = H5P.get_fill_time(plist_id)`

**Description** `fill_time = H5P.get_fill_time(plist_id)` returns the time when fill values are written to the dataset specified by the dataset creation property list `plist_id`. The `fill_time` output is one of the following values: `H5D_FILL_TIME_IFSET`, `H5D_FILL_TIME_ALLOC`, or `H5D_FILL_TIME_NEVER`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
fill_time = H5P.get_fill_time(dcpl);
switch(fill_time)
    case H5ML.get_constant_value('H5D_FILL_TIME_IFSET')
        fprintf('upon allocation if and only if fill value set by user\n');
    case H5ML.get_constant_value('H5D_FILL_TIME_ALLOC')
        fprintf('written when storage space is allocated\n');
    case H5ML.get_constant_value('H5D_FILL_TIME_NEVER')
        fprintf('fill values are never written\n');
end
```

**See Also** `H5P.get_fill_time` | `H5P.set_fill_value`

# H5P.get\_fill\_value

---

**Purpose** Return dataset fill value

**Syntax** `value = H5P.get_fill_value(plist_id,type_id)`

**Description** `value = H5P.get_fill_value(plist_id,type_id)` returns the dataset fill value defined in the dataset creation property list `plist_id`. The `type_id` input specifies the datatype of the returned fill value.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
type_id = H5T.copy('H5T_NATIVE_INT');
fill_value = H5P.get_fill_value(dcpl,type_id);
```

**See Also** `H5P.set_fill_value` | `H5P.get_fill_time` | `H5P.set_fill_time`

<b>Purpose</b>	Return information about filter in pipeline
<b>Syntax</b>	<pre>[filter,flags,cd_values,name] = H5P.get_filter(plist_id, index) [filter,flags,cd_values,name, filter_config] = H5P.get_filter(plist_id,index)</pre>
<b>Description</b>	<p>[filter,flags,cd_values,name] = H5P.get_filter(plist_id, index) returns information about the filter, specified by its filter index, in the filter pipeline, specified by the property list with which it is associated. This interface corresponds to the 1.6 version of H5Pget_filter in the HDF5 library.</p> <p>[filter,flags,cd_values,name, filter_config] = H5P.get_filter(plist_id,index) returns information about the filter, specified by its filter index, in the filter pipeline, specified by the property list with which it is associated. It also returns information about the filter. Consult the HDF5 documentation for H5Zget_filter_info for information about filter_config. This interface corresponds to the 1.8 version of H5Pget_filter in the HDF5 library.</p>
<b>See Also</b>	<p>H5P.get_nfilters   H5P.get_filter_by_id   H5P.modify_filter   H5P.remove_filter</p>

# H5P.get\_filter\_by\_id

---

**Purpose** Return information about specified filter

**Syntax** `[flags,cd_values,name,  
filter_config] = H5P.get_filter_by_id(plist_id,idx)`

**Description** `[flags,cd_values,name, filter_config] =`  
H5P.get\_filter\_by\_id(plist\_id,idx) returns information about the filter specified by the filter id, idx.

**See Also** H5P.get\_filter | H5P.get\_nfilters | H5P.modify\_filter |  
H5P.remove\_filter

**Purpose** Determine layout of raw data for dataset

**Syntax** `layout = H5P.get_layout(dcpl)`

**Description** `layout = H5P.get_layout(dcpl)` returns the layout of the raw data for the dataset specified by the dataset creation property list, `dcpl`. Possible values are: `H5D_COMPACT`, `H5D_CONTIGUOUS`, or `H5D_CHUNKED`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
layout = H5P.get_layout(dcpl);
switch(layout)
    case H5ML.get_constant_value('H5D_COMPACT')
        fprintf('layout is compact\n');
    case H5ML.get_constant_value('H5D_CONTIGUOUS')
        fprintf('layout is contiguous\n');
    case H5ML.get_constant_value('H5D_CHUNKED')
        fprintf('layout is chunked\n');
end
```

**See Also** `H5P.set_layout`

# H5P.get\_nfilters

---

**Purpose** Return number of filters in pipeline

**Syntax** `num_filters = H5P.get_nfilters(plist_id)`

**Description** `num_filters = H5P.get_nfilters(plist_id)` returns the number of filters defined in the filter pipeline associated with the dataset creation property list, `plist_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g4/world');
dcpl = H5D.get_create_plist(dset_id);
num_filters = H5P.get_nfilters(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** [H5P.get\\_filter](#) | [H5P.get\\_filter\\_by\\_id](#) | [H5P.modify\\_filter](#) | [H5P.remove\\_filter](#)

<b>Purpose</b>	Modify filter in pipeline
<b>Syntax</b>	<code>H5P.modify_filter(plist_id,filter_id,flags,cd_values)</code>
<b>Description</b>	<code>H5P.modify_filter(plist_id,filter_id,flags,cd_values)</code> modifies the specified filter in the filter pipeline. <code>plist_id</code> is a property list identifier. <code>flags</code> is a bit vector specifying certain general properties of the filter. <code>cd_values</code> specifies auxiliary data for the filter.
<b>See Also</b>	<code>H5P.get_filter</code>   <code>H5P.get_nfilters</code>   <code>H5P.get_filter_by_id</code>   <code>H5P.remove_filter</code>

# H5P.remove\_filter

---

**Purpose** Remove filter from property list

**Syntax** `H5P.remove_filter(plist_id,filter)`

**Description** `H5P.remove_filter(plist_id,filter)` removes the specified filter from the filter pipeline. `plist_id` is the dataset creation property list identifier.

**See Also** `H5P.get_filter` | `H5P.get_nfilters` | `H5P.get_filter_by_id` | `H5P.modify_filter`

**Purpose** Set timing for storage space allocation

**Syntax** `H5P.set_alloc_time(plist_id,alloc_time)`

**Description** `H5P.set_alloc_time(plist_id,alloc_time)` sets the timing for the allocation of storage space for a dataset's raw data. `plist_id` is a dataset creation property list. `alloc_time` can have any of the following values: `H5D_ALLOC_TIME_DEFAULT`, `H5D_ALLOC_TIME_EARLY`, `H5D_ALLOC_TIME_INC`, or `H5D_ALLOC_TIME_LATE`.

**Examples** Create a 1000x500 double precision dataset with late allocation time.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [1000 500];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
alloc_time = H5ML.get_constant_value('H5D_ALLOC_TIME_LATE');
H5P.set_alloc_time(dcpl,alloc_time);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5P.get_alloc_time`

# H5P.set\_chunk

---

<b>Purpose</b>	Set chunk size
<b>Syntax</b>	<code>H5P.set_chunk(plist_id,h5_chunk_dims)</code>
<b>Description</b>	<code>H5P.set_chunk(plist_id,h5_chunk_dims)</code> sets the size of the chunks used to store a chunked layout dataset. <code>plist_id</code> is a dataset creation property list identifier. <code>h5_chunk_dims</code> is an array specifying the size, in dataset elements, of each chunk.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_chunk_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

Create a two dimensional double precision dataset that has an initial size of [512 1024], but is also unlimited in both dimensions and has a chunk size of [512 1024].

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
unlimited = H5ML.get_constant_value('H5S_UNLIMITED');
dims = [512 1024];
h5_dims = fliplr(dims);
h5_maxdims = [unlimited unlimited];
space_id = H5S.create_simple(2,[1024 512],h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [512 1024];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
dset_id = H5D.create(fid, 'DS', type_id, space_id, dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** [H5P.get\\_chunk](#)

# H5P.set\_deflate

---

**Purpose** Set compression method and compression level

**Syntax** `H5P.set_deflate(plist_id,level)`

**Description** `H5P.set_deflate(plist_id,level)` sets the compression method for the dataset creation property list specified by `plist_id` to `H5D_COMPRESS_DEFLATE`. `level` specifies the compression level as a value from 0 and 9, inclusive. Lower values results in less compression.

**Examples** Create a two dimensional double precision dataset that has an initial size of [512 1024], but is also unlimited in both dimensions and has a chunk size of [512 1024] and a compression level of 5.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
unlimited = H5ML.get_constant_value('H5S_UNLIMITED');
dims = [512 1024];
h5_dims = fliplr(dims);
h5_maxdims = [unlimited unlimited];
space_id = H5S.create_simple(2,[1024 512],h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [512 1024];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_deflate(dcpl,5);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

<b>Purpose</b>	Add additional file to external file list
<b>Syntax</b>	<code>H5P.set_external(plist_id,name,offset,nbytes)</code>
<b>Description</b>	<code>H5P.set_external(plist_id,name,offset,nbytes)</code> adds the external file specified by name to the list of external files in the dataset creation property list, <code>plist_id</code> . The <code>offset</code> argument specifies the location, in bytes, where the data starts relative to the beginning of the file. <code>nbytes</code> is the number of bytes reserved in the file for the data. <code>nbytes</code> may also be given as 'H5F_UNLIMITED', in which case the external file may be of unlimited size.
<b>Examples</b>	<p>Create a dataset with an unlimited size external file.</p> <pre>fid = H5F.create('myfile.h5'); type_id = H5T.copy('H5T_NATIVE_DOUBLE'); dims = [100 50]; h5_dims = fliplr(dims); h5_maxdims = h5_dims; space_id = H5S.create_simple(2,h5_dims,h5_maxdims); dcpl = H5P.create('H5P_DATASET_CREATE'); H5P.set_external(dcpl,'myexternalfile.dat',0,'H5F_UNLIMITED'); dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl); data = rand(dims); dxpl = 'H5P_DEFAULT'; H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',dxpl,data); H5D.close(dset_id); H5F.close(fid);</pre>
<b>See Also</b>	<code>H5P.get_external</code>   <code>H5ML.get_constant_value</code>

# H5P.set\_fill\_time

---

**Purpose** Set time when fill values are written to dataset

**Syntax** `H5P.set_fill_time(plist_id,fill_time)`

**Description** `H5P.set_fill_time(plist_id,fill_time)` sets the timing for writing fill values to a dataset in the dataset creation property list `plist_id`. The timing can be specified by one of the following values: `H5D_FILL_TIME_IFSET`, `H5D_FILL_TIME_ALLOC`, or `H5D_FILL_TIME_NEVER`.

**Examples**

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 50];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
fill_time = H5ML.get_constant_value('H5D_FILL_TIME_ALLOC');
H5P.set_fill_time(dcpl,fill_time);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5P.get_fill_time` | `H5P.get_fill_value` | `H5P.set_fill_value`

<b>Purpose</b>	Set fill value for dataset creation property list
<b>Syntax</b>	<code>H5P.set_fill_value(plist_id,type_id,value)</code>
<b>Description</b>	<code>H5P.set_fill_value(plist_id,type_id,value)</code> sets the fill value for a the dataset creation property list specified by <code>plist_id</code> . The <code>value</code> argument specifies the fill value. <code>type_id</code> specifies the datatype of the fill value. Setting <code>value</code> to an empty array indicates that the fill value is to be undefined.
<b>Examples</b>	<p>Create a double precision dataset with a fill value of -999.</p> <pre>fid = H5F.create('myfile.h5'); type_id = H5T.copy('H5T_NATIVE_DOUBLE'); dims = [100 50]; h5_dims = flip1r(dims); h5_maxdims = h5_dims; space_id = H5S.create_simple(2,h5_dims,h5_maxdims); dcpl = H5P.create('H5P_DATASET_CREATE'); fill_time = H5ML.get_constant_value('H5D_FILL_TIME_ALLOC'); H5P.set_fill_time(dcpl,fill_time); type_id = H5T.copy('H5T_NATIVE_DOUBLE'); H5P.set_fill_value(dcpl,type_id,-999); dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl); H5D.close(dset_id); H5F.close(fid);</pre>

# H5P.set\_filter

---

**Purpose** Add filter to filter pipeline

**Syntax** `H5P.set_filter(plist_id,filter,flags,cd_values)`

**Description** `H5P.set_filter(plist_id,filter,flags,cd_values)` adds the specified filter and corresponding properties to the end of an output filter pipeline. `plist_id` is a property list identifier. `filter` is a filter identifier and should correspond to one of the following values:

`H5P_FILTER_DEFLATE`

`H5P_FILTER_SHUFFLE`

`H5P_FILTER_FLETCHER32`

`flags` is a bit vector specifying properties of the filter. `cd_values` is an array that contains auxiliary data for the filter.

**See Also** `H5P.set_deflate` | `H5P.set_fletcher32` | `H5P.set_shuffle`

**Purpose** Set Fletcher32 checksum filter in dataset creation

**Syntax** `H5P.set_fletcher32(plist_id)`

**Description** `H5P.set_fletcher32(plist_id)` sets the Fletcher32 checksum filter in the dataset creation property list specified by `plist_id`. The dataset creation property list must also have chunking enabled.

**Examples**

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [10 20];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_fletcher32(dcpl);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5P.set_deflate` | `H5P.set_shuffle`

# H5P.set\_layout

---

**Purpose** Set type of storage for dataset

**Syntax** `H5P.set_layout(dcpl,layout)`

**Description** `H5P.set_layout(dcpl,layout)` sets the type of storage used to store the raw data for the dataset creation property list, `dcpl`. The `layout` argument specifies the type of storage layout for raw data: `H5D_COMPACT`, `H5D_CONTIGUOUS`, or `H5D_CHUNKED`.

**Examples**

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
layout = H5ML.get_constant_value('H5D_CONTIGUOUS');
H5P.set_layout(dcpl,layout);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** [H5P.get\\_layout](#) | [H5P.set\\_chunk](#)

**Purpose** Set N-Bit filter

**Syntax** `H5P.set_nbit(plist_id)`

**Description** `H5P.set_nbit(plist_id)` sets the N-Bit filter, `H5Z_FILTER_NBIT`, in the dataset creation property list `plist_id`.

# H5P.set\_scaleoffset

---

**Purpose** Set Scale-Offset filter

**Syntax** `H5P.set_scaleoffset(plistId, scaleType, scaleFactor)`

**Description** `H5P.set_scaleoffset(plistId, scaleType, scaleFactor)` sets the Scale-Offset filter, `H5Z_FILTER_SCALEOFFSET`, for a dataset. For integer data types, the parameter `scaleType` should be set to the enumerated value `H5Z_S0_INT`. For floating-point data types, the `scaleType` should be the enumerated value `H5Z_S0_FLOAT_DSCALE`. Chunking must already be enabled on the dataset creation property list.

**See Also** `H5P.set_chunk`

**Purpose** Set shuffle filter

**Syntax** H5P.set\_shuffle(plist\_id)

**Description** H5P.set\_shuffle(plist\_id) sets the shuffle filter, H5Z\_FILTER\_SHUFFLE, in the dataset creation property list plist\_id. Compression must be enabled on the dataset creation property list in order to use the shuffle filter, and best results are usually obtained when the shuffle filter is set immediately prior to setting the deflate filter.

**Examples**

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [10 20];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_shuffle(dcpl);
H5P.set_deflate(dcpl,5);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** H5P.set\_deflate

# H5P.get\_alignment

---

**Purpose** Retrieve alignment properties

**Syntax** [threshold,alignment] = H5P.get\_alignment(plist\_id)

**Description** [threshold,alignment] = H5P.get\_alignment(plist\_id) retrieves the current settings for alignment properties from the file access property list specified by `plist_id`.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
[threshold,alignment] = H5P.get_alignment(fapl);
H5P.close(fapl);
H5F.close(fid);
```

**Purpose** Low-level file driver

**Syntax** `driver_id = H5P.get_driver(plist_id)`

**Description** `driver_id = H5P.get_driver(plist_id)` returns the identifier of the low-level file driver associated with the file access property list or data transfer property list specified by `plist_id`. See HDF5 documentation for a list of valid return values.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
driver_id = H5P.get_driver(fapl);
if ( driver_id == H5ML.get_constant_value('H5FD_SEC2') )
    fprintf('File driver is H5FD_SEC2.\n');
end
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5ML.get_constant_value`

# H5P.get\_family\_offset

---

**Purpose**            Offset for family file driver

**Syntax**            `offset = H5P.get_family_offset(fapl_id)`

**Description**       `offset = H5P.get_family_offset(fapl_id)` retrieves the value of `offset` from the file access property list, `fapl_id`. `offset` is the offset of the data in the HDF5 file that is stored on disk in the selected member file in a family of files.

**See Also**       `H5P.set_family_offset`

**Purpose** Information about core file driver properties

**Syntax** [increment,backing\_store] = H5P.get\_fapl\_core(fapl\_id)

**Description** [increment,backing\_store] = H5P.get\_fapl\_core(fapl\_id) queries the H5FD\_CORE driver properties as set by H5P.set\_fapl\_core. The fapl\_id argument specifies a file access property list. The return value increment specifies the size, in bytes, of memory increments. backing\_store is a Boolean flag indicating whether to write the file contents to disk when the file is closed.

**See Also** H5P.set\_fapl\_core

# H5P.get\_fapl\_family

---

**Purpose** File access property list information

**Syntax** [memb\_size,memb\_fapl\_id] = H5P.get\_fapl\_family(fapl\_id)

**Description** [memb\_size,memb\_fapl\_id] = H5P.get\_fapl\_family(fapl\_id) returns the size in bytes of each file member and the identifier of the file access property list for use with the family driver specified by fapl\_id.

**See Also** H5P.set\_fapl\_family

**Purpose** Information about multifile access property list

**Syntax** [memb\_map,memb\_fapl,memb\_name,memb\_addr,  
relax] = H5P.get\_fapl\_multi(fapl\_id)

**Description** [memb\_map,memb\_fapl,memb\_name,memb\_addr, relax] = H5P.get\_fapl\_multi(fapl\_id) returns information about the multifile access property list specified by fapl\_id. The memb\_map output maps memory usage types to other memory usage types. memb\_fapl is a property list for each memory usage type. memb\_name is the name generator for names of member files. relax is a Boolean value that, when non-zero, allows read-only access to incomplete file sets.

**See Also** H5P.set\_fapl\_multi

# H5P.get\_fcclose\_degree

---

**Purpose** File close degree

**Syntax** `degree = H5P.get_fcclose_degree(fapl_id)`

**Description** `degree = H5P.get_fcclose_degree(fapl_id)` returns the current setting of the file close degree property `fc_degree` in the file access property list specified by `fapl_id`. Possible return values are: `H5F_CLOSE_DEFAULT`, `H5F_CLOSE_WEAK`, `H5F_CLOSE_SEMI`, or `H5F_CLOSE_STRONG`.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
degree = H5P.get_fcclose_degree(fapl);
switch(degree)
    case H5ML.get_constant_value('H5F_CLOSE_DEFAULT')
        fprintf('file close degree is default\n');
    case H5ML.get_constant_value('H5F_CLOSE_WEAK')
        fprintf('file close degree is weak\n');
    case H5ML.get_constant_value('H5F_CLOSE_SEMI')
        fprintf('close degree is semi\n');
    case H5ML.get_constant_value('H5F_CLOSE_STRONG')
        fprintf('close degree is strong\n');
end
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5P.set_fcclose_degree`

<b>Purpose</b>	Library version bounds settings
<b>Syntax</b>	<code>[low,high] = H5P.get_libver_bounds(fapl_id)</code>
<b>Description</b>	<code>[low,high] = H5P.get_libver_bounds(fapl_id)</code> gets bounds on library version bounds settings that control the format versions used when creating objects in the file with access property list <code>fapl_id</code> .
<b>Examples</b>	<pre>fid = H5F.open('example.h5'); fapl = H5F.get_access_plist(fid); [low,high] = H5P.get_libver_bounds(fapl);</pre>
<b>See Also</b>	<code>H5F.get_access_plist</code>   <code>H5P.set_libver_bounds</code>

# H5P.get\_gc\_references

---

**Purpose** Garbage collection references setting

**Syntax** `gc_ref = H5P.get_gc_references(fapl_id)`

**Description** `gc_ref = H5P.get_gc_references(fapl_id)` returns the current setting for the garbage collection references property from the file access property list specified by `fapl_id`. If `gc_ref` is 1, garbage collection is on; if 0, garbage collection is off.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
gc_ref = H5P.get_gc_references(fapl);
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5P.set_gc_references`

**Purpose** Metadata cache configuration

**Syntax** `config_struct = H5P.get_mdc_config(plist_id)`

**Description** `config_struct = H5P.get_mdc_config(plist_id)` returns the current metadata cache configuration from the indicated file access property list.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
config = H5P.get_mdc_config(fapl);
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5P.set_mdc_config`

# H5P.get\_meta\_block\_size

---

**Purpose** Metadata block size setting

**Syntax** `sz = H5P.get_meta_block_size(fapl_id)`

**Description** `sz = H5P.get_meta_block_size(fapl_id)` returns the current minimum size, in bytes, of new metadata block allocations.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_meta_block_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5P.set_meta_block_size`

**Purpose** Type of data property for MULTI driver

**Syntax** `type = H5P.get_multi_type(fapl_id)`

**Description** `type = H5P.get_multi_type(fapl_id)` returns the type of data setting from the file access or data transfer property list, `fapl_id`.

This function should only be used with an HDF5 file written as a set of files with the MULTI file driver.

**See Also** `H5P.set_multi_type`

# H5P.get\_sieve\_buf\_size

---

**Purpose** Maximum data sieve buffer size

**Syntax** `sz = H5P.get_sieve_buf_size(fapl_id)`

**Description** `sz = H5P.get_sieve_buf_size(fapl_id)` returns the current maximum size of the data sieve buffer.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_sieve_buf_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5P.set_sieve_buf_size`

# H5P.get\_small\_data\_block\_size

---

**Purpose** Small data block size setting

**Syntax** `sz = H5P.get_small_data_block_size(fapl_id)`

**Description** `sz = H5P.get_small_data_block_size(fapl_id)` returns the current setting for the size of the small data block. `fapl_id` is a file access property list identifier.

**Examples**

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_small_data_block_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

**See Also** `H5P.set_small_data_block_size`

# H5P.set\_alignment

---

**Purpose** Set alignment properties for file access property list

**Syntax** `H5P.set_alignment(fapl_id, threshold, alignment)`

**Description** `H5P.set_alignment(fapl_id, threshold, alignment)` sets the alignment properties of the file access property list specified by `fapl_id` so that any file object greater than or equal in size to `threshold` (in bytes) is aligned on an address which is a multiple of `alignment`.

In most cases the default values of `threshold` and `alignment` result in the best performance.

**See Also** `H5P.get_alignment`

**Purpose** Set offset property for family of files

**Syntax** `H5P.set_family_offset(fapl_id,offset)`

**Description** `H5P.set_family_offset(fapl_id,offset)` sets offset property in the file access property list specified by `fapl_id` for low-level access to a file in a family of files. `offset` identifies a user-determined location from the beginning of the HDF5 file in bytes.

**See Also** `H5P.get_family_offset`

# H5P.set\_fapl\_core

---

**Purpose** Modify file access to use H5FD\_CORE driver

**Syntax** H5P.set\_fapl\_core(fapl\_id,increment,backing\_store)

**Description** H5P.set\_fapl\_core(fapl\_id,increment,backing\_store) modifies the file access property list to use the H5FD\_CORE driver. increment specifies the increment by which allocated memory is to be increased each time more memory is required. backing\_store is a Boolean flag that, when non-zero, indicates the file contents should be written to disk when the file is closed.

**Examples** Create a file image in memory only.

```
plist = 'H5P_DEFAULT';
ndatasets = 20;
block_size = 1024*1024;
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_core(fapl,2^16,false);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist,fapl);
space_id = H5S.create_simple(1, block_size, []);
type_id = H5T.copy('H5T_IEEE_F64LE');
data = zeros(block_size,1);
for j = 1:ndatasets
    dsname = sprintf('dset%02d', j);
    fprintf('Writing dataset %s...\n',dsname);
    dsid = H5D.create(fid,dsname,type_id,space_id,'H5P_DEFAULT');
    H5D.write(dsid,'H5ML_DEFAULT',space_id,space_id,plist,data);
    H5D.close(dsid);
end
H5P.close(fapl);
H5S.close(space_id);
H5T.close(type_id);
H5F.close(fid);
dir('myfile.h5');
```

**See Also** H5P.get\_fapl\_core

**Purpose**

Set file access to use family driver

**Syntax**

```
H5P.set_fapl_family(fapl_id,memb_size,memb_fapl_id)
```

**Description**

H5P.set\_fapl\_family(fapl\_id,memb\_size,memb\_fapl\_id) sets the file access property list, specified by fapl\_id, to use the family driver. memb\_size is the size in bytes of each file member. memb\_fapl\_id is the identifier of the file access property list to be used for each family member.

**Examples**

```
plist = 'H5P_DEFAULT';
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_family(fapl, 8192, plist);
fid = H5F.create('family%d.h5','H5F_ACC_TRUNC','H5P_DEFAULT',fapl);
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [50 25];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,[]);
dset_id = H5D.create(fid,'DS',type_id,space_id,plist)
data = reshape(1:prod(dims),dims);
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5P.close(fapl);
H5T.close(type_id);
H5S.close(space_id);
H5D.close(dset_id);
dir('* .h5');
h5disp('family%d.h5');
```

**See Also** H5P.get\_fapl\_family

# H5P.set\_fapl\_log

---

**Purpose** Set use of logging driver

**Syntax** `H5P.set_fapl_log(fapl_id,logfile,flags,buf_size)`

**Description** `H5P.set_fapl_log(fapl_id,logfile,flags,buf_size)` modifies the file access property list, `fapl_id`, to use the logging driver `H5FD_LOG`. `logfile` is the name of the file in which the logging entries are to be recorded. `flags` is a bit mask that specifies the types of activity to log. See the HDF5 documentation for a list of available flag settings. `buf_size` specifies the size of the logging buffer.

**Purpose** Set use of multifile driver

**Syntax** `H5P.set_fapl_multi(fapl_id,relax)`  
`H5P.set_fapl_multi(fapl_id,memb_map,memb_fapl,memb_name,  
memb_addr,relax)`

**Description** `H5P.set_fapl_multi(fapl_id,relax)` sets the file access property list, `fapl_id`, to access HDF5 files created with the multi-driver with default values provided by the HDF5 library. `relax` is a Boolean value that allows read-only access to incomplete file sets when set to 1.

`H5P.set_fapl_multi(fapl_id,memb_map,memb_fapl,memb_name,memb_addr,relax)` sets the file access property list to use the multifile driver. `memb_map` maps memory usage types to other memory usage types. `memb_fapl` contains a property list for each memory usage type. `memb_name` is a name generator for names of member files. `memb_addr` specifies the offsets within the virtual address space at which each type of data storage begins.

**See Also** `H5P.get_fapl_multi`

# H5P.set\_fapl\_sec2

---

**Purpose** Set file access for sec2 driver

**Syntax** H5P.set\_fapl\_sec2(fapl\_id)

**Description** H5P.set\_fapl\_sec2(fapl\_id) modifies the file access property list, fapl\_id, to use the H5FD\_SEC2 driver.

**Examples**

```
fcp1 = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_sec2(fapl);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcp1, fapl);
H5F.close(fid);
```

**Purpose**

Set file access for emulation of split file driver

**Syntax**

```
H5P.set_fapl_split(fapl_id,meta_ext,meta_plist_id,raw_ext,  
raw_plist_id)
```

**Description**

H5P.set\_fapl\_split(fapl\_id,meta\_ext,meta\_plist\_id,raw\_ext,raw\_plist\_id) is a compatibility function that enables the multi-file driver to emulate the split driver from HDF5 Releases 1.0 and 1.2. meta\_ext is a text string that specifies the metadata filename extension. meta\_plist\_id is a file access property list identifier for the metadata file. raw\_ext is a text string that specifies the raw data filename extension. raw\_plist\_id is the file access property list identifier for the raw data file.

# H5P.set\_fapl\_stdio

---

**Purpose** Set file access for standard I/O driver

**Syntax** H5P.set\_fapl\_stdio(fapl\_id)

**Description** H5P.set\_fapl\_stdio(fapl\_id) modifies the file access property list, fapl\_id, to use the standard I/O driver, H5FD\_STDIO.

**Examples**

```
fcp1 = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_stdio(fapl);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcp1, fapl);
H5F.close(fid);
```

**Purpose** Set file access for file close degree

**Syntax** `H5P.set_fcclose_degree(fapl_id,degree)`

**Description** `H5P.set_fcclose_degree(fapl_id,degree)` sets the file close degree property in the file access property list, `fapl_id`, to the value specified by degree. The degree argument can have any of the following values:

```
'H5F_CLOSE_WEAK'  
'H5F_CLOSE_SEMI'  
'H5F_CLOSE_STRONG'  
'H5F_CLOSE_DEFAULT'
```

**Examples**

```
fcpl = H5P.create('H5P_FILE_CREATE');  
fapl = H5P.create('H5P_FILE_ACCESS');  
H5P.set_fcclose_degree(fapl, 'H5F_CLOSE_STRONG');  
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);  
H5F.close(fid);
```

**See Also** `H5P.get_fcclose_degree`

# H5P.set\_gc\_references

---

**Purpose** Set garbage collection references flag

**Syntax** `H5P.set_gc_references(fapl_id,gc_ref)`

**Description** `H5P.set_gc_references(fapl_id,gc_ref)` sets the flag for garbage collecting references for the file specified by the file access property list identifier, `fapl_id`. The `gc_ref` argument is a flag setting reference garbage collection to on (1) or off (0).

**Examples**

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_gc_references(fapl,1);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

**See Also** `H5P.get_gc_references`

**Purpose**

Set library version bounds for objects

**Syntax**

```
H5P.get_libver_bounds(fapl_id,low,high)
```

**Description**

`H5P.get_libver_bounds(fapl_id,low,high)` sets bounds on library versions, and indirectly format versions, to be used when creating objects in the file with access property list `fapl_id`. The low argument must be set to either of `'H5F_LIBVER_EARLIEST'`, `'H5F_LIBVER_18'` or `'H5F_LIBVER_LATEST'`. The high argument must be set to `'H5F_LIBVER_18'` or `'H5F_LIBVER_LATEST'`.

**Examples**

Create an HDF5 file where objects are created using the latest available format for each object.

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_libver_bounds(fapl,'H5F_LIBVER_LATEST','H5F_LIBVER_LATEST');
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
```

**See Also**

`H5P.get_libver_bounds` | `H5ML.get_constant_value`

# H5P.set\_mdc\_config

---

**Purpose** Set initial metadata cache configuration

**Syntax** `H5P.set_mdc_config(plist_id,config_struct)`

**Description** `H5P.set_mdc_config(plist_id,config_struct)` sets the initial metadata cache configuration in the indicated file access property list to the supplied values. Before using this function, you should retrieve the current configuration using `H5P.get_mdc_config`.

Many of the fields in the structure, `config_struct`, are intended to be used only in close consultation with the HDF5 Group itself.

**See Also** `H5P.get_mdc_config`

- Purpose** Set minimum metadata block size
- Syntax** `H5P.set_meta_block_size(fapl_id,size)`
- Description** `H5P.set_meta_block_size(fapl_id,size)` sets the minimum metadata block size for the file access property list specified by `fapl_id`. The `size` argument specifies minimum size, in bytes, of metadata block allocations.
- Examples**
- ```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_meta_block_size(fapl,4096);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```
- See Also** `H5P.get_meta_block_size`

# H5P.set\_multi\_type

---

**Purpose** Specify type of data accessed with MULTI driver

**Syntax** `H5P.set_multi_type(fapl_id,type)`

**Description** `H5P.set_multi_type(fapl_id,type)` sets the type of data property in the file access or data transfer property list `fapl_id`. The `type` argument can have any of the following values: `H5FD_MEM_SUPER`, `H5FD_MEM_BTREE`, `H5FD_MEM_DRAW`, `H5FD_MEM_GHEAP`, `H5FD_MEM_LHEAP`, or `H5FD_MEM_OHDR`.

**See Also** `H5P.get_multi_type`

**Purpose** Set maximum size of data sieve buffer

**Syntax** H5P.set\_sieve\_buf\_size(fapl\_id,buffer\_size)

**Description** H5P.set\_sieve\_buf\_size(fapl\_id,buffer\_size) sets buffer\_size, the maximum size in bytes of the data sieve buffer, which is used by file drivers that are capable of using data sieving. fapl\_id is a file access property list identifier.

**Examples**

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_sieve_buf_size(fapl,131072);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

**See Also** H5P.get\_sieve\_buf\_size

# H5P.set\_small\_data\_block\_size

---

**Purpose** Set size of block reserved for small data

**Syntax** `H5P.set_small_data_block_size(fapl_id,size)`

**Description** `H5P.set_small_data_block_size(fapl_id,size)` sets the maximum size, in bytes, of a contiguous block reserved for small data. `fapl_id` is a file access property list identifier.

**Examples**

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_small_data_block_size(fapl,4096);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

**See Also** `H5P.get_small_data_block_size`

**Purpose** Return 1/2 rank of indexed storage B-tree

**Syntax** `ik = H5P.get_istore_k(plist_id)`

**Description** `ik = H5P.get_istore_k(plist_id)` returns the chunked storage B-tree 1/2 rank of the file creation property list specified by `plist_id`.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
ik = H5P.get_istore_k(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

**See Also** `H5P.set_istore_k`

# H5P.get\_sizes

---

**Purpose** Return size of offsets and lengths

**Syntax** `[sizeof_addr,sizeof_size] = H5P.get_sizes(fcpl)`

**Description** `[sizeof_addr,sizeof_size] = H5P.get_sizes(fcpl)` returns the size of the offsets and lengths used in an HDF5 file. `fcpl` specifies a file creation property list.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[soaddr, sosize] = H5P.get_sizes(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

**See Also** `H5P.set_sizes`

**Purpose** Return size of B-tree 1/2 rank and leaf node 1/2 size

**Syntax** `[ik, lk] = H5P.get_sym_k(plist_id)`

**Description** `[ik, lk] = H5P.get_sym_k(plist_id)` returns the size of the symbol table B-tree 1/2 rank, `ik`, and the symbol table leaf node 1/2 size, `lk`. The `plist_id` argument is a file creation property list identifier.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[ik, lk] = H5P.get_sym_k(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

**See Also** `H5P.set_sym_k`

# H5P.get\_userblock

---

**Purpose** Return size of user block

**Syntax** `sz = H5P.get_userblock(plist_id)`

**Description** `sz = H5P.get_userblock(plist_id)` returns the size of a user block in a file creation property list. `plist_id` is a property list identifier.

**Examples**

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
sz = H5P.get_userblock(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

**See Also** `H5P.set_userblock`

- Purpose** Return version information for file creation property list
- Syntax** `[superblock, freelist, stab, shhdr] = H5P.get_version(fcpl)`
- Description** `[superblock, freelist, stab, shhdr] = H5P.get_version(fcpl)` returns the version of the super block, the global freelist, the symbol table, and the shared object header. Retrieving this information requires the file creation property list.
- Examples**
- ```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[super, freelist, stab, shhdr] = H5P.get_version(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

# H5P.set\_istore\_k

---

**Purpose** Set size of parameter for indexing chunked datasets

**Syntax** `H5P.set_istore_k(plist_id, ik)`

**Description** `H5P.set_istore_k(plist_id, ik)` sets the size of the parameter used to control the B-trees for indexing chunked datasets for the file creation property list specified by `plist_id`. The `ik` argument is one half the rank of a tree that stores chunked raw data.

**Examples**

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_istore_k(fcpl, 64);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

**See Also** `H5P.get_istore_k`

**Purpose** Set byte size of offsets and lengths

**Syntax** `H5P.set_sizes(plist_id,sizeof_addr,sizeof_size)`

**Description** `H5P.set_sizes(plist_id,sizeof_addr,sizeof_size)` sets the byte size of the offsets and lengths used to address objects in an HDF5 file. `plist_id` is a file creation property list.

**See Also** `H5P.get_sizes`

# H5P.set\_sym\_k

---

**Purpose** Set size of parameters used to control symbol table nodes

**Syntax** `H5P.set_sym_k(plist_id, ik, lk)`

**Description** `H5P.set_sym_k(plist_id, ik, lk)` sets the size of parameters used to control the symbol table nodes for the file access property list, `plist_id`. The `ik` argument is one half the rank of a tree that stores a symbol table for a group. `lk` is one half of the number of symbols that can be stored in a symbol table node.

**Examples**

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_sym_k(fcpl, 32, 8);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

**See Also** `H5P.get_sym_k`

**Purpose** Set user block size

**Syntax** `H5P.set_userblock(plist_id,size)`

**Description** `H5P.set_userblock(plist_id,size)` sets the user block size of the file creation property list, `plist_id`.

**Examples**

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_userblock(fcpl,4096);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

**See Also** `H5P.get_userblock`

# H5P.get\_attr\_creation\_order

---

**Purpose** Return tracking order and indexing settings

**Syntax** `crt_order_flags = H5P.get_attr_phase_change(ocpl_id)`

**Description** `crt_order_flags = H5P.get_attr_phase_change(ocpl_id)` retrieves tracking and indexing settings for attribute creation order. If `crt_order_flags` is zero, then the attribute creation order is neither tracked or indexed. Otherwise the creation order flags should be one of the following constant values:

`H5P_CRT_ORDER_TRACKED`

`H5P_CRT_ORDER_INDEXED`

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
flags = H5P.get_attr_creation_order(dcpl);
switch ( flags )
    case 0
        fprintf('neither tracked nor indexed\n');
    case H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED')
        fprintf('tracked\n');
    case H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED')
        fprintf('indexed\n');
end
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5P.set_attr_creation_order` | `H5ML.get_constant_value`

- Purpose** Retrieve attribute phase change thresholds
- Syntax** `[max_compact,min_dense] = H5P.get_attr_phase_change(ocpl_id)`
- Description** `[max_compact,min_dense] = H5P.get_attr_phase_change(ocpl_id)` retrieves attribute phase change thresholds for the dataset or group with creation property list `ocpl_id`.
- `max_compact` is the maximum number of attributes to be stored in compact storage (default is 8).
- `min_dense` is the minimum number of attributes to be stored in dense storage (default is 6).
- Examples**
- ```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
[max_compact,min_dense] = H5P.get_attr_phase_change(dcpl);
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```
- See Also** `H5P.set_attr_phase_change`

# H5P.get\_copy\_object

---

**Purpose** Return properties to be used when object is copied

**Syntax** `copy_options = H5P.get_copy_object(ocpl_id)`

**Description** `copy_options = H5P.get_copy_object(ocpl_id)` retrieves the properties currently specified in the object copy property list `ocpl_id`, which will be invoked when a new copy is made of an existing object.

**Examples**

```
ocpl = H5P.create('H5P_OBJECT_COPY');  
options = H5P.get_copy_object(ocpl);
```

**See Also** `H5P.set_copy_object`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                         |

# H5P.set\_attr\_phase\_change

---

**Purpose** Set attribute storage phase change thresholds

**Syntax** `H5P.get_attr_phase_change(ocpl_id,max_compact,min_dense)`

**Description** `H5P.get_attr_phase_change(ocpl_id,max_compact,min_dense)` sets attribute storage phase change thresholds for the group or dataset with creation order property list `ocpl_id`.

`max_compact` is the maximum number of attributes to be stored in compact storage (default is 8).

`min_dense` is the minimum number of attributes to be stored in dense storage (default is 6).

**See Also** `H5P.get_attr_phase_change`

**Purpose**

Set properties to be used when objects are copied

**Syntax**

`H5P.set_copy_object(ocp_plist_id,copy_options)`

**Description**

`H5P.set_copy_object(ocp_plist_id,copy_options)` sets the properties in the object copy property list `ocp_plist_id` that will be invoked when a new copy is made of an existing object. `ocp_plist_id` is the object copy property list and specifies the properties governing the copying of the object.

Several flags, described below, are available for inclusion in the object copy property list:

**H50\_COPY\_SHALLOW\_HIERARCHY\_FLAG** Copy only immediate members of a group. Default behavior, without flag: Recursively copy all objects below the group.

**H50\_COPY\_EXPAND\_SOFT\_LINK\_FLAG** Expand soft links into new objects. Default behavior, without flag: Keep soft links as they are.

**H50\_COPY\_EXPAND\_EXT\_LINK\_FLAG** Expand external link into new objects. Default behavior, without flag: Keep external links as they are.

**H50\_COPY\_EXPAND\_REFERENCE\_FLAG** Copy objects that are pointed to by references. Default behavior, without flag: Update only the values of object references.

**H50\_COPY\_WITHOUT\_ATTR\_FLAG** Copy object without copying attributes. Default behavior, without flag: Copy object along with all its attributes.

# H5P.set\_copy\_object

---

## Examples

```
ocp_plist_id = H5P.create ('H5P_OBJECT_COPY');
option1 = H5ML.get_constant_value('H5O_COPY_EXPAND_SOFT_LINK_FLAG');
option2 = H5ML.get_constant_value('H5O_COPY_EXPAND_REFERENCE_FLAG');
copy_options = bitor(option1,option2);
H5P.set_copy_object(ocp_plist_id, copy_options);
```

# H5P.get\_create\_intermediate\_group

---

**Purpose** Determine creation of intermediate groups

**Syntax** `bool = H5P.get_create_intermediate_group(lcpl_id)`

**Description** `bool = H5P.get_create_intermediate_group(lcpl_id)` determines whether the link creation property list `lcpl_id` is set to enable creating missing intermediate groups.

**Examples**

```
lcpl = H5P.create('H5P_LINK_CREATE');
if H5P.get_create_intermediate_group(lcpl)
    fprintf('set to enable creating intermediate groups\n');
else
    fprintf('not set to enable creating intermediate groups\n');
end
```

**See Also** `H5P.set_create_intermediate_group`

# H5P.get\_link\_creation\_order

---

**Purpose** Query if link creation order is tracked

**Syntax** `crt_order_flags = H5P.get_link_phase_change(gcpl_id)`

**Description** `crt_order_flags = H5P.get_link_phase_change(gcpl_id)` queries whether link creation order is tracked or indexed in a group with creation property list identifier `gcpl_id`. The creation order flags should be one of the following constant values:

```
H5P_CRT_ORDER_TRACKED
H5P_CRT_ORDER_INDEXED
```

**Examples**

```
tracked = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED');
indexed = H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED');
gcpl = H5P.create('H5P_GROUP_CREATE');
order = H5P.get_link_creation_order(gcpl);
if bitand(order,tracked)
    fprintf('order is tracked\n');
end
if bitand(order,indexed)
    fprintf('order is indexed\n');
end
```

**See Also** `H5P.set_link_creation_order` | `H5ML.get_constant_value` | `bitand`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Query settings for conversion between groups                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p><code>[max_compact,min_dense] = H5P.get_link_phase_change(gcpl_id)</code> retrieves the settings for conversion between compact and dense groups.</p> <p><code>max_compact</code> is the maximum number of links to store as header messages in the group header before converting the group to the dense format. Groups that are in the compact format and exceed this number of links are automatically converted to the dense format.</p> <p><code>min_dense</code> is the minimum number of links to store in the dense format. Groups which are in dense format and in which the number of links falls below this number are automatically converted back to the compact format.</p> |
| <b>Examples</b>    | <pre>gcpl = H5P.create('H5P_GROUP_CREATE');<br/>[max_compact, min_dense] = H5P.get_link_phase_change(gcpl);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>See Also</b>    | <code>H5P.set_link_phase_change</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# H5P.set\_create\_intermediate\_group

---

**Purpose** Set creation of intermediate groups

**Syntax** H5P.set\_create\_intermediate\_group(lcpl\_id,flag)

**Description** H5P.set\_create\_intermediate\_group(lcpl\_id,flag) specifies in the link creation property list lcpl\_id whether to create missing intermediate groups.

**Examples** Enable the creation of intermediate groups.

```
fid = H5F.create('myfile.h5');
lcpl = H5P.create('H5P_LINK_CREATE');
H5P.set_create_intermediate_group(lcpl,1);
gid = H5G.create(fid,'/a/b/c/d',lcpl,'H5P_DEFAULT','H5P_DEFAULT');
H5G.close(gid);
H5F.close(fid);
```

**See Also** H5P.get\_create\_intermediate\_group

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set creation order tracking and indexing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>      | <code>H5P.set_link_creation_order(gcplId,crt_order_flags)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p><code>H5P.set_link_creation_order(gcplId,crt_order_flags)</code> sets creation order tracking and indexing for links in the group with group creation property list <code>gcpl_id</code>.</p> <p>The creation order flags should be one of the following constant values:</p> <pre>H5P_CRT_ORDER_TRACKED H5P_CRT_ORDER_INDEXED</pre> <p>If only <code>H5P_CRT_ORDER_TRACKED</code> is set, HDF5 will track link creation order in any group created with the group creation property list <code>gcpl_id</code>. If both <code>H5P_CRT_ORDER_TRACKED</code> and <code>H5P_CRT_ORDER_INDEXED</code> are set, HDF5 will track link creation order in the group and index links on that property.</p> |
| <b>Examples</b>    | <pre>tracked = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED'); indexed = H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED'); order = bitor(tracked,indexed); gcpl = H5P.create('H5P_GROUP_CREATE'); H5P.set_link_creation_order(gcpl,order);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>See Also</b>    | <code>H5P.get_link_creation_order</code>   <code>H5ML.get_constant_value</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# H5P.set\_link\_phase\_change

---

**Purpose** Set parameters for group conversion

**Syntax** `H5P.get_link_phase_change(gcpl_id,max_compact,min_dense)`

**Description** `H5P.get_link_phase_change(gcpl_id,max_compact,min_dense)` sets the parameters for conversion between compact and dense groups.

`max_compact` is the maximum number of links to store as header messages in the group header before converting the group to the dense format. Groups that are in the compact format and exceed this number of links are automatically converted to the dense format.

`min_dense` is the minimum number of links to store in the dense format. Groups which are in dense format and in which the number of links falls below this number are automatically converted back to the compact format.

**Examples**

```
gcpl = H5P.create('H5P_GROUP_CREATE');
H5P.set_link_phase_change(gcpl,10,8);
```

**See Also** `H5P.get_link_phase_change`

**Purpose** Return character encoding

**Syntax** `encoding = H5P.get_char_encoding(propertyList)`

**Description** `encoding = H5P.get_char_encoding(propertyList)` retrieves the character encoding used to encode strings or object names that are created with the property list `propertyList`. The values returned correspond to either `H5T_CSET_ASCII` or `H5T_CSET_UTF8`.

**See Also** `H5P.set_char_encoding` | `H5ML.get_constant_value`

# H5P.set\_char\_encoding

---

|                    |                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set character encoding used to encode strings                                                                                                                                                                                                                                                |
| <b>Syntax</b>      | <code>H5P.set_char_encoding(propList,encoding)</code>                                                                                                                                                                                                                                        |
| <b>Description</b> | <code>H5P.set_char_encoding(propList,encoding)</code> sets the character encoding used to encode strings or object names that are created with the property list <code>propList</code> . The values of encoding should either be <code>H5T_CSET_ASCII</code> or <code>H5T_CSET_UTF8</code> . |
| <b>See Also</b>    | <code>H5P.get_char_encoding</code>   <code>H5ML.get_constant_value</code>                                                                                                                                                                                                                    |

**Purpose** Create reference

**Syntax** `ref = H5R.create(loc_id,name,ref_type,space_id)`

**Description** `ref = H5R.create(loc_id,name,ref_type,space_id)` creates the reference, `ref`, of the type specified in `ref_type`, pointing to the object specified by name located at `loc_id`. The `ref_type` argument can be either 'H5R\_OBJECT', or 'H5R\_DATASET\_REGION'. The `space_id` argument should be -1, if `ref_type` is 'H5R\_OBJECT'.

**Examples** Create a double-precision dataset and a reference dataset.

```
fid = H5F.create('myfile.h5');
type1_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [10 5];
h5_dims = flip1r(dims);
h5_maxdims = h5_dims;
space1_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset1_id = H5D.create(fid,'my_double',type1_id,space1_id,dcpl);
type2_id = 'H5T_STD_REF_OBJ';
space2_id = H5S.create('H5S_SCALAR');
dset2_id = H5D.create(fid,'my_ref',type2_id,space2_id,dcpl);
ref_data = H5R.create(fid,'my_double','H5R_OBJECT',-1);
dxpl = 'H5P_DEFAULT';
H5D.write(dset2_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',dxpl,ref_data);
H5D.close(dset1_id);
H5D.close(dset2_id);
H5F.close(fid);
```

**See Also** `H5D.create`

# H5R.dereference

---

**Purpose** Open object specified by reference

**Syntax** `output = H5R.dereference(dataset,ref_type,ref)`

**Description** `output = H5R.dereference(dataset,ref_type,ref)` returns an identifier to the object specified by `ref` in the dataset specified by `dataset`.

**Examples**

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/reference');
ref_data = H5D.read(dset_id,'H5T_STD_REF_OBJ',space,space,plist);
deref_dset_id = H5R.dereference(dset_id,'H5R_OBJECT',ref_data(:,1));
H5D.close(dset_id);
H5D.close(deref_dset_id);
H5F.close(fid);
```

**See Also** `H5R.create` | `H5I.get_name`

**Purpose** Name of referenced object

**Syntax** `name = H5R.get_name(loc_id,ref_type,ref)`

**Description** `name = H5R.get_name(loc_id,ref_type,ref)` retrieves the name for the object identified by `ref`. The `loc_id` argument is the identifier for the dataset containing the reference or for the group containing that dataset. `ref_type` specifies the type of the reference `ref`. Valid values for `ref_type` are 'H5R\_OBJECT' or 'H5R\_DATASET\_REGION'.

**Examples**

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/reference');
ref_data = H5D.read(dset_id,'H5T_STD_REF_OBJ',space,space,plist);
name = H5R.get_name(dset_id,'H5R_OBJECT',ref_data(:,1));
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5I.get_name`

# H5R.get\_obj\_type

---

**Purpose** Type of referenced object

**Syntax** `obj_type = H5R.get_obj_type(id,ref_type,ref)`

**Description** `obj_type = H5R.get_obj_type(id,ref_type,ref)` returns the type of object that an object reference points to. Valid values for `ref_type` are: `H5R_OBJECT` or `H5R_DATASET_REGION`. Valid return values correspond to the following values.

|                           |                             |
|---------------------------|-----------------------------|
| 'H5O_TYPE_GROUP'          | Object is a group.          |
| 'H5O_TYPE_DATASET'        | Object is a dataset.        |
| 'H5O_TYPE_NAMED_DATATYPE' | Object is a named datatype. |

This function corresponds to the 1.8 interface version of `H5Rget_obj_type` in the HDF5 library C API.

## Examples

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/reference');
ref_data = H5D.read(dset_id, 'H5T_STD_REF_OBJ', space, space, plist);
obj_type = H5R.get_obj_type(fid, 'H5R_OBJECT', ref_data(:,1));
switch(obj_type)
    case H5ML.get_constant_value('H5O_TYPE_GROUP')
        fprintf('group\n');
    case H5ML.get_constant_value('H5O_TYPE_DATASET')
        fprintf('dataset\n');
    case H5ML.get_constant_value('H5O_TYPE_NAMED_DATATYPE')
        fprintf('named datatype\n');
end
H5D.close(dset_id);
H5F.close(fid);
```

**See Also** `H5ML.get_constant_value`

**Purpose** Copy of data space of specified region

**Syntax** `space_id = H5R.get_region(dataset,ref_type,ref)`

**Description** `space_id = H5R.get_region(dataset,ref_type,ref)` returns a data space with the specified region selected. `dataset` is used to identify the file containing the referenced region and can be any identifier for any object in the file.

**Examples**

```
space = 'H5S_ALL';
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/region_reference');
ref_data = H5D.read(dset_id,'H5T_STD_REF_DSETREG',space,space,plist);
space_id = H5R.get_region(fid,'H5R_DATASET_REGION',ref_data(:,1));
H5S.close(space_id);
H5D.close(dset_id);
H5F.close(fid);
```

# H5S.copy

---

**Purpose** Create copy of data space

**Syntax** `output = H5S.copy(space_id)`

**Description** `output = H5S.copy(space_id)` creates a new data space, which is an exact copy of the dataspace identified by `space_id`. The output argument is a data space identifier.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g2/dset2.1');
space1_id = H5D.get_space(dset_id);
space2_id = H5S.copy(space1_id);
[~,dims1] = H5S.get_simple_extent_dims(space1_id)
[~,dims2] = H5S.get_simple_extent_dims(space2_id)
```

**See Also** `H5D.get_space` | `H5S.get_simple_extent_dims`

**Purpose** Create new data space

**Syntax** `space_id = H5S.create(space_type)`

**Description** `space_id = H5S.create(space_type)` creates a new dataspace of the type specified by `space_type`, which can be specified by one of the following strings.

`'H5S_SCALAR'`

`'H5S_SIMPLE'`

`'H5S_NULL'`

`space_id` is the identifier for the new dataspace.

**Examples** Create a scalar dataspace.

```
space_id = H5S.create('H5S_SCALAR');  
numpoints = H5S.get_simple_extent_npoints(space_id);
```

**See Also** `H5S.get_simple_extent_npoints`

# H5S.close

---

|                    |                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Close data space                                                                                                                   |
| <b>Syntax</b>      | <code>H5S.close(space_id)</code>                                                                                                   |
| <b>Description</b> | <code>H5S.close(space_id)</code> releases and terminates access to a data space. <code>space_id</code> is a data space identifier. |
| <b>See Also</b>    | <code>H5A.get_space</code>   <code>H5D.get_space</code>                                                                            |

**Purpose** Create new simple data space

**Syntax** `space_id = H5S.create_simple(rank,h5_dims,h5_maxdims)`

**Description** `space_id = H5S.create_simple(rank,h5_dims,h5_maxdims)` creates a new simple data space and opens it for access. `rank` is the number of dimensions used in the data space. `h5_dims` is an array specifying the size of each dimension of the dataset. `h5_maxdims` is an array specifying the upper limit on the size of each dimension. `space_id` is a data space identifier.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples** Create a data space for a dataset with 10 rows and 5 columns.

```
dims = [10 5];
h5_dims = flip1r(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
```

---

Create a data space for a dataset with 10 rows and 5 columns such that the dataset is extendible along the column dimension.

```
dims = [10 5];
h5_dims = flip1r(dims);
maxdims = [10 H5ML.get_constant_value('H5S_UNLIMITED')];
h5_maxdims = flip1r(maxdims);
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
```

# H5S.create\_simple

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Copy extent from source to destination data space                                                                                                                                                                                                                                                                     |
| <b>Syntax</b>      | <code>H5S.extent_copy(dst_id,src_id)</code>                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <code>H5S.extent_copy(dst_id,src_id)</code> copies the extent from the source data space, <code>src_id</code> , to the destination data space, <code>dst_id</code> .                                                                                                                                                  |
| <b>Examples</b>    | <pre>space_id1 = H5S.create('H5S_SIMPLE'); dims = [100 200]; h5_dims = fliplr(dims); maxdims = [100 H5ML.get_constant_value('H5S_UNLIMITED')]; h5_maxdims = fliplr(maxdims); H5S.set_extent_simple(space_id1,2,h5_dims,h5_maxdims); space_id2 = H5S.create('H5S_SIMPLE'); H5S.extent_copy(space_id2,space_id1);</pre> |
| <b>See Also</b>    | <code>H5S.create</code>   <code>H5S.get_simple_extent_dims</code>  <br><code>H5S.set_extent_simple</code>                                                                                                                                                                                                             |

# H5S.get\_select\_bounds

---

**Purpose** Bounding box of data space selection

**Syntax** `[start,finish] = H5S.get_select_bounds(space_id)`

**Description** `[start,finish] = H5S.get_select_bounds(space_id)` returns the coordinates of the bounding box containing the current selection. `start` contains the starting coordinates of the bounding box and `finish` contains the coordinates of the diagonally opposite corner.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
start = fliplr([30 40]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_OR',start,[],[],block);
[start, finish] = H5S.get_select_bounds(space_id);
matlab_start = fliplr(start);
matlab_finish = fliplr(finish);
```

**See Also** `H5S.create_simple` | `H5S.select_hyperslab`

**Purpose** Number of element points in selection

**Syntax** `numpoints = H5S.get_select_elem_npoints(space_id)`

**Description** `numpoints = H5S.get_select_elem_npoints(space_id)` returns the number of element points in the current data space selection.

**Examples** Select the corner points of a data space.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
coords = fliplr(coords);
coords = coords';
H5S.select_elements(space_id,'H5S_SELECT_SET',coords)
numpoints = H5S.get_select_elem_npoints(space_id);
```

**See Also** `H5S.select_elements`

# H5S.get\_select\_elem\_pointlist

---

**Purpose** Element points in data space selection

**Syntax** `points = H5S.get_select_elem_pointlist(space_id,startpoint, numpoints)`

**Description** `points = H5S.get_select_elem_pointlist(space_id,startpoint, numpoints)` returns the list of element points in the current data space selection. `startpoint` specifies the element point to start with and `numpoints` specifies the total number of points.

`points` is a two-dimensional array of 0-based values specifying the coordinates of the elements. If `m` is the rank of the dataspace, then `points` will have size `[m x numpoints]`.

---

**Note** The ordering of the coordinate points is the same as the HDF5 library C API.

---

**Examples** Determine the first two points in the current selection.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
coords = fliplr(coords);
coords = coords';
H5S.select_elements(space_id,'H5S_SELECT_SET',coords);
points = H5S.get_select_elem_pointlist(space_id,0,2);
```

**Purpose**

List of hyperslab blocks

**Syntax**

```
blocklist = H5S.get_select_hyper_blocklist(space_id,  
startblock,numblocks)
```

**Description**

`blocklist = H5S.get_select_hyper_blocklist(space_id, startblock,numblocks)` returns a list of the hyperslab blocks currently selected. `space_id` is a dataspace identifier. `startblock` specifies the block to start with and `numblocks` specifies the number of hyperslab blocks to retrieve.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples**

```
dims = [100 200];  
h5_dims = fliplr(dims);  
space_id = H5S.create_simple(2,h5_dims,h5_dims);  
start = fliplr([10 20]); block = fliplr([20 25]);  
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);  
start = fliplr([20 30]); block = fliplr([20 25]);  
H5S.select_hyperslab(space_id,'H5S_SELECT_NOTB',start,[],[],block);  
numblocks = H5S.get_select_hyper_nblocks(space_id);  
for j = 1:numblocks  
    hblocks{j} = H5S.get_select_hyper_blocklist(space_id,j-1,1);  
end
```

**See Also**

`H5S.select_hyperslab` | `H5S.get_select_hyper_nblocks`

# H5S.get\_select\_hyper\_nblocks

---

**Purpose** Number of hyperslab blocks

**Syntax** `num_blocks = H5S.get_select_hyper_nblocks(space_id)`

**Description** `num_blocks = H5S.get_select_hyper_nblocks(space_id)` returns the number of hyperslab blocks in the current data space selection.

**Examples**

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
start = fliplr([20 30]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_NOTB',start,[],[],block);
nblocks = H5S.get_select_hyper_nblocks(space_id);
```

**See Also** `H5S.get_select_hyper_blocklist` | `H5S.select_hyperslab`

**Purpose** Number of elements in data space selection

**Syntax** `num_points = H5S.get_select_npoints(space_id)`

**Description** `num_points = H5S.get_select_npoints(space_id)` returns the number of elements in the current data space selection.

**Examples**

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
op = 'H5S_SELECT_SET';
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
n = H5S.get_select_npoints(space_id);
```

**See Also** `H5S.create_simple` | `H5S.select_hyperslab`

# H5S.get\_select\_type

---

**Purpose** Type of data space selection

**Syntax** `sel_type = H5S.get_select_type(space_id)`

**Description** `sel_type = H5S.get_select_type(space_id)` returns the data space selection type. Valid return values correspond to the following enumerated constants:

```
H5S_SEL_NONE  
H5S_SEL_POINTS  
H5S_SEL_HYPERSLABS  
H5S_SEL_ALL
```

**Examples**

```
dims = [100 200];  
h5_dims = flip1r(dims);  
space_id = H5S.create_simple(2,h5_dims,h5_dims);  
start = flip1r([10 20]); block = flip1r([20 30]);  
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);  
sel_type = H5S.get_select_type(space_id);  
switch(sel_type)  
    case H5ML.get_constant_value('H5S_SEL_NONE')  
        fprintf('no selection\n');  
    case H5ML.get_constant_value('H5S_SEL_POINTS');  
        fprintf('point selection\n');  
    case H5ML.get_constant_value('H5S_SEL_HYPERSLABS');  
        fprintf('hyperslab selection\n');  
end
```

**See Also** `H5S.select_elements` | `H5S.select_hyperslab` | `H5ML.get_constant_value`

**Purpose** Data space size and maximum size

**Syntax** `[numdims,h5_dims,  
h5_maxdims] = H5S.get_simple_extent_dims(space_id)`

**Description** `[numdims,h5_dims, h5_maxdims] = H5S.get_simple_extent_dims(space_id)` returns the number of dimensions in the data space, the size of each dimension, and the maximum size of each dimension.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples**

```
fid = H5F.open('example.h5');  
dset_id = H5D.open(fid,'/g2/dset2.2');  
space_id = H5D.get_space(dset_id);  
[ndims,h5_dims] = H5S.get_simple_extent_dims(space_id);  
matlab_dims = fliplr(h5_dims);
```

# H5S.get\_simple\_extent\_ndims

---

**Purpose** Data space rank

**Syntax** `output = H5S.get_simple_extent_ndims(space_id)`

**Description** `output = H5S.get_simple_extent_ndims(space_id)` returns the dimensionality (also called the rank) of a data space.

# H5S.get\_simple\_extent\_npoints

---

**Purpose**

Number of elements in data space

**Syntax**

```
output = H5S.get_simple_extent_npoints(space_id)
```

**Description**

`output = H5S.get_simple_extent_npoints(space_id)` returns the number of elements in the data space specified by `space_id`.

# H5S.get\_simple\_extent\_type

---

**Purpose** Data space class

**Syntax** `space_type = H5S.get_simple_extent_type(space_id)`

**Description** `space_type = H5S.get_simple_extent_type(space_id)` returns the data space class of the data space specified by `space_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
space_id = H5D.get_space(dset_id);
space_type = H5S.get_simple_extent_type(space_id);
switch(space_type)
    case H5ML.get_constant_value('H5S_SCALAR')
        fprintf('scalar\n');
    case H5ML.get_constant_value('H5S_SIMPLE')
        fprintf('simple\n');
    case H5ML.get_constant_value('H5S_NULL')
        fprintf('none\n');
end
```

**See Also** `H5S.create` | `H5D.get_space` | `H5ML.get_constant_value`

**Purpose** Determine if data space is simple

**Syntax** `output = H5S.is_simple(space_id)`

**Description** `output = H5S.is_simple(space_id)` returns a positive value if the data space specified by `space_id` is a simple data space, zero if it is not, and a negative value to indicate failure.

**Examples** Create a new data space and verify that it is simple.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
val = H5S.is_simple(space_id);
```

---

Create a null data space and verify that it is not simple.

```
space_id = H5S.create('H5S_NULL');
val = H5S.is_simple(space_id);
```

**See Also** `H5S.create` | `H5S.create_simple`

# H5S.offset\_simple

---

**Purpose** Set offset of simple data space

**Syntax** H5S.offset\_simple(space\_id,offset)

**Description** H5S.offset\_simple(space\_id,offset) specifies the offset of the simple data space specified by space\_id. This function allows the same shaped selection to be moved to different locations within a data space without requiring it to be redefined.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The h5\_start, h5\_stride, h5\_count and h5\_block parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
offset = fliplr([3 5]);
H5S.offset_simple(space_id,offset)
[start,finish] = H5S.get_select_bounds(space_id);
start = fliplr(start);
finish = fliplr(finish);
```

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Select entire extent of data space                                                                                                                                                                                                                                                                                       |
| <b>Syntax</b>      | <code>H5S.select_all(space_id)</code>                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <code>H5S.select_all(space_id)</code> selects the entire extent of the data space specified by <code>space_id</code> .                                                                                                                                                                                                   |
| <b>Examples</b>    | <pre>fid = H5F.open('example.h5'); dset_id = H5D.open(fid, '/g3/integer'); space_id = H5D.get_space(dset_id); num_points1 = H5S.get_select_npoints(space_id); H5S.select_none(space_id); num_points2 = H5S.get_select_npoints(space_id); H5S.select_all(space_id); num_points3 = H5S.get_select_npoints(space_id);</pre> |

# H5S.select\_elements

---

**Purpose** Specify coordinates to include in selection

**Syntax** `H5S.select_elements(space_id,op,h5_coord)`

**Description** `H5S.select_elements(space_id,op,h5_coord)` selects the array elements to be included in the selection for the data space specified by `space_id`. The `op` argument determines how the new selection is to be combined with the previously existing selection for the data space and can be specified by one of the following string values.

'H5S\_SELECT\_SET'

'H5S\_SELECT\_APPEND'

'H5S\_SELECT\_PREPEND'

`h5_coord` is a two-dimensional array of 0-based values specifying the coordinates of the elements being selected. If `m` is the rank of the data space and if `n` is the number of points, then `h5_coord` should be an `m`-by-`n` array.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_coord` parameter assumes coordinates have C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples** Select the corner points of a data space. In this case, `h5_coord` should have size 2x4.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
h5_coords = fliplr(coords);
h5_coords = h5_coords';
```

```
H5S.select_elements(space_id, 'H5S_SELECT_SET', h5_coords);
```

H5S.get_select_elem_pointlist
```

# H5S.select\_hyperslab

---

**Purpose** Select hyperslab region

**Syntax** `H5S.select_hyperslab(space_id,op,h5_start,h5_stride,h5_count,  
h5_block)`

**Description** `H5S.select_hyperslab(space_id,op,h5_start,h5_stride,h5_count,  
h5_block)` selects a hyperslab region to add to the current selected region for the data space specified by `space_id`. The `op` argument determines how the new selection is to be combined with the previously existing selection for the data space. Possible values include: `H5S_SELECT_SET`, `H5S_SELECT_OR`, `H5S_SELECT_AND`, `H5S_SELECT_XOR`, `H5S_SELECT_NOTA`, or `H5S_SELECT_NOTB`.

The `h5_start` array determines the starting coordinates of the hyperslab to select. The `h5_count` array determines how many blocks to select from the data space, in each dimension. The `h5_stride` array specifies how many elements to move in each dimension. The `h5_block` array determines the size of the element block selected from the data space.

If `h5_stride` is specified as `[]`, then a contiguous hyperslab is selected, as if each value in `h5_stride` were set to 1. If `h5_count` is specified as `[]`, the number of blocks selected along each dimension defaults to 1. If `h5_block` is specified as `[]`, then the block size defaults to a single element in each dimension, as if each value in the block array were set to 1.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples**

```
dims = [100 200];  
h5_dims = fliplr(dims);
```

```
space_id = H5S.create_simple(2,h5_dims,h5_dims);  
start = fliplr([10 20]); block = fliplr([20 30]);  
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
```

**See Also** [H5S.create\\_simple](#)

# H5S.select\_none

---

**Purpose**                 Reset selection region to include no elements

**Syntax**                 H5S.select\_none(space\_id)

**Description**           H5S.select\_none(space\_id) resets the selection region for the data space space\_id to include no elements.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
space_id = H5D.get_space(dset_id);
num_points1 = H5S.get_select_npoints(space_id);
H5S.select_none(space_id);
num_points2 = H5S.get_select_npoints(space_id);
```

**Purpose** Determine validity of selection

**Syntax** `output = H5S.select_valid(space_id)`

**Description** `output = H5S.select_valid(space_id)` returns a positive value if the selection of the data space `space_id` is within the extent of that data space, and zero if it is not. A negative value indicates failure.

**Examples**

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([90 190]); count = [11 11];
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],count,[]);
valid = H5S.select_valid(space_id);
```

**See Also** `H5S.create_simple` | `H5S.select_hyperslab`

# H5S.set\_extent\_none

---

**Purpose** Remove extent from data space

**Syntax** `H5S.set_extent_none(space_id)`

**Description** `H5S.set_extent_none(space_id)` removes the extent from a data space and sets the type to `H5S_NO_CLASS`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer2D');
space_id = H5D.get_space(dset_id);
H5S.set_extent_none(space_id);
extent_type = H5S.get_simple_extent_type(space_id);
switch(extent_type)
    case H5ML.get_constant_value('H5S_SCALAR')
        fprintf('scalar\n');
    case H5ML.get_constant_value('H5S_SIMPLE')
        fprintf('simple\n');
    case H5ML.get_constant_value('H5S_NO_CLASS')
        fprintf('no class\n');
end
```

**See Also** `H5S.get_simple_extent_dims`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set size of data space                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>      | <code>H5S.set_extent_simple(space_id,rank,h5_dims,h5_maxdims)</code>                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <code>H5S.set_extent_simple(space_id,rank,h5_dims,h5_maxdims)</code> sets the size of the data space identified by <code>space_id</code> . The <code>rank</code> argument is the number of dimensions used in the data space. <code>h5_dims</code> is an array specifying the size of each dimension of the dataset. <code>h5_maxdims</code> is an array specifying the upper limit on the size of each dimension. |

# H5T.close

---

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Close data type                                                                            |
| <b>Syntax</b>      | <code>H5T.close(type_id)</code>                                                            |
| <b>Description</b> | <code>H5T.close(type_id)</code> releases the data type specified by <code>type_id</code> . |
| <b>See Also</b>    | <code>H5A.get_type</code>   <code>H5D.get_type</code>                                      |

**Purpose** Commit transient data type

**Syntax** `H5T.commit(loc_id,name,type_id)`  
`H5T.commit(loc_id,name,type_id,lcpl_id,tcpl_id,tapl_id)`

**Description** `H5T.commit(loc_id,name,type_id)` commits a transient data type to a file, creating a new named data type. `loc_id` is a file or group identifier. `name` is the name of the data type and `type_id` is the data type id. This interface corresponds to the 1.6.x version of H5Tcommit.

`H5T.commit(loc_id,name,type_id,lcpl_id,tcpl_id,tapl_id)` commits a transient data type to a file, creating a new named data type. `loc_id` is a file or group identifier. `name` is the name of the data type and `type_id` is the data type id. `lcpl_id`, `tcpl_id`, and `tapl_id` are link creation, data type creation, and data type access property list identifiers. This interface corresponds to the 1.8.x version of H5Tcommit.

**Examples** Create a named variable-length data type.

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', plist_id, plist_id);
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');
vlen_type_id = H5T.vlen_create(base_type_id);
H5T.commit(fid, 'MyVlen', vlen_type_id);
H5T.close(vlen_type_id);
H5T.close(base_type_id);
H5F.close(fid);
```

**See Also** `H5T.close` | `H5T.committed`

# H5T.committed

---

**Purpose** Determine if data type is committed

**Syntax** `output = H5T.committed(type_id)`

**Description** `output = H5T.committed(type_id)` returns a positive value to indicate that the data type has been committed, and zero to indicate that it has not. A negative value indicates failure.

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');  
is_committed = H5T.committed(type_id);
```

**See Also** `H5T.commit`

**Purpose** Copy data type

**Syntax** `output_type_id = H5T.copy(type_id)`

**Description** `output_type_id = H5T.copy(type_id)` copies the existing data type identifier, a dataset identifier specified by `type_id`, or a predefined data type such as 'H5T\_NATIVE\_DOUBLE'. `output_type_id` is a data type identifier.

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
type_size = H5T.get_size(type_id);
```

**See Also** `H5T.get_size`

# H5T.create

---

**Purpose** Create new data type

**Syntax** `output = H5T.create(class_id,size)`

**Description** `output = H5T.create(class_id,size)` creates a new data type of the class specified by `class_id`, with the number of bytes specified by `size`. The output argument is a data type identifier.

**Examples** Create a signed 32-bit enumerated data type.

```
type_id = H5T.create('H5T_ENUM',4);
H5T.set_order(type_id,'H5T_ORDER_LE');
H5T.set_sign(type_id,'H5T_SGN_2');
H5T.enum_insert(type_id,'black',0);
H5T.enum_insert(type_id,'white',1);
```

**See Also** `H5T.set_order` | `H5T.set_sign`

**Purpose** Determine of data type contains specific class

**Syntax** `output = H5T.detect_class(type_id,class_id)`

**Description** `output = H5T.detect_class(type_id,class_id)` returns a positive value if the data type specified in `type_id` contains any data types of the data type class specified in `class_id`, or zero to indicate that it does not. A negative value indicates failure.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/vlen');
type_id = H5D.get_type(dset_id);
has_double = H5T.detect_class(type_id, 'H5T_FLOAT');
```

**See Also** `H5D.get_type`

# H5T.equal

---

**Purpose** Determine equality of data types

**Syntax** `output = H5T.equal(type1_id,type2_id)`

**Description** `output = H5T.equal(type1_id,type2_id)` returns a positive number if the data type identifiers refer to the same data type, and zero to indicate that they do not. A negative value indicates failure. Either of the input values could be a string corresponding to an HDF5 data type.

**Examples** Determine if the data type of a dataset is a 32-bit little endian integer.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer2D');
dtype_id = H5D.get_type(dset_id);
if H5T.equal(dtype_id, 'H5T_STD_I32LE')
    fprintf('32-bit little endian integer\n');
end
```

**See Also** `H5D.get_type`

**Purpose**

Data type class identifier

**Syntax**

```
class_id = H5T.get_class(type_id)
```

**Description**

`class_id = H5T.get_class(type_id)` returns the data type class identifier of the data type specified by `type_id`.

Valid class identifiers include:

```
H5T_INTEGER  
H5T_FLOAT  
H5T_STRING  
H5T_BITFIELD  
H5T_OPAQUE  
H5T_COMPOUND  
H5T_ENUM  
H5T_VLEN  
H5T_ARRAY
```

**Examples**

```
fid = H5F.open('example.h5');  
dset_id = H5D.open(fid, '/g3/enum');  
type_id = H5D.get_type(dset_id);  
class_id = H5T.get_class(type_id);  
switch(class_id)  
    case H5ML.get_constant_value('H5T_INTEGER')  
        fprintf('Integer\n');  
    case H5ML.get_constant_value('H5T_FLOAT')  
        fprintf('Floating point\n');  
    case H5ML.get_constant_value('H5T_STRING')  
        fprintf('String\n');  
    case H5ML.get_constant_value('H5T_BITFIELD')  
        fprintf('Bitfield\n');  
    case H5ML.get_constant_value('H5T_OPAQUE')
```

## H5T.get\_class

---

```
        fprintf('Opaque\n');
    case H5ML.get_constant_value('H5T_COMPOUND')
        fprintf('Compound\n');
    case H5ML.get_constant_value('H5T_ENUM')
        fprintf('Enumerated\n');
    case H5ML.get_constant_value('H5T_VLEN')
        fprintf('Variable length\n');
    case H5ML.get_constant_value('H5T_ARRAY')
        fprintf('Array\n');
end
```

# H5T.get\_native\_type

---

**Purpose** Native data type of dataset data type

**Syntax** `output = H5T.get_native_type(type_id,direction)`

**Description** `output = H5T.get_native_type(type_id,direction)` returns the equivalent native data type for the dataset data type specified in `type_id`. The `direction` argument indicates the order in which the library searches for a native data type match and must be either `'H5T_DIR_ASCEND'` or `'H5T_DIR_DESCEND'`.

**Purpose** Size of data type in bytes

**Syntax** `type_size = H5T.get_size(type_id)`

**Description** `type_size = H5T.get_size(type_id)` returns the size of a data type in bytes. `type_id` is a data type identifier.

**Examples** Determine the size of the data type for a specific dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/bitfield2D');
type_id = H5D.get_type(dset_id);
type_size = H5T.get_size(type_id);
```

**See Also** `H5T.set_size` | `H5D.get_type`

# H5T.get\_super

---

**Purpose** Base data type

**Syntax** `super_type_id = H5T.get_super(type_id)`

**Description** `super_type_id = H5T.get_super(type_id)` returns the base data type from which the data type specified by `type_id` is derived.

**Examples** Retrieve the base data type for an enumerated dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/enum');
dtype_id = H5D.get_type(dset_id);
super_type_id = H5T.get_super(dtype_id);
```

**Purpose** Lock data type

**Syntax** `H5T.lock(type_id)`

**Description** `H5T.lock(type_id)` locks the data type specified by `type_id`, making it read-only and non-destructible.

# H5T.open

---

**Purpose** Open named data type

**Syntax** `type_id = H5T.open(loc_id,name)`

**Description** `type_id = H5T.open(loc_id,name)` opens a named data type at the location specified by `loc_id` and returns an identifier for the data type. `loc_id` is either a file or group identifier.

This function corresponds to the `H5Topen1` function in the HDF5 library C API.

**See Also** [H5T.close](#) | [H5A.open](#) | [H5D.open](#) | [H5G.open](#) | [H5O.open](#)

**Purpose** Create array data type object

**Syntax**  
`array_type_id = H5T.array_create(base_id,h5_dims)`  
`array_type_id = H5T.array_create(base_id,rank,h5_dims,perms)`

**Description** `array_type_id = H5T.array_create(base_id,h5_dims)` creates a new array data type object. This interface corresponds to the 1.8 library version of `H5Tarray_create`.

`array_type_id = H5T.array_create(base_id,rank,h5_dims,perms)` creates a new array data type object. This interface corresponds to the 1.6 library version of `H5Tarray_create`. The `perms` parameter is not used at this time and can be omitted.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

**Examples** Create a 100-by-200 double precision array data type.

```
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');  
dims = [100 200];  
h5_dims = fliplr(dims);  
array_type = H5T.array_create(base_type_id,h5_dims);
```

**See Also** `H5T.get_array_dims` | `H5T.get_array_ndims`

# H5T.get\_array\_dims

---

## Purpose

Array dimension extents

## Syntax

```
dimsizes = H5T.get_array_dims(type_id)
[ndims,dimsizes,perm] = H5T.get_array_dims(type_id)
```

## Description

`dimsizes = H5T.get_array_dims(type_id)` returns the sizes of the dimensions and the dimension permutations of the specified array data type object. This interface corresponds to the 1.8 version of `H5Tget_array_dims`.

`[ndims,dimsizes,perm] = H5T.get_array_dims(type_id)` corresponds to the 1.6 version of the interface. It is strongly deprecated.

---

**Note** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/array2D');
type_id = H5D.get_type(dset_id);
h5_dims = H5T.get_array_dims(type_id);
dims = fliplr(h5_dims);
```

## See Also

`H5T.array_create` | `H5T.get_array_ndims`

**Purpose** Rank of array data type

**Syntax** `output = H5T.get_array_ndims(type_id)`

**Description** `output = H5T.get_array_ndims(type_id)` returns the rank, the number of dimensions, of an array data type object.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/array2D');
type_id = H5D.get_type(dset_id);
ndims = H5T.get_array_ndims(type_id);
```

**See Also** `H5T.get_array_dims`

# H5T.get\_cset

---

**Purpose** Character set of string data type

**Syntax** `cset = H5T.get_cset(type_id)`

**Description** `cset = H5T.get_cset(type_id)` returns the character set type of the data type specified by `type_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/string');
type_id = H5D.get_type(dset_id);
cset = H5T.get_cset(type_id);
switch(cset)
    case H5ML.get_constant_value('H5T_CSET_ASCII')
        fprintf('ASCII\n');
    case H5ML.get_constant_value('H5T_CSET_UTF8')
        fprintf('UTF-8\n');
end
```

**See Also** `H5T.set_cset`

**Purpose** Exponent bias of floating-point type

**Syntax** `output = H5T.get_ebias(type_id)`

**Description** `output = H5T.get_ebias(type_id)` returns the exponent bias of a floating-point type. `type_id` is data type identifier.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
ebias = H5T.get_ebias(type_id);
```

**See Also** `H5T.set_ebias`

# H5T.get\_fields

---

**Purpose** Floating-point data type bit field information

**Syntax** `[spos, epos, esize, mpos, msize] = H5T.get_fields(type_id)`

**Description** `[spos, epos, esize, mpos, msize] = H5T.get_fields(type_id)` returns information about the locations of the various bit fields of a floating point data type. `type_id` is a data type identifier. `spos` is the floating-point sign bit. `epos` is the exponent bit-position. `esize` is the size of the exponent in bits. `mpos` is the mantissa bit-position. `msize` is the size of the mantissa in bits.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
[spos, epos, esize, mpos, msize] = H5T.get_fields(type_id);
```

**Purpose** Internal padding type for floating-point data types

**Syntax** `pad_type = H5T.get_inpad(type_id)`

**Description** `pad_type = H5T.get_inpad(type_id)` returns the internal padding type for unused bits in floating-point data types. `type_id` is a data type identifier. `pad_type` can be `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
pad_type = H5T.get_inpad(type_id);
switch(pad_type)
    case H5ML.get_constant_value('H5T_PAD_ZERO')
        fprintf('pad zero\n');
    case H5ML.get_constant_value('H5T_PAD_ONE')
        fprintf('pad one\n');
    case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
        fprintf('pad background\n');
end
```

**See Also** `H5T.set_inpad`

# H5T.get\_norm

---

**Purpose** Mantissa normalization type

**Syntax** `norm_type = H5T.get_norm(type_id)`

**Description** `norm_type = H5T.get_norm(type_id)` returns the mantissa normalization of a floating-point data type. `type_id` is a data type identifier. `norm_type` can be `H5T_NORM_IMPLIED`, `H5T_NORM_MSBSET`, or `H5T_NORM_NONE`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
norm_type = H5T.get_norm(type_id);
switch(norm_type)
    case H5ML.get_constant_value('H5T_NORM_IMPLIED')
        fprintf('MSB of mantissa is not stored, always 1\n');
    case H5ML.get_constant_value('H5T_NORM_MSBSET')
        fprintf('MSB of mantissa is always 1\n');
    case H5ML.get_constant_value('H5T_NORM_NONE')
        fprintf('mantissa is not normalized\n');
end
```

**See Also** `H5T.set_norm`

**Purpose** Bit offset of first significant bit

**Syntax** `offset = H5T.get_offset(type_id)`

**Description** `offset = H5T.get_offset(type_id)` returns the offset of the first significant bit. `type_id` is a data type identifier.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
offset = H5T.get_offset(type_id);
```

**See Also** `H5T.set_offset`

# H5T.get\_order

---

**Purpose** Byte order of atomic data type

**Syntax** `output = H5T.get_order(type_id)`

**Description** `output = H5T.get_order(type_id)` returns the byte order of an atomic data type. `type_id` is a data type identifier. Possible return values are the constant values corresponding to the following strings:

```
'H5T_ORDER_LE'  
'H5T_ORDER_BE'  
'H5T_ORDER_VAX'
```

**Examples**

```
fid = H5F.open('example.h5');  
dset_id = H5D.open(fid, '/g2/dset2.2');  
type_id = H5D.get_type(dset_id);  
switch(H5T.get_order(type_id))  
    case H5ML.get_constant_value('H5T_ORDER_LE')  
        fprintf('little endian\n');  
    case H5ML.get_constant_value('H5T_ORDER_BE')  
        fprintf('big endian\n');  
    case H5ML.get_constant_value('H5T_ORDER_VAX')  
        fprintf('vax\n');  
end
```

**See Also** `H5T.set_order` | `H5ML.get_constant_value`

**Purpose** Padding type of least and most-significant bits

**Syntax** [lsb,msb] = H5T.get\_pad(type\_id)

**Description** [lsb,msb] = H5T.get\_pad(type\_id) returns the padding type of the least and most-significant bit padding. type\_id is a data type identifier. lsb is the least-significant bit padding type. msb is the most-significant bit padding type. Values for lsb and msb can be H5T\_PAD\_ZERO, H5T\_PAD\_ONE, or H5T\_PAD\_BACKGROUND.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
type_id = H5D.get_type(dset_id);
[lsb,msb] = H5T.get_pad(type_id);
switch(lsb)
    case H5ML.get_constant_value('H5T_PAD_ZERO')
        fprintf('lsb pad type is zeros\n');
    case H5ML.get_constant_value('H5T_PAD_ONE')
        fprintf('lsb pad type is ones\n');
    case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
        fprintf('lsb pad type is background\n');
end
switch(msb)
    case H5ML.get_constant_value('H5T_PAD_ZERO')
        fprintf('msb pad type is zeros\n');
    case H5ML.get_constant_value('H5T_PAD_ONE')
        fprintf('msb pad type is ones\n');
    case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
        fprintf('msb pad type is background\n');
end
```

**See Also** H5T.set\_pad

# H5T.get\_precision

---

**Purpose** Precision of atomic data type

**Syntax** `output = H5T.get_precision(type_id)`

**Description** `output = H5T.get_precision(type_id)` returns the precision of an atomic data type. `type_id` is a data type identifier.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
type_id = H5D.get_type(dset_id);
numbits = H5T.get_precision(type_id);
```

**See Also** `H5T.set_precision`

**Purpose** Sign type for integer data type

**Syntax** `sign_type = H5T.get_sign(type_id)`

**Description** `sign_type = H5T.get_sign(type_id)` returns the sign type for an integer type. `type_id` is a data type identifier. Valid types are: `H5T_SGN_NONE` or `H5T_SGN_2`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
type_id = H5D.get_type(dset_id);
sign_type = H5T.get_sign(type_id);
switch(sign_type)
    case H5ML.get_constant_value('H5T_SGN_NONE')
        fprintf('Unsigned integer type.\n');
    case H5ML.get_constant_value('H5T_SGN_2')
        fprintf('Signed integer type.\n');
end
```

**See Also** `H5T.set_sign`

# H5T.get\_strpad

---

**Purpose** Storage mechanism for string data type

**Syntax** `output = H5T.get_strpad(type_id)`

**Description** `output = H5T.get_strpad(type_id)` returns the storage mechanism (padding type) for a string data type. Possible values are:

|                               |                 |
|-------------------------------|-----------------|
| <code>H5T_STR_NULLPAD</code>  | Pad with zeros  |
| <code>H5T_STR_NULLTERM</code> | Null-terminate  |
| <code>H5T_STR_SPACEPAD</code> | Pad with spaces |

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/string');
type_id = H5D.get_type(dset_id);
padding = H5T.get_strpad(type_id);
switch(padding)
    case H5ML.get_constant_value('H5T_STR_NULLTERM')
        fprintf('null-terminated\n');
    case H5ML.get_constant_value('H5T_STR_NULLPAD')
        fprintf('padded with zeros\n');
    case H5ML.get_constant_value('H5T_STR_SPACEPAD')
        fprintf('padded with spaces\n');
end
```

**See Also** `H5T.set_strpad`

**Purpose** Set character dataset for string data type

**Syntax** `H5T.set_cset(type_id, cset)`

**Description** `H5T.set_cset(type_id, cset)` sets the character encoding used to create strings. The only valid type is `H5T_CSET_ASCII`.

**Examples**

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,10);
encoding = H5ML.get_constant_value('H5T_CSET_ASCII');
H5T.set_cset(type_id,encoding);
```

**See Also** `H5T.get_cset`

# H5T.set\_ebias

---

**Purpose** Set exponent bias of floating-point data type

**Syntax** `H5T.set_ebias(type_id,ebias)`

**Description** `H5T.set_ebias(type_id,ebias)` sets the exponent bias of a floating-point type. `type_id` is a data type identifier. `ebias` is an exponent bias value.

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
H5T.set_size(type_id,32);
H5T.set_ebias(type_id,99);
```

**See Also** `H5T.get_ebias`

**Purpose** Set sizes and locations of floating-point bit fields

**Syntax** `H5T.set_fields(type_id, spos, epos, esize, mpos, msize)`

**Description** `H5T.set_fields(type_id, spos, epos, esize, mpos, msize)` sets the locations and sizes of the various floating-point bit fields. `spos` is the sign position. `epos` is the exponent in bits. `esize` is the size of exponent in bits. `mpos` is the mantissa bit position. `msize` is the size of the mantissa in bits.

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
H5T.set_fields(type_id,30,24,6,0,2);
```

**See Also** `H5T.get_fields`

# H5T.set\_inpad

---

**Purpose** Specify how unused internal bits are to be filled

**Syntax** `H5T.set_inpad(type_id,pad)`

**Description** `H5T.set_inpad(type_id,pad)` sets how unused internal bits of a floating point type are filled. `type_id` is the identifier of the data type. `inpad` specifies how to fill the bits: `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND` (leave background alone).

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
pad_type = H5ML.get_constant_value('H5T_PAD_ZERO');
H5T.set_inpad(type_id,pad_type);
```

**See Also** `H5T.get_inpad`

**Purpose** Set mantissa normalization of floating-point data type

**Syntax** `H5T.set_norm(type_id,norm)`

**Description** `H5T.set_norm(type_id,norm)` sets the mantissa normalization of a floating-point data type. Valid normalization types are: `H5T_NORM_IMPLIED`, `H5T_NORM_MSBSET`, or `H5T_NORM_NONE`.

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
norm_type = H5ML.get_constant_value('H5T_NORM_MSBSET');
H5T.set_norm(type_id,norm_type);
```

**See Also** `H5T.get_norm`

# H5T.set\_offset

---

**Purpose** Set bit offset of first significant bit

**Syntax** `H5T.set_offset(type_id,offset)`

**Description** `H5T.set_offset(type_id,offset)` sets the bit offset of the first significant bit. `type_id` is the identifier of the data type. `offset` specifies the number of bits of padding that appear.

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_INT');  
H5T.set_offset(type_id,16);
```

**See Also** `H5T.get_offset`

|                    |                                                                                                                                                                                                                                                                |

| <b>Syntax</b>      | <code>H5T.set_order(type_id,type_order)</code>                                                                                                                                                                                                                 |
| <b>Description</b> | <p><code>H5T.set_order(type_id,type_order)</code> sets the byte ordering of an atomic data type. <code>type_order</code> can be one of the following values:</p> <p><code>H5T_ORDER_LE</code><br/><code>H5T_ORDER_BE</code><br/><code>H5T_ORDER_VAX</code></p> |
| <b>Examples</b>    | <p>Create a big endian 32-bit integer type.</p> <pre>type_id = H5T.copy('H5T_NATIVE_INT'); order = H5ML.get_constant_value('H5T_ORDER_BE'); H5T.set_order(type_id,order);</pre>                                                                                |
| <b>See Also</b>    | <code>H5T.get_order</code>   <code>H5ML.get_constant_value</code>                                                                                                                                                                                              |

# H5T.set\_pad

---

**Purpose** Set padding type for least and most significant bits

**Syntax** `H5T.set_pad(type_id,lsb,msb)`

**Description** `H5T.set_pad(type_id,lsb,msb)` sets the padding type for the least and most-significant bits. `type_id` is the identifier of the data type. `lsb` specifies the padding type for least-significant bits; `msb` for most-significant bits. Valid padding types are `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND` (leave background alone).

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_INT');
lsb = H5ML.get_constant_value('H5T_PAD_ONE');
msb = H5ML.get_constant_value('H5T_PAD_ZERO');
H5T.set_pad(type_id,lsb,msb);
```

**See Also** `H5T.get_pad`

**Purpose**

Set precision of atomic data type

**Syntax**

```
H5T.set_precision(type_id,prec)
```

**Description**

H5T.set\_precision(type\_id,prec) sets the precision of an atomic data type. type\_id is a data type identifier. prec specifies the number of bits of precision for the data type.

# H5T.set\_sign

---

**Purpose** Set sign property for integer data type

**Syntax** `H5T.set_sign(type_id,sign)`

**Description** `H5T.set_sign(type_id,sign)` sets the sign property for an integer type. `type_id` is a data type identifier. `sign` specifies the sign type. Valid values are `H5T_SGN_NONE` or `H5T_SGN_2`.

**Examples**

```
type_id = H5T.copy('H5T_NATIVE_LONG');
sgn = H5ML.get_constant_value('H5T_SGN_NONE');
H5T.set_sign(type_id,sgn);
```

**See Also** `H5T.get_sign`

**Purpose** Set size of data type in bytes

**Syntax** `H5T.set_size(type_id,type_size)`

**Description** `H5T.set_size(type_id,type_size)` sets the total size in bytes for the data type specified by `type_id`. The string 'H5T\_VARIABLE' can also be used if a variable length string is desired.

**Examples** Create a variable length string with null termination.

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,'H5T_VARIABLE');
H5T.set_strpad(type_id,'H5T_STR_NULLTERM');
```

**See Also** `H5T.get_size`

# H5T.set\_strpad

---

**Purpose** Set storage mechanism for string data type

**Syntax** `H5T.set_strpad(type_id,storage_type)`

**Description** `H5T.set_strpad(type_id,storage_type)` defines the storage mechanism for the string data type identified by `type_id`. The storage type may be one of the following values.

|                                 |                    |
|---------------------------------|--------------------|
| <code>'H5T_STR_NULLTERM'</code> | Null terminated    |
| <code>'H5T_STR_NULLPAD'</code>  | Padded with zeros  |
| <code>'H5T_STR_SPACEPAD'</code> | Padded with spaces |

**Examples** Create a ten-character string data type with space padding.

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,10);
H5T.set_strpad(type_id,'H5T_STR_SPACEPAD');
```

**See Also** `H5T.get_strpad`

**Purpose** Data type class for compound data type member

**Syntax** `output = H5T.get_member_class(type_id, membno)`

**Description** `output = H5T.get_member_class(type_id, membno)` returns the data type class of the compound data type member specified by `membno`. The `type_id` argument is the data type identifier of a compound object.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
type_id = H5D.get_type(dset_id);
member_name = H5T.get_member_name(type_id, 0);
member_class = H5T.get_member_class(type_id, 0);
```

**See Also** `H5T.get_member_name`

# H5T.get\_member\_index

---

**Purpose** Index of compound or enumeration type member

**Syntax** `idx = H5T.get_member_index(type_id,name)`

**Description** `idx = H5T.get_member_index(type_id,name)` returns the index of a field of a compound data type or an element of an enumeration data type. `type_id` is a data type identifier and `name` is a text string that identifies the target field or element.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
type_id = H5D.get_type(dset_id);
idx = H5T.get_member_index(type_id, 'b');
```

**See Also** `H5T.get_member_name`

**Purpose** Name of compound or enumeration type member

**Syntax** `name = H5T.get_member_name(type_id, membno)`

**Description** `name = H5T.get_member_name(type_id, membno)` returns the name of a field of a compound data type or an element of an enumeration data type. `type_id` is a data type identifier. `membno` is a zero-based index of the field or element whose name is to be retrieved.

**Examples** Determine the name of the first field of a compound dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
dtype_id = H5D.get_type(dset_id);
member_name = H5T.get_member_name(dtype_id, 0);
```

**See Also** `H5T.get_member_index`

# H5T.get\_member\_offset

---

**Purpose** Offset of field of compound data type

**Syntax** `output = H5T.get_member_offset(type_id, membno)`

**Description** `output = H5T.get_member_offset(type_id, membno)` returns the byte offset of the field specified by `membno` in the compound data type specified by `type_id`. Note that zero (0) is a valid offset.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
type_id = H5D.get_type(dset_id);
idx = H5T.get_member_offset(type_id, 1);
```

**See Also** `H5T.get_member_name`

**Purpose** Data type of specified member

**Syntax** `type_id = H5T.get_member_type(type_id, membno)`

**Description** `type_id = H5T.get_member_type(type_id, membno)` returns the data type of the member specified by `membno` in the data type specified by `type_id`.

**Examples** Get the size of the data type of the first member of a compound data type.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
compound_type_id = H5D.get_type(dset_id);
member_type_id = H5T.get_member_type(compound_type_id, 0);
type_size = H5T.get_size(member_type_id);
```

**See Also** `H5D.get_type`

# H5T.get\_nmembers

---

**Purpose**            Number of elements in enumeration type

**Syntax**            `output = H5T.get_nmembers(type_id)`

**Description**       `output = H5T.get_nmembers(type_id)` retrieves the number of fields in a compound data type or the number of members of an enumeration data type. `type_id` is a data type identifier.

**Examples**           Determine the number of fields in a compound dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
dtype_id = H5D.get_type(dset_id);
nmembers = H5T.get_nmembers(dtype_id);
```

**Purpose** Add member to compound data type

**Syntax** `H5T.insert(type_id,name,offset,member_datatype)`

**Description** `H5T.insert(type_id,name,offset,member_datatype)` adds another member to the compound data type specified by `type_id`. The `name` argument is a text string that specifies the name of the new member, which must be unique in the compound data type. `offset` specifies where you want to insert the new member and `member_datatype` specifies the data type identifier of the new member.

**Examples**

```
type_id = H5T.create('H5T_COMPOUND',16);
H5T.insert(type_id,'first',0,'H5T_NATIVE_DOUBLE');
H5T.insert(type_id,'second',8,'H5T_NATIVE_INT');
H5T.insert(type_id,'third',12,'H5T_NATIVE_UINT');
```

**See Also** `H5T.create`

# H5T.pack

---

**Purpose** Recursively remove padding from compound data type

**Syntax** `H5T.pack(type_id)`

**Description** `H5T.pack(type_id)` recursively removes padding from within a compound data type to make it more efficient (space-wise) to store that data. `type_id` is a data type identifier.

**Purpose** Create new enumeration data type

**Syntax** `output = H5T.enum_create(parent_id)`

**Description** `output = H5T.enum_create(parent_id)` creates a new enumeration data type based on the specified base data type, `parent_id`, which must be an integer type. `output` is a data type identifier for the new enumeration data type.

**Examples**

```
parent_id = H5T.copy('H5T_NATIVE_UINT');
type_id = H5T.enum_create(parent_id);
H5T.enum_insert(type_id, 'red', 1);
H5T.enum_insert(type_id, 'green', 2);
H5T.enum_insert(type_id, 'blue', 3);
H5T.close(type_id);
H5T.close(parent_id);
```

**See Also** `H5T.enum_insert`

# H5T.enum\_insert

---

**Purpose** Insert enumeration data type member

**Syntax** `H5T.enum_insert(type_id,name,value)`

**Description** `H5T.enum_insert(type_id,name,value)` inserts a new enumeration data type member into the enumeration data type specified by `type_id`. The `name` argument is a text string that specifies the name of the new member of the enumeration and `value` is the value of the member.

**Examples**

```
parent_id = H5T.copy('H5T_NATIVE_UINT');
type_id = H5T.enum_create(parent_id);
H5T.enum_insert(type_id,'red',1);
H5T.enum_insert(type_id,'green',2);
H5T.enum_insert(type_id,'blue',3);
H5T.close(type_id);
H5T.close(parent_id);
```

**See Also** `H5T.enum_create`

**Purpose** Name of enumeration data type member

**Syntax** `name = H5T.enum_nameof(type_id,value)`

**Description** `name = H5T.enum_nameof(type_id,value)` returns the symbol name corresponding to a member of an enumeration data type. `type_id` specifies the enumeration data type. `value` identifies the member of the enumeration.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/enum');
type_id = H5D.get_type(dset_id);
name0 = H5T.enum_nameof(type_id,int32(0));
name1 = H5T.enum_nameof(type_id,int32(1));
```

**See Also** `H5T.enum_valueof`

# H5T.enum\_valueof

---

**Purpose** Value of enumeration data type member

**Syntax** `value = H5T.enum_valueof(type_id,member_name)`

**Description** `value = H5T.enum_valueof(type_id,member_name)` returns the value corresponding to a specified member of an enumeration data type. `type_id` specifies the enumeration data type and `member_name` specifies the member.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/enum');
type_id = H5D.get_type(dset_id);
num_members = H5T.get_nmembers(type_id);
for j = 1:num_members
    member_name{j} = H5T.get_member_name(type_id,j-1);
    member_value(j) = H5T.enum_valueof(type_id,member_name{j});
end
```

**See Also** `H5T.get_member_name` | `H5T.get_nmembers`

**Purpose** Value of enumeration data type member

**Syntax** `value = H5T.get_member_value(type_id,membno)`

**Description** `value = H5T.get_member_value(type_id,membno)` returns the value of the enumeration data type member specified by `membno`. The `type_id` argument is the data type identifier for the enumeration data type.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/enum');
type_id = H5D.get_type(dset_id);
num_members = H5T.get_nmembers(type_id);
for j = 1:num_members
    member_name{j} = H5T.get_member_name(type_id,j-1);
    member_value(j) = H5T.get_member_value(type_id,j-1);
end
```

**See Also** `H5T.get_member_name` | `H5T.get_nmembers`

# H5T.get\_tag

---

**Purpose** Tag associated with opaque data type

**Syntax** `tag = H5T.get_tag(type_id)`

**Description** `tag = H5T.get_tag(type_id)` returns the tag associated with the opaque data type specified by `type_id`.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/opaque');
dtype_id = H5D.get_type(dset_id);
tag = H5T.get_tag(dtype_id);
```

**See Also** `H5T.set_tag`

|                    |                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Tag opaque data type with description                                                                                                                                        |
| <b>Syntax</b>      | <code>H5T.set_tag(type_id,tag)</code>                                                                                                                                        |
| <b>Description</b> | <code>H5T.set_tag(type_id,tag)</code> tags the opaque data type specified by <code>type_id</code> , with the descriptive ASCII string identifier, <code>tag</code> .         |
| <b>Examples</b>    | Create an opaque data type with a length of 4 bytes and a particular tag.<br><pre>type_id = H5T.create('H5T_OPAQUE',4);<br/>H5T.set_tag(type_id,'Created by MATLAB.');</pre> |
| <b>See Also</b>    | <code>H5T.create</code>   <code>H5T.get_tag</code>                                                                                                                           |

# H5T.is\_variable\_str

---

**Purpose** Determine if data type is variable-length string

**Syntax** `output = H5T.is_variable_str(type_id)`

**Description** `output = H5T.is_variable_str(type_id)` returns a positive value if the data type specified by `type_id` is a variable-length string and zero if it is not. A negative value indicates failure.

**Examples**

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/VLstring2D');
type_id = H5D.get_type(dset_id);
if H5T.is_variable_str(type_id) > 0
    fprintf('variable length string\n');
end
```

**See Also** `H5T.vlen_create` | `H5T.get_size` | `H5D.get_type`

**Purpose** Create new variable-length data type

**Syntax** `vlen_type_id = H5T.vlen_create(base_id)`

**Description** `vlen_type_id = H5T.vlen_create(base_id)` creates a new variable-length (VL) data type. `base_id` specifies the base type of the data type to create.

**Examples** Create a variable length data type for 64-bit floating-point numbers.

```
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');  
vlen_type_id = H5T.vlen_create(base_type_id);
```

**See Also** `H5T.is_variable_str`

# H5Z.filter\_avail

---

**Purpose** Determine if filter is available

**Syntax** `output = H5Z.filter_avail(filter_id)`

**Description** `output = H5Z.filter_avail(filter_id)` determines whether the filter specified by the filter identifier is available to the application. `filter_id` can be specified by one of the following strings or its numeric equivalent.

```
'H5Z_FILTER_DEFLATE'  
'H5Z_FILTER_SHUFFLE'  
'H5Z_FILTER_FLETCHER32'  
'H5Z_FILTER_SZIP'  
'H5Z_FILTER_NBIT'  
'H5Z_FILTER_SCALEOFFSET'
```

**Examples** Determine if the shuffle filter is available.

```
bool = H5Z.filter_avail('H5Z_FILTER_SHUFFLE');
```

**See Also** `H5ML.get_constant_value`

**Purpose**

Information about filter

**Syntax**

```
filter_config_flags = H5Z.get_filter_info(filter)
```

**Description**

`filter_config_flags = H5Z.get_filter_info(filter)` retrieves information about the filter specified by its identifier. At present, the information returned is the filter's configuration flags, indicating whether the filter is configured to decode data, to encode data, neither, or both. `filter_config_flags` should be used with the HDF5 constant values `H5Z_FILTER_CONFIG_ENCODE_ENABLED` and `H5Z_FILTER_CONFIG_DECODE_ENABLED` in a bitwise AND operation. If the resulting value is 0, then the encode or decode functionality is not available.

**Examples**

Determine if encoding is enabled for the deflate filter.

```
flags = H5Z.get_filter_info('H5Z_FILTER_DEFLATE');  
functionality = H5ML.get_constant_value('H5Z_FILTER_CONFIG_ENCODE_ENABLED');  
enabled = bitand(flags,functionality) > 0;
```

**See Also**

`H5Z.filter_avail` | `H5ML.get_constant_value` | `bitand`

# hadamard

---

**Purpose** Hadamard matrix

**Syntax** `H = hadamard(n)`

**Description** `H = hadamard(n)` returns the Hadamard matrix of order `n`.

**Definitions** Hadamard matrices are matrices of 1's and -1's whose columns are orthogonal,

$$H' * H = n * I$$

where `[n n]=size(H)` and `I = eye(n,n)` .

They have applications in several different areas, including combinatorics, signal processing, and numerical analysis, [1], [2].

An `n`-by-`n` Hadamard matrix with `n > 2` exists only if `rem(n,4) = 0`. This function handles only the cases where `n`, `n/12`, or `n/20` is a power of 2.

**Examples** The command `hadamard(4)` produces the 4-by-4 matrix:

```
1   1   1   1
1  -1   1  -1
1   1  -1  -1
1  -1  -1   1
```

**See Also** `compan` | `hankel` | `toeplitz`

**Purpose**

Abstract class for deriving handle classes

**Syntax**

```
classdef MyHandleClass < handle
```

**Description**

`classdef MyHandleClass < handle` makes *MyHandleClass* a subclass of the `handle` class.

The `handle` class is the superclass for all classes that follow `handle` semantics. A *handle* is a reference to an object. If you copy an object's `handle`, MATLAB copies only the `handle` and both the original and copy refer to the same object data. If a function modifies a `handle` object passed as an input argument, the modification affects the original input object.

In contrast, nonhandle objects (that is, value objects) are not references. Functions must return modified value objects to the caller to cause change to the object outside of the function's workspace.

See “Modifying Objects” for information on passing objects to functions.

Handle object behavior is like that of Handle Graphics objects, where the `handle` of a graphics object always refers to a particular instance regardless of whether you save the `handle` when you create the object, store it in another variable, or obtain it with convenience functions like `findobj`, `gca`, and so on.

If you want to create a class that defines events, you must derive that class from the `handle` class.

The `handle` class is an abstract class, so you cannot create an instance of this class directly. You use the `handle` class to derive other classes, which can be concrete classes whose instances are `handle` objects. See “Handle Classes” for information on using `handle` classes.

**Handle Class Methods**

When you derive a class from the `handle` class, your class inherits the following methods.

# handle

---

| Method                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>addlistener</code>                                                                                                                          | Creates a listener for the specified event and assigns a callback function to execute when the event occurs.                                                                                                                                                                                                                                                                                                                         |
| <code>notify</code>                                                                                                                               | Broadcast a notice that a specific event is occurring on a specified handle object or array of handle objects.                                                                                                                                                                                                                                                                                                                       |
| <code>delete</code>                                                                                                                               | Handle object destructor method that is called when the object's lifecycle ends.                                                                                                                                                                                                                                                                                                                                                     |
| <code>findobj</code>                                                                                                                              | Finds objects matching the specified conditions from the input array of handle objects.                                                                                                                                                                                                                                                                                                                                              |
| <code>findprop</code>                                                                                                                             | Returns a <code>meta.property</code> objects associated with the specified property name.                                                                                                                                                                                                                                                                                                                                            |
| <code>isvalid</code>                                                                                                                              | Returns a logical array in which elements are true if the corresponding elements in the input array are valid handles. This method is <b>Sealed</b> so you cannot override it in a handle subclass.                                                                                                                                                                                                                                  |
| <code>eq</code><br><code>ne</code><br><code>lt</code><br><code>le</code><br><code>gt</code><br><code>ge</code><br><code>relationaloperator</code> | Relational functions return a logical array of the same size as the pair of input handle object arrays. Comparisons use a number associated with each handle. You can assume that the same two handles will compare as equal and the repeated comparison of any two handles will yield the same result in the same MATLAB session. Different handles are always not-equal. The order of handles is purely arbitrary, but consistent. |

## Handle Class Events

The handle class defines one event:

`ObjectBeingDestroyed`

This event is triggered when the handle object is about to be destroyed. If you define a listener for this event, its callback executes before MATLAB destroys the handle object.

You can add a listener for this event using the `addlistener` method. See “Events and Listeners — Syntax and Techniques” for more information on using events and listeners.

You can define a `delete` method for a handle subclass that MATLAB calls when the object is destroyed. See “Handle Class Destructor”.

## Handle Subclasses

You can use the following abstract `handle` subclasses to derive more specialized `handle` classes:

- `hgsetget` – use when you want to create a handle class that inherits `set` and `get` methods having the same behavior as Handle Graphics `set` and `get` functions.
- `dynamicprops` – use when you want to create a handle class that allows you to add instance data (dynamically defined properties) to objects.
- `matlab.mixin.Copyable` – use to add a `copy` method to a handle subclass.

## Useful Functions

- `properties` — list the class public properties
- `methods` — list the class methods
- `events` — list the events defined by the class

Note that `ishandle` does not test for handle class objects. Use `isa` instead.

# hankel

---

## Purpose

Hankel matrix

## Syntax

```
H = hankel(c)
H = hankel(c,r)
```

## Description

`H = hankel(c)` returns the square Hankel matrix whose first column is `c` and whose elements are zero below the first anti-diagonal.

`H = hankel(c,r)` returns a Hankel matrix whose first column is `c` and whose last row is `r`. If the last element of `c` differs from the first element of `r`, the last element of `c` prevails.

## Definitions

A Hankel matrix is a matrix that is symmetric and constant across the anti-diagonals, and has elements  $h(i,j) = p(i+j-1)$ , where vector  $p = [c \ r(2:end)]$  completely determines the Hankel matrix.

## Examples

A Hankel matrix with anti-diagonal disagreement is

```
c = 1:3; r = 7:10;
h = hankel(c,r)
h =
     1     2     3     8
     2     3     8     9
     3     8     9    10

p = [1 2 3 8 9 10]
```

**Purpose**

Summary of MATLAB HDF4 capabilities

**Description**

The MATLAB software provides a set of low-level functions that enable you to access the HDF4 library developed by the National Center for Supercomputing Applications (NCSA). For information about HDF4, go to the HDF Web page at <http://www.hdfgroup.org>.

---

**Note** This section does not apply to MATLAB HDF5 capabilities, which is a completely separate, incompatible format.

---

The following table lists all the HDF4 application programming interfaces (APIs) supported by MATLAB with the name of the MATLAB function used to access the API. To use these functions, you must be familiar with the HDF library. For more information about using these MATLAB functions, see “Importing Hierarchical Data Format (HDF4) Files” and “Exporting to Hierarchical Data Format (HDF4) Files”.

Call `help functionname` to display help for any of these functions in the Command Window.

| <b>Application Programming Interface</b> | <b>Description</b>                                                                                                    | <b>MATLAB Function</b> |

`hdfinfo` | `hdfread`

# hdf5info

---

## Purpose

Information about HDF5 file

---

**Note** `hdf5info` will be removed in a future version. Use `h5info` instead.

---

## Syntax

```
fileinfo = hdf5info(filename)
fileinfo = hdf5info(...,'ReadAttributes',B00L)
[...] = hdf5info(...,'V71Dimensions', B00L)
```

## Description

`fileinfo = hdf5info(filename)` returns a structure `fileinfo` whose fields contain information about the contents of the HDF5 file `filename`. `filename` is a string that specifies the name of the HDF5 file.

`fileinfo = hdf5info(...,'ReadAttributes',B00L)` specifies whether `hdf5info` returns the values of the attributes or just information describing the attributes. By default, `hdf5info` reads in attribute values (`B00L = true`).

`[...] = hdf5info(...,'V71Dimensions', B00L)` specifies whether to report the dimensions of data sets and attributes as they were returned in previous versions of `hdf5info` (MATLAB 7.1 [R14SP3] and earlier). If `B00L` is true, `hdf5info` swaps the first two dimensions of the data set. This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, swapping these dimensions may not correctly reflect the intent of the data in the file and may invalidate metadata. When `B00L` is false (the default), `hdf5info` returns data dimensions that correctly reflect the data ordering as it is written in the file—each dimension in the output variable matches the same dimension in the file.

---

**Note** If you use the 'V71Dimensions' parameter and intend on passing the `fileinfo` structure returned to the `hdf5read` function, you should also specify the 'V71Dimensions' parameters with `hdf5read`. If you do not, `hdf5read` uses the new behavior when reading the data set and certain metadata returned by `hdf5info` does not match the actual data returned by `hdf5read`.

---

## Examples

```
fileinfo = hdf5info('example.h5');
```

To get more information about the contents of the HDF5 file, look at the `GroupHierarchy` field in the `fileinfo` structure returned by `hdf5info`.

```
toplevel = fileinfo.GroupHierarchy
```

```
toplevel =
```

```
    Filename: [1x64 char]
         Name: '/'
         Groups: [1x2 struct]
        Datasets: []
       Datatypes: []
         Links: []
    Attributes: [1x2 struct]
```

To probe further into the file hierarchy, keep examining the `Groups` field.

`hdf5read`, `hdf5write`

# hdf5read

---

**Purpose** Read HDF5 file

---

**Note** `hdf5read` will be removed in a future version. Use `h5read` instead.

---

**Syntax**

```
data = hdf5read(filename,datasetname)
attr = hdf5read(filename,attributename)
[data, attr] = hdf5read(...,'ReadAttributes',B00L)
data = hdf5read(hinfo)
[...] = hdf5read(..., 'V71Dimensions', B00L)
```

**Description** `data = hdf5read(filename,datasetname)` reads all the data in the data set `datasetname` that is stored in the HDF5 file `filename` and returns it in the variable `data`. To determine the names of data sets in an HDF5 file, use the `hdf5info` function.

The return value, `data`, is a multidimensional array. `hdf5read` maps HDF5 data types to native MATLAB data types, whenever possible. If it cannot represent the data using MATLAB data types, `hdf5read` uses one of the HDF5 data type objects. For example, if an HDF5 file contains a data set made up of an enumerated data type, `hdf5read` uses the `hdf5.h5enum` object to represent the data in the MATLAB workspace. The `hdf5.h5enum` object has data members that store the enumerations (names), their corresponding values, and the enumerated data.

---

**Note** `hdf5read` performs best when reading numeric datasets. If you need to read string, compound, or variable length datasets, MathWorks strongly recommends that you use the low-level HDF5 interface function, `H5D.read`. To read a subset of a dataset, you must use the low-level interface.

---

`attr = hdf5read(filename,attributename)` reads all the metadata in the attribute `attributename`, stored in the HDF5 file `filename`, and

returns it in the variable `attr`. To determine the names of attributes in an HDF5 file, use the `hdf5info` function.

`[data, attr] = hdf5read(..., 'ReadAttributes', B00L)` reads all the data, as well as all of the associated attribute information contained within that data set. By default, `B00L` is false.

`data = hdf5read(hinfo)` reads all of the data in the data set specified in the structure `hinfo` and returns it in the variable `data`. The `hinfo` structure is extracted from the output returned by `hdf5info`, which specifies an HDF5 file and a specific data set.

`[...] = hdf5read(..., 'V71Dimensions', B00L)` specifies whether to change the majority of data sets read from the file. If `B00L` is true, `hdf5read` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `B00L` is false (the default), the data dimensions correctly reflect the data ordering as it is written in the file — each dimension in the output variable matches the same dimension in the file.

## Examples

Use `hdf5info` to get information about an HDF5 file and then use `hdf5read` to read a data set, using the information structure (`hinfo`) returned by `hdf5info` to specify the data set.

```
hinfo = hdf5info('example.h5');
dset = hdf5read(hinfo.GroupHierarchy.Groups(2).Datasets(1));
```

`hdf5info` | `hdf5write`

# hdf5write

---

## Purpose

Write data to file in HDF5 format

---

**Note** `hdf5write` will be removed in a future version. Use `h5write` instead.

---

## Syntax

```
hdf5write(filename,location,dataset)
hdf5write(filename,details,dataset)
hdf5write(filename,details,attribute)
hdf5write(filename, details1, dataset1, details2, dataset2,
    ...)
hdf5write(filename,...,'WriteMode',mode,...)
hdf5write(..., 'V71Dimensions', BOOL)
```

## Description

`hdf5write(filename,location,dataset)` writes the data `dataset` to the HDF5 file, `filename`. If `filename` does not exist, `hdf5write` creates it. If `filename` exists, `hdf5write` overwrites the existing file, by default, but you can also append data to an existing file using an optional syntax.

`location` defines where to write the data set in the file. HDF5 files are organized in a hierarchical structure similar to a UNIX directory structure. `location` is a string that resembles a UNIX path.

`hdf5write` maps the data in `dataset` to HDF5 data types according to rules outlined below.

`hdf5write(filename,details,dataset)` writes `dataset` to `filename` using the values in the `details` structure. For a data set, the `details` structure can contain the following fields.

| Field Name | Description                          | Data Type       |
|------------|--------------------------------------|-----------------|
| Location   | Location of the data set in the file | Character array |
| Name       | Name to attach to the data set       | Character array |

`hdf5write(filename,details,attribute)` writes the metadata attribute to `filename` using the values in the `details` structure. For an attribute, the `details` structure can contain following fields.

| Field Name | Description                                                                                       | Data Type       |
|------------|---------------------------------------------------------------------------------------------------|-----------------|
| AttachedTo | Location of the object this attribute modifies                                                    | Structure array |
| AttachType | Identifies what kind of object this attribute modifies; possible values are 'group' and 'dataset' | Character array |
| Name       | Name to attach to the data set                                                                    | Character array |

`hdf5write(filename, details1, dataset1, details2, dataset2, ...)` writes multiple data sets and associated attributes to `filename` in one operation. Each data set and attribute must have an associated `details` structure.

`hdf5write(filename,...,'WriteMode',mode,...)` specifies whether `hdf5write` overwrites the existing file (the default) or appends data sets and attributes to the file. Possible values for `mode` are 'overwrite' and 'append'.

`hdf5write(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets written to the file. If `BOOL` is true, `hdf5write` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data written to the file correctly reflects the data ordering of the data sets — each dimension in the file's data sets matches the same dimension in the corresponding MATLAB variable.

# hdf5write

## Data Type Mappings

The following table lists how `hdf5write` maps the data type from the workspace into an HDF5 file. If the data in the workspace that is being written to the file is a MATLAB data type, `hdf5write` uses the following rules when translating MATLAB data into HDF5 data objects.

| MATLAB Data Type           | HDF5 Data Set or Attribute                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Numeric                    | Corresponding HDF5 native data type. For example, if the workspace data type is <code>uint8</code> , the <code>hdf5write</code> function writes the data to the file as 8-bit integers. The size of the HDF5 dataspace is the same size as the MATLAB array.                                                                                                                                                                                 |
| String                     | Single, null-terminated string                                                                                                                                                                                                                                                                                                                                                                                                               |
| Cell array of strings      | Multiple, null-terminated strings, each the same length. Length is determined by the length of the longest string in the cell array. The size of the HDF5 dataspace is the same size as the cell array.                                                                                                                                                                                                                                      |
| Cell array of numeric data | Numeric array, the same dimensions as the cell array. The elements of the array must all have the same size and type. The data type is determined by the first element in the cell array.                                                                                                                                                                                                                                                    |
| Structure array            | HDF5 compound type. Individual fields in the structure employ the same data translation rules for individual data types. For example, a cell array of strings becomes a multiple, null-terminated strings.                                                                                                                                                                                                                                   |
| HDF5 objects               | If the data being written to the file is composed of HDF5 objects, <code>hdf5write</code> uses the same data type when writing to the file. For all HDF5 objects, except <code>HDF5.h5enum</code> objects, the dataspace has the same dimensions as the array of HDF5 objects passed to the function. For <code>HDF5.h5enum</code> objects, the size and dimensions of the data set in the HDF5 file is the same as the object's Data field. |

## Examples

Write a 5-by-5 data set of `uint8` values to the root group.

```
hdf5write('myfile.h5', '/dataset1', uint8(magic(5)))
```

Write a 2-by-2 string data set in a subgroup.

```
dataset = {'north', 'south'; 'east', 'west'};
hdf5write('myfile2.h5', '/group1/dataset1.1', dataset);
```

Write a data set and attribute to an existing group.

```
dset = single(rand(10,10));
dset_details.Location = '/group1/dataset1.2';
dset_details.Name = 'Random';

attr = 'Some random data';
attr_details.Name = 'Description';
attr_details.AttachedTo = '/group1/dataset1.2/Random';
attr_details.AttachType = 'dataset';

hdf5write('myfile2.h5', dset_details, dset, ...
         attr_details, attr, 'WriteMode', 'append');
```

Write a data set using objects.

```
dset = hdf5.h5array(magic(5));
hdf5write('myfile3.h5', '/g1/objects', dset);
```

## See Also

[hdf5read](#) | [hdf5info](#)

# hdfinfo

---

**Purpose** Information about HDF4 or HDF-EOS file

**Syntax**  
S = hdfinfo(filename)  
S = hdfinfo(filename,mode)

**Description** S = hdfinfo(filename) returns a structure S whose fields contain information about the contents of an HDF4 or HDF-EOS file. filename is a string that specifies the name of the HDF4 file.

S = hdfinfo(filename,mode) reads the file as an HDF4 file, if mode is 'hdf', or as an HDF-EOS file, if mode is 'eos'. If mode is 'eos', only HDF-EOS data objects are queried. To retrieve information on the entire contents of a file containing both HDF4 and HDF-EOS objects, mode must be 'hdf'.

---

**Note** hdfinfo can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To get information about an HDF5 file, use hdf5info.

---

The set of fields in the returned structure S depends on the individual file. Fields that can be present in the S structure are shown in the following table.

| Mode | Field Name  | Description                        | Return Type     |
|------|-------------|------------------------------------|-----------------|
| HDF  | Attributes  | Attributes of the data set         | Structure array |
|      | Description | Annotation description             | Cell array      |
|      | Filename    | Name of the file                   | String          |
|      | Label       | Annotation label                   | Cell array      |
|      | Raster8     | Description of 8-bit raster images | Structure array |

| Mode | Field Name | Description                         | Return Type     |
|------|------------|-------------------------------------|-----------------|
|      | Raster24   | Description of 24-bit raster images | Structure array |
|      | SDS        | Description of scientific data sets | Structure array |
|      | Vdata      | Description of Vdata sets           | Structure array |
|      | Vgroup     | Description of Vgroups              | Structure array |
| EOS  | Filename   | Name of the file                    | String          |
|      | Grid       | Grid data                           | Structure array |
|      | Point      | Point data                          | Structure array |
|      | Swath      | Swath data                          | Structure array |

Those fields in the table above that contain structure arrays are further described in the tables shown below.

## Fields Common to Returned Structure Arrays

Structure arrays returned by `hdfinfo` contain some common fields. These are shown in the table below. Not all structure arrays will contain all of these fields.

| Field Name  | Description                                          | Data Type       |
|-------------|------------------------------------------------------|-----------------|
| Attributes  | Data set attributes. Contains fields Name and Value. | Structure array |
| Description | Annotation description                               | Cell array      |
| Filename    | Name of the file                                     | String          |
| Label       | Annotation label                                     | Cell array      |

| Field Name | Description                          | Data Type |
|------------|--------------------------------------|-----------|
| Name       | Name of the data set                 | String    |
| Rank       | Number of dimensions of the data set | Double    |
| Ref        | Data set reference number            | Double    |
| Type       | Type of HDF or HDF-EOS object        | String    |

## Fields Specific to Certain Structures

Structure arrays returned by `hdfinfo` also contain fields that are unique to each structure. These are shown in the tables below.

### Fields of the Attribute Structure

| Field Name | Description                    | Data Type         |
|------------|--------------------------------|-------------------|
| Name       | Attribute name                 | String            |
| Value      | Attribute value or description | Numeric or string |

### Fields of the Raster8 and Raster24 Structures

| Field Name | Description                                                                       | Data Type |
|------------|-----------------------------------------------------------------------------------|-----------|
| HasPalette | 1 (true) if the image has an associated palette, otherwise 0 (false) (8-bit only) | Logical   |
| Height     | Height of the image, in pixels                                                    | Number    |
| Interlace  | Interlace mode of the image (24-bit only)                                         | String    |
| Name       | Name of the image                                                                 | String    |
| Width      | Width of the image, in pixels                                                     | Number    |

**Fields of the SDS Structure**

| <b>Field Name</b> | <b>Description</b>                                                                                                                                                                          | <b>Data Type</b> |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| DataType          | Data precision                                                                                                                                                                              | String           |
| Dims              | Dimensions of the data set. Contains fields Name, DataType, Size, Scale, and Attributes. Scale is an array of numbers to place along the dimension and demarcate intervals in the data set. | Structure array  |
| Index             | Index of the SDS                                                                                                                                                                            | Number           |

**Fields of the Vdata Structure**

| <b>Field Name</b> | <b>Description</b>                                                 | <b>Data Type</b> |
|-------------------|--------------------------------------------------------------------|------------------|
| DataAttributes    | Attributes of the entire data set. Contains fields Name and Value. | Structure array  |
| Class             | Class name of the data set                                         | String           |
| Fields            | Fields of the Vdata. Contains fields Name and Attributes.          | Structure array  |
| NumRecords        | Number of data set records                                         | Double           |
| IsAttribute       | 1 (true) if Vdata is an attribute, otherwise 0 (false)             | Logical          |

## Fields of the Vgroup Structure

| Field Name | Description                             | Data Type       |
|------------|-----------------------------------------|-----------------|
| Class      | Class name of the data set              | String          |
| Raster8    | Description of the 8-bit raster image   | Structure array |
| Raster24   | Description of the 24-bit raster image  | Structure array |
| SDS        | Description of the Scientific Data sets | Structure array |
| Tag        | Tag of this Vgroup                      | Number          |
| Vdata      | Description of the Vdata sets           | Structure array |
| Vgroup     | Description of the Vgroups              | Structure array |

## Fields of the Grid Structure

| Field Name  | Description                                                                                                                           | Data Type       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Columns     | Number of columns in the grid                                                                                                         | Number          |
| DataFields  | Description of the data fields in each Grid field of the grid. Contains fields Name, Rank, Dims, NumberType, FillValue, and TileDims. | Structure array |
| LowerRight  | Lower right corner location, in meters                                                                                                | Number          |
| Origin Code | Origin code for the grid                                                                                                              | Number          |
| PixRegCode  | Pixel registration code                                                                                                               | Number          |

**Fields of the Grid Structure (Continued)**

| <b>Field Name</b> | <b>Description</b>                                                                                                                             | <b>Data Type</b> |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Projection        | Projection code, zone code, sphere code, and projection parameters of the grid. Contains fields ProjCode, ZoneCode, SphereCode, and ProjParam. | Structure        |
| Rows              | Number of rows in the grid                                                                                                                     | Number           |
| UpperLeft         | Upper left corner location, in meters                                                                                                          | Number           |

**Fields of the Point Structure**

| <b>Field Name</b> | <b>Description</b>                                                                                         | <b>Data Type</b> |
|-------------------|------------------------------------------------------------------------------------------------------------|------------------|
| Level             | Description of each level of the point. Contains fields Name, NumRecords, FieldNames, DataType, and Index. | Structure        |

**Fields of the Swath Structure**

| <b>Field Name</b> | <b>Description</b>                                                                     | <b>Data Type</b> |
|-------------------|----------------------------------------------------------------------------------------|------------------|
| DataFields        | Data fields in the swath. Contains fields Name, Rank, Dims, NumberType, and FillValue. | Structure array  |
| GeolocationFields | Geolocation fields in the swath. Contains fields Name,                                 | Structure array  |

## Fields of the Swath Structure (Continued)

| Field Name | Description                                                                                     | Data Type |
|------------|-------------------------------------------------------------------------------------------------|-----------|
|            | Rank, Dims, NumberType, and FillValue.                                                          |           |
| IdxMapInfo | Relationship between indexed elements of the geolocation mapping. Contains fields Map and Size. | Structure |
| MapInfo    | Relationship between data and geolocation fields. Contains fields Map, Offset, and Increment.   | Structure |

## Examples

To retrieve information about the file `example.hdf`,

```
fileinfo = hdfinfo('example.hdf')
```

```
fileinfo =  
    Filename: 'example.hdf'  
    SDS: [1x1 struct]  
    Vdata: [1x1 struct]
```

And to retrieve information from this about the scientific data set in `example.hdf`,

```
sds_info = fileinfo.SDS  
  
sds_info =  
    Filename: 'example.hdf'  
    Type: 'Scientific Data Set'  
    Name: 'Example SDS'  
    Rank: 2  
    DataType: 'int16'  
    Attributes: []
```

```
    Dims: [2x1 struct]
    Label: {}
    Description: {}
    Index: 0
```

## See Also

[hdfread](#) | [hdf](#)

# hdfread

---

**Purpose** Read data from HDF4 or HDF-EOS file

**Syntax**

```
data = hdfread(filename, datasetname)
data = hdfread(hinfo)
data = hdfread(...,param,value,...)
data = hdfread(filename,EOSname,param,value,...)
[data,map] = hdfread(...)
```

**Description** `data = hdfread(filename, datasetname)` returns all the data in the data set specified by `datasetname` from the HDF4 or HDF-EOS file specified by `filename`. To determine the name of a data set in an HDF4 file, use the `hdfinfo` function.

---

**Note** `hdfread` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To read data from an HDF5 file, use `h5read`.

---

`data = hdfread(hinfo)` returns all the data in the data set specified by the `structurehinfo`, returned by the `hdfinfo` function. Specify the field in the `hinfo` structure that relates to a particular type of data set, and use indexing to specify which data set, when there are more than one. See “Example 2” on page 1-2760 for more information.

`data = hdfread(...,param,value,...)` returns subsets of the data according to the specified parameter and value pairs. See the tables below to find the valid parameters and values for different types of data sets.

`data = hdfread(filename,EOSname,param,value,...)` subsets the data field from the HDF-EOS point, grid, or swath specified by `EOSname`.

`[data,map] = hdfread(...)` returns the image data and the colormap map for an 8-bit raster image.

## Subsetting Parameters

The following tables show the subsetting parameters that can be used with the `hdfread` function for certain types of HDF4 data. These data types are

- HDF Scientific Data (SD)
- HDF Vdata (V)
- HDF-EOS Grid Data
- HDF-EOS Point Data
- HDF-EOS Swath Data

Note the following:

- If a parameter requires multiple values, use a cell array to store the values. For example, the 'Index' parameter requires three values: `start`, `stride`, and `edge`. Enclose these values in curly braces as a cell array.

```
hdfread(..., 'Index', {start, stride, edge})
```

- All values that are indices are 1-based.

### Subsetting Parameters for HDF Scientific Data (SD) Data Sets

When you are working with HDF SD files, `hdfread` supports the parameters listed in this table.

# hdfread

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Index'   | <p>Three-element cell array, {start, stride, edge}, specifying the location, range, and values to be read from the data set</p> <ul style="list-style-type: none"><li>• <b>start</b> — A 1-based array specifying the position in the file to begin reading<br/>Default: 1, start at the first element of each dimension. The values specified must not exceed the size of any dimension of the data set.</li><li>• <b>stride</b> — A 1-based array specifying the interval between the values to read<br/>Default: 1, read every element of the data set.</li><li>• <b>edge</b> — A 1-based array specifying the length of each dimension to read<br/>Default: An array containing the lengths of the corresponding dimensions</li></ul> |

For example, this code reads the data set `Example SDS` from the HDF file `example.hdf`. The 'Index' parameter specifies that `hdfread` start reading data at the beginning of each dimension, read until the end of each dimension, but only read every other data value in the first dimension.

```
data = hdfread('example.hdf', 'Example SDS', 'Index', {[1],[2 1],[1]})
```

## Subsetting Parameters for HDF Vdata Sets

When you are working with HDF Vdata files, `hdfread` supports these parameters.

| Parameter     | Description                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------|
| 'Fields'      | Text string specifying the name of the field to be read. When specifying multiple field names, use a cell array. |
| 'FirstRecord' | 1-based number specifying the record from which to begin reading                                                 |
| 'NumRecords'  | Number specifying the total number of records to read                                                            |

For example, this code reads the Vdata set `Example Vdata` from the HDF file `example.hdf`.

```
data = hdfread('example.hdf', 'Example Vdata', 'FirstRecord', 2, 'NumRecords', 5)
```

## Subsetting Parameters for HDF-EOS Grid Data

When you are working with HDF-EOS grid data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive parameters — You can only specify one of these parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Required Parameter</b>                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 'Fields'                                      | String specifying the field to be read. You can specify only one field name for a Grid data set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Mutually Exclusive Optional Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 'Index'                                       | <p>Three-element cell array, {start, stride, edge}, specifying the location, range, and values to be read from the data set</p> <p><b>start</b> — An array specifying the position in the file to begin reading</p> <p>Default: 1, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set.</p> <p><b>stride</b> — An array specifying the interval between the values to read</p> <p>Default: 1, read every element of the data set.</p> <p><b>edge</b> — An array specifying the length of each dimension to read</p> <p>Default: An array containing the lengths of the corresponding dimensions</p> |

# hdfread

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Interpolate'              | Two-element cell array, {longitude, latitude}, specifying the longitude and latitude points that define a region for bilinear interpolation. Each element is an N-length vector specifying longitude and latitude coordinates.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 'Pixels'                   | Two-element cell array, {longitude, latitude}, specifying the longitude and latitude coordinates that define a region. Each element is an N-length vector specifying longitude and latitude coordinates. This region is converted into pixel rows and columns with the origin in the upper left corner of the grid.<br><br>Note: This is the pixel equivalent of reading a 'Box' region.                                                                                                                                                                                                                                                                                      |
| 'Tile'                     | Vector specifying the coordinates of the tile to read, for HDF-EOS Grid files that support tiles                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Optional Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 'Box'                      | Two-element cell array, {longitude, latitude}, specifying the longitude and latitude coordinates that define a region. longitude and latitude are each two-element vectors specifying longitude and latitude coordinates.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 'Time'                     | Two-element cell array, [start stop], where start and stop are numbers that specify the start and end-point for a period of time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 'Vertical'                 | Two-element cell array, {dimension, range}<br><br>dimension — String specifying the name of the data set field to be read from. You can specify only one field name for a Grid data set.<br><br>range — Two-element array specifying the minimum and maximum range for the subset. If dimension is a dimension name, then range specifies the range of elements to extract. If dimension is a field name, then range specifies the range of values to extract.<br><br>'Vertical' subsetting can be used alone or in conjunction with 'Box' or 'Time'. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to hdfread. |

For example,

```
data = hdfread('grid.hdf','PolarGrid','Fields','ice_temp','Index', {[5 10],[1],[15 20]})
```

### Subsetting Parameters for HDF-EOS Point Data

When you are working with HDF-EOS Point data, `hdfread` has two required parameters and three optional parameters.

| Parameter                                     | Description                                                                                                                                                                                                              |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Required Parameters</b>                    |                                                                                                                                                                                                                          |
| 'Fields'                                      | String naming the data set field to be read. For multiple field names, use a comma-separated list.                                                                                                                       |
| 'Level'                                       | 1-based number specifying which level to read from in an HDF-EOS Point data set                                                                                                                                          |
| <b>Mutually Exclusive Optional Parameters</b> |                                                                                                                                                                                                                          |
| 'Box'                                         | Two-element cell array, {longitude,latitude}, specifying the longitude and latitude coordinates that define a region. longitude and latitude are each two-element vectors specifying longitude and latitude coordinates. |
| 'RecordNumbers'                               | Vector specifying the record numbers to read                                                                                                                                                                             |
| 'Time'                                        | Two-element cell array, [start stop], where start and stop are numbers that specify the start and endpoint for a period of time                                                                                          |

For example,

```
hdfread(...,'Fields',{field1, field2},...
           'Level',level,'RecordNumbers',[1:50, 200:250])
```

### Subsetting Parameters for HDF-EOS Swath Data

When you are working with HDF-EOS Swath data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters

# hdfread

- Mutually exclusive

You can only use one of the mutually exclusive parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Required Parameter</b>                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 'Fields'                                      | String naming the data set field to be read. You can specify only one field name for a Swath data set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Mutually Exclusive Optional Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 'Index'                                       | <p>Three-element cell array, {start, stride, edge}, specifying the location, range, and values to be read from the data set</p> <ul style="list-style-type: none"><li>• <b>start</b> — An array specifying the position in the file to begin reading<br/>Default: 1, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set.</li><li>• <b>stride</b> — An array specifying the interval between the values to read<br/>Default: 1, read every element of the data set.</li><li>• <b>edge</b> — An array specifying the length of each dimension to read<br/>Default: An array containing the lengths of the corresponding dimensions</li></ul> |
| 'Time'                                        | <p>Three-element cell array, {start, stop, mode}, where <b>start</b> and <b>stop</b> specify the beginning and the endpoint for a period of time, and <b>mode</b> is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met:</p> <ul style="list-style-type: none"><li>• Its midpoint is within the box (<code>mode='midpoint'</code>).</li><li>• Either endpoint is within the box (<code>mode='endpoint'</code>).</li></ul>                                                                                                                                                                                |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Optional Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 'Box'                      | <p>Three-element cell array, {longitude, latitude, mode} specifying the longitude and latitude coordinates that define a region. longitude and latitude are two-element vectors that specify longitude and latitude coordinates. mode is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met:</p> <ul style="list-style-type: none"> <li>• Its midpoint is within the box (mode='midpoint').</li> <li>• Either endpoint is within the box (mode='endpoint').</li> <li>• Any point is within the box (mode='anypoint').</li> </ul>                                                               |
| 'Vertical'                 | <p>Two-element cell array, {dimension, range}</p> <ul style="list-style-type: none"> <li>• dimension is a string specifying either a dimension name or field name to subset the data by.</li> <li>• range is a two-element vector specifying the minimum and maximum range for the subset. If dimension is a dimension name, then range specifies the range of elements to extract. If dimension is a field name, then range specifies the range of values to extract.</li> </ul> <p>'Vertical' subsetting can be used alone or in conjunction with 'Box' or 'Time'. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to hdfread.</p> |

For example,

```
hdfread('swath.hdf', 'Example Swath', 'Fields', 'Temperature', ...
        'Time', {5000, 6000, 'midpoint'})
```

# hdfread

---

## Examples

### Example 1

Specify the name of the HDF file and the name of the data set. This example reads a data set named 'Example SDS' from a sample HDF file.

```
data = hdfread('sd.hdf','temperature')
```

### Example 2

Use data returned by `hdfinfo` to specify the data set to read.

- 1 Call `hdfinfo` to retrieve information about the contents of the HDF file.

```
fileinfo = hdfinfo('sd.hdf')  
fileinfo =
```

```
    Filename: 'C:\Program Files\matlab\toolbox\matlab\imagesci\sd.hdf'  
    Attributes: [1x1 struct]  
           SDS: [1x2 struct]  
           Vdata: [1x1 struct]
```

- 2 Extract the structure containing information about the particular data set you want to import from the data returned by `hdfinfo`. The example uses the structure in the SDS field to retrieve a scientific data set.

```
sds_info = fileinfo.SDS(2)
```

```
sds_info =  
  
    Filename: [1x73 char]  
           Type: 'Scientific Data Set'  
           Name: 'temperature'  
           Rank: 2  
           DataType: 'double'  
    Attributes: [1x11 struct]  
           Dims: [2x1 struct]  
           Label: {}
```

```
Description: {}  
Index: 1
```

**3** Pass this structure to `hdfread` to import the data in the data set.

```
data = hdfread(sds_info)
```

### Example 3

You can use the information returned by `hdfinfo` to check the size of the data set.

```
sds_info.Dims.Size  
ans =  
    16  
ans =  
    5
```

Using the 'index' parameter with `hdfread`, you can read a subset of the data in the data set. This example specifies a starting index of [3 3], an interval of 1 between values ([ ] meaning the default value of 1), and a length of 10 rows and 2 columns.

```
data = hdfread(sds_info, 'Index', {[3 3],[],[10 2]});
```

```
data(:,1)  
ans =  
    7  
    8  
    9  
   10  
   11  
   12  
   13  
   14  
   15  
   16
```

```
data(:,2)
```

# hdfread

---

```
ans =  
     8  
     9  
    10  
    11  
    12  
    13  
    14  
    15  
    16  
    17
```

## Example 4

This example uses the `Vdata` field from the information returned by `hdfinfo` to read two fields of the data, `Idx` and `Temp`.

```
s = hdfinfo('example.hdf');  
data1 = hdfread(s.Vdata(1), 'Fields', {'Idx', 'Temp', 'Dewpt'})  
  
data1 =  
  
    [1x10 int16]  
    [1x10 int16]  
    [1x10 int16]
```

## See Also

[hdfinfo](#) | [hdf](#)

**Purpose**

Browse and import data from HDF4 or HDF-EOS files

---

**Note** hdfstool will be removed in a future release. To read data from an HDF file, use `hdfread`, `matlab.io.hdf4.sd`, `matlab.io.hdfeos.gd`, or `matlab.io.hdfeos.sw` instead.

---

**Syntax**

```
hdfstool
hdfstool(filename)
h = hdfstool(...)
```

**Description**

`hdfstool` starts the HDF Import Tool, a graphical user interface used to browse the contents of HDF4 and HDF-EOS files and import data and subsets of data from these files. To open an HDF4 or HDF-EOS file, select **Open** from the **Home** tab. You can open multiple files in the HDF Import Tool by selecting **Open** from the **Home** tab.

`hdfstool(filename)` opens the HDF4 or HDF-EOS file specified by `filename` in the HDF Import Tool.

`h = hdfstool(...)` returns a handle `h` to the HDF Import Tool. To close the tool from the command line, use `close(h)`.

**Examples**

```
hdfstool('example.hdf');
```

**See Also**

```
hdf | hdfinfo | hdfread | uiimport
```

# height

---

**Purpose** Number of table rows

**Syntax** H = height(T)

**Description** H = height(T) returns the number of rows in the table, T.  
height(T) is equivalent to size(T,1).

**Input Arguments** **T - Input table**  
table  
Input table, specified as a table.

## **Examples** **Number of Table Rows**

Create a table, T.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};  
Age = [38;43;38;40;49];  
Height = [71;69;64;67;64];  
Weight = [176;163;131;133;119];  
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

T =

|          | Age | Height | Weight | BloodPressure |    |
|----------|-----|--------|--------|---------------|----|
|          | —   | —      | —      | —             |    |
| Smith    | 38  | 71     | 176    | 124           | 93 |
| Johnson  | 43  | 69     | 163    | 109           | 77 |
| Williams | 38  | 64     | 131    | 125           | 83 |
| Jones    | 40  | 67     | 133    | 117           | 75 |
| Brown    | 49  | 64     | 119    | 122           | 80 |

Find the number of rows in table T.

```
H = height(T)
```

```
H =
```

```
5
```

T contains five rows; `height` does not count the variable names.

# help

---

**Purpose** Help for functions in Command Window

**Syntax** `help`  
`help name`

**Description** `help` lists all primary help topics in the Command Window. Each main help topic corresponds to a folder name on the MATLAB search path.

`help name` displays the help text for the functionality specified by `name`, such as a function, method, class, or toolbox.

- Tips**
- Some help text displays the names of functions in uppercase characters to make them stand out from the rest of the text. When typing these function names, use lowercase. For function names that appear in mixed case (such as `javaObject`), type the names as shown.
  - To prevent long descriptions from scrolling off the screen before you have time to read them, enter `more on`, and then enter the `help` statement.
  - Some classes require that you specify the package name to display the help text. To identify the package name, create an instance of the class, and then call `class(obj)`.

**Input Arguments**

**name**  
String that specifies an operator symbol (such as `+`) or the name of a function, class, method, package, toolbox folder, or other functionality.

Some classes and other packaged items require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, such as:

```
help className.name  
help packageName.name  
help packageName.className.name
```

If `name` is overloaded, that is, appears in multiple folders on the search path, `help` displays the help text for the first instance of `name` found on the search path, and displays a hyperlinked list of the overloaded functions and their folders.

When `name` specifies the name or partial path of a toolbox folder:

- If the folder contains a nonempty `Contents.m` file, the `help` function displays the file. `Contents.m` contains a list of MATLAB program files in the folder and their descriptions. If `Contents.m` exists, but is empty, MATLAB responds with `No help found for name.`
- If the folder does not contain a `Contents.m` file, the `help` function lists the first line of help text for each program file in the folder.
- If `name` is the name of both a function and a toolbox, `help` displays the associated text for both the toolbox and the function.

## Examples

### Functions and Overloaded Methods

Display help for the MATLAB `close` function.

```
help close
```

Because `close` refers to the name of a function and to the name of several methods, the help text includes hyperlinks to the overloaded methods.

Request help for the Database Toolbox™ `close` method.

```
help database.close
```

### Package, Class, and Method Help

Display help for the `containers` package, `Map` class, and the `isKey` method.

```
help containers  
help containers.Map  
help containers.Map.isKey
```

Not all packages, classes, and associated methods or events require complete specification. For example, display the help for the `throwAsCaller` method of the `MException` class.

```
help throwAsCaller
```

## Functions in Folder

List all of the functions in the folder `matlabroot/toolbox/matlab/general` by specifying a partial path.

```
help general
```

## Alternatives

View more extensive help using the `doc` command or the Function Browser. To open the Function Browser, click its icon, .

## How To

- “Ways to Get Function Help”
- “Add Help for Your Program”

**Purpose** Open Help browser to access online documentation

---

**Note** helpbrowser will be removed in a future release. Use doc instead.

---

**Syntax** helpbrowser

**Description** helpbrowser displays the Help browser, open to its default startup page.

**See Also** doc | help

**How To**

- “Ways to Get Function Help”

# helpdesk

---

**Purpose** Open Help browser

---

**Note** helpdesk will be removed in a future release. Use doc instead.

---

**Syntax** helpdesk

**Description** helpdesk opens the Help browser to the default startup page. In previous releases, helpdesk displayed the Help Desk, which was the precursor to the Help browser.

**See Also** doc

**Purpose** Create and open help dialog box

**Syntax**

```
helpdlg  
helpdlg('helpstring')  
helpdlg('helpstring','dlgname')  
h = helpdlg(...)
```

**Description** helpdlg creates a nonmodal help dialog box or brings the named help dialog box to the front.

---

**Note** A nonmodal dialog box enables the user to interact with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

helpdlg displays a dialog box named 'Help Dialog' containing the string 'This is the default help string.'

helpdlg('helpstring') displays a dialog box named 'Help Dialog' containing the string specified by 'helpstring'.

helpdlg('helpstring','dlgname') displays a dialog box named 'dlgname' containing the string 'helpstring'.

h = helpdlg(...) returns the handle of the dialog box.

**Tips** MATLAB wraps the text in 'helpstring' to fit the width of the dialog box. The dialog box remains on your screen until you press the **OK** button or the **Enter** key. After either of these actions, the help dialog box disappears.

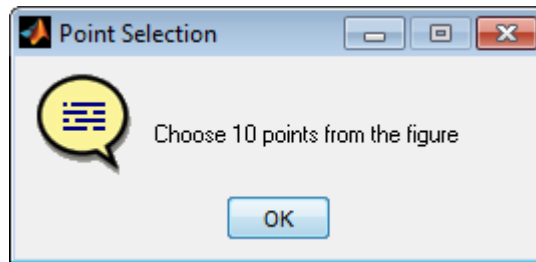

**Examples** The statement

```
helpdlg('Choose 10 points from the figure','Point Selection');
```

displays this dialog box:

# helpdlg

---

**Purpose** Provide access to help comments for all functions

---

**Note** helpwin will be removed in a future release. Use doc instead.

---

**Syntax** helpwin  
helpwin topic

**Description** helpwin lists topics for groups of functions in the MATLAB Help browser. It shows brief descriptions of the topics and provides links to display help comments for the functions. You cannot follow links in the helpwin list of functions if the MATLAB software is busy (for example, running a program).

helpwin topic displays help information for the topic. If topic is a folder, it displays all functions in the folder. If topic is a function, helpwin displays help for that function. From the page, you can access a list of folders (**Default Topics** link) as well as the reference page help for the function (**Go to online doc** link). You cannot follow links in the helpwin list of functions if MATLAB is busy (for example, running a program).

**Examples** Typing  
helpwin datafun  
displays the functions in the datafun folder and a brief description of each.

Typing  
helpwin fft  
displays the help for the fft function.

# hess

---

**Purpose** Hessenberg form of matrix

**Syntax**  
 $H = \text{hess}(A)$   
 $[P, H] = \text{hess}(A)$   
 $[AA, BB, Q, Z] = \text{hess}(A, B)$

**Description**  $H = \text{hess}(A)$  finds  $H$ , the Hessenberg form of matrix  $A$ .  
 $[P, H] = \text{hess}(A)$  produces a Hessenberg matrix  $H$  and a unitary matrix  $P$  so that  $A = P^*H^*P'$  and  $P' * P = \text{eye}(\text{size}(A))$ .  
 $[AA, BB, Q, Z] = \text{hess}(A, B)$  for square matrices  $A$  and  $B$ , produces an upper Hessenberg matrix  $AA$ , an upper triangular matrix  $BB$ , and unitary matrices  $Q$  and  $Z$  such that  $Q^*A^*Z = AA$  and  $Q^*B^*Z = BB$ .

**Definitions** A Hessenberg matrix is zero below the first subdiagonal. If the matrix is symmetric or Hermitian, the form is tridiagonal. This matrix has the same eigenvalues as the original, but less computation is needed to reveal them.

**Examples**  $H$  is a 3-by-3 eigenvalue test matrix:

```
H =  
  -149    -50   -154  
   537    180    546  
   -27     -9    -25
```

Its Hessenberg form introduces a single zero in the (3,1) position:

```
hess(H) =  
  -149.0000    42.2037   -156.3165

## Purpose

Superclass for heterogeneous array formation

## Description

`matlab.mixin.Heterogeneous` is an abstract class that provides support for the formation of heterogeneous arrays. A heterogeneous array is an array of objects that differ in their specific class, but are all derived from or are instances of a root class. The root class derives directly from `matlab.mixin.Heterogeneous`.

## Heterogeneous Hierarchy

Use `matlab.mixin.Heterogeneous` to define hierarchies of classes whose instances you can combine into heterogeneous arrays.

The following class definition enables the formation of heterogeneous arrays that combine instances of any classes derived from `HierarchyRoot`.

```
classdef HierarchyRoot < matlab.mixin.Heterogeneous
% HierarchyRoot is a direct subclass of matlab.mixin.Heterogeneous
% HierarchyRoot is the root of this heterogeneous hierarchy
```

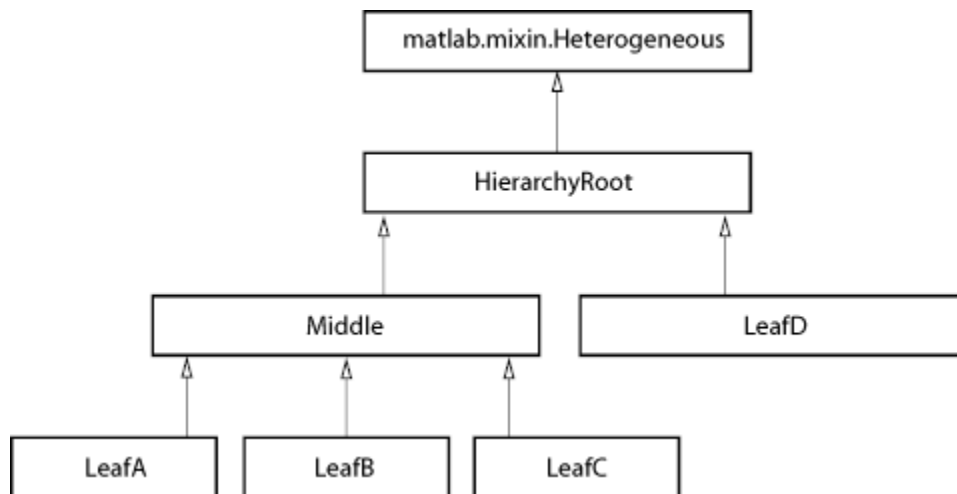

Deriving the `HierarchyRoot` class directly from `matlab.mixin.Heterogeneous` enables the `HierarchyRoot` class to become the root of a hierarchy of classes. You can combine instances of the members of this hierarchy into a heterogeneous array. Only instances of classes derived from the same root class can combine to form a valid heterogeneous array.

## Class of a Heterogeneous Array

The class of a heterogeneous array is always the class of the most specific superclass common to all objects in the array. For example, suppose you define the following class hierarchy:

# matlab.mixin.Heterogeneous

---

Forming an array (harray) of an instance of LeafA with an instance of LeafB creates an array of class Middle:

```
harray = [LeafA,LeafB];  
class(harray)  
ans =  
Middle
```

Forming an array (harray) of an instance of LeafC with an instance of LeafD creates an array of class HierarchyRoot:

```
harray = [LeafC,LeafD];  
class(harray)  
ans =  
HierarchyRoot
```

Forming an array (harray) of an instance of LeafA with an other instance of LeafA creates a homogeneous array of class LeafA:

```
harray = [LeafA,LeafA];  
class(harray)  
ans =
```

LeafA

---

**Note** You cannot form heterogeneous arrays that include instances of classes that are not derived from the same hierarchy root (that is, the `HierarchyRoot` class in the hierarchy shown previously).

---

### Forming a Heterogeneous Array

Heterogeneous arrays are the result of operations that produces arrays containing instances of two or more classes from the heterogeneous hierarchy. Usually, concatenation or indexed assignment form these arrays. For example, these statements form `harray` using indexed assignment:

```
harray(1) = LeafA;  
harray(2) = LeafC;  
class(harray)  
ans =  
Middle
```

### Growing the Array Can Change Its Class

Assigning new objects into an array containing objects derived from `matlab.mixin.Heterogeneous` can change the class of the array. For example, given a homogeneous array containing objects only of the `LeafA` class:

```
harray = [LeafA,LeafA,LeafA];  
class(harray)  
ans =  
LeafA
```

Adding an object of another class derived from the same root to `harray` converts the array's class to the most specific superclass:

```
harray(4) = LeafB;  
class(harray)  
ans =
```

Middle

## Method Dispatching

When MATLAB invokes a method for which the dominant argument is a heterogeneous array, the method:

- Must be defined for the class of the heterogeneous array, either directly by the class of the array or inherited from a superclass.
- Must be `Sealed = true` (cannot be overridden by a subclass).

The class of the heterogeneous array determines which class method executes for any given method invocation, as is the case with a homogeneous array. MATLAB does not consider the class of individual elements in the array when dispatching to methods.

## Sealing Inherited Methods

The requirement that methods called on a heterogeneous array be `Sealed = true` ensures correct and predictable behavior with all array elements.

You must override methods that are inherited from outside the heterogeneous hierarchy if these methods are not `Sealed = true` and you want to call these methods on heterogeneous arrays.

For example, suppose you define a heterogeneous array by subclassing `hgsetget`, in addition to `matlab.mixin.Heterogeneous`. Override the `set` method to call the `hgsetget` superclass method as required by your class design:

```
methods(Sealed)
function varargout = set(obj,varargin)
    if nargin == 0
        set@hgsetget(obj, varargin{:}); % Call superclass set method
    else
        varargout{:} = set@hgsetget(obj,varargin{:});
    end
end
end
```

Method implementations can take advantage of the fact that, given a heterogeneous array `harray`, and a scalar index `n`, the expression

```
harray(n)
```

is not a heterogeneous array. Therefore, when invoking a method on a single element of a heterogeneous array, special requirements for heterogeneous arrays do not apply.

## Defining the Default Object

When working with object arrays (both heterogeneous and homogeneous), MATLAB creates default objects to fill in missing array elements by calling the class constructor with no arguments. Filling in missing array elements becomes necessary in cases such as:

- Indexed assignment creates an array with gaps. For example, if `harray` is not previously defined:

```
harray(5) = LeafA;
```

- Loading a heterogeneous array from a MAT-file when MATLAB cannot find the class definition of a specific object.

The `matlab.mixin.Heterogeneous` class provides a default implementation of a method called `getDefaultScalarElement`. This method returns an instance of the root class of the heterogeneous hierarchy, unless the root class is abstract.

If the root class is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy, you can override the `getDefaultScalarElement` method to return an instance of a class derived from the root class.

## Defining the `getDefaultScalarElement` Method

Specify the class of the default object by overriding the `matlab.mixin.Heterogeneous` method called `getDefaultScalarElement` in the root class of the heterogeneous

# matlab.mixin.Heterogeneous

---

hierarchy. You can override `getDefaultScalarElement` only in the root class (direct subclasses of `matlab.mixin.Heterogeneous`).

`getDefaultScalarElement` has the following signature:

```
methods (Static, Sealed, Access = protected)
    function default_object = getDefaultScalarElement
        ...
    end
end
```

The `getDefaultScalarElement` method must satisfy these criteria:

- Static — MATLAB calls this method without an object.
- Protected — MATLAB calls this method, object users do not.
- Sealed (not required) — Seal this method to ensure users of the heterogeneous hierarchy do not change the intended behavior of the class.
- It must return a scalar object
- It must pass the `isa` test for the root class, that is:

```
(isa(getDefaultScalarElement, 'HierarchyRoot'))
```

where *HierarchyRoot* is the name of the heterogeneous hierarchy root class. This means the default object can be an instance of any class derived from the root class.

## Cannot Redefine Indexing or Concatenation

The use of heterogeneous arrays requires consistent indexing and concatenation behaviors. Therefore, subclasses of `matlab.mixin.Heterogeneous` cannot change their default indexed reference, indexed assignment, or concatenation behavior.

You cannot override the following methods in your subclasses:

- `cat`

- horzcat
- vertcat
- subref
- subsasign

In cases involving multiple inheritance in which your subclass inherits from superclasses in addition to `matlab.mixin.Heterogeneous`, the superclasses cannot define any of these methods.

### **Default Concatenation Behavior**

Statements of the form:

```
a = [obj1,obj2,...];
```

create an array, `a`, containing the objects listed in brackets.

Concatenating `Heterogeneous` objects of the same specific class retains the class of the objects and does not form a heterogeneous array.

Concatenating `Heterogeneous` objects derived from the same root superclass, but that are of different specific classes, yields a heterogeneous array. MATLAB does not attempt to convert the class of any array members if all are part of the same root hierarchy.

### **Indexed Assignment Behavior**

Statements of the form:

```
a(m:n) = [objm,...objn];
```

assign the right-hand side objects to the array elements (`m:n`), specified on the left side of the assignment.

Indexed assignment to a heterogeneous array can:

- Increase or decrease the size of the array
- Overwrite existing array elements
- Change property values of objects within the array

- Change the class of the array
- Change whether the array is heterogeneous

## Indexed Reference Behavior

Statements of the form:

```
a = harray(m:n);
```

assign the elements of `harray` referenced by indices `m:n`, to array `a`.

Indexed reference on a heterogeneous array returns a sub-range of the original array. Depending on the specific elements within that sub-range (`m:n`), the result might have a different class than the original array, and might not be heterogeneous.

## Converting Nonmember Objects

If you attempt to form a heterogeneous array with objects that are not derived from the same root class, MATLAB calls the `convertObject` method, if it exists, to convert objects to the dominant class. Implementing a `convertObject` method enables the formation of heterogeneous arrays containing objects that are not part of the heterogeneous hierarchy.

## When Is Conversion Necessary

Suppose there are two classes `A` and `B`, where `B` is not derived from `matlab.mixin.Heterogeneous`, or where `A` and `B` are derived from different root classes that are derived from `matlab.mixin.Heterogeneous`.

MATLAB attempts to call the `convertObject` method implemented by the root class of `A` in the following cases:

- The indexed assignment:  
$$A(k) = B$$
- Horizontal and vertical concatenations:  
$$[A,B] \text{ and } [A;B]$$

Implement a `convertObject` method if you want to support conversion of objects whose class is not defined in your heterogeneous hierarchy. You do not need to implement this method if your class design does not require this conversion.

## Implementing `convertObject`

Only the root class of the heterogeneous hierarchy can implement a `convertObject` method.

The `convertObject` method must have the following signature:

```
Method (Static, Sealed, Access = protected)
    function converted_object = convertObject('DominantClassName',object
        ...
    end
end
```

For indexed assignment  $A(k) = B$  and concatenation  $[A,B]$ :

- *DominantClassName* — Name of the class of the array A
- `objectToConvert` — Object to be converted, B in this case
- `converted_object` — Legal member of the heterogeneous hierarchy to which A belongs

You must implement `convertObject` to return a valid object of class A or MATLAB issues an error.

## Handle Compatibility

The `matlab.mixin.Heterogeneous` class is handle compatible. It can be combined with either handle or value classes when defining a subclass using multiple superclasses. See “Supporting Both Handle and Value Subclasses” for information on handle compatibility.

The `matlab.mixin.Heterogeneous` class is a value class. To learn how value classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation

# matlab.mixin.Heterogeneous

---

`handle`

## How To

- Class Attributes
- Property Attributes
- “Creating Subclasses — Syntax and Techniques”

**Purpose** Concatenation for heterogeneous arrays

**Syntax** `C = cat(dim,A,B)`

**Description** `C = cat(dim,A,B)` concatenates objects `A` and `B` along the dimension `dim`. The class of object arrays `A` and `B` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

- If `A` and `B` are of the same class, the class of the resulting array is unchanged.
- If `A` and `B` are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array and the array's class is that of the most specific superclass shared by `A` and `B`.

The `cat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

## Input Arguments

**dim**

Scalar dimension along which to concatenate arrays

**A**

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as `B`

**B**

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as `A`

## Output Arguments

**C**

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by `A` and `B`.

# matlab.mixin.Heterogeneous.cat

---

## Attributes

## See Also

`matlab.mixin.Heterogeneous` | `cat`

# matlab.mixin.Heterogeneous.getDefaultScalarElement

## Purpose

Return default object for heterogeneous array operations

## Syntax

```
defaultObject = getDefaultScalarElement
```

## Description

`defaultObject = getDefaultScalarElement` returns the default object for a heterogeneous hierarchy. Override this method if the “Root Class” on page 1-2788 is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy. `getDefaultScalarElement` must return an instance of another member of the heterogeneous hierarchy.

The `matlab.mixin.Heterogeneous` class provided a default implementation of this method that returns an instance of the “Root Class” on page 1-2788.

MATLAB calls the `getDefaultScalarElement` method when requiring a default object. See `matlab.mixin.Heterogeneous` for more information on heterogeneous arrays and default objects.

## Tips

- Override `getDefaultScalarElement` only if the “Root Class” on page 1-2788 is not suitable as a default object.
- Override `getDefaultScalarElement` only in the “Root Class” on page 1-2788 of the heterogeneous hierarchy.
- `getDefaultScalarElement` must return a scalar object.
- `getDefaultScalarElement` must be a static method with protected access. While not required by MATLAB, you can seal this method to prevent overriding by other classes.
- MATLAB returns an error if the value returned by `getDefaultScalarElement` is not scalar or is not an instance of a class that is a valid member of the hierarchy.

## Output Arguments

### **defaultObject**

The default object for heterogeneous array operations.

# matlab.mixin.Heterogeneous.getDefaultScalarElement

---

## Definitions

### Root Class

Root class – The direct subclass of `matlab.mixin.Heterogeneous` that forms the root of a heterogeneous hierarchy. Classes of objects that you can combine into heterogeneous arrays must derive from this root class.

## Attributes

|        |                   |
|--------|-------------------|
| Static | true              |
| Access | Protected         |
| Sealed | true not required |

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

## Examples

This example describes a heterogeneous hierarchy with a root class (`FinancialObjects`) that is an abstract class and cannot, therefore, be used for the default object. The `FinancialObjects` class definition includes an override of the `getDefaultScalarElement` method which returns an instance of the `Assets` class as the default object.

# matlab.mixin.Heterogeneous.getDefaultScalarElement

If the FinancialObjects class is abstract, override getDefaultScalarElement to return an Assets object as the default object.

The root class can override the getDefaultScalarElement method that is defined in matlab.mixin.Heterogeneous class and return an Assets object as the default object.

```
classdef FinancialObjects < matlab.mixin.Heterogeneous
    methods (Abstract)
        val = determineCurrentValue(obj)
    end
    methods (Static, Sealed, Access = protected)
        function default_object = getDefaultScalarElement
            default_object = Assets;
        end
    end
end
```

## See Also

matlab.mixin.Heterogeneous

# matlab.mixin.Heterogeneous.horzcat

---

**Purpose** Horizontal concatenation for heterogeneous arrays

**Syntax** `C = horzcat(A1,A2,...)`

**Description** `C = horzcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of rows.

The class of object arrays `A1,A2,...` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

```
C = horzcat(A1,A2,...)
```

for the expressions:

```
C = [A1,A2,...]
```

```
C = [A1 A2 ...]
```

when `A1` is an array of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

## Input Arguments

**A1**

Object array of class `matlab.mixin.Heterogeneous`

**A2**

Object array of class `matlab.mixin.Heterogeneous`

## Output Arguments

**C**

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

## Attributes

Sealed

true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.Heterogeneous` | `horzcat`

# matlab.mixin.Heterogeneous.vertcat

---

**Purpose** Vertical concatenation for heterogeneous arrays

**Syntax** `C = vertcat(A1,A2,...)`

**Description** `C = vertcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of columns.

The class of object arrays `A1,A2,...` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

```
C = vertcat(A1,A2,...)
```

for the expression:

```
C = [A1;A2;...]
```

when `A1` and `A2`, and so on are arrays of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

## Input Arguments

**A1**

Object array of class `matlab.mixin.Heterogeneous`

**A2**

Object array of class `matlab.mixin.Heterogeneous`

## Output Arguments

**C**

Array resulting from the specified vertical concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

## Attributes

Sealed

true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.Heterogeneous` | `vertcat`

# hex2dec

---

**Purpose** Convert hexadecimal number string to decimal number

**Syntax** `d = hex2dec('hex_value')`

**Description** `d = hex2dec('hex_value')` converts *hex\_value* to its floating-point integer representation. The argument *hex\_value* is a hexadecimal integer stored in a MATLAB string or cell array of strings. The value of *hex\_value* must be smaller than hexadecimal 10,000,000,000,000.

If *hex\_value* is a cell array of strings, each row is interpreted as a hexadecimal string.

**Examples** `hex2dec('3ff')`

```
ans =
```

```
    1023
```

For a character array S,

```
S =
```

```
0FF
```

```
2DE
```

```
123
```

```
hex2dec(S)
```

```
ans =
```

```
    255
```

```
    734
```

```
    291
```

**See Also** `dec2hex` | `format` | `hex2num` | `sprintf`

**Purpose** Convert hexadecimal number string to double-precision number

**Syntax** `n = hex2num(S)`

**Description** `n = hex2num(S)`, where `S` is a 16 character string or cell array of strings representing a hexadecimal number, returns the IEEE double-precision floating-point number `n` that it represents. Fewer than 16 characters are padded on the right with zeros. If `S` is a cell array of strings, each row is interpreted as a double-precision number.

NaNs, infinities and denorms are handled correctly.

**Examples** `hex2num('400921fb54442d18')`

returns `Pi`.

`hex2num('bff')`

returns

`ans =`

`-1`

**See Also** `num2hex` | `hex2dec` | `sprintf` | `format`

# hgexport

---

**Purpose** Export figure

**Syntax** `hgexport(h,filename)`  
`hgexport(h,'-clipboard')`

**Description** `hgexport(h,filename)` writes figure `h` to the file `filename`.  
`hgexport(h,'-clipboard')` writes figure `h` to the Microsoft Windows clipboard.

The format in which the figure is exported is determined by which renderer you use. The Painters renderer generates a metafile. The ZBuffer and OpenGL renderers generate a bitmap.

**Alternatives** Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see [How to Print or Export](#).

**See Also** `print`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create hggroup object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>      | <pre>h = hggroup h = hggroup(..., 'PropertyName', propertyvalue, ...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Properties</b>  | For a list of properties, see Hggroup Properties.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p><code>h = hggroup</code> creates an hggroup object as a child of the current axes and returns its handle, <code>h</code>.</p> <p><code>h = hggroup(..., 'PropertyName', propertyvalue, ...)</code> creates an hggroup object with the property values specified in the argument list. For a description of the properties, see Hggroup Properties.</p> <p>An hggroup object can be the parent of any axes children except light objects, as well as other hggroup objects. You can use hggroup objects to form a group of objects that can be treated as a single object with respect to the following cases:</p> <ul style="list-style-type: none"><li>• <b>Visible</b> — Setting the hggroup object's <code>Visible</code> property also sets each child object's <code>Visible</code> property to the same value.</li><li>• <b>Selectable</b> — Setting each hggroup child object's <code>HitTest</code> property to <code>off</code> enables you to select all children by clicking any child object.</li><li>• <b>Current object</b> — Setting each hggroup child object's <code>HitTest</code> property to <code>off</code> enables the hggroup object to become the current object when any child object is picked. See the next section for an example.</li></ul> |
| <b>Examples</b>    | <p>This example defines a callback for the <code>ButtonDownFcn</code> property of an hggroup object. In order for the hggroup to receive the mouse button down event that executes the <code>ButtonDownFcn</code> callback, the <code>HitTest</code> properties of all the line objects must be set to <code>off</code>. The event is then passed up the hierarchy to the hggroup.</p> <p>The following function creates a random set of lines that are parented to an hggroup object. The local function <code>set_lines</code> defines a callback that executes when the mouse button is pressed over any of the lines.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

# hggroup

The callback simply increases the widths of all the lines by 1 with each button press.

---

**Note** If you are using the MATLAB help browser, you can run this example or open it in the MATLAB editor.

---

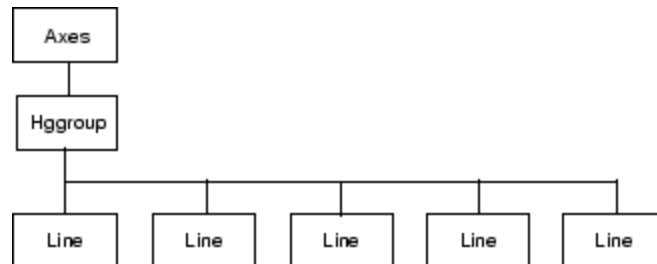

```
function doc_hggroup
hg = hggroup('ButtonDownFcn',@set_lines);
hl = line(randn(5),randn(5),'HitTest','off','Parent',hg);

function set_lines(cb,eventdata)
hl = get(cb,'Children');% cb is handle of hggroup object
lw = get(hl,'LineWidth');% get current line widths
set(hl,{'LineWidth'},num2cell([lw{:}]+1,[5,1]))
```

Note that selecting any one of the lines selects all the lines. (To select an object, enable plot edit mode by selecting **Plot Edit** from the **Tools** menu.)

## Instance Diagram for This Example

The following diagram shows the object hierarchy created by this example.

## Setting Default Properties

You can set default hggroup properties on the axes, figure, and root object levels:

```
set(0, 'DefaultHggroupProperty', PropertyValue...)  
set(gcf, 'DefaultHggroupProperty', PropertyValue...)  
set(gca, 'DefaultHggroupProperty', PropertyValue...)
```

where *Property* is the name of the hggroup property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the hggroup properties.

## How To

- “Group Objects”
- “Function Handle Callbacks”

# Hgggroup Properties

---

## **Purpose**

Hgggroup properties

## **Creating Hgggroup Objects**

Use hgggroup to create hgggroup objects.

## **Modifying Properties**

You can set and query graphics object properties using the `set` and `get` commands.

To change the default values of properties, see “Setting Default Property Values”.

See “Group Objects” for general information on this type of object.

## **Hgggroup Property Descriptions**

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of hgggroup objects in legends.* Specifies whether this hgggroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the hgggroup object is displayed in a figure legend.

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                                                   |
|-------------------------------|----------------------------------------------------------------------------------|
| on                            | Include the hgroup object in a legend as one entry, but not its children objects |
| off                           | Do not include the hgroup or its children in a legend (default)                  |
| children                      | Include only the children of the hgroup as separate entries in the legend        |

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-to-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

# Hgroup Properties

---

BusyAction  
cancel | {queue}

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

ButtonDownFcn  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the children of the `hgroup` object. Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure).

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the hggroup object.* An array containing the handles of all objects parented to the hggroup object (whether visible or not).

Note that if a child object's `HandleVisibility` property is `callback` or `off`, its handle does not appear in the hggroup `Children` property unless you set the `Root ShowHiddenHandles` property to `on`:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips stairs plots to the axes plot box by default. If you set `Clipping` to `off`, lines might be displayed outside the axes plot box.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object creation.* Executes when MATLAB creates an hggroup object. You must define this property as a default value for hggroup objects or in a call to the hggroup function to create a new hggroup object. For example, the statement:

```
set(0, 'DefaultHggroupCreateFcn', @myCreateFcn)
```

defines a default value on the root level that applies to every hggroup object created in that MATLAB session. Whenever you create an hggroup object, the function associated with the function handle `@myCreateFcn` executes.

# Hggroup Properties

---

MATLAB executes the callback after setting all the hggroup object's properties. Setting the `CreateFcn` property on an existing hggroup object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when the hggroup object is deleted (for example, this might happen when you issue a `delete` command on the hggroup object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See ["Function Handle Callbacks"](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the hgroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* This property controls the technique MATLAB uses to draw and erase hgroup child objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.

# Hgroup Properties

---

- **none** — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is `none`). That is, it isn't erased correctly if there are objects behind it.
- **background** — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing the hgroup object.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

### Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

### Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

### Overriding Handle Visibility

# Hgggroup Properties

---

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

## Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* `HitTest` determines whether the hgggroup object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the hgggroup child objects. Note that to pick the hgggroup object, its children must have their `HitTest` property set to `off`.

If the hgggroup object's `HitTest` is `off`, clicking it picks the object behind it.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

Parent  
axes handle

# Hgroup Properties

---

*Parent of hgroup object.* This property contains the handle of the hgroup object's parent object. The parent of an hgroup object is the axes, hgroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

**Selected**  
on | {off}

*Is object selected?* When you set this property to on, MATLAB displays selection handles at the corners and midpoints of hgroup child objects if the SelectionHighlight property is also on (the default).

**SelectionHighlight**  
{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing selection handles on the hgroup child objects. When SelectionHighlight is off, MATLAB does not draw the handles.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, create an hgroup object and set the Tag property:

```
t = hgroup('Tag','group1')
```

When you want to access the object, use findobj to find its handle. For example:

```
h = findobj('Tag','group1');
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For hgroup objects, Type is 'hgroup'. The following statement finds all the hgroup objects in the current axes.

```
t = findobj(gca,'Type','hgroup');
```

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the hgroup object.* Assign this property the handle of a uicontextmenu object created in the hgroup object's figure. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click the hgroup object.

## UserData

array

*User-specified data.* Data you want to associate with the hgroup object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Visibility of hgroup object and its children.* By default, hgroup object visibility is on. This means all children of the hgroup are visible unless the child object's Visible property is off. Setting an hgroup object's Visible property to off also makes its children invisible.

# Hgroup Properties

---

**See Also**

hgroup

**Purpose**

Load Handle Graphics object hierarchy from file

**Syntax**

```
h = hgload('filename')  
[h,old_prop_values] = hgload(...,property_structure)  
hgload(...,'all')
```

**Description**

`h = hgload('filename')` loads Handle Graphics objects and its children (if any) from the FIG-file specified by `filename` and returns handles to the top-level objects. If `filename` contains no extension, then the MATLAB software adds the `.fig` extension.

`[h,old_prop_values] = hgload(...,property_structure)` overrides the properties on the top-level objects stored in the FIG-file with the values in `property_structure`, and returns their previous values in `old_prop_values`.

`property_structure` must be a structure having field names that correspond to property names and values that are the new property values.

`old_prop_values` is a cell array equal in length to `h`, containing the old values of the overridden properties for each object. Each cell contains a structure having field names that are property names, each of which contains the original value of each property that has been changed. Any property specified in `property_structure` that is not a property of a top-level object in the FIG-file is not included in `old_prop_values`.

`hgload(...,'all')` overrides the default behavior, which does not reload nonserializable objects saved in the file. These objects include the default toolbars and default menus. This option is obsolete and will be removed in a future release.

Nonserializable objects (such as the default toolbars and the default menus) are normally not reloaded because they are loaded from different files at figure creation time. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files. Passing the string `all` to `hgload` ensures that any nonserializable objects contained in the file are also reloaded.

# hgload

---

Note that, by default, `hgsave` excludes nonserializable objects from the FIG-file unless you use the `all` flag.

**Alternatives** Use the **File > Open** on the figure window menu to access figure files with the **Open** dialog.

**See Also** `hgsave` | `open`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Save Handle Graphics object hierarchy to file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax</b>      | <pre>hgsave('filename') hgsave(h,'filename') hgsave(...,'all') hgsave(...,'-v6') hgsave(...,'-v7.3')</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p><code>hgsave('filename')</code> saves the current figure to a file named <code>filename</code>.</p> <p><code>hgsave(h,'filename')</code> saves the objects identified by the array of handles <code>h</code> to a file named <code>filename</code>. If you do not specify an extension for <code>filename</code>, then the extension <code>.fig</code> is appended. If <code>h</code> is a vector, none of the handles in <code>h</code> may be ancestors or descendents of any other handles in <code>h</code>.</p> <p><code>hgsave(...,'all')</code> overrides the default behavior, which does not save nonserializable objects. Nonserializable objects include the default toolbars and default menus. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files and also reduces the size of FIG-files. Passing the string <code>all</code> to <code>hgsave</code> ensures that nonserializable objects are also saved. This option is obsolete and will be removed in a future release.</p> <p>The default behavior of <code>hgload</code> is to ignore nonserializable objects in the file at load time. You can override this behavior using the <code>all</code> argument with <code>hgload</code>.</p> <p><code>hgsave(...,'-v6')</code> saves the FIG-file in a format that can be loaded by versions prior to MATLAB 7.</p> <p><code>hgsave(...,'-v7.3')</code> saves the FIG-file in a format that can be loaded only by MATLAB versions 7.3 and above. This format, based on HDF5 files, is intended for saving FIG-files larger than 2 GB.</p> <p>You can make <code>-v6</code> or <code>-v7.3</code> your default format for saving MAT-files and FIG-files by setting a preference, which will eliminate the need to specify the flag each time you save. See “MAT-Files Preferences” in the MATLAB Desktop Tools and Development Environment documentation.</p> |

## Full Backward Compatibility

When creating a figure you want to save and use in a MATLAB version prior to MATLAB 7, use the 'v6' option with the plotting function and the '-v6' option for hgsave. Check the reference page for the plotting function you are using for more information.

See “Plot Objects and Backward Compatibility” for more information.

## Alternatives

Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see [How to Print or Export](#).

## See Also

hgload | open | save

**Purpose** Abstract class used to derive handle class with set and get methods

**Syntax** `classdef myclass < hgsetget`

**Description** `classdef myclass < hgsetget` makes *myclass* a subclass of the `hgsetget` class, which is a subclass of the `handle` class.

Use the `hgsetget` class to derive classes that inherit `set` and `get` methods that behave like Handle Graphics `set` and `get` functions.

### Methods

When you derive a class from the `hgsetget` class, your class inherits the following methods.

| Method               | Purpose                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>set</code>     | Assigns values to the specified properties or returns a cell array of possible values for writable properties.                                              |
| <code>get</code>     | Returns value of specified property or a struct with all property values.                                                                                   |
| <code>setdisp</code> | Called when <code>set</code> is called with no output arguments and a handle array, but no property name. Override this method to change what set displays. |
| <code>getdisp</code> | Called when <code>get</code> is called with no output arguments and handle array, but no property name. Override this method to change what get displays.   |

**How To** • “Implementing a Set/Get Interface for Properties”

# hgtransform

---

**Purpose** Create hgtransform graphics object

**Syntax**  
`h = hgtransform`  
`h = hgtransform('PropertyName',propertyvalue,...)`

**Properties** For a list of properties, see Hgtransform Properties.

**Description** `h = hgtransform` creates an hgtransform object and returns its handle.

`h = hgtransform('PropertyName',propertyvalue,...)` creates an hgtransform object with the property value settings specified in the argument list. For a description of the properties, see Hgtransform Properties.

hgtransform objects can contain other objects, which lets you treat the hgtransform and its children as a single entity with respect to visibility, size, orientation, etc. You can group objects by parenting them to a single hgtransform object (i.e., setting the object's Parent property to the hgtransform object's handle):

```
h = hgtransform;  
surface('Parent',h,...)
```

The primary advantage of parenting objects to an hgtransform object is that you can perform *transforms* (for example, translation, scaling, rotation, etc.) on the child objects in unison.

The parent of an hgtransform object is either an axes object or another hgtransform.

Although you cannot see an hgtransform object, setting its Visible property to `off` makes all its children invisible as well.

## Exceptions and Limitations

- An hgtransform object can be the parent of any number of axes child objects belonging to the same axes, except for light objects.
- hgtransform objects can never be the parent of axes objects and therefore can contain objects only from a single axes.

- hgtransform objects can be the parent of other hgtransform objects within the same axes.
- You cannot transform image objects because images are not true 3-D objects. Texture mapping the image data to a surface CData enables you to produce the effect of transforming an image in 3-D space.

---

**Note** Many plotting functions clear the axes (i.e., remove axes children) before drawing the graph. Clearing the axes also deletes any hgtransform objects in the axes.

---

## Examples

### Transforming a Group of Objects

This example shows how to create a 3-D star with a group of surface objects parented to a single hgtransform object. The hgtransform then rotates the object about the z-axis while scaling its size.

---

**Tip** If you are using the MATLAB Help browser, you can run this example or open it in the MATLAB Editor.

---

- 1 Create an axes and adjust the view. Set the axes limits to prevent auto limit selection during scaling.

```
ax = axes('XLim',[-1.5 1.5],'YLim',[-1.5 1.5],...  
         'ZLim',[-1.5 1.5]);  
view(3); grid on; axis equal
```

- 2 Create the objects you want to parent to the hgtransform object.

```
[x y z] = cylinder([.2 0]);  
h(1) = surface(x,y,z,'FaceColor','red');  
h(2) = surface(x,y,-z,'FaceColor','green');  
h(3) = surface(z,x,y,'FaceColor','blue');  
h(4) = surface(-z,x,y,'FaceColor','cyan');
```

# hgtransform

---

```
h(5) = surface(y,z,x,'FaceColor','magenta');  
h(6) = surface(y,-z,x,'FaceColor','yellow');
```

- 3** Create an hgtransform object and parent the surface objects to it. The figure should not change from the image above.

```
t = hgtransform('Parent',ax);  
set(h,'Parent',t)
```

- 4** Select a renderer and show the objects.

```
set(gcf,'Renderer','opengl')  
drawnow
```

- 5 Initialize the rotation and scaling matrix to the identity matrix (`eye`). Again, the image should not change.

```
Rz = eye(4);  
Sxy = Rz;
```

- 6 Form the  $z$ -axis rotation matrix and the scaling matrix. Rotate group and scale by using the increasing values of  $r$ .

```
for r = 1:.1:2*pi  
    % Z-axis rotation matrix  
    Rz = makehgtform('zrotate',r);  
    % Scaling matrix  
    Sxy = makehgtform('scale',r/4);
```

# hgtransform

---

```
% Concatenate the transforms and  
% set the hgtransform Matrix property  
    set(t,'Matrix',Rz*Sxy)  
    drawnow  
end  
pause(1)
```

7 Reset to the original orientation and size using the identity matrix.

```
set(t,'Matrix',eye(4))
```

## Transforming Objects Independently

This example creates two `hgtransform` objects to illustrate how to transform each independently within the same axes. A translation transformation moves one `hgtransform` object away from the origin.

---

**Tip** If you are using the MATLAB Help browser, you can run this example or open it in the MATLAB Editor.

---

- 1 Create and set up the axes object that will be the parent of both `hgtransform` objects. Set the limits to accommodate the translated object.

# hgtransform

---

```
ax = axes('XLim',[-2 1],'YLim',[-2 1],'ZLim',[-1 1]);  
view(3); grid on; axis equal
```

**2** Create the surface objects to group.

```
[x y z] = cylinder([.3 0]);  
h(1) = surface(x,y,z,'FaceColor','red');  
h(2) = surface(x,y,-z,'FaceColor','green');  
h(3) = surface(z,x,y,'FaceColor','blue');  
h(4) = surface(-z,x,y,'FaceColor','cyan');  
h(5) = surface(y,z,x,'FaceColor','magenta');  
h(6) = surface(y,-z,x,'FaceColor','yellow');
```

- 3** Create the hgtransform objects and parent them to the same axes. The figure should not change.

```
t1 = hgtransform('Parent',ax);  
t2 = hgtransform('Parent',ax);
```

- 4** Set the renderer to use OpenGL.

```
set(gcf,'Renderer','opengl')
```

- 5** Parent the surfaces to hgtransform t1, then copy the surface objects and parent the copies to hgtransform t2. This figure should not change.

# hgtransform

---

```
set(h,'Parent',t1)
h2 = copyobj(h,t2);
```

- 6 Translate the second hgtransform object away from the first hgtransform object and display the result.

```
Txy = makehgtform('translate',[-1.5 -1.5 0]);
set(t2,'Matrix',Txy)
drawnow
```

- 7 Rotate both hgtransform objects in opposite directions. The final image for this step is the same as for step 6. However, you should run the code to see the rotations.

```
% Rotate 10 times (2pi radians = 1 rotation)
for r = 1:.1:20*pi
    % Form z-axis rotation matrix
    Rz = makehgtform('zrotate',r);
    % Set transforms for both hgtransform objects
    set(t1,'Matrix',Rz)
    set(t2,'Matrix',Txy*inv(Rz))
    drawnow
end
```

## Setting Default Properties

You can set default hgtransform properties on the axes, figure, and root object levels:

```
set(0,'DefaultHgtransformPropertyName',propertyvalue,...)
set(gcf,'DefaultHgtransformPropertyName',propertyvalue,...)
set(gca,'DefaultHgtransformPropertyName',propertyvalue,...)
```

*PropertyName* is the name of the hgtransform property and *propertyvalue* is the specified value. Use `set` and `get` to access hgtransform properties.

## How To

- “Group Objects”

# Hgtransform Properties

---

## **Purpose**

Hgtransform properties

## **Creating Hgtransform Objects**

Use `hgtransform` to create `hgtransform` objects.

## **Modifying Properties**

You can set and query graphics object properties using the `set` and `get` commands.

To change the default values of properties, see “Setting Default Property Values”.

See “Group Objects” for general information on this type of object.

## **Hgtransform Property Descriptions**

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of hgtransform objects in legends.* Specifies whether this `hgtransform` object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the `hgtransform` object is displayed in a figure legend.

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------|
| on                            | Include the hgtransform object in a legend as one entry, but not its children objects |
| off                           | Do not include the hgtransform or its children in a legend (default)                  |
| children                      | Include only the children of the hgtransform as separate entries in the legend        |

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

# Hgtransform Properties

---

`BusyAction`  
`cancel` | `{queue}`

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is within the extent of the hgtransform object, but not over another graphics object. The extent of an hgtransform object is the smallest rectangle that encloses all the children. Note that you cannot execute the hgtransform object's button down function if it has no children.

Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure

associated with the mouse button press and an empty event structure).

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the hgtransform object.* An array containing the handles of all graphics objects parented to the hgtransform object (whether visible or not).

The graphics objects that can be children of an hgtransform are images, lights, lines, patches, rectangles, surfaces, and text. You can change the order of the handles and thereby change the stacking of the objects on the display.

Note that if a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in the hgtransform `Children` property unless you set the `Root ShowHiddenHandles` property to `on`.

## Clipping

{on} | off

*Clipping mode.* This property has no effect on hgtransform objects.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object creation.* Executes when MATLAB creates an hgtransform object. You must define this property as a default value for hgtransform objects. For example, the statement:

```
set(0, 'DefaultHgtransformCreateFcn', @myCreateFcn)
```

# Hgtransform Properties

---

defines a default value on the root level that applies to every hgtransform object created in a MATLAB session. Whenever you create an hgtransform object, the function associated with the function handle `@myCreateFcn` executes.

MATLAB executes the callback after setting all the hgtransform object's properties. Setting the `CreateFcn` property on an existing hgtransform object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when the hgtransform object is deleted (for example, this might happen when you issue a `delete` command on the hgtransform object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which can be queried using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

DisplayName  
string

*String used by legend.* The legend function uses the DisplayName property to label the hgtransform object in the legend. The default is an empty string.

- If you specify string arguments with the legend function, MATLAB set DisplayName to the corresponding string and uses that string for the legend.
- If DisplayName is empty, legend creates a string of the form, ['data' *n*], where *n* is the number assigned to the object based on its location in the list of legend entries. However, legend does not set DisplayName to this string.
- If you edit the string directly in an existing legend, MATLAB set DisplayName to the edited string.
- If you specify a string for the DisplayName property and create the legend using the figure toolbar, then MATLAB uses the string defined by DisplayName.
- To add a legend programmatically that uses the DisplayName string, call legend with the toggle or show option.

See “Controlling Legends” for more information and examples.

EraseMode  
{normal} | none | xor | background

*Erase mode.* This property controls the technique MATLAB uses to draw and erase hgtransform child objects (light objects have no erase mode). Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- normal — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all

# Hgtransform Properties

---

objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.

- **none** — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- **xor**— Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is `none`). That is, it isn't erased correctly if there are objects behind it.
- **background** — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Set the axes background color with the axes `Color` property.

Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing the hgtransform object.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in

# Hgtransform Properties

---

the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

## Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* `HitTest` determines whether the `hgtransform` object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click within the limits of the `hgtransform` object. If `HitTest` is `off`, clicking the `hgtransform` picks the object behind it.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB

handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

# Hgtransform Properties

---

## Matrix

4-by-4 matrix

*Transformation matrix applied to hgtransform object and its children.* The hgtransform object applies the transformation matrix to all its children.

See “Group Objects” for more information and examples.

## Parent

figure handle

*Parent of hgtransform object.* This property contains the handle of the hgtransform object’s parent object. The parent of an hgtransform object is the axes, hgroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Is object selected?* When you set this property to on, MATLAB displays selection handles on all child objects of the hgtransform if the SelectionHighlight property is also on (the default).

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing selection handles on the objects parented to the hgtransform. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `hgtransform` object and set the `Tag` property:

```
t = hgtransform('Tag','subgroup1')
```

When you want to access the `hgtransform` object to add another object, use `findobj` to find the `hgtransform` object's handle. The following statement adds a line to `subgroup1` (assuming `x` and `y` are defined).

```
line('XData',x,'YData',y,'Parent',findobj('Tag','subgroup1'))
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For `hgtransform` objects, `Type` is `'hgtransform'`. The following statement finds all the `hgtransform` objects in the current axes.

```
t = findobj(gca,'Type','hgtransform');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the hgtransform object.* Assign this property the handle of a `uicontextmenu` object created in the `hgtransform` object's figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the extent of the `hgtransform` object.

# Hgtransform Properties

---

UserData  
array

*User-specified data.* Data you want to associate with the hgtransform object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

Visible  
{on} | off

*Visibility of hgtransform object and its children.* By default, hgtransform object visibility is on. This means all children of the hgtransform are visible unless the child object's `Visible` property is off. Setting an hgtransform object's `Visible` property to off also makes its children invisible.

## See Also

hgtransform

**Purpose**

Remove hidden lines from mesh plot

**Syntax**

```
hidden on  
hidden off  
hidden
```

**Description**

Hidden line removal draws only those lines that are not obscured by other objects in a 3-D view. The `hidden` function only applies to surface plot objects that have a uniform `FaceColor`.

`hidden on` turns on hidden line removal for the current mesh plot so lines in the back of a mesh are hidden by those in front. This is the default behavior.

`hidden off` turns off hidden line removal for the current mesh plot.

`hidden` toggles the hidden line removal state.

**Algorithms**

When a surface graphics object has a uniform `FaceColor` matching the `Color` property of the axes, `hidden off` sets the `FaceColor` of the surface object to `'none'`.

`hidden on` sets the `FaceColor` property of such surface objects to match the axes `Color` property (or to match that of the figure, if axes `Color` is `'none'`).

**Examples**

By default hidden lines are removed (`hidden on`) for mesh plots, such as this one of the `peaks` function.

```
mesh(peaks)  
colormap hsv
```

# hidden

---

Set hidden line removal off to show the obscured parts of the mesh.

```
hidden off
```

# hilb

---

**Purpose** Hilbert matrix

**Syntax** `H = hilb(n)`

**Description** `H = hilb(n)` returns the Hilbert matrix of order `n`.

**Definitions** The Hilbert matrix is a notable example of a poorly conditioned matrix [1]. The elements of the Hilbert matrices are  $H(i,j) = 1/(i + j - 1)$ .

**Examples** Even the fourth-order Hilbert matrix shows signs of poor conditioning.

```
cond(hilb(4)) =  
1.5514e+04
```

**References** [1] Forsythe, G. E. and C. B. Moler, *Computer Solution of Linear Algebraic Systems*, Prentice-Hall, 1967, Chapter 19.

**See Also** `invhilb`

**Purpose**

Histogram plot

**Syntax**

```
hist(data)
hist(data,nbins)
hist(data,xvalues)

hist(axes_handle, __ )

nelements = hist( __ )
[nelements,centers] = hist( __ )
```

**Description**

`hist(data)` creates a histogram bar plot of `data`. Elements in `data` are sorted into 10 equally spaced bins along the *x*-axis between the minimum and maximum values of `data`. Bins are displayed as rectangles such that the height of each rectangle indicates the number of elements in the bin.

`hist(data,nbins)` sorts `data` into the number of bins specified by `nbins`.

`hist(data,xvalues)` uses the values in vector `xvalues` to determine the bin intervals and sorts `data` into the number of bins determined by `length(xvalues)`. To specify the bin centers, set `xvalues` equal to a vector of evenly spaced values. The first and last bins extend to cover the minimum and maximum values in `data`.

`hist(axes_handle, __ )` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`nelements = hist( __ )` returns a row vector, `nelements`, indicating the number of elements in each bin.

# hist

---

`[nelements,centers] = hist( ___ )` returns an additional row vector, `centers`, indicating the location of each bin center on the  $x$ -axis. To plot the histogram, you can use `bar(centers,nelements)`.

## Input Arguments

### **data** - Data to distribute among bins

vector or matrix

Data to distribute among bins, specified as a vector or a matrix.

- If `data` is a vector, then one histogram is created.
- If `data` is a matrix, then a histogram is created separately for each column. Each histogram plot is displayed on the same figure with a different color.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **nbins** - Number of bins

10 (default) | scalar

Number of bins, specified as a scalar.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **xvalues** - Values to calculate bin intervals

vector

Values to calculate bin intervals, specified as a vector.

- If the values in `xvalues` are equally spaced, then these values are the bin centers.
- If the values in `xvalues` are not equally spaced, then these values are indicated by markers along the  $x$ -axis, but are not the actual bin centers. Instead, MATLAB calculates the bin edges as the midpoints

between consecutive values in vector `xvalues`. To specify directly the bin edges use `histc`.

The first and last bins extend to cover the minimum and maximum values in data.

### Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### `axes_handle` - Axes handle

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## Output Arguments

### `nelements` - Number of elements in each bin

row vector

Number of elements in each bin, returned as a row vector.

### `centers` - Bin centers

row vector

Bin centers, returned as a row vector. If used with the syntax `[nelements,centers] = hist(data,xvalues)`, then the output `centers` is equal to the input `xvalues`.

## Examples

### Create Histogram Bar Plot with Vector Input

```
figure
data = [0,2,9,2,5,8,7,3,1,9,4,3,5,8,10,0,1,2,9,5,10];
hist(data)
```

# hist

---

The values in data are sorted among 10 equally spaced bins between 0 and 10, the minimum and maximum values.

## Create Histogram Bar Plot with Matrix Input

Initialize the random-number generator to make the output of `randn` repeatable. Generate 1,000 normally distributed pseudorandom numbers and create a histogram bar plot.

```
figure  
rng(0, 'twister')
```

```
data = randn(1000,3);  
hist(data)
```

The values in data are sorted among 10 equally spaced bins between the minimum and maximum values. Columns of data are sorted separately and the histogram for each column is plotted with a different color.

## Specify Number of Bins

Initialize the random-number generator to make the output of `randn` repeatable. Generate 1,000 normally distributed pseudorandom numbers.

```
rng(0,'twister')  
data = randn(1000,1);
```

Create a histogram plot of data sorted into 50 equally spaced bins.

```
figure  
nbins = 50;  
hist(data,nbins)
```

### Specify Bin Intervals

Create a figure divided into three subplots. Plot a histogram of the same data set in all three subplots using different bin intervals for each histogram.

First, initialize the random-number generator to make the output of `randn` repeatable. Generate 1,000 normally distributed pseudorandom numbers.

```
rng(0, 'twister')
```

# hist

---

```
data = randn(1000,1);
```

In the upper subplot specify the bin centers using a vector of evenly spaced values that span the values in `data`.

```
figure  
subplot(3,1,1)  
xvalues1 = -4:4;  
hist(data,xvalues1)
```

In the middle subplot specify the bin centers using a vector of evenly spaced values that do not span the values in `data`. Notice that the first and last bins extend to cover the minimum and maximum values in `data`.

```
subplot(3,1,2)  
xvalues2 = -2:2;  
hist(data,xvalues2)
```

In the lower subplot set the bin intervals using a vector of unevenly spaced values. These unevenly spaced values are not used as the bin centers. MATLAB indicates the specified values by markers along the *x*-axis.

```
subplot(3,1,3)  
xvalues3 = [-4,-2.5,0,0.5,1,3];  
hist(data,xvalues3)
```

### Specify Axes for Histogram Bar Plot

Initialize the random-number generator to make the output of `randn` repeatable. Generate 1,000 normally distributed pseudorandom numbers.

```
rng(0,'twister')  
data = randn(1000,1);
```

# hist

---

Create a figure with handles to two subplots. In the upper subplot, plot a histogram of `data` sorted into 50 equally spaced bins. In the lower subplot, plot a histogram of the same data and use bins with centers at -3, 0, and 3.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

hist(s(1),data,50)

xvalues = [-3,0,3];
hist(s(2),data,xvalues)
```

### Plot Histogram Using Bar

Initialize the random-number generator to make the output of `randn` repeatable. Generate 1,000 normally distributed pseudorandom numbers.

```
rng(0,'twister')  
data = randn(1000,1);
```

# hist

---

Sort data into 10 equally spaced bins. Get the number of elements in each bin and the locations of the bin centers.

```
[nelements,centers] = hist(data)
```

```
nelements =  
    4    27    88   190   270   243   123    38    13     4  
centers =  
   -2.8915  -2.2105  -1.5294  -0.8484  -0.1673   0.5137   1.1947
```

Use `bar` to plot the histogram.

```
figure  
bar(centers,nelements)
```

### Change Histogram Color Properties

Initialize the random-number generator to make the output of `randn` repeatable. Generate 1,000 normally distributed pseudorandom numbers and create a histogram bar plot.

```
figure
rng(0,'twister')
data = randn(1000,1);
hist(data)
```

# hist

---

Get the handle to the patch object that creates the histogram bar plot.

```
h = findobj(gca,'Type','patch');
```

Use the handle to change the face color and the edge color of the bars plotted.

```
set(h,'FaceColor',[0 .5 .5],'EdgeColor','w')
```

**Tips**

The *x*-axis reflects the range of values in `data`. The *y*-axis ranges from 0 to the greatest number of elements deposited in any bin.

**See Also**

`bar` | `ColorSpec` | `histc` | `mode` | `patch` | `rose` | `stairs`

# histc

---

**Purpose** Histogram bin count

**Syntax**

```
bincounts = histc(x,binranges)
bincounts = histc(x,binranges,dim)
[bincounts,ind]= histc( ___ )
```

**Description** `bincounts = histc(x,binranges)` counts the number of values in `x` that are within each specified bin range. The input, `binranges`, determines the endpoints for each bin. The output, `bincounts`, contains the number of elements from `x` in each bin. Use `bar(binranges,bincounts,'histc')` to plot the histogram.

- If `x` is a vector, then `histc` returns `bincounts` as a vector of histogram bin counts.
- If `x` is a matrix, then `histc` operates along each column of `x` and returns `bincounts` as a matrix of histogram bin counts for each column.

`bincounts = histc(x,binranges,dim)` operates along the dimension `dim`.

`[bincounts,ind]= histc( ___ )` returns `ind`, an array the same size as `x` indicating the bin number that each entry in `x` sorts into. Use this syntax with any of the previous input argument combinations.

## Input Arguments

### **x - values to be sorted**

vector | matrix

Values to be sorted, specified as a vector or a matrix. The bin counts do not include values in `x` that are NaN or that lie outside the specified bin ranges. If `x` contains complex values, then `histc` ignores the imaginary parts and uses only the real parts.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**binranges - Bin ranges**

vector | matrix

Bin ranges, specified as a vector of monotonically nondecreasing values or a matrix of monotonically nondecreasing values running down each successive column. The values in `binranges` determine the left and right endpoints for each bin. If `binranges` contains complex values, then `histc` ignores the imaginary parts and uses only the real parts.

If `binranges` is a matrix, then `histc` determines the bin ranges by using values running down successive columns. Each bin includes the left endpoint, but does not include the right endpoint. The last bin consists of the scalar value equal to last value in `binranges`.

For example, if `binranges` equals the vector `[0,5,10,13]`, then `histc` creates four bins. The first bin includes values greater than or equal to 0 and strictly less than 5. The second bin includes values greater than or equal to 5 and less than 10, and so on. The last bin contains the scalar value 13.

**Data Types**single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical**dim - Dimension along which to operate**

scalar

Dimension along which to operate, specified as a scalar.

**Data Types**single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical**Output Arguments****bincounts - Number of elements in each bin**

vector | matrix

Number of elements in each bin, returned as a vector or a matrix that is the same size as `x`. The last entry in `bincounts` is the number of values in `x` that equal the last entry in `binranges`.

## ind - bin index numbers

vector | matrix

Bin index numbers, returned as a vector or a matrix that is the same size as x.

## Examples

### Create Histogram Plot

Initialize the random number generator to make the output of randn repeatable.

```
rng(0,'twister')
```

Define x as 100 normally distributed random numbers. Define bin ranges between -4 and 4. Determine the number of values in x that are within each specified bin range. Return the number of elements in each bin in bincounts.

```
x = randn(100,1);  
binranges = -4:4;  
[bincounts] = histc(x,binranges)
```

```
bincounts =
```

```
0  
2  
17  
28  
32  
16  
3  
2  
0
```

To plot the histogram, use the bar function.

```
figure  
bar(binranges,bincounts,'histc')
```

### Return Bin Numbers for Histogram

Defined ages as a vector of ages. Sort ages into bins with varying ranges between 0 and 75.

```
ages = [3,12,24,15,5,74,23,54,31,23,64,75];  
binranges = [0,10,25,50,75];
```

# histc

---

```
[bincounts,ind] = histc(ages,binranges)
```

```
bincounts =
```

```
     2     5     1     3     1
```

```
ind =
```

```
     1     2     2     2     1     4     2     4     3     2     4     5
```

`bincounts` contains the number of values in each bin. `ind` indicates the bin numbers.

## Tips

- If values in `x` lie outside the specified bin ranges, then `histc` does not include these values in the bin counts. Start and end the `binranges` vector with `-inf` and `inf` to ensure that all values in `x` are included in the bin counts.

| <b>Purpose</b>     | Retain current graph when adding new graphs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Syntax</b>      | <pre>hold on hold off hold all hold hold(axes_handle,...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>The <code>hold</code> function controls whether MATLAB clears the current graph when you make subsequent calls to plotting functions (the default), or adds a new graph to the current graph.</p> <p><code>hold on</code> retains the current graph and adds another graph to it. MATLAB adjusts the axes limits, tick marks, and tick labels as necessary to display the full range of the added graph.</p> <p><code>hold off</code> resets hold state to the default behavior, in which MATLAB clears the existing graph and resets axes properties to their defaults before drawing new plots.</p> <p><code>hold all</code> holds the graph and the current line color and line style so that subsequent plotting commands do not reset the <code>ColorOrder</code> and <code>LineStyleOrder</code> property values to the beginning of the list. Plotting commands continue cycling through the predefined colors and line styles from where the last graph stopped in the list.</p> <p><code>hold</code> reverses the current hold state. If the hold state is currently on, then a <code>hold</code> command sets the state to off. Similarly, if the hold state is currently off, then a <code>hold</code> command sets the state to on.</p> <p><code>hold(axes_handle,...)</code> applies the hold to the axes identified by the handle <code>axes_handle</code>. If several axes objects exist in a figure window, each axes has its own hold state. <code>hold</code> also creates an axes if one does not exist.</p> <p>Test the hold state using the <code>ishold</code> function.</p> |
| <b>Examples</b>    | Create a graph, set <code>hold</code> to on, then create another graph in the same axes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

# hold

---

```
x = -pi:pi/20:pi;
plot(sin(x))
hold on
plot(cos(x))
hold off
```

If the range of subsequently added data is much greater than the original data, the original graph can become difficult to see in one axes. In these cases, it is usually better to use two separate axes. See `subplot` to create multiple axes in one figure.

## Algorithm

`hold` toggles the `NextPlot` axes property between the `add` and `replace`.

`hold on` sets the `NextPlot` property of the current figure and axes to `add`. `hold off` sets the `NextPlot` property of the current axes to `replace`.

## How To

- `NextPlot`
- “Controlling Graphics Output”

**Purpose** Send cursor home

**Syntax** home

**Description** home moves the cursor to the upper-left corner of the window. When using the MATLAB desktop, home also scrolls the visible text in the window up and out of view. You can use the scroll bar to see what was previously on the screen.

**Examples** Execute a MATLAB command that displays something in the Command Window and then run the home function. home moves the cursor to the upper-left corner of the screen and clears the screen.

```
magic(5)
```

```
ans =
```

```
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

```
home
```

**See Also** clc

# horzcat

---

**Purpose** Concatenate arrays horizontally

**Syntax** `C = horzcat(A1, ..., AN)`

**Description** `C = horzcat(A1, ..., AN)` horizontally concatenates arrays `A1, ..., AN`. All arrays in the argument list must have the same number of rows.

- If the inputs are multidimensional arrays, `horzcat` concatenates along the second dimension. The first and remaining dimensions must match.
- If the inputs are tables, `horzcat` concatenates by matching row names when present, or by matching position for tables that do not have row names. All the table inputs must have unique variable names and the row names for all tables that have them must be identical, except for order.

`horzcat` assigns values for the `Description` and `UserData` properties in `C` using the first nonempty value for the corresponding property in the tables `A1, ..., AN`.

MATLAB calls `C = horzcat(A1, A2, ...)` for the syntax `C = [A1 A2 ...]` when any of the inputs are an object.

**Tips** You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”.

## **Examples**      **Horizontally Concatenate Two Matrices**

Create a 3-by-5 matrix, `A`.

```
A = magic(5);
```

```
A(4:5,:) = []
```

```
A =
```

```
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
```

Create a 3-by-3 matrix, B.

```
B = magic(3)*100
```

```
B =
```

```
    800    100    600
    300    500    700
    400    900    200
```

Horizontally concatenate A and B.

```
C = horzcat(A,B)
```

```
C =
```

```
    17    24     1     8    15   800   100   600
    23     5     7    14    16   300   500   700
     4     6    13    20    22   400   900   200
```

## Horizontally Concatenate Two Tables

Create a table, A, with three rows and two variables.

```
A = table([5;6;5],['M';'M';'M'],...
          'VariableNames',{'Age' 'Gender'},...
          'RowNames',{'Thomas' 'Gordon' 'Percy'})
```

```
A =
```

```
      Age  Gender
```

# horzcat

---

```
      ---      -----
Thomas  5      M
Gordon  6      M
Percy   5      M
```

Create a table, B, with three rows and three variables.

```
B = table([45;41;40],[45;32;34],{'NY';'CA';'MA'},...
    'VariableNames',{'Height' 'Weight' 'Birthplace'},...
    'RowNames',{'Percy' 'Gordon' 'Thomas'})
```

B =

```
      Height      Weight      Birthplace
      -----      -----      -----
Percy   45         45         'NY'
Gordon  41         32         'CA'
Thomas  40         34         'MA'
```

Horizontally concatenate A and B.

```
C = horzcat(A,B)
```

C =

```
      Age      Gender      Height      Weight      Birthplace
      ---      -----      -----      -----      -----
Thomas  5      M         40         34         'MA'
Gordon  6      M         41         32         'CA'
Percy   5      M         45         45         'NY'
```

The order of rows in C matches the order in A.

## How To

- “Redefining Concatenation for Your Class”

**Purpose** Horizontal concatenation for `tscollection` objects

**Syntax** `tsc = horzcat(tsc1,tsc2,...)`

**Description** `tsc = horzcat(tsc1,tsc2,...)` performs horizontal concatenation for `tscollection` objects:

```
tsc = [tsc1 tsc2 ...]
```

This operation combines multiple `tscollection` objects, which must have the same time vectors, into one `tscollection` containing `timeseries` objects from all concatenated collections.

**See Also** `tscollection` | `vertcat` (`tscollection`)

# hsv2rgb

---

**Purpose** Convert HSV colormap to RGB colormap

**Syntax** `M = hsv2rgb(H)`  
`rgb_image = hsv2rgb(hsv_image)`

**Description** `M = hsv2rgb(H)` converts a hue-saturation-value (HSV) colormap to a red-green-blue (RGB) colormap. `H` is an  $m$ -by-3 matrix, where  $m$  is the number of colors in the colormap. The columns of `H` represent hue, saturation, and value, respectively. `M` is an  $m$ -by-3 matrix. Its columns are intensities of red, green, and blue, respectively.

`rgb_image = hsv2rgb(hsv_image)` converts the HSV image to the equivalent RGB image. HSV is an  $m$ -by- $n$ -by-3 image array whose three planes contain the hue, saturation, and value components for the image. RGB is returned as an  $m$ -by- $n$ -by-3 image array whose three planes contain the red, green, and blue components for the image.

**Tips** As `H(:, 1)` varies from 0 to 1, the resulting color varies from red through yellow, green, cyan, blue, and magenta, and returns to red. When `H(:, 2)` is 0, the colors are unsaturated (i.e., shades of gray). When `H(:, 2)` is 1, the colors are fully saturated (i.e., they contain no white component). As `H(:, 3)` varies from 0 to 1, the brightness increases.

The MATLAB hsv colormap uses `hsv2rgb([huesaturationvalue])` where hue is a linear ramp from 0 to 1, and saturation and value are all 1's.

**See Also** `brighten` | `colormap` | `rgb2hsv`

**Purpose** Square root of sum of squares

**Syntax** `c = hypot(a,b)`

**Description** `c = hypot(a,b)` returns the element-wise result of the following equation, computed to avoid underflow and overflow:

$$c = \sqrt{\text{abs}(a).^2 + \text{abs}(b).^2}$$

Inputs `a` and `b` must follow these rules:

- Both `a` and `b` must be single- or double-precision, floating-point arrays.
- The sizes of the `a` and `b` arrays must either be equal, or one a scalar and the other nonscalar. In the latter case, `hypot` expands the scalar input to match the size of the nonscalar input.
- If `a` or `b` is an empty array (0-by-N or N-by-0), the other must be the same size or a scalar. The result `c` is an empty array having the same size as the empty input(s).

`hypot` returns the following in output `c`, depending upon the types of inputs:

- If the inputs to `hypot` are complex (`w+xi` and `y+zi`), then the statement `c = hypot(w+xi,y+zi)` returns the *positive real* result

$$c = \sqrt{\text{abs}(w).^2 + \text{abs}(x).^2 + \text{abs}(y).^2 + \text{abs}(z).^2}$$

- If `a` or `b` is `-Inf`, `hypot` returns `Inf`.
- If neither `a` nor `b` is `Inf`, but one or both inputs is `NaN`, `hypot` returns `NaN`.
- If all inputs are finite, the result is finite. The one exception is when both inputs are very near the value of the MATLAB constant `realmax`. The reason for this is that the equation `c = hypot(realmax,realmax)` is theoretically  $\sqrt{2} * \text{realmax}$ , which overflows to `Inf`.

## Examples

### Example 1

To illustrate the difference between using the `hypot` function and coding the basic `hypot` equation in M-code, create an anonymous function that performs the same function as `hypot`, but without the consideration to underflow and overflow that `hypot` offers:

```
myhypot = @(a,b) sqrt(abs(a).^2+abs(b).^2);
```

Find the upper limit at which your coded function returns a useful value. You can see that this test function reaches its maximum at about `1e154`, returning an infinite result at that point:

```
myhypot(1e153,1e153)
ans =
    1.4142e+153
```

```
myhypot(1e154,1e154)
ans =
    Inf
```

Do the same using the `hypot` function, and observe that `hypot` operates on values up to about `1e308`, which is approximately equal to the value for `realmax` on your computer (the largest double-precision floating-point number you can represent on a particular computer):

```
hypot(1e308,1e308)
ans =
    1.4142e+308
```

```
hypot(1e309,1e309)
ans =
    Inf
```

### Example 2

`hypot(a,a)` theoretically returns `sqrt(2)*abs(a)`, as shown in this example:

```
x = 1.271161e308;
```

```
y = x * sqrt(2)
y =
  1.7977e+308
```

```
y = hypot(x,x)
y =
  1.7977e+308
```

**Purpose**            Imaginary unit

**Syntax**            `i`  
                      `a+bi`  
                      `x+i*y`

**Description**        As the basic imaginary unit `sqrt(-1)`, `i` is used to enter complex numbers. You can also use the character `j` as the imaginary unit. If you want to create a complex number without using `i` and `j`, you can use the `complex` function.

Since `i` is a function, it can be overridden and used as a variable. However, it is best to avoid using `i` and `j` for variable names if you intend to use them in complex arithmetic.

If desired, you can use the character `i` without a multiplication sign as a suffix in forming a complex numerical constant.

For speed and improved robustness, you can replace complex `i` and `j` by `1i`. For example, instead of using

```
a = i;
```

use

```
a = 1i;
```

**Examples**            `Z = 2+3i`  
                      `Z = x+i*y`  
                      `Z = r*exp(i*theta)`

**See Also**            `conj` | `imag` | `j` | `real`

**Purpose** Incomplete Cholesky factorization

**Syntax**  
`L = ichol(A)`  
`L = ichol(A,opts)`

**Description** `L = ichol(A)` performs the incomplete Cholesky factorization of `A` with zero-fill.  
`L = ichol(A,opts)` performs the incomplete Cholesky factorization of `A` with options specified by `opts`.  
 By default, `ichol` references the lower triangle of `A` and produces lower triangular factors.

**Input Arguments** **A**  
 Sparse matrix

**opts**  
 Structure with up to five fields:

| diagcomp   | Perform compensated incomplete Cholesky with the specified coefficient | Real nonnegative scalar used as a global diagonal shift $\alpha$ in forming the incomplete Cholesky factor. That is, instead of performing incomplete Cholesky on $A$ , the factorization of $A + \alpha \cdot \text{diag}(\text{diag}(A))$ is formed. The default value is 0.                                                                        |
| shape      | Determines which triangle is referenced and returned                   | Valid values are 'upper' and 'lower'. If 'upper' is specified, only the upper triangle of $A$ is referenced and $R$ is constructed such that $A$ is approximated by $R' * R$ . If 'lower' is specified, only the lower triangle of $A$ is referenced and $L$ is constructed such that $A$ is approximated by $L * L'$ . The default value is 'lower'. |

## Tips

- The factor given by this routine may be useful as a preconditioner for a system of linear equations being solved by iterative methods such as `pcg` or `minres`.
- `ichol` works only for sparse square matrices

## Examples

### Incomplete Cholesky Factorization

This example generates an incomplete Cholesky factorization.

Start with a symmetric positive definite matrix,  $A$ :

```
N = 100;  
A = delsq(numgrid('S',N));
```

A is the two-dimensional, five-point discrete negative Laplacian on a 100-by-100 square grid with Dirichlet boundary conditions. The size of A is  $98 \times 98 = 9604$  (not 10000 as the borders of the grid are used to impose the Dirichlet conditions).

The no-fill incomplete Cholesky factorization is a factorization which contains only nonzeros in the same position as A contains nonzeros. This factorization is extremely cheap to compute. Although the product  $L \cdot L'$  is typically very different from A, the product  $L \cdot L'$  will match A on its pattern up to round-off.

```
L = ichol(A);  
norm(A-L*L', 'fro') ./ norm(A, 'fro');  
ans =  
    9.1599e-002
```

```
norm(A - (L*L') .* spones(A), 'fro') ./ norm(A, 'fro');  
ans =  
    4.9606e-017
```

`ichol` may also be used to generate incomplete Cholesky factorizations with threshold dropping. As the drop tolerance decreases, the factor tends to get more dense and the product  $L \cdot L'$  tends to be a better approximation of A. The following plots show the relative error of the incomplete factorization plotted against the drop tolerance as well as the ratio of the density of the incomplete factors to the density of the complete Cholesky factor.

The relative error is typically on the same order as the drop tolerance, although this is not guaranteed.

### Using a Preconditioner

Use the same matrix A as in the previous example:

```
N = 100;  
A = delsq(numgrid('S',N));
```

Create an incomplete Cholesky factorization as a preconditioner for `pcg`. Use a constant vector as the right hand side. As a baseline, execute `pcg` without a preconditioner:

```
b = ones(size(A,1),1);
tol = 1e-6; maxit = 100;
[x0,f10,rr0,it0,rv0] = pcg(A,b,tol,maxit);
```

Note that `f10 = 1` indicating that `pcg` did not drive the relative residual to the requested tolerance in the maximum allowed iterations. Try the no-fill incomplete Cholesky factorization as a preconditioner:

```
L1 = ichol(A);
[x1,f11,rr1,it1,rv1] = pcg(A,b,tol,maxit,L1,L1');
```

`f11 = 0`, indicating that `pcg` converged to the requested tolerance and did so in 59 iterations (the value of `it1`). Since this matrix is a discretized Laplacian, however, using modified incomplete Cholesky can create a better preconditioner. A modified incomplete Cholesky factorization constructs an approximate factorization that preserves the action of the operator on the constant vector. That is,  $\text{norm}(A*e - L*(L'*e))$  will be approximately zero for  $e = \text{ones}(\text{size}(A,2),1)$  even though  $\text{norm}(A-L*L', 'fro')/\text{norm}(A, 'fro')$  is not close to zero.

---

**Note** It is not necessary to specify `type` for this syntax since `nofill` is the default, but it is good practice.

---

```
opts.type = 'nofill'; opts.michol = 'on';
L2 = ichol(A,opts);
e = ones(size(A,2),1);
norm(A*e-L2*(L2'*e))
ans =
    3.7983e-014

[x2,f12,rr2,it2,rv2] = pcg(A,b,tol,maxit,L2,L2');
```

pcg converges ( $f_{12} = 0$ ) but in only 38 iterations. Plotting all three convergence histories shows the convergence:

```
semilogy(0:maxit,rv0./norm(b),'b. ');
hold on;
semilogy(0:it1,rv1./norm(b),'r. ');
semilogy(0:it2,rv2./norm(b),'k. ');
legend('No Preconditioner','IC(0)','MIC(0)');
```

The plot shows that the modified incomplete Cholesky preconditioner creates a much faster convergence.

You can also try incomplete Cholesky factorizations with threshold dropping. The following plot shows convergence of pcg with preconditioners constructed with various drop tolerances.

```
L3 = ichol(A, struct('type','ict','droptol',1e-1));
[x3,f13,rr3,it3,rv3] = pcg(A,b,tol,maxit,L3,L3');
```

```
L4 = ichol(A, struct('type','ict','droptol',1e-2));  
[x4,fl4,rr4,it4,rv4] = pcg(A,b,tol,maxit,L4,L4');  
L5 = ichol(A, struct('type','ict','droptol',1e-3));  
[x5,fl5,rr5,it5,rv5] = pcg(A,b,tol,maxit,L5,L5');  
figure; semilogy(0:maxit,rv0./norm(b),'b-','linewidth',2);  
hold on;  
semilogy(0:it3,rv3./norm(b),'b-.','linewidth',2);  
semilogy(0:it4,rv4./norm(b),'b--','linewidth',2);  
semilogy(0:it5,rv5./norm(b),'b:','linewidth',2);  
legend('No Preconditioner','ICT(1e-1)','ICT(1e-2)', ...  
      'ICT(1e-3)','Location','SouthEast');
```

Note the incomplete Cholesky preconditioner constructed with drop tolerance  $1e-2$  is denoted as  $ICT(1e-2)$ .

As with the zero-fill incomplete Cholesky, the threshold dropping factorization can benefit from modification (i.e. `opts.michol = 'on'`) since the matrix arises from an elliptic partial differential equation.

As with MIC(0), the modified threshold based dropping incomplete Cholesky will preserve the action of the preconditioner on constant vectors, that is  $\text{norm}(A*e-L*(L'*e))$  will be approximately zero.

### Using the diagcomp Option

This example illustrates using the `diagcomp` option of `ichol`. Incomplete Cholesky factorizations of positive definite matrices do not always exist. The following code constructs a random symmetric positive definite matrix and attempts to solve a linear system using `pcg`.

```
S = rng('default');
A = sprandsym(1000,1e-2,1e-4,1);
rng(S);
b = full(sum(A,2));
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-6,100);
```

Since convergence is not attained, try to construct an incomplete Cholesky preconditioner:

```
L = ichol(A,struct('type','ict','droptol',1e-3));
Error using ichol
Encountered nonpositive pivot.
```

If `ichol` breaks down as above, you can use the `diagcomp` option to construct a shifted incomplete Cholesky factorization. That is, instead of constructing  $L$  such that  $L*L'$  approximates  $A$ , `ichol` with diagonal compensation constructs  $L$  such that  $L*L'$  approximates  $M = A + \alpha*\text{diag}(\text{diag}(A))$  without explicitly forming  $M$ . As incomplete factorizations always exist for diagonally dominant matrices,  $\alpha$  can be found to make  $M$  diagonally dominant:

```
alpha = max(sum(abs(A),2)./diag(A))-2
alpha =
    62.9341
```

```
L1 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-6,100,L1,L1');
```

Here, `pcg` still fails to converge to the desired tolerance within the desired number of iterations, but as the plot below shows, convergence is better for `pcg` with this preconditioner than with no preconditioner. Choosing a smaller `alpha` may help. With some experimentation, we can settle on an appropriate value for `alpha`:

```
alpha = .1;
L2 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-6,100,L2,L2');
```

Now, `pcg` converges and a plot can show the convergence histories with each preconditioner:

```
semilogy(0:100,rv0./norm(b),'b. ');
hold on;
semilogy(0:100,rv1./norm(b),'r. ');
semilogy(0:it2,rv2./norm(b),'k. ');
legend('No Preconditioner','\alpha \approx 63','\alpha = .1');
xlabel('Iteration Number');
ylabel('Relative Residual');
```

# idivide

---

**Purpose** Integer division with rounding option

**Syntax**

```
C = idivide(A, B, opt)
C = idivide(A, B)
C = idivide(A, B, 'fix')
C = idivide(A, B, 'round')
C = idivide(A, B, 'floor')
C = idivide(A, B, 'ceil')
```

**Description** `C = idivide(A, B, opt)` is the same as `A./B` for integer classes except that fractional quotients are rounded to integers using the optional rounding mode specified by `opt`. The default rounding mode is `'fix'`. Inputs `A` and `B` must be real and must have the same dimensions unless one is a scalar. At least one of the arguments `A` and `B` must belong to an integer class, and the other must belong to the same integer class or be a scalar double. The result `C` belongs to the integer class.

`C = idivide(A, B)` is the same as `A./B` except that fractional quotients are rounded toward zero to the nearest integers.

`C = idivide(A, B, 'fix')` is the same as the syntax shown immediately above.

`C = idivide(A, B, 'round')` is the same as `A./B` for integer classes. Fractional quotients are rounded to the nearest integers.

`C = idivide(A, B, 'floor')` is the same as `A./B` except that fractional quotients are rounded toward negative infinity to the nearest integers.

`C = idivide(A, B, 'ceil')` is the same as `A./B` except that the fractional quotients are rounded toward infinity to the nearest integers.

## Examples

```
a = int32([-2 2]);
b = int32(3);

idivide(a,b)           % Returns [0 0]
idivide(a,b,'floor')  % Returns [-1 0]
idivide(a,b,'ceil')   % Returns [0 1]
```

```
idivide(a,b,'round')    % Returns [-1 1]
```

# if/elseif/else

---

**Purpose** Execute statements if condition is true

**Syntax**

```
if expression
    statements
elseif expression
    statements
else
    statements
end
```

**Description** `if expression, statements, end` evaluates an expression, and executes a group of statements when the expression is true.

`elseif` and `else` are optional, and execute statements only when previous expressions in the `if` block are false. An `if` block can include multiple `elseif` statements.

An evaluated expression is true when the result is nonempty and contains all nonzero elements (logical or real numeric). Otherwise, the expression is false.

Expressions can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

---

**Note** Within the condition *expression* of an `if` or `while` statement, logical operators `&` and `|` behave as short-circuit operators. This behavior is the same as `&&` and `||`, respectively. Since `&&` and `||` consistently short-circuit in `if` and `while` condition expressions and statements, it is good practice to use `&&` and `||` instead of `&` and `|` within *expression*.

---

**Tips**

- You can nest any number of `if` statements. Each `if` statement requires an `end` keyword.

- Avoid adding a space within the `elseif` keyword (`else if`). The space creates a nested `if` statement that requires its own `end` keyword.

## Examples

Assign to a matrix values that depend on their indices.

```
% Preallocate a matrix
nrows = 10;
ncols = 10;
myData = ones(nrows, ncols);

% Loop through the matrix
for r = 1:nrows
    for c = 1:ncols

        if r == c
            myData(r,c) = 2;
        elseif abs(r - c) == 1
            myData(r,c) = -1;
        else
            myData(r,c) = 0;
        end

    end
end
```

---

Respond to command-line input. Because the input string could be more than one character, use `strcmp` rather than `==` to test for equality.

```
reply = input('Would you like to see an echo? (y/n): ', 's');
if strcmp(reply, 'y')
    disp(reply)
end
```

Find the indices of values in a vector that are greater than a specified limit.

## if/elseif/else

---

```
A = rand(1,10);
limit = .75;

B = (A > limit); % B is a vector of logical values
if any(B)
    fprintf('Indices of values > %4.2f: \n', limit);
    disp(find(B))
else
    disp('All values are below the limit.')
end
```

---

Concatenate two variables when they are the same size. To avoid an error when the variables have different dimensions, compare the sizes using `isequal` rather than the `==` operator.

```
A = ones(2,3); % Two-dimensional array
B = rand(3,4,5); % Three-dimensional array

if isequal(size(A), size(B))
    C = [A; B];
else
    warning('A and B are not the same size.');
```

```
    C = [];
end
```

---

Take advantage of short-circuiting to avoid error or warning messages.

```
x = 42;
if exist('myfunction.m') && (myfunction(x) >= pi)
    disp('Condition is true')
end
```

**Purpose** Inverse fast Fourier transform

**Syntax**

```
y = ifft(X)
y = ifft(X,n)
y = ifft(X,[],dim)
y = ifft(X,n,dim)
y = ifft(..., 'symmetric')
y = ifft(..., 'nonsymmetric')
```

**Description** `y = ifft(X)` returns the inverse discrete Fourier transform (DFT) of vector `X`, computed with a fast Fourier transform (FFT) algorithm. If `X` is a matrix, `ifft` returns the inverse DFT of each column of the matrix.

`ifft` tests `X` to see whether vectors in `X` along the active dimension are *conjugate symmetric*. If so, the computation is faster and the output is real. An `N`-element vector `x` is conjugate symmetric if  $x(i) = \text{conj}(x(\text{mod}(N-i+1,N)+1))$  for each element of `x`.

If `X` is a multidimensional array, `ifft` operates on the first non-singleton dimension.

`y = ifft(X,n)` returns the `n`-point inverse DFT of vector `X`.

`y = ifft(X,[],dim)` and `y = ifft(X,n,dim)` return the inverse DFT of `X` across the dimension `dim`.

`y = ifft(..., 'symmetric')` causes `ifft` to treat `X` as conjugate symmetric along the active dimension. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft(..., 'nonsymmetric')` is the same as calling `ifft(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft(fft(X))` equals `X` to within roundoff error.

**Algorithms** The algorithm for `ifft(X)` is the same as the algorithm for `fft(X)`, except for a sign change and a scale factor of  $n = \text{length}(X)$ . As for `fft`, the execution time for `ifft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have

---

only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `ifft` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

### Data Type Support

`ifft` supports inputs of data types `double` and `single`. If you call `ifft` with the syntax `y = ifft(X, ...)`, the output `y` has the same data type as the input `X`.

**Purpose** 2-D inverse fast Fourier transform

**Syntax**

```
Y = ifft2(X)
Y = ifft2(X,m,n)
y = ifft2(..., 'symmetric')
y = ifft2(..., 'nonsymmetric')
```

**Description** `Y = ifft2(X)` returns the two-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifft2` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `M`-by-`N` matrix `X` is conjugate symmetric if  $X(i,j) = \text{conj}(X(\text{mod}(M-i+1, M) + 1, \text{mod}(N-j+1, N) + 1))$  for each element of `X`.

`Y = ifft2(X,m,n)` returns the `m`-by-`n` inverse fast Fourier transform of matrix `X`.

`y = ifft2(..., 'symmetric')` causes `ifft2` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft2(..., 'nonsymmetric')` is the same as calling `ifft2(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft2(fft2(X))` equals `X` to within roundoff error.

**Algorithms** The algorithm for `ifft2(X)` is the same as the algorithm for `fft2(X)`, except for a sign change and scale factors of `[m,n] = size(X)`. The execution time for `ifft2` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `iff2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

### Data Type Support

`iff2` supports inputs of data types `double` and `single`. If you call `iff2` with the syntax `y = iff2(X, ...)`, the output `y` has the same data type as the input `X`.

**Purpose** N-D inverse fast Fourier transform

**Syntax**

```
Y = ifftn(X)
Y = ifftn(X,siz)
y = ifftn(..., 'symmetric')
y = ifftn(..., 'nonsymmetric')
```

**Description** `Y = ifftn(X)` returns the n-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifftn` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An  $N_1$ -by- $N_2$ -by- ...  $N_k$  array `X` is conjugate symmetric if

$$X(i_1, i_2, \dots, i_k) = \text{conj}(X(\text{mod}(N_1 - i_1 + 1, N_1) + 1, \text{mod}(N_2 - i_2 + 1, N_2) + 1, \dots, \text{mod}(N_k - i_k + 1, N_k) + 1))$$

for each element of `X`.

`Y = ifftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the inverse transform. The size of the result `Y` is `siz`.

`y = ifftn(..., 'symmetric')` causes `ifftn` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifftn(..., 'nonsymmetric')` is the same as calling `ifftn(...)` without the argument `'nonsymmetric'`.

**Tips** For any `X`, `ifftn(fft(X))` equals `X` within roundoff error.

**Algorithms** `ifftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
    Y = ifft(Y,[],p);
end
```

---

This computes in-place the one-dimensional inverse DFT along each dimension of  $X$ .

The execution time for `ifftn` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `ifftn` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

## Data Type Support

`ifftn` supports inputs of data types `double` and `single`. If you call `ifftn` with the syntax `y = ifftn(X, ...)`, the output `y` has the same data type as the input `X`.

# ifftshift

---

**Purpose** Inverse FFT shift

**Syntax** `ifftshift(X)`  
`ifftshift(X,dim)`

**Description** `ifftshift(X)` swaps the left and right halves of the vector  $X$ . For matrices, `ifftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth. If  $X$  is a multidimensional array, `ifftshift(X)` swaps “half-spaces” of  $X$  along each dimension.

`ifftshift(X,dim)` applies the `ifftshift` operation along the dimension `dim`.

---

**Note** `ifftshift` undoes the results of `fftshift`. If the matrix  $X$  contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original  $X$ . Simply performing `fftshift(X)` twice will not produce  $X$ .

**Purpose** Sparse incomplete LU factorization

**Syntax**

```
ilu(A,setup)
[L,U] = ilu(A,setup)
[L,U,P] = ilu(A,setup)
```

**Description** `ilu` produces a unit lower triangular matrix, an upper triangular matrix, and a permutation matrix.

`ilu(A,setup)` computes the incomplete LU factorization of `A`. `setup` is an input structure with up to five setup options. The fields must be named exactly as shown in the table below. You can include any number of these fields in the structure and define them in any order. Any additional fields are ignored.

| Field Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| thresh     | <p>Pivot threshold between 0 (forces diagonal pivoting) and 1, the default, which always chooses the maximum magnitude entry in the column to be the pivot.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

`ilu(A,setup)` returns  $L+U$ -`speye(size(A))`, where  $L$  is a unit lower triangular matrix and  $U$  is an upper triangular matrix.

`[L,U] = ilu(A,setup)` returns a unit lower triangular matrix in  $L$  and an upper triangular matrix in  $U$ .

`[L,U,P] = ilu(A,setup)` returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$ , and a permutation matrix in  $P$ .

## Tips

These incomplete factorizations may be useful as preconditioners for a system of linear equations being solved by iterative methods such as BICG (BiConjugate Gradients), GMRES (Generalized Minimum Residual Method).

## Limitations

`ilu` works on sparse square matrices only.

## Examples

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'crout';
setup.milu = 'row';
setup.droptol = 0.1;
[L,U] = ilu(A,setup);
e = ones(size(A,2),1);
norm(A*e-L*U*e)
```

ans =

```
1.4251e-014
```

This shows that  $A$  and  $L*U$ , where  $L$  and  $U$  are given by the modified Crout ILU, have the same row-sum.

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'nofill';
nnz(A)
```

```
ans =  
  
    7840  
  
nnz(lu(A))  
ans =  
  
    126478  
  
nnz(ilu(A,setup))  
ans =  
  
    7840
```

This shows that A has 7840 nonzeros, the complete LU factorization has 126478 nonzeros, and the incomplete LU factorization, with 0 level of fill-in, has 7840 nonzeros, the same amount as A.

**Purpose** Convert image to movie frame

**Syntax** `f = im2frame(X,map)`  
`f = im2frame(X)`

**Description** `f = im2frame(X,map)` converts the indexed image `X` and associated colormap `map` into a movie frame `f`. If `X` is a truecolor (m-by-n-by-3) image, then `map` is optional and has no effect.

Typical usage:

```
M(1) = im2frame(X1,map);  
M(2) = im2frame(X2,map);  
...  
M(n) = im2frame(Xn,map);  
movie(M)
```

`f = im2frame(X)` converts the indexed image `X` into a movie frame `f` using the current colormap if `X` contains an indexed image.

**See Also** `frame2im` | `movie`

# im2java

---

**Purpose** Convert image to Java image

**Syntax**

```
jimage = im2java(I)
jimage = im2java(X,MAP)
jimage = im2java(RGB)
```

**Description** To work with a MATLAB image in the Java environment, you must convert the image from its MATLAB representation into an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(I)` converts the intensity image `I` to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(X,MAP)` converts the indexed image `X`, with colormap `MAP`, to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(RGB)` converts the RGB image `RGB` to an instance of the Java image class, `java.awt.Image`.

**Class Support** The input image can be of class `uint8`, `uint16`, or `double`.

---

**Note** Java requires `uint8` data to create an instance of the Java image class, `java.awt.Image`. If the input image is of class `uint8`, `jimage` contains the same `uint8` data. If the input image is of class `double` or `uint16`, `im2java` makes an equivalent image of class `uint8`, rescaling or offsetting the data as necessary, and then converts this `uint8` representation to an instance of the Java image class, `java.awt.Image`.

---

**Examples** This example reads an image into the MATLAB workspace and then uses `im2java` to convert it into an instance of the Java image class.

```
I = imread('ngc6543a.jpg');
javaImage = im2java(I);
frame = javax.swing.JFrame;
icon = javax.swing.ImageIcon(javaImage);
label = javax.swing.JLabel(icon);
```

```
frame.getContentPane.add(label);  
frame.pack  
frame.show
```

# imag

---

**Purpose**            Imaginary part of complex number

**Syntax**             $Y = \text{imag}(Z)$

**Description**       $Y = \text{imag}(Z)$  returns the imaginary part of the elements of array  $Z$ .

**Examples**             $\text{imag}(2+3i)$

ans =

3

**See Also**            `conj` | `i` | `j` | `real`

**Purpose**

Display image object

**Syntax**

```
image(C)
image(x,y,C)
image(x,y,C,'PropertyName',PropertyValue,...)
image('PropertyName',PropertyValue,...)
handle = image(...)
```

**Properties**

For a list of properties, see Image Properties.

**Description**

`image` creates an image graphics object by interpreting each element in a matrix as an index into the figure's colormap or directly as RGB values, depending on the data specified.

The `image` function has two forms:

- A high-level function that calls `newplot` to determine where to draw the graphics objects and sets the following axes properties:
  - `XLim` and `YLim` to enclose the image
  - Layer to top to place the image in front of the tick marks and grid lines
  - `YDir` to reverse
  - `View` to `[0 90]`
- A low-level function that adds the image to the current axes without calling `newplot`. The low-level function argument list can contain only property name/property value pairs.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

# image

---

`image(C)` displays matrix `C` as an image. Each element of `C` specifies the color of a rectangular segment in the image.

`image(x,y,C)`, where `x` and `y` are two-element vectors, specifies the range of the `x`- and `y`-axis labels, but produces the same image as `image(C)`. This can be useful, for example, if you want the axis tick labels to correspond to real physical dimensions represented by the image. If `x(1) > x(2)` or `y(1) > y(2)`, the image is flipped left-right or up-down, respectively. It can also be useful when you want to place the image within a set of axes already created. In this case, use `hold on` with the current figure and enter `x` and `y` values corresponding to the corners of the desired image location. The image is stretched and oriented as applicable.

`image(x,y,C,'PropertyName',PropertyValue,...)` is a high-level function that also specifies property name/property value pairs. For a description of the properties, see [Image Properties](#). This syntax calls `newplot` before drawing the image.

`image('PropertyName',PropertyValue,...)` is the low-level syntax of the `image` function. It specifies only property name/property value pairs as input arguments.

`handle = image(...)` returns the handle of the image object it creates. You can obtain the handle with all forms of the `image` function.

## Tips

Image data can be either indexed or true color. An indexed image stores colors as an array of indices into the figure colormap. A true color image does not use a colormap; instead, the color values for each pixel are stored directly as RGB triplets. In MATLAB graphics, the `CData` property of a truecolor image object is a three-dimensional (`m`-by-`n`-by-3) array. This array consists of three `m`-by-`n` matrices (representing the red, green, and blue color planes) concatenated along the third dimension.

The `imread` function reads image data into MATLAB arrays from graphics files in various standard formats, such as TIFF. You can write MATLAB image data to graphics files using the `imwrite` function. `imread` and `imwrite` both support a variety of graphics file formats and compression schemes.

When you read image data into the MATLAB workspace using `imread`, the data is usually stored as an array of 8-bit integers. However, `imread` also supports reading 16-bit-per-pixel data from TIFF and PNG files. These are more efficient storage methods than the double-precision (64-bit) floating-point numbers that MATLAB typically uses. However, it is necessary to interpret 8-bit and 16-bit image data differently from 64-bit data. This table summarizes these differences.

You cannot interactively pan or zoom outside the *x*-limits or *y*-limits of an image, unless the axes limits are already been set outside the bounds of the image, in which case there is no such restriction. If other objects (such as lineseries) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

| <b>Image Type</b>  | <b>Double-Precision Data (double Array)</b>                                                                                                                                   | <b>8-Bit Data (uint8 Array)<br/>16-Bit Data (uint16 Array)</b>                                                                                                                                  |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indexed (colormap) | Image is stored as a two-dimensional (m-by-n) array of integers in the range [1, length(colormap)]; colormap is an m-by-3 array of floating-point values in the range [0, 1]. | Image is stored as a two-dimensional (m-by-n) array of integers in the range [0, 255] (uint8) or [0, 65535] (uint16); colormap is an m-by-3 array of floating-point values in the range [0, 1]. |
| True color (RGB)   | Image is stored as a three-dimensional (m-by-n-by-3) array of floating-point values in the range [0, 1].                                                                      | Image is stored as a three-dimensional (m-by-n-by-3) array of integers in the range [0, 255] (uint8) or [0, 65535] (uint16).                                                                    |

By default, `image` plots the *y*-axis from lowest to highest value, top to bottom. To reverse this, type `set(gca, 'YDir', 'normal')`. This will reverse both the *y*-axis and the image.

## Indexed Images

In an indexed image of class `double`, the value 1 points to the first row in the colormap, the value 2 points to the second row, and so on. In a `uint8` or `uint16` indexed image, there is an offset; the value 0 points to the first row in the colormap, the value 1 points to the second row, and so on.

If you want to convert a `uint8` or `uint16` indexed image to `double`, you need to add 1 to the result. For example,

```
X64 = double(X8) + 1;
```

or

```
X64 = double(X16) + 1;
```

To convert from `double` to `uint8` or `uint16`, you need to first subtract 1, and then use `round` to ensure all the values are integers.

```
X8 = uint8(round(X64 - 1));
```

or

```
X16 = uint16(round(X64 - 1));
```

When you write an indexed image using `imwrite`, values are automatically converted if necessary.

## Colormaps

MATLAB colormaps are always `m`-by-3 arrays of double-precision floating-point numbers in the range [0, 1]. In most graphics file formats, colormaps are stored as integers, but MATLAB colormaps cannot have integer values. `imread` and `imwrite` automatically convert colormap values when reading and writing files.

## True Color Images

In a true color image of class `double`, the data values are floating-point numbers in the range [0, 1]. In a true color image of class `uint8`, the

data values are integers in the range [0, 255], and for true color images of class `uint16` the data values are integers in the range [0, 65535].

If you want to convert a true color image from one data type to the other, you must rescale the data. For example, this statement converts a `uint8` true color image to `double`.

```
RGB64 = double(RGB8)/255;
```

or for `uint16` images,

```
RGB64 = double(RGB16)/65535;
```

This statement converts a `double` true color image to `uint8`:

```
RGB8 = uint8(round(RGB64*255));
```

or to obtain `uint16` images, type

```
RGB16 = uint16(round(RGB64*65535));
```

When you write a true color image using `imwrite`, values are automatically converted if necessary.

## Examples

Load a mat-file containing a photograph of a colorful primate. Display the indexed image using its associated colormap.

```
load mandrill
figure('color','k')
image(X)
colormap(map)
axis off; % Remove axis ticks and numbers
axis image; % Set aspect ratio to obtain square pixels
```

# image

---

---

Load a JPEG image file of the Cat's Eye Nebula from the Hubble Space Telescope (image courtesy NASA). Display the original image using its RGB color values (left) as a subplot. Create a linked subplot (same size and scale) to display the transformed intensity image as a heat map (right).

```
figure
ax(1) = subplot(1,2,1);
rgb = imread('ngc6543a.jpg');
```

```
image(rgb); title('RGB image')
ax(2) = subplot(1,2,2);
im = mean(rgb,3);
image(im); title('Intensity Heat Map')
colormap(hot(256))
linkaxes(ax,'xy')
axis(ax,'image')
```

# image

---

## Setting Default Properties

You can set default image properties on the axes, figure, and root object levels:

```
set(0, 'DefaultImageProperty', PropertyValue...)  
set(gcf, 'DefaultImageProperty', PropertyValue...)  
set(gca, 'DefaultImageProperty', PropertyValue...)
```

where *Property* is the name of the image property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access image properties.

## Tutorials

For more information, see “Working with Images in MATLAB Graphics”  
.

## See Also

`colormap` | `imagesc` | `imfinfo` | `imread` | `imwrite` | `newplot` | `pcolor`  
| `surface` | Image Properties

## Purpose

Define image properties

## Creating Image Objects

Use `image` to create image objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Image Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`AlphaData`

m-by-n matrix of `double` or `uint8`

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current `alphamap` (`AlphaDataMapping` set to `direct`)

# Image Properties

---

- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

## `AlphaDataMapping`

`none` | `direct` | `{scaled}`

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data. Values for this property are:

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range.
- `scaled` — Transform the `AlphaData` to span the portion of the `alphamap` indicated by the axes `ALim` property, linearly mapping data values to alpha values (the default).
- `direct` — Use the `AlphaData` as indices directly into the `alphamap`. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the `alphamap`, and values greater than `length(alphamap)` to the last alpha value in the `alphamap`. Values with a decimal portion are fixed to the nearest, lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the `alphamap`).

## `Annotation`

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this image object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the image object is displayed in a figure legend:

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                        |
|-------------------------------|-------------------------------------------------------|
| on                            | Represent this image object in a legend (default)     |
| off                           | Do not include this image object in a legend          |
| children                      | Same as on because image objects do not have children |

## Setting the `IconDisplayStyle` property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to

# Image Properties

---

perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## CData

matrix | m-by-n-by-3 array

*The image data.* A matrix or 3-D array of values specifying the color of each rectangular area defining the image. `image(C)` assigns the values of `C` to `CData`. MATLAB determines the coloring of the image in one of three ways:

- Using the elements of `CData` as indices into the current colormap (the default) (`CDataMapping` set to `direct`)
- Scaling the elements of `CData` to range between the values `min(get(gca,'CLim'))` and `max(get(gca,'CLim'))` (`CDataMapping` set to `scaled`)
- Interpreting the elements of `CData` directly as RGB values (true color specification)

Note that the behavior of NaNs in image `CData` is not defined. See the image `AlphaData` property for information on using transparency with images.

A true color specification for `CData` requires an m-by-n-by-3 array of RGB values. The first page contains the red component, the second page the green component, and the third page the blue component of each element in the image. RGB values range from 0 to 1. The following picture illustrates the relative dimensions of `CData` for the two color models.

# Image Properties

---

Indexed Colors

True Colors

If CData has only one row or column, the height or width respectively is always one data unit and is centered about the first YData or XData element respectively. For example, using a 4-by-1 matrix of random data:

```
C = rand(4,1);  
image(C, 'CDataMapping', 'scaled')  
axis image
```

produces

`CDataMapping`  
scaled | {direct}

*Direct or scaled indexed colors.* Determines whether MATLAB interprets the values in `CData` as indices into the figure colormap (the default) or scales the values according to the values of the axes `CLim` property.

When `CDataMapping` is `direct`, the values of `CData` should be in the range 1 to `length(get(gcf, 'Colormap'))`. If you use true color specification for `CData`, this property has no effect. If `CData` is of type `logical`, values of 0 index the first color of the colormap and values of 1 index the second color.

# Image Properties

---

Children  
handle

The empty matrix; image objects have no children.

Clipping  
{on} | off

*Clipping mode.* By default, MATLAB clips images to the axes rectangle. If you set `Clipping` to `off`, the image can be displayed outside the axes rectangle. For example, if you create an image, set `hold` to `on`, freeze axis scaling (with `axis manual`), and then create a larger image, it extends beyond the axis limits.

CreateFcn  
string | function handle

*Callback routine executed during object creation.* This property defines a callback routine that executes when MATLAB creates an image object. You must define this property as a default value for images or in a call to the `image` function to create a new image object. For example, the statement:

```
set(0, 'DefaultImageCreateFcn', 'axis image')
```

defines a default value on the root level that sets the aspect ratio and the axis limits so the image has square pixels. MATLAB executes this routine after setting all image properties. Setting this property on an existing image object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the image object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

# Image Properties

---

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object’s color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### `HandleVisibility`

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

# Image Properties

---

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## Interruptible

off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Image Properties

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## Parent

handle of parent axes, hgroup, or hgtransform

*Parent of object.* Handle of the object’s parent. The parent is normally the axes, hgroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

`SelectionHighlight`  
{on} | off

*Object highlighted when selected.*

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`Tag`  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

`Type`  
string (read-only)

# Image Properties

---

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For image objects, `Type` is always `'image'`.

## UIContextMenu

handle of uicontextmenu object

*Associate context menu with object.* Handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

[1 size(CData,2)] by default

*Control placement of image along x-axis.* A vector specifying the locations of the centers of the elements `CData(1,1)` and `CData(m,n)`, where `CData` has a size of `m`-by-`n`. Element `CData(1,1)` is centered over the coordinate defined by the first

elements in `XData` and `YData`. Element `CData(m,n)` is centered over the coordinate defined by the last elements in `XData` and `YData`. The centers of the remaining elements of `CData` are evenly distributed between those two points.

The width of each `CData` element is determined by the expression:

$$(XData(2) - XData(1)) / (\text{size}(CData, 2) - 1)$$

You can also specify a single value for `XData`. In this case, `image` centers the first element at this coordinate and centers each following element one unit apart.

`YData`

`[ 1 size(CData,1) ]` by default

*Control placement of image along y-axis.* A vector specifying the locations of the centers of the elements `CData(1,1)` and `CData(m,n)`, where `CData` has a size of `m`-by-`n`. Element `CData(1,1)` is centered over the coordinate defined by the first elements in `XData` and `YData`. Element `CData(m,n)` is centered over the coordinate defined by the last elements in `XData` and `YData`. The centers of the remaining elements of `CData` are evenly distributed between those two points.

The height of each `CData` element is determined by the expression:

$$(YData(2) - YData(1)) / (\text{size}(CData, 1) - 1)$$

You can also specify a single value for `YData`. In this case, `image` centers the first element at this coordinate and centers each following element one unit apart.

## See Also

`image`

# imagesc

---

**Purpose** Scale data and display image object

**Syntax**

```
imagesc(C)
imagesc(x,y,C)
imagesc(...,clims)
imagesc('PropertyName',PropertyValue,...)
h = imagesc(...)
```

**Description** The `imagesc` function scales image data to the full range of the current colormap and displays the image. (See “Examples” on page 1-2935 for an illustration.)

`imagesc(C)` displays `C` as an image. Each element of `C` corresponds to a rectangular area in the image. The values of the elements of `C` are indices into the current colormap that determine the color of each patch.

`imagesc(x,y,C)` displays `C` as an image and specifies the bounds of the  $x$ - and  $y$ -axis with vectors `x` and `y`. If `x(1) > x(2)` or `y(1) > y(2)`, the image is flipped left-right or up-down, respectively. If `x` and `y` are scalars, the image is translated to the specified location `(x,y)` such that the upper left corner of the image starts at `(x,y)`.

`imagesc(...,clims)` normalizes the values in `C` to the range specified by `clims` and displays `C` as an image. `clims` is a two-element vector that limits the range of data values in `C`. These values map to the full range of values in the current colormap.

`imagesc('PropertyName',PropertyValue,...)` is the low-level syntax of the `imagesc` function. It specifies only property name/property value pairs as input arguments. See Image Properties for a list of the property names and their values.

`h = imagesc(...)` returns the handle for an image graphics object.

## Tips

$x$  and  $y$  do not affect the elements in  $C$ ; they only affect the annotation of the axes. If  $\text{length}(x) > 2$  or  $\text{length}(y) > 2$ , `imagesc` ignores all except the first and last elements of the respective vector.

`imagesc` creates an image with `CDataMapping` set to `scaled`, and sets the axes `CLim` property to the value passed in `clims`.

You cannot interactively pan or zoom outside the  $x$ -limits or  $y$ -limits of an image.

By default, `imagesc` plots the  $y$ -axis from lowest to highest value, top to bottom. To reverse this, type `set(gca, 'YDir', 'normal')`. This will reverse both the  $y$ -axis and the image.

## Examples

You can expand midrange color resolution by mapping low values to the first color and high values to the last color in the colormap by specifying color value limits (`clims`). If the size of the current colormap is 81-by-3, the statements

```
clims = [ 10 60 ]
imagesc(C,clims)
```

map the data values in  $C$  to the colormap as shown in this illustration and the code that follows:

# imagesc

---

In this example, the left image maps to the gray colormap using the statements

```
load clown
figure
subplot(1,2,1)
imagesc(X)
colormap(gray)
axis image
title('Default CLim (= [1 81])')
```

The right image has values between 10 and 60 scaled to the full range of the gray colormap using the statements

```
subplot(1,2,2)
clims = [10 60];
imagesc(X,clims)
colormap(gray)
axis image
title('CLim = [10 60]')
```

This example shows how to shift the image starting from origin to a position (100, 100),

```
i = imread('eight.tif');
```

```
figure; subplot(2,2,1); imagesc(i);
axis([0 400 0 400]);
colormap(gray);
subplot(2,2,2); imagesc(100,100,i);
axis([0 400 0 400]);
colormap(gray);
```

The figure output is as:

The top right corner of the image is now starting from (100,100) instead of the origin.

Passing vector values with the image scales the image to the specified size of 400-by-400.

```
figure; imagesc(1:400,1:400,i);
colormap(gray);
```

# imagesc

---

## See Also

`image` | `imfinfo` | `imread` | `imwrite` | `colorbar` | `colormap` | `pcolor`  
| `surface` | `surf`

**Purpose** Approximate indexed image by reducing number of colors

**Syntax**

```
[Y,newmap] = imapprox(X,map,n)
[Y,newmap] = imapprox(X,map,tol)
Y = imapprox(X,map,newmap)
Y = imapprox(...,dither_option)
```

**Description** [Y,newmap] = imapprox(X,map,n) approximates the colors in the indexed image X and associated colormap map by using minimum variance quantization. imapprox returns the indexed image Y with colormap newmap, which has at most n colors.

[Y,newmap] = imapprox(X,map,tol) approximates the colors in X and map through uniform quantization. newmap contains at most  $(\text{floor}(1/\text{tol})+1)^3$  colors. tol must be between 0 and 1.0.

Y = imapprox(X,map,newmap) approximates the colors in map by using colormap mapping to find the colors in newmap that best match the colors in map.

Y = imapprox(...,dither\_option) enables or disables dithering. dither\_option is a string that can have one of these values.

| Value               | Description                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------|
| {'dither'}(default) | Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution.       |
| 'nodither'          | Maps each color in the original image to the closest color in the new map. No dithering is performed. |

**Class Support** The input image X can be of class uint8, uint16, or double. The output image Y is of class uint8 if the length of newmap is less than or equal to 256. If the length of newmap is greater than 256, Y is of class double.

**Algorithms** imapprox uses rgb2ind to create a new colormap that uses fewer colors.

## Examples

Load an indexed image of a mandrill's face. Display image  $X$  using its associated colormap,  $map$ , which has 220 colors.

```
load mandrill
figure('color','k')
image(X)
colormap(map)
size(map)           % See that the color map has 220 entries

ans =
    220     3

axis off           % Remove axis ticks and numbers
axis image        % Set aspect ratio to obtain square pixels
```

Reduce the number of colors in the indexed image from 220 to only 16 colors by producing a new image, `Y`, and its associated colormap, `newmap`:

```
figure('color','k')
[Y, newmap] = imapprox(X, map, 16);
size(newmap)      % See that the new color map has 16 entries
```

```
ans =
    16     3
```

# imapprox

---

```
image(Y)
colormap(newmap)
axis off           % Remove axis ticks and numbers
axis image        % Set aspect ratio to obtain square pixels
```

**Purpose**

Information about graphics file

**Syntax**

```
info = imfinfo(filename)
info = imfinfo(filename,fmt)
info = imfinfo(URL)
```

**Description**

`info = imfinfo(filename)` returns a structure whose fields contain information about an image in a graphics file, `filename`. The file must be in the current folder or in a folder on the MATLAB path.

The format of the file is inferred from its contents.

- If `filename` is a TIFF, HDF, ICO, GIF, or CUR file containing more than one image, then `info` is a structure array with one element for each image in the file. For example, `info(3)` would contain information about the third image in the file.

`info = imfinfo(filename,fmt)` additionally looks for a file named `filename.fmt`, if MATLAB cannot find a file named `filename`.

`info = imfinfo(URL)` returns information about the image at the specified Internet resource, `URL`.

**Input Arguments****filename - Name of graphics file**

string

Name of graphics file, specified as a string.

**Example:** 'myImage.jpg'

**Data Types**

char

**fmt - Image format**

string

# imfinfo

---

Image format, specified as a string. The possible values for `fmt` are contained in the MATLAB file format registry. To view of list of these formats, run the `imformats` command.

**Example:** `'gif'`

## Data Types

`char`

## URL - Image location

`string`

Image location, specified as a string. URL must include the protocol type (e.g., `http://`).

## Data Types

`char`

## Output Arguments

## `info` - Information about graphics file

`structure array`

Information about the graphics file, returned as a structure array. The set of fields in `info` depends on the individual file and its format. This table lists the nine fields that always appear, and describes their values.

| Field Name  | Description                                                                                                                                   | Value   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|---------|
| Filename    | Name of the file or the Internet URL specified. If the file is not in the current folder, the string contains the full path name of the file. | string  |
| FileModDate | Date when the file was last modified.                                                                                                         | string  |
| FileSize    | Size of the file, in bytes.                                                                                                                   | integer |

| Field Name    | Description                                                                                                                                                                                           | Value            |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Format        | File format, as specified by <i>fmt</i> . For formats with more than one possible extension (for example, JPEG and TIFF files), <i>imfinfo</i> returns the first variant in the file format registry. | string           |
| FormatVersion | File format version.                                                                                                                                                                                  | string or number |
| Width         | Image width, in pixels.                                                                                                                                                                               | integer          |
| Height        | Image height, in pixels.                                                                                                                                                                              | integer          |
| BitDepth      | Number of bits per pixel.                                                                                                                                                                             | integer          |
| ColorType     | Image type. <i>ColorType</i> includes, but is not limited to, 'truecolor' for a truecolor (RGB) image, 'grayscale' for a grayscale intensity image, or 'indexed' for an indexed image.                | string           |

Additional fields returned by some file formats:

- **JPEG and TIFF only** — If *filename* contains Exchangeable Image File Format (EXIF) tags, then *info* might also contain 'DigitalCamera' or 'GPSInfo' (global positioning system information) fields.
- **GIF only** — *imfinfo* returns the value of the 'DelayTime' field in hundredths of seconds.
- **JPEG2000 only** — The *info* structure contains an m-by-3 cell array, 'ChannelDefinition'. The first column of 'ChannelDefinition' reports a channel position as it exists in the file. The second column reports the type of channel, and the third column reports the channel mapping.

## Examples

### Return Information About Graphics File

Find information about the example image, `ngc6543a.jpg`.

```
info = imfinfo('ngc6543a.jpg')
```

```
info =
```

```

[imformats](#) | [imread](#) | [imwrite](#)

**Purpose** Manage image file format registry

**Syntax**

```

imformats
formats = imformats
formats = imformats('fmt')
formats = imformats(format_struct)
formats = imformats('factory')

```

**Description** `imformats` displays a table of information listing all the values in the MATLAB file format registry. This registry determines which file formats are supported by the `imfinfo`, `imread`, and `imwrite` functions.

`formats = imformats` returns a structure containing all the values in the MATLAB file format registry. The following table lists the fields in the order they appear in the structure.

| Field                    | Value                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>ext</code>         | A cell array of strings that specify filename extensions that are valid for this format                                         |
| <code>isa</code>         | A string specifying the name of the function that determines if a file is a certain format. This can also be a function handle. |
| <code>info</code>        | A string specifying the name of the function that reads information about a file. This can also be a function handle.           |
| <code>read</code>        | A string specifying the name of the function that reads image data in a file. This can also be a function handle.               |
| <code>write</code>       | A string specifying the name of the function that writes MATLAB data to a file. This can also be a function handle.             |
| <code>alpha</code>       | Returns 1 if the format has an alpha channel, 0 otherwise                                                                       |
| <code>description</code> | A text description of the file format                                                                                           |

---

**Note** The values for the `isa`, `info`, `read`, and `write` fields must be functions on the MATLAB search path or function handles.

---

`formats = imformats('fmt')` searches the known formats in the MATLAB file format registry for the format associated with the filename extension `'fmt'`. If found, `imformats` returns a structure containing the characteristics and function names associated with the format. Otherwise, it returns an empty structure.

`formats = imformats(format_struct)` sets the MATLAB file format registry to the values in `format_struct`. The output structure, `formats`, contains the new registry settings.

---

**Caution** Using `imformats` to specify values in the MATLAB file format registry can result in the inability to load any image files. To return the file format registry to a working state, use `imformats` with the `'factory'` setting.

---

`formats = imformats('factory')` resets the MATLAB file format registry to the default format registry values. This removes any user-specified settings.

Changes to the format registry do not persist between MATLAB sessions. To have a format always available when you start MATLAB, add the appropriate `imformats` command to the MATLAB startup file, `startup.m`, located in `$MATLAB/toolbox/local` on UNIX systems, or `$MATLAB\toolbox\local` on Windows systems.

## Examples

```
formats = imformats;
formats(1)

ans =

           ext: {'bmp'}
```

```
isa: @isbmp
info: @imbmpinfo
read: @readbmp
write: @writebmp
alpha: 0
description: 'Windows Bitmap (BMP)'
```

## See Also

`imfinfo` | `imread` | `imwrite` | `path`

# import

---

**Purpose** Add package or class to current import list

**Syntax**

```
import package_name.class_name
import package_name.function_name
import package_name.*
import package_name.class_name1 package_name.class_name2...
import package_name1.* package_name2.*...
L = import
import
```

**Description** `import package_name.class_name` adds the fully qualified class name to the current import list.

`import package_name.function_name` adds the specified package-based function.

`import package_name.*` adds the specified package name. Note that *package\_name* must be followed by `.*`.

`import package_name.class_name1 package_name.class_name2...` adds multiple fully qualified class names.

`import package_name1.* package_name2.*...` adds multiple package names.

`L = import` with no input arguments returns a cell array of strings containing the current import list, without adding to it.

`import` with no input arguments displays the current import list, without adding to it.

The `import` function allows your code to refer to an imported class or function using fewer or no package prefixes.

The `import` function only affects the import list of the function within which it is used. When invoked at the command prompt, `import` uses the import list for the MATLAB command environment. If `import` is used in a script invoked from a function, it affects the import list of the function. If `import` is used in a script that is invoked from the command prompt, it affects the import list for the command environment.

The `import` list of a function is persistent across calls to that function and is only cleared when the function is cleared.

To clear the current import list, use the following command.

```
clear import
```

This command may only be invoked at the command prompt. Attempting to use `clear import` within a function results in an error.

## Importing MATLAB Packages and Classes

You can import packages and classes into a MATLAB workspace (from the command line or in a function definition). For example:

```
import packagename.*
```

imports all classes and package functions so that you can reference those classes and functions by their simple names, without the package qualifier.

You can import just a single class from a package:

```
import packagename.ClassName  
import Classname
```

You must still use the class name to call static methods:

```
ClassName.staticMethod()
```

For more information on how `import` works with MATLAB classes and packages, see “Importing Classes”.

## Tips

The `import` function allows your code to refer to an imported class by class name only, rather than with the fully qualified class name. `import` is particularly useful in streamlining calls to constructors, where most references to Java classes occur.

If you use the `import` function in a control statement, for example, `if` or `switch`, or in a function, MATLAB limits the scope of the variables

# import

---

to that block of code. If you use the variables outside the function or control block, MATLAB displays an error message.

## Limitations

- `import` cannot load a Java JAR package created by the MATLAB Builder™ JA product.

## Examples

To add the `containers.Map` class to the current import list:

```
import containers.Map
myMap = Map('KeyType', 'char', 'ValueType', 'double');
```

---

To import two Java packages:

```
import java.util.Enumeration java.lang.String
s = String('hello'); % Create java.lang.String object
methods Enumeration % List java.util.Enumeration methods
```

---

To add the `java.awt` package:

```
import java.awt.*
f = Frame; % Create java.awt.Frame object
```

---

This example uses `import` in a function to call members of a .NET class in the `System.Drawing` namespace. Create the `getPrinterInfo` function:

```
function ptr = getPrinterInfo
import System.Drawing.Printing.*;
ptr = PrinterSettings;
end
```

To call the function, type:

```
NET.addAssembly('System.Drawing');
```

```
printer = getPrinterInfo;
```

## See Also

`clear` | `load` | `importdata`

# importdata

---

## Purpose

Load data from file

## Syntax

```
A = importdata(filename)
A = importdata('-pastespecial')
A = importdata(___,delimiterIn)
A = importdata(___,delimiterIn,headerlinesIn)
[A,delimiterOut,headerlinesOut] = importdata(___)
```

## Description

`A = importdata(filename)` loads data into array `A`.

`A = importdata('-pastespecial')` loads data from the system clipboard rather than from a file.

`A = importdata(___,delimiterIn)` interprets `delimiterIn` as the column separator in ASCII file, `filename`, or the clipboard data. You can use `delimiterIn` with any of the input arguments in the above syntaxes.

`A = importdata(___,delimiterIn,headerlinesIn)` loads data from ASCII file, `filename`, or the clipboard, reading numeric data starting from line `headerlinesIn+1`.

`[A,delimiterOut,headerlinesOut] = importdata(___)` additionally returns the detected delimiter character for the input ASCII file in `delimiterOut` and the detected number of header lines in `headerlinesOut`, using any of the input arguments in the previous syntaxes.

## Input Arguments

### **filename** - Name and extension of file to import

string

Name and extension of the file to import, specified as a string. If `importdata` recognizes the file extension, it calls the MATLAB helper function designed to import the associated file format (such as `load`

for MAT-files or `xlsread` for spreadsheets). Otherwise, `importdata` interprets the file as a delimited ASCII file.

For ASCII files and spreadsheets, `importdata` expects to find numeric data in a rectangular form (that is, like a matrix). Text headers can appear above or to the left of the numeric data, as follows:

- Column headers or file description text at the top of the file, above the numeric data.
- Row headers to the left of the numeric data.

**Example:** `'myFile.jpg'`

## Data Types

`char`

## **delimiterIn - Column separator character**

`string`

Column separator character, specified as a string. The default character is interpreted from the file. Use `'\t'` for tab.

**Example:** `','`

**Example:** `' '`

## Data Types

`char`

## **headerlinesIn - Number of text header lines in ASCII file**

`nonnegative scalar integer`

Number of text header lines in the ASCII file, specified as a nonnegative scalar integer. If you do not specify `headerlinesIn`, the `importdata` function detects this value in the file.

## Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |  
`uint16` | `uint32` | `uint64`

## Output Arguments

### A - Data from the file

matrix | multidimensional array | scalar structure array

Data from the file, returned as a matrix, multidimensional array, or scalar structure array, depending on the characteristics of the file. Based on the file format of the input file, `importdata` calls a helper function to read the data. When the helper function returns more than one nonempty output, `importdata` combines the outputs into a struct array.

This table lists the file formats associated with helper functions that can return more than one output, and the possible fields in the structure array, `A`.

| File Format                  | Possible Fields                                                                                  | Class                                                                                                                                                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAT-files                    | One field for each variable                                                                      | Associated with each variable.                                                                                                                                                                                                                     |
| ASCII files and Spreadsheets | <code>data</code><br><code>textdata</code><br><code>colheaders</code><br><code>rowheaders</code> | For ASCII files, <code>data</code> contains a double array. Other fields contain cell arrays of strings. <code>textdata</code> includes row and column headers. For spreadsheets, each field contains a struct, with one field for each worksheet. |
| Images                       | <code>cdata</code><br><code>colormap</code><br><code>alpha</code>                                | See <code>imread</code> .                                                                                                                                                                                                                          |
| Audio files                  | <code>data</code><br><code>fs</code>                                                             | See <code>audioread</code> .                                                                                                                                                                                                                       |

The MATLAB helper functions for most other supported file formats return one output. For more information about the class of each output, see the functions listed in “Supported File Formats”.

If the ASCII file or spreadsheet contains either column or row headers, but not both, `importdata` returns a `colheaders` or `rowheaders` field in the output structure, where:

- `colheaders` contains only the last line of column header text. `importdata` stores all text in the `textdata` field.
- `rowheaders` is created only when the file or worksheet contains a single column of row headers.

### **delimiterOut - Detected column separator in the input ASCII file**

string

Detected column separator in the input ASCII file, returned as a string.

### **headerlinesOut - Detected number of text header lines in the input ASCII file**

integer

Detected number of text header lines in the input ASCII file, returned as an integer.

## **Examples**

### **Import and Display an Image**

Import and display the image `ngc6543a.jpg`.

```
A = importdata('ngc6543a.jpg');  
image(A);
```

The output, `A`, is class `uint8` because the helper function, `imread`, returns empty results for `colormap` and `alpha`.

### **Import a Text File and Specify Delimiter and Column Header**

Using a text editor, create a space-delimited ASCII file with column headers called `myfile01.txt`.

# importdata

---

```
Day1 Day2 Day3 Day4 Day5 Day6 Day7
95.01 76.21 61.54 40.57 5.79 20.28 1.53
23.11 45.65 79.19 93.55 35.29 19.87 74.68
60.68 1.85 92.18 91.69 81.32 60.38 44.51
48.60 82.14 73.82 41.03 0.99 27.22 93.18
89.13 44.47 17.63 89.36 13.89 19.88 46.60
```

Import the file, specifying the space delimiter and the single column header.

```
filename = 'myfile01.txt';
delimiterIn = ' ';
headerlinesIn = 1;
A = importdata(filename,delimiterIn,headerlinesIn);
```

View columns 3 and 5.

```
for k = [3, 5]
    disp(A.colheaders{1, k})
    disp(A.data(:, k))
    disp(' ')
end
```

```
Day3
61.5400
79.1900
92.1800
73.8200
17.6300
```

```
Day5
5.7900
35.2900
81.3200
0.9900
13.8900
```

## Import a Text File and Return Detected Delimiter

Using a text editor, create a comma-delimited ASCII file called `myfile02.txt`.

```
1,2,3
4,5,6
7,8,9
```

Import the file, and display the output data and detected delimiter character.

```
filename = 'myfile02.txt';
[A,delimiterOut]=importdata(filename)
```

```
A =
```

```
     1     2     3
     4     5     6
     7     8     9
```

```
delimiterOut =
```

```
,
```

## Import Data from Clipboard

Copy the following lines to the clipboard. Select the text, right-click, and then select **Copy**.

```
1,2,3
4,5,6
7,8,9
```

Import the clipboard data into MATLAB by typing the following.

```
A = importdata('-pastespecial')
```

# importdata

---

A =

|   |   |   |
|---|---|---|
| 1 | 2 | 3 |
| 4 | 5 | 6 |
| 7 | 8 | 9 |

## Tips

- To import ASCII files with nonnumeric characters outside of column or row headers, including columns of character data or formatted dates or times, use `textscan` instead of `importdata`.

## See Also

`load` | `save` | `textscan` | `xlsread` | `imread` | `uiimport`

## Concepts

- “Supported File Formats”
- “Ways to Import Text Files”
- “Import Mixed Text and Numeric Data from Text Files”
- “Ways to Import Spreadsheets”
- “Process a Sequence of Files”

**Purpose** Read image from graphics file

**Syntax**

```
A = imread(filename, fmt)
[X, map] = imread(...)
[...] = imread(filename)
[...] = imread(URL,...)
[...] = imread(...,Param1,Val1,Param2,Val2...)
```

**Description** `A = imread(filename, fmt)` reads a grayscale or color image from the file specified by the string `filename`. If the file is not in the current folder, or in a folder on the MATLAB path, specify the full pathname.

The text string `fmt` specifies the format of the file by its standard file extension. For example, specify 'gif' for Graphics Interchange Format files. To see a list of supported formats, with their file extensions, use the `imformats` function. If `imread` cannot find a file named `filename`, it looks for a file named `filename.fmt`.

The return value `A` is an array containing the image data. If the file contains a grayscale image, `A` is an M-by-N array. If the file contains a truecolor image, `A` is an M-by-N-by-3 array. For TIFF files containing color images that use the CMYK color space, `A` is an M-by-N-by-4 array. See TIFF in the Format-Specific Information section for more information.

The class of `A` depends on the bits-per-sample of the image data, rounded to the next byte boundary. For example, `imread` returns 24-bit color data as an array of `uint8` data because the sample size for each color component is 8 bits. See “Tips” on page 1-2962 for a discussion of bitdepths, and see “Format-Specific Information” on page 1-2962 for more detail about supported bit depths and sample sizes for a particular format.

`[X, map] = imread(...)` reads the indexed image in `filename` into `X` and its associated colormap into `map`. Colormap values in the image file are automatically rescaled into the range `[0,1]`.

`[...] = imread(filename)` attempts to infer the format of the file from its content.

[...] = imread(URL,...) reads the image from an Internet URL. The URL must include the protocol type (e.g., http://).

[...] = imread(...,Param1,Val1,Param2,Val2...) specifies parameters that control various characteristics of the operations for specific formats. For more information, see “Format-Specific Information” on page 1-2962.

## Tips

- Bit depth is the number of bits used to represent each image pixel. Bit depth is calculated by multiplying the bits-per-sample with the samples-per-pixel. Thus, a format that uses 8-bits for each color component (or sample) and three samples per pixel has a bit depth of 24. Sometimes the sample size associated with a bit depth can be ambiguous: does a 48-bit bit depth represent six 8-bit samples, four 12-bit samples, or three 16-bit samples? See “Format-Specific Information” on page 1-2962 for sample size information to avoid this ambiguity.

## Format-Specific Information

The following sections provide information about the support for specific formats, listed in alphabetical order by format name. These sections include information about format-specific syntaxes, if they exist.

### BMP — Windows Bitmap

| Supported Bitdepths | No Compression | RLE Compression | Output Class | Notes                            |
|---------------------|----------------|-----------------|--------------|----------------------------------|
| 1-bit               | y              | —               | logical      |                                  |
| 4-bit               | y              | y               | uint8        |                                  |
| 8-bit               | y              | y               | uint8        |                                  |
| 16-bit              | y              | —               | uint8        | 1 sample/pixel                   |
| 24-bit              | y              | —               | uint8        | 3 samples/pixel                  |
| 32-bit              | y              | —               | uint8        | 3 samples/pixel (1 byte padding) |

### CUR — Cursor File

| Supported Bitdepths | No Compression | Compression | Output Class |
|---------------------|----------------|-------------|--------------|
| 1-bit               | y              | —           | logical      |
| 4-bit               | y              | —           | uint8        |
| 8-bit               | y              | —           | uint8        |

Format-specific syntaxes:

`[...] = imread(..., idx)` reads in one image from a multi-image icon or cursor file. `idx` is an integer value that specifies the order that the image appears in the file. For example, if `idx` is 3, `imread` reads

the third image in the file. If you omit this argument, `imread` reads the first image in the file.

`[A, map, alpha] = imread(...)` returns the AND mask for the resource, which can be used to determine the transparency information. For cursor files, this mask may contain the only useful data.

---

**Note** By default, Microsoft Windows cursors are 32-by-32 pixels. MATLAB pointers must be 16-by-16. You will probably need to scale your image. If you have Image Processing Toolbox™, you can use its `imresize` function.

---

## GIF – Graphics Interchange Format

| Supported Bitdepths | Output Class |
|---------------------|--------------|
| 1-bit               | logical      |
| 2-bit to 8-bit      | uint8        |

Format-specific syntaxes:

`[...] = imread(..., idx)` reads in one or more frames from a multiframe (i.e., animated) GIF file. `idx` must be an integer scalar or vector of integer values. For example, if `idx` is 3, `imread` reads the third image in the file. If `idx` is 1:5, `imread` returns only the first five frames.

`[...] = imread(..., 'frames', idx)` is the same as the syntax above except that `idx` can be 'all'. In this case, all the frames are read and returned in the order that they appear in the file.

---

**Note** Because of the way that GIF files are structured, all the frames must be read when a particular frame is requested. Consequently, it is much faster to specify a vector of frames or 'all' for `idx` than to call `imread` in a loop when reading multiple frames from the same GIF file.

---

**HDF4 – Hierarchical Data Format**

| Supported Bitdepths | Raster Image with colormap | Raster image without colormap | Output Class | Notes           |
|---------------------|----------------------------|-------------------------------|--------------|-----------------|
| 8-bit               | y                          | y                             | uint8        |                 |
| 24-bit              | –                          | y                             | uint8        | 3 samples/pixel |

Format-specific syntaxes:

`[...] = imread(..., ref)` reads in one image from a multi-image HDF4 file. `ref` is an integer value that specifies the reference number used to identify the image. For example, if `ref` is 12, `imread` reads the image whose reference number is 12. (Note that in an HDF4 file the reference numbers do not necessarily correspond to the order of the images in the file. You can use `imfinfo` to match image order with reference number.) If you omit this argument, `imread` reads the first image in the file.

**ICO – Icon File**

See “CUR — Cursor File” on page 1-2963

**JPEG – Joint Photographic Experts Group**

`imread` can read any baseline JPEG image as well as JPEG images with some commonly used extensions. For information about support for JPEG 2000 files, see JPEG 2000.

# imread

| Supported Bits-per-sample | Lossy Compression | Lossless Compression | Output Class | Notes            |
|---------------------------|-------------------|----------------------|--------------|------------------|
| 8-bit                     | y                 | y                    | uint8        | Grayscale or RGB |
| 12-bit                    | y                 | y                    | uint16       | Grayscale or RGB |
| 16-bit                    | –                 | y                    | uint16       | Grayscale        |

## JPEG 2000 – Joint Photographic Experts Group 2000

For information about JPEG files, see JPEG.

---

**Note** Indexed JPEG 2000 images are not supported. Only JP2 compatible color spaces are supported for JP2/JPX files. By default, all image channels are returned in the order they are stored in the file.

---

| Supported Bits-per-sample | Lossy Compression | Lossless Compression | Output Class    | Notes            |
|---------------------------|-------------------|----------------------|-----------------|------------------|
| 1-bit                     | y                 | y                    | logical         | Grayscale only   |
| 2- to 8-bit               | y                 | y                    | uint8 or int8   | Grayscale or RGB |
| 9- to 16-bit              | y                 | y                    | uint16 or int16 | Grayscale or RGB |

Format-specific syntaxes:

```
[...] = imread(..., 'Param1', value1, 'Param2', value2, ...)
```

uses parameter-value pairs to control the read operation, described in the following table.

| Parameter        | Value                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'ReductionLevel' | A non-negative integer specifying the reduction in the resolution of the image. For a reduction level $L$ , the image resolution is reduced by a factor of $2^L$ . Its default value is 0 implying no reduction. The reduction level is limited by the total number of decomposition levels as specified by the 'WaveletDecompositionLevels' field in the structure returned by the imfinfo function. |
| 'PixelRegion'    | {ROWS, COLS} — The imread function returns the sub-image specified by the boundaries in ROWS and COLS. ROWS and COLS must both be two-element vectors that denote the 1-based indices [START STOP]. If 'ReductionLevel' is greater than 0, then ROWS and COLS are coordinates in the reduced-sized image.                                                                                             |
| 'V79Compatible'  | A logical value. If true, the image returned is transformed to grayscale or RGB, consistent with previous versions of imread (MATLAB 7.9 [R2009b] and earlier). Use this option to transform YCC images into RGB. The default is false.                                                                                                                                                               |

### PBM — Portable Bitmap

| Supported Bitdepths | Raw Binary | ASCII (Plain) Encoded | Output Class |
|---------------------|------------|-----------------------|--------------|
| 1-bit               | y          | y                     | logical      |

## PCX – Windows Paintbrush

| Supported Bitdepths | Output Class | Notes                            |
|---------------------|--------------|----------------------------------|
| 1-bit               | logical      | Grayscale only                   |
| 8-bit               | uint8        | Grayscale or indexed             |
| 24-bit              | uint8        | RGB<br>Three 8-bit samples/pixel |

## PGM – Portable Graymap

| Supported Bitdepths | Raw Binary | ASCII (Plain) Encoded | Output Class                                     | Notes             |
|---------------------|------------|-----------------------|--------------------------------------------------|-------------------|
| 8-bit               | y          | –                     | uint8                                            |                   |
| 16-bit              | y          | –                     | uint16                                           |                   |
| Arbitrary           | –          | y                     | 1-bit to 8-bit: uint8<br>9-bit to 16-bit: uint16 | Values are scaled |

## PNG – Portable Network Graphics

| Supported Bitdepths | Output Class | Notes                |
|---------------------|--------------|----------------------|
| 1-bit               | logical      | Grayscale            |
| 2-bit               | uint8        | Grayscale            |
| 4-bit               | uint8        | Grayscale            |
| 8-bit               | uint8        | Grayscale or Indexed |
| 16-bit              | uint16       | Grayscale or Indexed |

| Supported Bitdepths | Output Class | Notes                              |
|---------------------|--------------|------------------------------------|
| 24-bit              | uint8        | RGB<br>Three 8-bit samples/pixel.  |
| 48-bit              | uint16       | RGB<br>Three 16-bit samples/pixel. |

Format-specific syntaxes:

`[...] = imread(..., 'BackgroundColor', BG)` composites any transparent pixels in the input image against the color specified in BG. If BG is 'none', then no compositing is performed. If the input image is indexed, BG must be an integer in the range `[1, P]` where P is the colormap length. If the input image is grayscale, BG should be an integer in the range `[0, 1]`. If the input image is RGB, BG should be a three-element vector whose values are in the range `[0, 1]`. The string 'BackgroundColor' may be abbreviated.

`[A, map, alpha] = imread(...)` returns the alpha channel if one is present; otherwise alpha is `[]`. Note that map may be empty if the file contains a grayscale or truecolor image.

If you specify the alpha output argument, BG defaults to 'none', if not specified. Otherwise, if the PNG file contains a background color chunk, that color is used as the default value for BG. If alpha is not used and the file does not contain a background color chunk, then the default value for BG is 1 for indexed images; 0 for grayscale images; and `[0 0 0]` for truecolor (RGB) images.

## PPM – Portable Pixmap

| Supported Bitdepths | Raw Binary | ASCII (Plain) Encoded | Output Class |
|---------------------|------------|-----------------------|--------------|
| Up to 16-bit        | y          | –                     | uint8        |
| Arbitrary           | –          | y                     |              |

## RAS – Sun™ Raster

The following table lists the supported bitdepths, compression, and output classes for RAS files.

| Supported Bitdepths | Output Class | Notes                                      |
|---------------------|--------------|--------------------------------------------|
| 1-bit               | logical      | Bitmap                                     |
| 8-bit               | uint8        | Indexed                                    |
| 24-bit              | uint8        | RGB<br>Three 8-bit samples/pixel           |
| 32-bit              | uint8        | RGB with Alpha<br>Four 8-bit samples/pixel |

## TIFF – Tagged Image File Format

Most images supported by the TIFF specification or LibTIFF can be read by `imread`.

`imread` supports the following TIFF capabilities:

- Any number of samples-per-pixel
- CCITT group 3 and 4 FAX, Packbits, JPEG, LZW, Deflate, ThunderScan compression, and uncompressed images
- Logical, grayscale, indexed color, truecolor and hyperspectral images
- RGB, CMYK, CIELAB, ICCLAB color spaces. If the color image uses the CMYK color space, `A` is an M-by-N-by-4 array. To determine which color space is used, use `imfinfo` to get information about the graphics file and look at the value of the `PhotometricInterpretation` field. If a file contains CIELAB color data, `imread` converts it to ICCLAB before bringing it into the MATLAB workspace because 8- or 16-bit TIFF CIELAB-encoded values use a mixture of signed and unsigned data types that cannot be represented as a single MATLAB array.
- Data organized into tiles or scanlines

**Note**

- YCbCr images are converted into the RGB colorspace.
- All grayscale images are read as if black=0, white=largest value.
- 1-bit images are returned as class `logical`.
- CIELab images are converted into ICCLab colorspace.

The following are format-specific syntaxes for TIFF files.

`A = imread(...)` returns color data that uses the RGB, CIE LAB, ICCLAB, or CMYK color spaces. If the color image uses the CMYK color space, `A` is an M-by-N-by-4 array.

`[...] = imread(..., 'Param1', value1, 'Param2', value2, ...)` uses parameter/value pairs to control the read operation. The following table lists the parameters you can use.

| Parameter     | Value                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Index'       | Positive integer specifying which image to read. For example, if you specify the value 3, <code>imread</code> reads the third image in the file. If you omit this argument, <code>imread</code> reads the first image in the file.                                 |
| 'Info'        | Structure array returned by <code>imfinfo</code> .<br>Note: When reading images from a multi-image TIFF file, passing the output of <code>imfinfo</code> as the value of the 'Info' argument helps <code>imread</code> locate the images in the file more quickly. |
| 'PixelRegion' | Cell array, {Rows, Cols}, specifying the boundaries of the region. Rows and Cols must be either two- or three-element vectors. If you specify two elements, the values denote the 1-based indices [start stop]. If you specify                                     |

# imread

| Parameter | Value                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------|
|           | three elements, the values denote the 1-based indices [start increment stop], to allow image downsampling. |

For copyright information, see the `libtiffcopyright.txt` file.

## XWD – X Window Dump

The following table lists the supported bitdepths, compression, and output classes for XWD files.

| Supported Bitdepths | ZPixmap | XYBitmaps | XPixmap | Output Class |
|---------------------|---------|-----------|---------|--------------|
| 1-bit               | y       | –         | y       | logical      |
| 8-bit               | y       | –         | –       | uint8        |

## Class Support

For most image file formats, `imread` uses 8 or fewer bits per color plane to store image pixels. The following table lists the class of the returned array for the data types used by the file formats.

| Data Type Used in File       | Class of Array Returned by <code>imread</code>                                                      |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| 1-bit per pixel              | logical                                                                                             |
| 2- to 8-bits per color plane | uint8                                                                                               |
| 9- to 16-bit per pixel       | uint16 (BMP, JPEG, PNG, and TIFF)<br>For the 16-bit BMP packed format (5-6-5), MATLAB returns uint8 |

---

**Note** For indexed images, `imread` always reads the colormap into an array of class `double`, even though the image array itself may be of class `uint8` or `uint16`.

---

## Examples

### Read and Display Image

Read a sample image.

```
A = imread('ngc6543a.jpg');
```

`imread` returns a 650-by-600-by-3 array, `A`.

Display the image.

```
image(A)
```

# imread

---

## Convert Indexed Image to RGB

Read an image and convert it to an RGB image.

Read the first image in the sample indexed image file, `corn.tif`.

```
[X,map] = imread('corn.tif');
```

X is a 415-by-312 array of type `uint8`.

Verify that the colormap, `map`, is not empty, and convert the data in `X` to RGB.

```
if ~isempty(map)
    Im = ind2rgb(X,map);
end
```

View the size and class of `X`.

```
whos Im
```

| Name | Size      | Bytes   | Class  | Attributes |
|------|-----------|---------|--------|------------|
| Im   | 415x312x3 | 3107520 | double |            |

`X` is now a 415-by-312-by-3 array of type `double`.

### Read Specific Image in Multi-Page TIFF File

Read the third image in the sample file, `corn.tif`.

```
[X,map] = imread('corn.tif',3);
```

### Return Alpha Channel of PNG Image

Return the alpha channel of the sample image, `peppers.png`.

```
[X,map,alpha] = imread('peppers.png');
alpha
```

```
alpha =
```

```
[]
```

No alpha channel is present, so `alpha` is empty.

### Read Specified Region of TIFF Image

Read a specific region of pixels of the sample image, `corn.tif`.

Specify the `'PixelRegion'` parameter with a cell array of vectors indicating the boundaries of the region to read. The first vector specifies

# imread

---

the range of rows to read, and the second vector specifies the range of columns to read.

```
A = imread('corn.tif','PixelRegion',[1,2],[2,5]);
```

`imread` reads the image data in rows 1–2 and columns 2–5 from `corn.tif` and returns the 2-by-4 array, `A`.

## See Also

`double` | `fread` | `image` | `imfinfo` | `imformats` | `imwrite` | `ind2rgb` | `uint8` | `uint16`

**Purpose** Write image to graphics file

**Syntax**

```
imwrite(A,filename)
imwrite(A,map,filename)

imwrite( __ ,fmt)

imwrite( __ ,Name,Value)
```

**Description** `imwrite(A,filename)` writes image data `A` to the file specified by `filename`, inferring the file format from the extension. `imwrite` creates the new file in your current folder. The bit depth of the output image depends on the data type of `A` and the file format. For most formats:

- If `A` is of data type `uint8`, then `imwrite` outputs 8-bit values.
- If `A` is of data type `uint16` and the output file format supports 16-bit data (JPEG, PNG, and TIFF), then `imwrite` outputs 16-bit values. If the output file format does not support 16-bit data, then `imwrite` errors.
- If `A` is a grayscale or RGB color image of data type `double` or `single`, then `imwrite` assumes the dynamic range is `[0,1]` and automatically scales the data by 255 before writing it to the file as 8-bit values. If the data in `A` is `single`, convert `A` to `double` before writing to a GIF or TIFF file.
- If `A` is of data type `logical`, then `imwrite` assumes the data is a binary image and writes it to the file with a bit depth of 1, if the format allows it. BMP, PNG, or TIFF formats accept binary images as input arrays.

If `A` contains indexed image data, you should additionally specify the `map` input argument.

`imwrite(A,map,filename)` writes the indexed image in `A` and its associated colormap, `map`, to the file specified by `filename`.

- If `A` is an indexed image of data type `double` or `single`, then `imwrite` converts the indices to zero-based indices by subtracting 1 from each element, and then writes the data as `uint8`. If the data in `A` is `single`, convert `A` to `double` before writing to a GIF or TIFF file.

`imwrite( ___, fmt )` writes the image in the format specified by `fmt`, regardless of the file extension in `filename`. You can specify `fmt` after the input arguments in any of the previous syntaxes.

`imwrite( ___, Name, Value )` specifies additional parameters for output GIF, HDF, JPEG, PBM, PGM, PNG, PPM, and TIFF files, using one or more name-value pair arguments, in addition to any of the arguments in the previous syntaxes.

## Input Arguments

### **A - Image data to write**

`matrix`

Image data to write, specified as a full (nonsparse) matrix.

- For grayscale images, `A` can be `m-by-n`.
- For indexed images, `A` can be `m-by-n`. Specify the associated colormap in the `map` input argument.
- For truecolor images, `A` must be `m-by-n-by-3`.

For TIFF files, `A` can be an `m-by-n-by-4` array containing color data that uses the CMYK color space.

For multiframe GIF files, `A` can be an `m-by-n-by-1-by-p` array containing grayscale or indexed images, where `p` is the number of frames to write. RGB images are not supported in this case.

### **Data Types**

`double` | `single` | `uint8` | `uint16` | `logical`

### **filename - Name of output file**

`string`

Name of the output file including the file extension, specified as a string. For a list of the image types that `imwrite` can write, see the description for the `fmt` input argument.

**Example:** `'myFile.gif'`

### Data Types

char

### map - Colormap of indexed image

m-by-3 array

Colormap associated with indexed image data in `A`, specified as an m-by-3 array. `map` must be a valid MATLAB colormap. See `colormap` for a list of built-in MATLAB colormaps. Most image file formats do not support colormaps with more than 256 entries.

**Example:** `[0,0,0;0.5,0.5,0.5;1,1,1]`

**Example:** `jet(60)`

### Data Types

double

### fmt - Format of output file

string

Format of the output file, specified as one of the following strings.

This table also summarizes the types of images that `imwrite` can write. The MATLAB file format registry determines which file formats are supported. See `imformats` for more information about this registry.

For certain formats, `imwrite` can accept additional name-value pair arguments. To view these arguments, click the linked format names below.

| Value of fmt    | Format of Output File                             | Description                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'bmp'           | Windows Bitmap (BMP)                              | 1-bit, 8-bit, and 24-bit uncompressed images                                                                                                                                                                              |

| 'jpg' or 'jpeg' | Joint Photographic Experts Group (JPEG)           | 8-bit, 12-bit, and 16-bit Baseline JPEG images<br><hr/> <b>Note</b> <code>imwrite</code> converts indexed images to RGB before writing data to JPEG files, because the JPEG format does not support indexed images. <hr/> |
| 'jp2' or 'jpx'  | JPEG 2000 — Joint Photographic Experts Group 2000 | 1-bit, 8-bit, and 16-bit JPEG 2000 images                                                                                                                                                                                 |
| 'pbm'           | Portable Bitmap (PBM)                             | Any 1-bit PBM image, ASCII (plain) or raw (binary) encoding                                                                                                                                                               |
| 'pcx'           | Windows Paintbrush (PCX)                          | 8-bit images                                                                                                                                                                                                              |

| <b>Value of<br/>fmt</b> | <b>Format of<br/>Output File</b>         | <b>Description</b>                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'pgm'                   | Portable<br>Graymap<br>(PGM)             | Any standard PGM image; ASCII (plain) encoded with arbitrary color depth; raw (binary) encoded with up to 16 bits per gray value                                                                                                                          |
| 'png'                   | Portable<br>Network<br>Graphics<br>(PNG) | 1-bit, 2-bit, 4-bit, 8-bit, and 16-bit grayscale images; 8-bit and 16-bit grayscale images with alpha channels; 1-bit, 2-bit, 4-bit, and 8-bit indexed images; 24-bit and 48-bit truecolor images; 24-bit and 48-bit truecolor images with alpha channels |
| 'pnm'                   | Portable<br>Anymap<br>(PNM)              | Any of the PPM/PGM/PBM formats, chosen automatically                                                                                                                                                                                                      |
| 'ppm'                   | Portable<br>Pixmap<br>(PPM)              | Any standard PPM image: ASCII (plain) encoded with arbitrary color depth or raw (binary) encoded with up to 16 bits per color component                                                                                                                   |
| 'ras'                   | Sun Raster<br>(RAS)                      | Any RAS image, including 1-bit bitmap, 8-bit indexed, 24-bit truecolor and 32-bit truecolor with alpha                                                                                                                                                    |

| Value of <code>fmt</code> | Format of Output File           | Description                                                                                                                                                                                                                                                                                                            |
|---------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'tif' or 'tiff'           | Tagged Image File Format (TIFF) | Baseline TIFF images, including: <ul style="list-style-type: none"><li>• 1-bit, 8-bit, 16-bit, 24-bit, and 48-bit uncompressed images and images with packbits, LZW, or Deflate compression</li><li>• 1-bit images with CCITT 1D, Group 3, and Group 4 compression</li><li>• CIELAB, ICCLAB, and CMYK images</li></ul> |
| 'xwd'                     | X Windows Dump (XWD)            | 8-bit ZPixmap                                                                                                                                                                                                                                                                                                          |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `imwrite(A, 'myFile.png', 'BitDepth', 8)` writes the data in `A` using 8 bits to represent each pixel.

## GIF — Graphics Interchange Format

### 'BackgroundColor' - Color to use as background color

scalar integer

Color to use as background color for the indexed image, specified as the comma-separated pair consisting of 'BackgroundColor' and a scalar integer corresponding to the colormap index.

The background color is used for some disposal methods in animated GIFs.

- If image data A is `uint8` or `logical`, then the colormap index is zero-based.
- If image data A is `double`, then the colormap index is one-based.

The default background color corresponds to the first color in the colormap.

**Example:** `'BackgroundColor',15`

### **'Comment' - Comment to add to image**

`string` | cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of `'Comment'` and a string or a 1-by-n cell array of strings. For a cell array of strings, `imwrite` adds a carriage return after each string.

**Example:** `'Comment',{'Sample #314','January 5, 2013'}`

### **Data Types**

`char` | `cell`

### **'DelayTime' - Delay before displaying next image**

0.5 (default) | scalar value in the range [0,655]

Delay before displaying next image, in seconds, specified as the comma-separated pair consisting of `'DelayTime'` and a scalar value in the range [0,655]. A value of 0 displays images as fast as your hardware allows.

**Example:** `'DelayTime',60`

### **'DisposalMethod' - Disposal method of animated GIF**

`'doNotSpecify'` (default) | `'leaveInPlace'` | `'restoreBG'` | `'restorePrevious'`

Disposal method of an animated GIF, specified as the comma-separated pair consisting of `'DisposalMethod'` and one of the following strings.

| Value of DisposalMethod  | Result                                                                    |
|--------------------------|---------------------------------------------------------------------------|
| 'doNotSpecify' (default) | Replace one full-size, nontransparent frame with another.                 |
| 'leaveInPlace'           | Any pixels not covered up by the next frame continue to display.          |
| 'restoreBG'              | The background color or background tile shows through transparent pixels. |
| 'restorePrevious'        | Restore to the state of a previous, undisposed frame.                     |

**Example:** 'DisposalMethod', 'restoreBG'

### 'Location' - Offset of screen relative to image

[0,0] (default) | two-element vector

Offset of the screen relative to the image, measured from the top left corner of each, specified as the comma-separated pair consisting of 'Location' and a two-element vector. The first vector element specifies the offset from the top, and the second element specifies the offset from the left, in pixels.

**Example:** 'Location', [10,15]

### Data Types

double

### 'LoopCount' - Number of times to repeat animation

Inf (default) | Integer in the range [0, 65535]

Number of times to repeat the animation, specified as the comma-separated pair consisting of 'LoopCount' and either an integer in the range [0, 65535], or the value Inf. If you specify 0, the animation plays once. If you specify the value 1, the animation plays twice, and so on. A LoopCount value of Inf causes the animation to continuously loop.

To enable animation within Microsoft PowerPoint®, specify a value for 'LoopCount' within the range [1,65535]. Some Microsoft applications interpret the value 0 to mean do not loop at all.

**Example:** 'LoopCount',3

### **'ScreenSize' - Height and width of frame**

height and width of input image (default) | two-element vector

Height and width of the frame, specified as the comma-separated pair consisting of 'ScreenSize' and a two-element vector. When you use the ScreenSize argument with 'Location', it provides a way to write frames to the image that are smaller than the whole frame. 'DisposalMethod' determines the fill value for pixels outside the frame.

**Example:** 'ScreenSize',[1000 1060]

### **Data Types**

double

### **'TransparentColor' - Color to use as transparent color**

scalar integer

Color to use as transparent color for the image, specified as the comma-separated pair consisting of 'TransparentColor' and a scalar integer corresponding to the colormap index.

- If image data A is uint8 or logical, then indexing begins at 0.
- If image data A is double, then indexing begins at 1.

**Example:** 'TransparentColor',20

### **'WriteMode' - Writing mode**

'overwrite' (default) | 'append'

Writing mode, specified as the comma-separated pair consisting of 'WriteMode' and either 'overwrite' or 'append'. In overwrite mode, imwrite overwrites an existing file,filename. In append mode, imwrite adds a single frame to the existing file.

**Example:** 'WriteMode', 'append'

## HDF4 — Hierarchical Data Format

### 'Compression' - Compression scheme

'none' (default) | 'jpeg' | 'rle'

Compression scheme, specified as the comma-separated pair consisting of 'Compression' and one of the following strings.

| Value of Compression | Result                                                            |
|----------------------|-------------------------------------------------------------------|
| 'none' (default)     | No compression                                                    |
| 'jpeg'               | JPEG compression. Valid only for grayscale and RGB images.        |
| 'rle'                | Run-length encoding. Valid only for grayscale and indexed images. |

**Example:** 'Compression', 'jpeg'

### 'Quality' - Quality of JPEG-compressed file

75 (default) | scalar in the range [0,100]

Quality of the JPEG-compressed file, specified as the comma-separated pair consisting of 'Quality' and a scalar in the range [0,100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression. This parameter applies only if 'Compression' is 'jpeg'.

**Example:** 'Quality', 25

### 'WriteMode' - Writing mode

'overwrite' (default) | 'append'

Writing mode, specified as the comma-separated pair consisting of 'WriteMode' and either 'overwrite' or 'append'. In overwrite mode, `imwrite` overwrites an existing file, `filename`. In append mode, `imwrite` adds a single frame to the existing file.

**Example:** `'WriteMode','append'`

## JPEG — Joint Photographic Experts Group

### **'BitDepth' - Number of bits per pixel**

8 (default) | scalar

Number of bits per pixel, specified as the comma-separated pair consisting of `'BitDepth'` and a scalar.

- For grayscale images, the `BitDepth` value can be 8, 12, or 16. The default value is 8. For 16-bit images, the `'Mode'` name-value pair argument must be `'lossless'`.
- For color images, the `BitDepth` value is the number of bits per plane, and can be 8 or 12. The default is 8 bits per plane.

**Example:** `'BitDepth',12`

### **'Comment' - Comment to add to image**

string | character array | n-by-1 cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of `'Comment'` and a single string, a character array, or an n-by-1 cell array of strings. `imwrite` writes each row of input as a comment in the JPEG file.

**Example:** `'Comment',{'First line';'second line';'third line'}`

### **Data Types**

char | cell

### **'Mode' - Type of compression**

`'lossy'` (default) | `'lossless'`

Type of compression, specified as the comma-separated pair consisting of `'Mode'` and one of the following strings:

- `'lossy'`
- `'lossless'`

**Example:** 'Mode', 'lossless'

## **'Quality' - Quality of output file**

75 (default) | scalar in the range [0,100]

Quality of the output file, specified as the comma-separated pair consisting of 'Quality' and a scalar in the range [0,100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression. A Quality value of 100 does not write a lossless JPEG image. Instead, use the 'Mode', 'lossless' name-value pair argument.

**Example:** 'Quality', 100

## **JPEG 2000— Joint Photographic Experts Group 2000**

### **'Comment' - Comment to add to image**

string | character array | cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a single string, a character array, or a cell array of strings. `imwrite` writes each row of input as a comment in the JPEG 2000 file.

**Example:** 'Comment', {'First line'; 'second line'; 'third line'}

**Example:** 'Comment', {'First line', 'second line', 'third line'}

### **Data Types**

cell | char

### **'CompressionRatio' - Target compression ratio**

1 (default) | scalar

Target compression ratio, specified as the comma-separated pair consisting of 'CompressionRatio' and a real scalar greater than or equal to 1. The compression ratio is the ratio of the input image size to the output compressed size. For example, a value of 2.0 implies that the

output image size is half of the input image size or less. A higher value implies a smaller file size and reduced image quality. The compression ratio does not take into account the header size.

Specifying `CompressionRatio` is valid only when `'Mode'` is `'lossy'`.

**Example:** `'CompressionRatio',3`

### **'Mode' - Type of compression**

`'lossy'` (default) | `'lossless'`

Type of compression, specified as the comma-separated pair consisting of `'Mode'` and one of the following strings:

- `'lossy'`
- `'lossless'`

**Example:** `'Mode','lossless'`

### **'ProgressionOrder' - Order of packets in code stream**

`'LRCP'` (default) | `'RLCP'` | `'RPCL'` | `'PCRL'` | `'CPRL'`

Order of packets in the code stream, specified as the comma-separated pair consisting of `'ProgressionOrder'` and one of the following strings:

- `'LRCP'`
- `'RLCP'`
- `'RPCL'`
- `'PCRL'`
- `'CPRL'`

The characters in the text strings represent the following: L = layer, R = resolution, C = component and P = position.

**Example:** `'ProgressionOrder','RLCP'`

### **'QualityLayers' - Number of quality layers**

1 (default) | integer in the range [1,20]

Number of quality layers, specified as the comma-separated pair consisting of 'QualityLayers' and an integer in the range [1,20].

**Example:** 'QualityLayers',8

## **'ReductionLevels' - Number of reduction levels**

4 (default) | integer in the range [1,8]

Number of reduction levels, or wavelet decomposition levels, specified as the comma-separated pair consisting of 'ReductionLevels' and an integer in the range [1,8].

**Example:** 'ReductionLevels',6

## **'TileSize' - Tile height and width**

image size (default) | two-element vector

Tile height and width, specified as the comma-separated pair consisting of 'TileSize' and a two-element vector. The minimum size you can specify is [128 128].

**Example:** 'TileSize',[130 130]

## **PBM-, PGM-, and PPM — Portable Bitmap, Graymap, Pixmap**

### **'Encoding' - Encoding**

'rawbits' (default) | 'ASCII'

Encoding, specified as the comma-separated pair consisting of 'Encoding' and either 'rawbits' for binary encoding, or 'ASCII' for plain encoding.

**Example:** 'Encoding','ASCII'

### **'MaxValue' - Maximum gray or color value**

scalar

Maximum gray or color value, specified as the comma-separated pair consisting of 'MaxValue' and a scalar.

Available only for PGM and PPM files. For PBM files, this value is always 1.

If the image array is `uint16`, then the default value for `MaxValue` is 65535. Otherwise, the default value is 255.

**Example:** `'MaxValue',510`

### **PNG — Portable Network Graphics**

In addition to the following name-value pair arguments, you can use any parameter name that satisfies the PNG specification for keywords. That is, the name uses only printable characters, contains 80 or fewer characters, and does not contain leading or trailing spaces. The value corresponding to these user-specified names must be a string that contains no control characters other than linefeed.

#### **'Alpha' - Transparency of each pixel**

matrix of values in the range [0,1]

Transparency of each pixel, specified as the comma-separated pair consisting of `'Alpha'` and a matrix of values in the range [0,1]. The row and column dimensions of the Alpha matrix must be the same as those of the image data array. You can specify Alpha only for grayscale (m-by-n) and truecolor (m-by-n-by-3) image data.

---

**Note** You cannot specify both `'Alpha'` and `'Transparency'` at the same time.

---

#### **Data Types**

`double` | `uint8` | `uint16`

#### **'Author' - Author information**

string

Author information, specified as the comma-separated pair consisting of `'Author'` and a string.

**Example:** "Author", 'Ann Smith'

## Data Types

char

## 'Background' - Background color when compositing transparent pixels

scalar in the range [0,1] | integer in the range [1,P] | 3-element vector in the range [0,1]

Background color when compositing transparent pixels, specified as the comma-separated pair consisting of 'Background' and a value dependent on the image data, as follows.

| Image Type       | Form of Background Value                                                                                                                                                     |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Grayscale images | Scalar in the range [0,1].                                                                                                                                                   |
| Indexed images   | Integer in the range [1,P], where P is the colormap length. For example, 'Background',50 sets the background color to the color specified by the 50th index in the colormap. |
| Truecolor images | Three-element vector of RGB intensities in the range [0,1]. For example, 'Background',[0 1 1] sets the background color to cyan.                                             |

## Data Types

double

## 'BitDepth' - Number of bits per pixel

scalar

Number of bits per pixel, specified as the comma-separated pair consisting of 'BitDepth' and a scalar. Depending on the output image, the scalar can be one of the following values.

| <b>Image Type</b>                      | <b>Allowed Values for BitDepth</b> |
|----------------------------------------|------------------------------------|
| Grayscale images                       | 1, 2, 4, 8, or 16                  |
| Grayscale images with an alpha channel | 8 or 16                            |
| Indexed images                         | 1, 2, 4, or 8                      |
| Truecolor images                       | 8 or 16                            |

- If the image is of class `double` or `uint8`, then the default bit depth is 8 bits per pixel.
- If the image is `uint16`, then the default is 16 bits per pixel.
- If the image is `logical`, then the default is 1 bit per pixel.

**Example:** `'BitDepth',4`

### **'Chromaticities' - Reference white point and primary chromaticities**

8-element vector

Reference white point and primary chromaticities, specified as the comma-separated pair consisting of `'Chromaticities'` and an 8-element vector, `[wx wy rx ry gx gy bx by]`. The elements `wx` and `wy` are the chromaticity coordinates of the white point, and the elements `rx`, `ry`, `gx`, `gy`, `bx`, and `by` are the chromaticity coordinates of the three primary colors.

If you specify `Chromaticities`, you should also specify the `Gamma` name-value pair argument.

**Example:**

`'Chromaticities',[0.312,0.329,0.002,0.002,0.001,0.001,0.115,0.312]`

### **Data Types**

`double`

### **'Comment' - Comment to add to image**

`string`

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a string.

## **'Copyright' - Copyright notice**

string

Copyright notice, specified as the comma-separated pair consisting of 'Copyright' and a string.

## **'CreationTime' - Time of original image creation**

string

Time of original image creation, specified as a string.

## **'Description' - Description of image**

string

Description of the image, specified as the comma-separated pair consisting of 'Description' and a string.

## **'Disclaimer' - Legal disclaimer**

string

Legal disclaimer, specified as the comma-separated pair consisting of 'Disclaimer' and a string.

## **'Gamma' - File gamma**

scalar

File gamma, specified as the comma-separated pair consisting of 'Gamma' and a scalar.

**Example:** 'Gamma',2.2

## **'ImageModTime' - Time of last image modification**

serial date number | date string

Time of the last image modification, specified as the comma-separated pair consisting of 'ImageModTime' and a MATLAB serial date number

or a date string that can be converted to a date vector using the `datevec` function. Values should be in Coordinated Universal Time (UTC).

The default `ImageModTime` value is the time when you call `imwrite`.

**Example:** `'ImageModTime','17-Jan-2013 11:23:10'`

### **Data Types**

`double` | `char`

### **'InterlaceType' - Interlacing scheme**

`'none'` (default) | `'adam7'`

Interlacing scheme, specified as the comma-separated pair consisting of `'InterlaceType'` and either `'none'` for no interlacing, or `'adam7'` to use the Adam7 algorithm.

**Example:** `'InterlaceType','adam7'`

### **'ResolutionUnit' - Unit for image resolution**

`'unknown'` (default) | `'meter'`

Unit for image resolution, specified as the comma-separated pair consisting of `'ResolutionUnit'` and either `'unknown'` or `'meter'`. If you specify `ResolutionUnit`, you must include at least one of the `XResolution` and `YResolution` name-value pair arguments. When the value of `ResolutionUnit` is `'meter'`, the `XResolution` and `YResolution` values are interpreted in pixels per meter.

**Example:** `'ResolutionUnit','meter','XResolution',1000`

### **'SignificantBits' - Number of bits to regard as significant**

`[]` (default) | `scalar` | `vector`

Number of bits in the data array to regard as significant, specified as the comma-separated pair consisting of `'SignificantBits'` and a scalar or a vector in the range `[1,BitDepth]`. Depending on the output image type, the value must be in the following form.

| Image Type                               | Form of SignificantBits Value |
|------------------------------------------|-------------------------------|
| Grayscale image without an alpha channel | Scalar                        |
| Grayscale image with an alpha channel    | 2-element vector              |
| Indexed image                            | 3-element vector              |
| Truecolor image without an alpha channel | 3-element vector              |
| Truecolor image with an alpha channel    | 4-element vector              |

**Example:** 'SignificantBits',[2,3]

### **'Software' - Software used to create the image**

string

Software used to create the image, specified as the comma-separated pair consisting of 'Software' and a string.

### **'Source' - Device used to create the image**

string

Device used to create the image, specified as the comma-separated pair consisting of 'Source' and a string.

### **'Transparency' - Pixels to consider transparent**

[ ] (default) | scalar in the range [0,1] | vector

Pixels to consider transparent when no alpha channel is used, specified as the comma-separated pair consisting of 'Transparency' and a scalar or a vector. Depending on the output image, the value must be in the following form.

| <b>Image Type</b> | <b>Form of Transparency Value</b>                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Grayscale images  | Scalar in the range [0,1], indicating the grayscale color to be considered transparent.                                                                                                                        |
| Indexed images    | Q-element vector of values in the range [0,1], where Q is no larger than the colormap length and each value indicates the transparency associated with the corresponding colormap entry. In most cases, Q = 1. |
| Truecolor images  | 3-element vector of RGB intensities in the range [0,1], indicating the truecolor color to consider transparent.                                                                                                |

---

**Note** You cannot specify both 'Transparency' and 'Alpha' at the same time.

---

**Example:** 'Transparency',[1 1 1]

#### **Data Types**

double

#### **'Warning' - Warning of nature of content**

string

Warning of nature of content, specified as the comma-separated pair consisting of 'Warning' and a string.

#### **'XResolution' - Image resolution in horizontal direction**

scalar

Image resolution in the horizontal direction, in pixels/unit, specified as the comma-separated pair consisting of 'XResolution' and a scalar. Define the unit by specifying the ResolutionUnit name-value pair argument.

If you do not also specify YResolution, then the XResolution value applies to both the horizontal and vertical directions.

**Example:** 'XResolution',900

### **'YResolution' - Image resolution in vertical direction**

scalar

Image resolution in the vertical direction, in pixels/unit, specified as the comma-separated pair consisting of 'YResolution' and a scalar. Define the unit by specifying the ResolutionUnit name-value pair argument.

If you do not also specify XResolution, then the YResolution value applies to both the horizontal and vertical directions.

**Example:** 'YResolution',900

## **RAS — Sun Raster Graphic**

### **'Alpha' - Transparency of each pixel**

[] (default) | matrix

Transparency of each pixel, specified as the comma-separated pair consisting of 'Alpha' and a matrix with row and column dimensions the same as those of the image data array.

Valid only for truecolor (m-by-n-by-3) image data.

### **Data Types**

double | single | uint8 | uint16

### **'Type' - Image type**

'standard' (default) | 'rgb' | 'rle'

Image type, specified as the comma-separated pair consisting of 'Type' and one of the following strings.

| Value of Type        | Description                                          |
|----------------------|------------------------------------------------------|
| 'standard' (default) | Uncompressed, B-G-R color order for truecolor images |
| 'rgb'                | Uncompressed, R-G-B color order for truecolor images |
| 'rle'                | Run-length encoding of 1-bit and 8-bit images        |

Example: 'Type', 'rgb'

## TIFF — Tagged Image File Format

### 'ColorSpace' - Color space representing color data

'rgb' (default) | 'cielab' | 'icclab'

Color space representing the color data, specified as the comma-separated pair consisting of 'ColorSpace' and one of the following strings:

- 'rgb'
- 'cielab'
- 'icclab'

Valid only when the image data array, A, is truecolor (m-by-n-by-3). To use the CMYK color space in a TIFF file, do not use the 'ColorSpace' name-value pair argument. Instead, specify an m-by-n-by-4 image data array.

imwrite can write color image data that uses the  $L^*a^*b^*$  color space to TIFF files. The 1976 CIE  $L^*a^*b^*$  specification defines numeric values that represent luminance ( $L^*$ ) and chrominance ( $a^*$  and  $b^*$ ) information. To store  $L^*a^*b^*$  color data in a TIFF file, the values must be encoded to fit into either 8-bit or 16-bit storage. imwrite can store  $L^*a^*b^*$  color data in a TIFF file using the following encodings:

- CIELAB encodings — 8-bit and 16-bit encodings defined by the TIFF specification

- ICCLAB encodings — 8-bit and 16-bit encodings defined by the International Color Consortium

The output class and encoding used by `imwrite` depends on the class of the input image data array and the `ColorSpace` value, as shown in the following table. (The 8-bit and 16-bit CIELAB encodings cannot be input arrays because they use a mixture of signed and unsigned values and cannot be represented as a single MATLAB array.)

| Input Class and Encoding                                                                                                                                                             | Value of ColorSpace | Output Class and Encoding |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|---------------------------|
| 8-bit ICCLAB<br><br>Values are integers in the range [0 255]. $L^*$ values are multiplied by 255/100. 128 is added to both the $a^*$ and $b^*$ values.                               | 'icclab'            | 8-bit ICCLAB              |
|                                                                                                                                                                                      | 'cielab'            | 8-bit CIELAB              |
| 16-bit ICCLAB<br><br>Values are integers in the range [0, 65280]. $L^*$ values are multiplied by 65280/100. 32768 is added to both the $a^*$ and $b^*$ values, which are represented | 'icclab'            | 16-bit ICCLAB             |
|                                                                                                                                                                                      | 'cielab'            | 16-bit CIELAB             |

| Input Class and Encoding                                                                                                                                                                             | Value of ColorSpace | Output Class and Encoding |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|---------------------------|
| as integers in the range [0,65535].                                                                                                                                                                  |                     |                           |
| Double-precision 1976 CIE $L^*a^*b^*$ values<br><br>$L^*$ is in the dynamic range [0, 100]. $a^*$ and $b^*$ can take any value. Setting $a^*$ and $b^*$ to 0 (zero) produces a neutral color (gray). | 'icclab'            | 8-bit ICCLAB              |
|                                                                                                                                                                                                      | 'cielab'            | 8-bit CIELAB              |

**Example:** 'ColorSpace','cielab'

### 'Compression' - Compression scheme

'packbits' | 'none' | 'lzw' | 'deflate' | 'jpeg' | 'ccitt' | 'fax3' | 'fax4'

Compression scheme, specified as the comma-separated pair consisting of 'Compression' and one of the following strings:

- 'packbits' (default for nonbinary images)
- 'none'
- 'lzw'
- 'deflate'
- 'jpeg'
- 'ccitt' (binary images only, and the default for such images)
- 'fax3' (binary images only)

- 'fax4' (binary images only)

'jpeg' is a lossy compression scheme; other compression modes are lossless. Also, if you specify 'jpeg' compression, you must specify the 'RowsPerStrip' parameter and the value must be a multiple of 8.

**Example:** 'Compression','none'

## **'Description' - Image description**

string

Image description, specified by the comma-separated pair consisting of 'Description' and a string. This is the text that `imfinfo` returns in the ImageDescription field for the output image.

**Example:** 'Description','Sample 2A301'

## **'Resolution' - X- and Y-resolution**

72 (default) | scalar | two-element vector

X- and Y-resolution, specified as the comma-separated pair consisting of 'Resolution' and a scalar indicating both resolution, or a two-element vector containing the X-Resolution and Y-Resolution.

**Example:** 'Resolution',80

**Example:** 'Resolution',[320,72]

## **Data Types**

double

## **'RowsPerStrip' - Number of rows to include in each strip**

scalar

Number of rows to include in each strip, specified as the comma-separated pair consisting of 'RowsPerStrip' and a scalar. The default value is such that each strip is about 8 kilobytes.

You must specify RowsPerStrip if you specify 'jpeg' compression. The value must be a multiple of 8.

**Example:** 'RowsPerStrip',16

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**'WriteMode' - Writing mode**

'overwrite' (default) | 'append'

Writing mode, specified as the comma-separated pair consisting of 'WriteMode' and either 'overwrite' or 'append'. In overwrite mode, `imwrite` overwrites an existing file. In append mode, `imwrite` adds a page to the existing file.

**Example:** 'WriteMode', 'append'

**Examples****Resize and Save Image**

Read the sample image, `ngc6543a.jpg`, and the resize it to 500-by-500.

```
A = imread('ngc6543a.jpg');  
B = imresize(A,[500 500]);
```

Write the resized image data, `B`, to a file.

```
imwrite(B,'myNewFile.tif');
```

`imwrite` writes the file, `myNewFile.tif`, to the current folder.

**Write Indexed Image Data to PNG**

Write an indexed image array and its associated colormap to a PNG file.

Load sample image data from the file, `clown.mat`.

```
load clown.mat
```

The image array `X` and its associated colormap, `map`, are loaded into the MATLAB workspace.

Write the data to a new PNG file.

```
imwrite(X,map,'myclown.png')
```

`imwrite` creates the file, `myclown.png`, in your current folder.

View the new file by opening it outside of MATLAB.

## Write Indexed Image with MATLAB Colormap

Write image data to a new PNG file with the built-in MATLAB colormap, `copper`.

Load sample image data from the file `clown.mat`.

```
load clown.mat
```

The image array `X` and its associated colormap, `map`, are loaded into the MATLAB workspace. `map` is a matrix of 81 RGB vectors.

Define a copper-tone colormap with 81 RGB vectors. Then, write the image data to a PNG file using the new colormap.

```
newmap = copper(81);
```

```
imwrite(X,newmap,'copperclown.png');
```

`imwrite` creates the file, `copperclown.png`, in your current folder.

View the new file by opening it outside of MATLAB.

### **Write Grayscale Image to PNG**

Write a 50-by-50 array, `A`, of grayscale values to a PNG file.

```
A = rand(50,50);  
imwrite(A,'myGray.png','png');
```

The third input, `'png'`, specifies that the output file is a PNG file.

### **Write Truecolor Image to JPEG**

Create and write truecolor image data to a JPEG file.

Create a 49-by-49-by-3 array of random RGB values.

```
A = rand(49,49);  
A(:,:,2) = rand(49,49);  
A(:,:,3) = rand(49,49);
```

Write the image data to a JPEG file, specifying the output format using the string, 'jpg'. Add a comment to the file using the 'Comment' name-value pair argument.

```
imwrite(A,'newImage.jpg','jpg','Comment','My JPEG file')
```

View information about the new file.

```
imfinfo('newImage.jpg')
```

```
ans =
```

```
      Filename: 'S:\newImage.jpg'  
      FileModDate: '25-Jan-2013 16:18:41'  
      FileSize: 2339  
      Format: 'jpg'  
      FormatVersion: ''  
      Width: 49  
      Height: 49  
      BitDepth: 24  
      ColorType: 'truecolor'  
      FormatSignature: ''  
      NumberOfSamples: 3  
      CodingMethod: 'Huffman'  
      CodingProcess: 'Sequential'  
      Comment: {'My JPEG file'}
```

## Write Multiple Images to TIFF File

Write multiple images to a single multipage TIFF file.

Create two sets of random image data, im1 and im2.

```
im1 = rand(50,40,3);  
im2 = rand(50,50,3);
```

Write the first image to a new TIFF file. Then, append the second image to the same file.

```
imwrite(im1,'myMultipageFile.tif');  
imwrite(im2,'myMultipageFile.tif','WriteMode','append');
```

## Write Animated GIF

Animate a series of plots and write the result to a GIF file.

Define the x-axis limits for the plot and specify the output file name.

```
x = 0:0.01:1;  
figure  
filename = 'testAnimated.gif';
```

Call `frame2im` to get image data from a single movie frame. Because three-dimensional data is not supported for GIF files, call `rgb2ind` to convert the RGB data in the image data, `im`, to an indexed image, `A`, with a colormap, `map`. Call `imwrite` with the name-value pair argument, `'WriteMode','append'`, to append multiple images to the first image.

```
for n = 1:0.5:5  
    y = x.^n;  
    plot(x,y)  
    drawnow  
    frame = getframe(1);  
    im = frame2im(frame);  
    [A,map] = rgb2ind(im,256);  
    if n == 1;  
        imwrite(A,map,filename,'gif','LoopCount',Inf,'DelayTime',1);  
    else  
        imwrite(A,map,filename,'gif','WriteMode','append','DelayTime',1);  
    end  
end
```

`imwrite` writes the GIF file to your current folder. Name-value pair `'LoopCount',Inf` causes the animation to continuously loop.

# imwrite

---

'DelayTime', 1 specifies a 1-second delay between the display of each image in the animation.

**Purpose** (Will be removed) Incenters of specified simplices

---

**Note** `incenters(TriRep)` will be removed in a future release. Use `incenter(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax**

```
IC = inceters(TR,SI)
[IC RIC] = inceters(TR, SI)
```

**Description**

`IC = inceters(TR,SI)` returns the coordinates of the incenter of each specified simplex `SI`.

`[IC RIC] = inceters(TR, SI)` returns the inceters and the corresponding radius of the inscribed circle/sphere.

**Input Arguments**

|    |                                                                                                                                                                                                                                                                                                                               |
|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TR | Triangulation representation.                                                                                                                                                                                                                                                                                                 |
| SI | Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If <code>SI</code> is not specified the incenter information for the entire triangulation is returned, where the incenter associated with simplex <code>i</code> is the <code>i</code> 'th row of <code>IC</code> . |

**Output Arguments**

|     |                                                                                                                                                                                                                                                                                                              |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IC  | <code>m</code> -by- <code>n</code> matrix, where <code>m = length(SI)</code> , the number of specified simplices, and <code>n</code> is the dimension of the space where the triangulation resides. Each row <code>IC(i,:)</code> represents the coordinates of the incenter of simplex <code>SI(i)</code> . |
| RIC | Vector of length <code>length(SI)</code> , the number of specified simplices.                                                                                                                                                                                                                                |

# TriRep.incenters

---

## Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## Examples

### Example 1

Load a 3-D triangulation:

```
load tetmesh
```

Use TriRep to compute the incenters of the first five tetrahedra.

```
trep = TriRep(tet, X)
ic = incenters(trep, [1:5]')
```

### Example 2

Query a 2-D triangulation created with DelaunayTri.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Compute incenters of the triangles:

```
ic = incenters(dt);
```

Plot the triangles and incenters:

```
triplot(dt);
axis equal;
axis([-0.2 1.2 -0.2 1.2]);
hold on;
plot(ic(:,1),ic(:,2),'*r');
hold off;
```

# DelaunayTri.inOutStatus

---

**Purpose** (Will be removed) Status of triangles in 2-D constrained Delaunay triangulation

---

**Note** `inOutStatus(DelaunayTri)` will be removed in a future release. Use `isInterior(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

**Syntax** `IN = inOutStatus(DT)`

**Description** `IN = inOutStatus(DT)` returns the in/out status of the triangles in a 2-D constrained Delaunay triangulation of a geometric domain. Given a Delaunay triangulation that has a set of constrained edges that define a bounded geometric domain. The *i*'th triangle in the triangulation is classified as inside the domain if `IN(i) = 1` and outside otherwise.

---

**Note** `inOutStatus` is only relevant for 2-D constrained Delaunay triangulations where the imposed edge constraints bound a closed geometric domain.

---

**Input Arguments** `DT` Delaunay triangulation.

**Output Arguments** `IN` Logical array of length equal to the number of triangles in the triangulation. The constrained edges in the triangulation define the boundaries of a valid geometric domain.

## Examples

Create a geometric domain that consists of a square with a square hole:

```
outerprofile = [-5 -5; -3 -5; -1 -5; 1 -5; 3 -5; ...  
 5 -5; 5 -3; 5 -1; 5 1; 5 3;...  
 5 5; 3 5; 1 5; -1 5; -3 5; ...  
 -5 5; -5 3; -5 1; -5 -1; -5 -3; ];  
innerprofile = outerprofile.*0.5;  
profile = [outerprofile; innerprofile];  
outercons = [(1:19)' (2:20)'; 20 1;];  
innercons = [(21:39)' (22:40)'; 40 21];  
edgeconstraints = [outercons; innercons];
```

Create a constrained Delaunay triangulation of the domain:

```
dt = DelaunayTri(profile, edgeconstraints)  
subplot(1,2,1);  
triplot(dt);  
hold on;  
plot(dt.X(outercons',1), dt.X(outercons',2), ...  
      '-r', 'LineWidth', 2);  
plot(dt.X(innercons',1), dt.X(innercons',2), ...  
      '-r', 'LineWidth', 2);  
axis equal;  
% Plot showing interior and exterior  
% triangles with respect to the domain.  
hold off;  
subplot(1,2,2);  
inside = inOutStatus(dt);  
triplot(dt(inside, :), dt.X(:,1), dt.X(:,2));  
hold on;  
plot(dt.X(outercons',1), dt.X(outercons',2), ...  
      '-r', 'LineWidth', 2);  
plot(dt.X(innercons',1), dt.X(innercons',2), ...  
      '-r', 'LineWidth', 2);  
axis equal;  
% Plot showing interior triangles only  
hold off;
```

# ind2sub

---

**Purpose** Subscripts from linear index

**Syntax** `[I,J] = ind2sub(siz,IND)`  
`[I1,I2,I3,...,In] = ind2sub(siz,IND)`

**Description** The `ind2sub` command determines the equivalent subscript values corresponding to a single index into an array.

`[I,J] = ind2sub(siz,IND)` returns the matrices `I` and `J` containing the equivalent row and column subscripts corresponding to each linear index in the matrix `IND` for a matrix of size `siz`. `siz` is a vector with `ndim(A)` elements (in this case, 2), where `siz(1)` is the number of rows and `siz(2)` is the number of columns.

---

**Note** For matrices, `[I,J] = ind2sub(size(A),find(A>5))` returns the same values as `[I,J] = find(A>5)`.

---

`[I1,I2,I3,...,In] = ind2sub(siz,IND)` returns `n` subscript arrays `I1,I2,...,In` containing the equivalent multidimensional array subscripts equivalent to `IND` for an array of size `siz`. `siz` is an `n`-element vector that specifies the size of each array dimension.

## Examples **Example 1 – Two-Dimensional Matrices**

The mapping from linear indexes to subscript equivalents for a 3-by-3 matrix is

This code determines the row and column subscripts in a 3-by-3 matrix, of elements with linear indices 3, 4, 5, 6.

```
IND = [3 4 5 6]
s = [3,3];
[I,J] = ind2sub(s,IND)
```

```
I =
     3     1     2     3
```

```
J =
     1     2     2     2
```

### Example 2 – Three-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 2-by-2-by-2 array is

# ind2sub

This code determines the subscript equivalents in a 2-by-2-by-2 array, of elements whose linear indices 3, 4, 5, 6 are specified in the IND matrix.

```
IND = [3 4;5 6];  
s = [2,2,2];  
[I,J,K] = ind2sub(s,IND)
```

I =

```
1 2  
1 2
```

J =

```
2 2  
1 1
```

K =

```
1 1  
2 2
```

## Example 3 – Effects of Returning Fewer Outputs

When calling `ind2sub` for an N-dimensional matrix, you would typically supply N output arguments in the call: one for each dimension of the matrix. This example shows what happens when you return three, two, and one output when calling `ind2sub` on a 3-dimensional matrix.

The matrix is 2-by-2-by-2 and the linear indices are 1 through 8:

```
dims = [2 2 2];  
indices = [1 2 3 4 5 6 7 8];
```

The 3-output call to `ind2sub` returns the expected subscripts for the 2-by-2-by-2 matrix:

```
[rowsub colsub pagsub] = ind2sub(dims, indices)  
rowsub =  
     1     2     1     2     1     2     1     2  
colsub =  
     1     1     2     2     1     1     2     2  
pagsub =  
     1     1     1     1     2     2     2     2
```

If you specify only two outputs (row and column), `ind2sub` still returns a subscript for each specified index, but drops the third dimension from the matrix, returning subscripts for a 2-dimensional, 2-by-4 matrix instead:

```
[rowsub colsub] = ind2sub(dims, indices)  
rowsub =  
     1     2     1     2     1     2     1     2  
colsub =  
     1     1     2     2     3     3     4     4
```

If you specify one output (row), `ind2sub` drops both the second and third dimensions from the matrix, and returns subscripts for a 1-dimensional, 1-by-8 matrix instead:

```
[rowsub] = ind2sub(dims, indices)  
rowsub =  
     1     2     3     4     5     6     7     8
```

# Inf

---

**Purpose** Infinity

**Syntax**

```
Inf
Inf('double')
Inf('single')
Inf(n)
Inf(m,n)
Inf(m,n,p,...)
Inf(...,classname)
Inf(...,'like',p)
```

**Description** Inf returns the IEEE arithmetic representation for positive infinity. Infinity results from operations like division by zero and overflow, which lead to results too large to represent as conventional floating-point values.

Inf('double') is the same as Inf with no inputs.

Inf('single') is the single precision representation of Inf.

Inf(n) is an n-by-n matrix of Infs.

Inf(m,n) or inf([m,n]) is an m-by-n matrix of Infs.

Inf(m,n,p,...) or Inf([m,n,p,...]) is an m-by-n-by-p-by-... array of Infs.

---

**Note** The size inputs m, n, p, ... should be nonnegative integers. Negative integers are treated as 0.

---

Inf(...,classname) is an array of Infs of class specified by the string classname. classname can be either 'single' or 'double'.

Inf(...,'like',p) is an array of Infs of the same data type, sparsity, and complexity (real or complex) as the single or double precision numeric variable p.

**Examples**

$1/0$ ,  $1.e1000$ ,  $2^{2000}$ , and  $\exp(1000)$  all produce Inf.

$\log(0)$  produces -Inf.

Inf - Inf and Inf/Inf both produce NaN (Not-a-Number).

`isinf` | NaN

# inferiorto

---

**Purpose** Specify inferior class relationship

**Syntax** `inferiorto('class1','class2',...)`

**Description** `inferiorto('class1','class2',...)` establishes that the class invoking this function in its constructor has lower precedence than the classes in the argument list. MATLAB uses this precedence to determine which method or function MATLAB calls in any given situation.

Use this function only from a constructor that calls the `class` function to create objects (classes defined before MATLAB 7.6).

**Examples** Specify class precedence.

Suppose `a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. Suppose the constructor method of `class_c` contains the statement:

```
inferiorto('class_a')
```

This function call establishes `class_a` as taking precedence over `class_c` for function dispatching. Therefore, either of the following two statements:

```
e = fun(a,c);  
e = fun(c,a);
```

Invoke `class_a`/fun.

If you call a function with two objects having an unspecified relationship, the two objects have equal precedence. In this case, MATLAB calls the method of the left-most object. So `fun(b, c)` calls `class_b`/fun, while `fun(c, b)` calls `class_c`/fun.

| <b>Purpose</b>       | Construct inline object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Compatibility</b> | <code>inline</code> will be removed in a future release. Use “Anonymous Functions” instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax</b>        | <code>inline(expr)</code><br><code>inline(expr, arg1, arg2, ...)</code><br><code>inline(expr, n)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>   | <p><code>inline(expr)</code> constructs an inline function object from the MATLAB expression contained in the string <code>expr</code>. The input argument to the inline function is automatically determined by searching <code>expr</code> for an isolated lower case alphabetic character, other than <code>i</code> or <code>j</code>, that is not part of a word formed from several alphabetic characters. If no such character exists, <code>x</code> is used. If the character is not unique, the one closest to <code>x</code> is used. If two characters are found, the one later in the alphabet is chosen.</p> <p><code>inline(expr, arg1, arg2, ...)</code> constructs an inline function whose input arguments are specified by the strings <code>arg1, arg2, ...</code>. Multicharacter symbol names may be used.</p> <p><code>inline(expr, n)</code> where <code>n</code> is a scalar, constructs an inline function whose input arguments are <code>x, P1, P2, ...</code>.</p> |
| <b>Tips</b>          | <p>Three commands related to <code>inline</code> allow you to examine an inline function object and determine how it was created.</p> <p><code>char(fun)</code> converts the inline function into a character array. This is identical to <code>formula(fun)</code>.</p> <p><code>argnames(fun)</code> returns the names of the input arguments of the inline object <code>fun</code> as a cell array of strings.</p> <p><code>formula(fun)</code> returns the formula for the inline object <code>fun</code>.</p> <p>A fourth command <code>vectorize(fun)</code> inserts a <code>.</code> before any <code>^</code>, <code>*</code> or <code>/</code> in the formula for <code>fun</code>. The result is a vectorized version of the inline function.</p>                                                                                                                                                                                                                                     |

## Examples

### Example 1

This example creates a simple inline function to square a number.

```
g = inline('t^2')
g =
```

```
    Inline function:
    g(t) = t^2
```

You can convert the result to a string using the char function.

```
char(g)
```

```
ans =
```

```
t^2
```

### Example 2

This example creates an inline function to represent the formula  $f = 3\sin(2x^2)$ . The resulting inline function can be evaluated with the argnames and formula functions.

```
f = inline('3*sin(2*x.^2)')
```

```
f =
```

```
    Inline function:
    f(x) = 3*sin(2*x.^2)
```

```
argnames(f)
```

```
ans =
```

```
    'x'
```

```
formula(f)
```

```
ans =
```

```
3*sin(2*x.^2)
```

### Example 3

This call to `inline` defines the function `f` to be dependent on two variables, `alpha` and `x`:

```
f = inline('sin(alpha*x)')  
  
f =  
    Inline function:  
    f(alpha,x) = sin(alpha*x)
```

If `inline` does not return the desired function variables or if the function variables are in the wrong order, you can specify the desired variables explicitly with the `inline` argument list.

```
g = inline('sin(alpha*x)', 'x', 'alpha')  
  
g =  
    Inline function:  
    g(x,alpha) = sin(alpha*x)
```

**Purpose**

Names of functions, MEX-files, classes in memory

**Syntax**

```
M = inmem
[M,X] = inmem
[M,X,C] = inmem
[...] = inmem('-completenames')
```

**Description**

`M = inmem` returns a cell array of strings containing the names of the functions that are currently loaded.

`[M,X] = inmem` returns an additional cell array `X` containing the names of the MEX-files that are currently loaded.

`[M,X,C] = inmem` also returns a cell array `C` containing the names of the classes that are currently loaded.

`[...] = inmem('-completenames')` returns not only the names of the currently loaded function and MEX-files, but the path and filename extension for each as well. No additional information is returned for loaded classes.

**Examples****Functions in Memory**

List the functions that remain in memory after calling the `magic` function.

```
clear all
magic(10);

M = inmem

M =
    'workspacefunc'
    'magic'
```

The function list includes `magic` and additional functions that are in memory in your current session.

## **MEX-Files in Memory**

Call a sample MEX-function named `arrayProduct`, and then verify that the MEX-function is in memory.

```
clear all
sampleFolder = fullfile(matlabroot,'extern','examples','mex');
addpath(sampleFolder);
```

```
s = 5;
A = [1.5, 2, 9];
B = arrayProduct(s,A);
```

```
[M,X] = inmem('-completenames');
X
```

```
X =
    'matlabroot\extern\examples\mex\arrayProduct.mexw64'
```

## **See Also**

```

```

**Purpose** Inner join between two tables

**Syntax**

```
C = innerjoin(A,B)
C = innerjoin(A,B,Name,Value)
[C,ia,ib] = innerjoin( ___ )
```

**Description** `C = innerjoin(A,B)` creates the table, `C`, as the inner join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The inner join retains only the rows that match between `A` and `B` with respect to the key variables. `C` contains all nonkey variables from `A` and `B`.

`C = innerjoin(A,B,Name,Value)` performs the inner-join operation with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the variables to use as key variables.

`[C,ia,ib] = innerjoin( ___ )` also returns index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

## Input Arguments

**A,B - Input tables**  
tables

Input tables, specified as tables.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' ' ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** 'Keys', 2 uses the second variable in A and the second variable in B as key variables.

## **'Keys' - Variables to use as keys**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of 'Keys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the 'Keys' name-value pair argument with the 'LeftKeys' and 'RightKeys' name-value pair arguments.

**Example:** 'Keys', [1 3] uses the first and third variables in A and B as a key variables.

## **'LeftKeys' - Variables to use as keys in A**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `innerjoin` pairs key values based on their order.

**Example:** 'LeftKeys', 1 uses only the first variable in A as a key variable.

## **'RightKeys' - Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of 'RightKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'RightKeys' name-value pair argument in conjunction with the 'LeftKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `innerjoin` pairs key values based on their order.

**Example:** 'RightKeys',3 uses only the third variable in B as a key variable.

#### **'LeftVariables' - Variables from A to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of 'LeftVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'LeftVariables' to include or exclude key variables, as well as nonkey variables from the output, C.

By default, `innerjoin` includes all variables from A.

#### **'RightVariables' - Variables from B to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from B to include in C, specified as the comma-separated pair consisting of 'RightVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'RightVariables' to include or exclude key variables, as well as nonkey variables from the output, C.

By default, `innerjoin` includes all the variables from B except the key variables.

## **Output Arguments**

### **C - Inner join from A and B**

table

Inner join from A and B, returned as a table. The output table, C, contains one row for each pair of rows in tables A and B that share the same combination of values in the key variables. If A and B contain

# innerjoin

---

variables with the same name, `innerjoin` adds a unique suffix to the corresponding variable names in C.

In general, if there are  $m$  rows in table A and  $n$  rows in table B that all contain the same combination of values in the key variables, table C contains  $m*n$  rows for that combination.

C is sorted by the values in the key variables and contains the horizontal concatenation of  $A(ia, LeftVars)$  and  $B(ib, RightVars)$ . By default, `LeftVars` consists of all the variables of A, and `RightVars` consists of all the nonkey variables from B. Otherwise, `LeftVars` consists of the variables specified by the 'LeftVariables' name-value pair argument, and `RightVars` is the variables specified by the 'RightVariables' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the output table, C. For more information, see [Table Properties](#).

## **ia - Index to A**

column vector

Index to A, returned as a column vector. Each element of `ia` identifies the row in table A that corresponds to that row in the output table, C.

## **ib - Index to B**

column vector

Index to B, returned as a column vector. Each element of `ib` identifies the row in table B that corresponds to that row in the output table, C.

## **Definitions**

### **Key Variable**

Variable used to match and combine data between the input tables, A and B.

## **Examples**

### **Inner-Join Operation of Tables with One Variable in Common**

Create a table, A.

```
A = table([5;12;23;2;6],...
          {'cereal';'pizza';'salmon';'cookies';'pizza'},...
          'VariableNames',{'Age','FavoriteFood'})
```

A =

| Age | FavoriteFood |
|-----|--------------|
| 5   | 'cereal'     |
| 12  | 'pizza'      |
| 23  | 'salmon'     |
| 2   | 'cookies'    |
| 6   | 'pizza'      |

Create a table, B, with one variable in common with A.

```
B = table({'cereal';'cookies';'pizza';'salmon';'cake'},...
          [110;160;140;367;243],...
          {'A-';'D';'B';'B';'C-'},...
          'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

B =

| FavoriteFood | Calories | NutritionGrade |
|--------------|----------|----------------|
| 'cereal'     | 110      | 'A-'           |
| 'cookies'    | 160      | 'D'            |
| 'pizza'      | 140      | 'B'            |
| 'salmon'     | 367      | 'B'            |
| 'cake'       | 243      | 'C-'           |

Use the `innerjoin` function to create a new table, C, with data from tables A and B.

```
C = innerjoin(A,B)
```

# innerjoin

---

C =

| Age | FavoriteFood | Calories | NutritionGrade |
|-----|--------------|----------|----------------|
| 5   | 'cereal'     | 110      | 'A-'           |
| 2   | 'cookies'    | 160      | 'D'            |
| 12  | 'pizza'      | 140      | 'B'            |
| 6   | 'pizza'      | 140      | 'B'            |
| 23  | 'salmon'     | 367      | 'B'            |

Table C is sorted by the key variable, FavoriteFood.

## Inner-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...  
        'VariableNames',{'Key1' 'Var1'})
```

A =

| Key1 | Var1 |
|------|------|
| 'a'  | 1    |
| 'b'  | 2    |
| 'c'  | 3    |
| 'e'  | 11   |
| 'h'  | 17   |

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a' 'b' 'd' 'e'},[4 5 6 7]',...  
        'VariableNames',{'Key1' 'Var2'})
```

B =

| Key1 | Var2 |
|------|------|
| 'a'  | 4    |
| 'b'  | 5    |
| 'd'  | 6    |
| 'e'  | 7    |

Use the `innerjoin` function to create a new table, C, with data from tables A and B. Retain only rows whose values in the variable Key1 match.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in C and rows in A and B respectively.

```
[C,ia,ib] = innerjoin(A,B)
```

C =

| Key1 | Var1 | Var2 |
|------|------|------|
| 'a'  | 1    | 4    |
| 'b'  | 2    | 5    |
| 'e'  | 11   | 7    |

ia =

1  
2  
4

ib =

# innerjoin

---

```
1  
2  
4
```

Table C is sorted by the values in the key variable, Key1, and contains the horizontal concatenation of A(ia,:) and B(ib,'Var2').

## Inner-Join Operation of Tables Using Left and Right Keys

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

A =

| Var1 | Var2 | Var3 |
|------|------|------|
| 10   | 5    | 10   |
| 4    | 4    | 3    |
| 2    | 9    | 8    |
| 3    | 6    | 8    |
| 7    | 1    | 4    |

Create a table, B, with common values in the second variable as the first variable of table A.

```
B = table([6;1;1;6;8],[2;3;4;5;6])
```

B =

| Var1 | Var2 |
|------|------|
| 6    | 2    |
| 1    | 3    |
| 1    | 4    |
| 6    | 5    |
| 8    | 6    |

Use the `innerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Use the first variable of `A` and the second variable of `B` as key variables.

```
[C,ia,ib] = innerjoin(A,B,'LeftKeys',1,'RightKeys',2)
```

`C =`

| <u>Var1_A</u> | <u>Var2</u> | <u>Var3</u> | <u>Var1_B</u> |
|---------------|-------------|-------------|---------------|
| 2             | 9           | 8           | 6             |
| 3             | 6           | 8           | 1             |
| 4             | 4           | 3           | 1             |

`ia =`

```
3  
4  
2
```

`ib =`

```
1  
2  
3
```

Table `C` retains only the rows that match between `A` and `B` with respect to the key variables.

Table `C` contains the horizontal concatenation of `A(ia,:)` and `B(ib,'Var1')`.

## See Also

`join` | `outerjoin`

# inpolygon

---

**Purpose** Points inside polygonal region

**Syntax** `IN = inpolygon(X,Y,xv,yv)`  
`[IN ON] = inpolygon(X,Y,xv,yv)`

**Description** `IN = inpolygon(X,Y,xv,yv)` returns a matrix `IN` the same size as `X` and `Y`. Each element of `IN` is assigned the value 1 or 0 depending on whether the point  $(X(p,q), Y(p,q))$  is inside the polygonal region whose vertices are specified by the vectors `xv` and `yv`. In particular:

`IN(p,q) = 1` If  $(X(p,q), Y(p,q))$  is inside the polygonal region or on the polygon boundary

`IN(p,q) = 0` If  $(X(p,q), Y(p,q))$  is outside the polygonal region

`[IN ON] = inpolygon(X,Y,xv,yv)` returns a second matrix `ON` the same size as `X` and `Y`. Each element of `ON` is assigned the value 1 or 0 depending on whether the point  $(X(p,q), Y(p,q))$  is on the boundary of the polygonal region whose vertices are specified by the vectors `xv` and `yv`. In particular:

`ON(p,q) = 1` If  $(X(p,q), Y(p,q))$  is on the polygon boundary

`ON(p,q) = 0` If  $(X(p,q), Y(p,q))$  is inside or outside the polygon boundary

## Examples

```
L = linspace(0,2.*pi,6); xv = cos(L)';yv = sin(L)';  
xv = [xv ; xv(1)]; yv = [yv ; yv(1)];  
x = randn(250,1); y = randn(250,1);  
in = inpolygon(x,y,xv,yv);  
plot(xv,yv,x(in),y(in), 'r+',x(~in),y(~in), 'bo')
```

# input

---

**Purpose** Request user input

**Syntax**  
`result = input(prompt)`  
`str = input(prompt,'s')`

**Description** `result = input(prompt)` displays the `prompt` string on the screen, waits for input from the keyboard, evaluates any expressions in the input, and returns the result. To evaluate expressions, the `input` function can use variables in the current workspace.

- If you press the **Return** key without entering anything, then `input` returns an empty matrix.
- If you enter an invalid expression at the prompt, then MATLAB displays the relevant error message, and then redisplay the prompt.

`str = input(prompt,'s')` returns the entered text as a MATLAB string, without evaluating expressions.

## Input Arguments

**prompt - Query that requests input**  
string

Query that requests input, specified as a string.

To create a prompt that spans several lines, use `'\n'` to indicate each new line. To include a backslash (`'\'`) in the prompt, use `'\\'`.

**Data Types**  
char

## Output Arguments

**result - Result calculated from input**  
array

Result calculated from input, returned as an array. The type and dimensions of the array depend upon the response to the prompt.

**str - Exact text of input**  
string

Exact text of input, returned as a string.

## Data Types

char

## Examples

### Numeric or Evaluated Input

Request a numeric input, and then multiply the input by 10.

```
prompt = 'What is the original value? ';  
result = input(prompt)  
largernum = result * 10
```

At the prompt, enter a numeric value or array, such as 42.

```
result =  
    42  
  
largernum =  
    420
```

The input function also accepts expressions. For example, rerun the code.

```
prompt = 'What is the original value? ';  
result = input(prompt)  
largernum = result * 10
```

At the prompt, enter magic(3).

```
result =  
    8     1     6  
    3     5     7  
    4     9     2  
  
largernum =  
    80    10    60  
    30    50    70  
    40    90    20
```

# input

---

The expression does not need to return a numeric result. For example:

```
prompt = 'What color is the sun? ';  
result = input(prompt)
```

At the prompt, type `upper('yellow')`.

```
result =  
YELLOW
```

## Unprocessed Text Input

Request a simple text response that requires no evaluation.

```
prompt = 'Do you want more? Y/N [Y]: ';  
str = input(prompt, 's');  
if isempty(str)  
    str = 'Y';  
end
```

The `input` function returns the text exactly as typed. If the input is empty, this code assigns a default value, 'Y', to the output string, `str`.

## See Also

`keyboard` | `inputdlg` | `menu` | `ginput` | `uicontrol`

## Purpose

Create and open input dialog box

## Syntax

```
answer = inputdlg(prompt)
answer = inputdlg(prompt,dlg_title)
answer = inputdlg(prompt,dlg_title,num_lines)
answer = inputdlg(prompt,dlg_title,num_lines,defAns)
answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)
```

## Description

`answer = inputdlg(prompt)` creates a modal dialog box and returns user input for multiple prompts in the cell array. `prompt` is a cell array containing prompt strings.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`answer = inputdlg(prompt,dlg_title)` `dlg_title` specifies a title for the dialog box.

`answer = inputdlg(prompt,dlg_title,num_lines)` `num_lines` specifies the number of lines for each user-entered value. `num_lines` can be a scalar, column vector, or a  $m \times 2$  array.

- If `num_lines` is a scalar, it applies to all prompts.
- If `num_lines` is a column vector, each element specifies the number of lines of input for a prompt.
- If `num_lines` is an array, it must be size  $m$ -by-2, where  $m$  is the number of prompts on the dialog box. Each row refers to a prompt. The first column specifies the number of lines of input for a prompt. The second column specifies the width of the field in characters.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns)` `defAns` specifies the default value to display for each prompt. `defAns` must contain the same number of elements as `prompt` and all elements must be strings.

# inputdlg

---

```
answer =  
inputdlg(prompt,dlg_title,num_lines,defAns,options) If  
options is the string 'on', the dialog is made resizable in the  
horizontal direction. If options is a structure, the fields shown in  
the following table are recognized:
```

| Field       | Description                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------|
| Resize      | Can be 'on' or 'off' (default). If 'on', the window is resizable horizontally.                               |
| WindowStyle | Can be either 'normal' or 'modal' (default).                                                                 |
| Interpreter | Can be either 'none' (default) or 'tex'. If the value is 'tex', the prompt strings are rendered using LaTeX. |

If the user clicks the **Cancel** button to close an `inputdlg` box, the dialog returns an empty cell array:

```
answer =  
    {}
```

## Tips

`inputdlg` uses the `uiwait` function to suspend execution until the user responds.

The returned variable `answer` is a cell array containing strings, one string per text entry field, starting from the top of the dialog box.

To convert a member of the cell array to a number, use `str2num`. To do this, you can add the following code to the end of any of the examples below:

```
[val status] = str2num(answer{1}); % Use curly bracket for subscript  
if ~status  
    % Handle empty value returned for unsuccessful conversion  
    % ...  
end  
% val is a scalar or matrix converted from the first input
```

Users can enter scalar or vector values into `inputdlg` fields; `str2num` converts space- and comma-delimited strings into row vectors, and semicolon-delimited strings into column vectors. For example, if `answer{1}` contains `'1 2 3;4 -5 6+7i'`, the conversion produces:

```
val = str2num(answer{1})
val =
    1.0000    2.0000    3.0000
    4.0000   -5.0000    6.0000 + 7.0000i
```

## Examples

### Example 1

Create a dialog box to input an integer and colormap name. Allow one line for each value.

```
prompt = {'Enter matrix size:', 'Enter colormap name:'};
dlg_title = 'Input';
num_lines = 1;
def = {'20', 'hsv'};
answer = inputdlg(prompt,dlg_title,num_lines,def);
```

### Example 2

Create a dialog box named to accept comma-separated numbers. MATLAB stores accepts the input as a string, so convert the string to numbers using `str2num`.

```
x = inputdlg('Enter space-separated numbers:', 'Sample', [1 50]);
```

# inputdlg

---

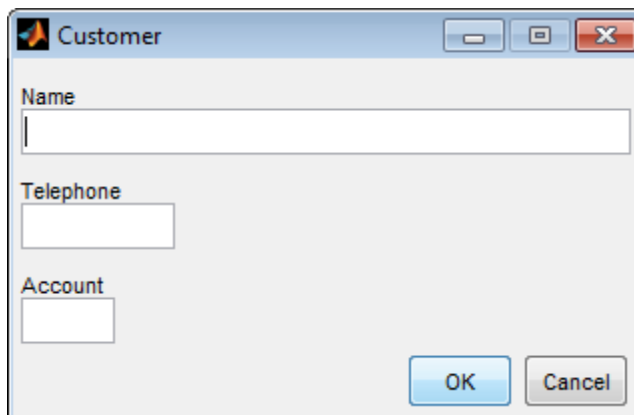

```
data = str2num(x{:});
```

## Example 3

Create a dialog box to display input fields of different widths.

```
x = inputdlg({'Name','Telephone','Account'}, 'Customer', [1 50; 1 12; 1 7
```

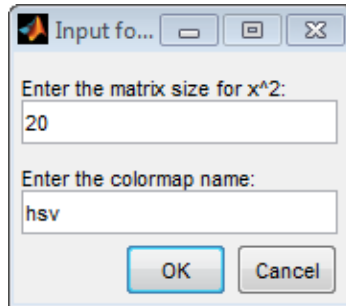

## Example 4

Create a dialog box using the default options. Then, use the options to make it resizable and not modal, and to interpret the text using LaTeX.

```
prompt={'Enter the matrix size for x^2:',...  
        'Enter the colormap name:'};  
name='Input for Peaks function';  
numlines=1;
```

```
defaultanswer={'20','hsv'};  
answer=inputdlg(prompt,name,numlines,defaultanswer);
```

```
options.Resize='on';  
options.WindowStyle='normal';  
options.Interpreter='tex';  
  
answer=inputdlg(prompt,name,numlines,defaultanswer,options);
```

# inputname

---

**Purpose** Variable name of function input

**Syntax** `inputname(argnum)`

**Description** This command can be used only inside the body of a function. `inputname(argnum)` returns the workspace variable name corresponding to the argument number *argnum*. If the input argument has no name (for example, if it is an expression instead of a variable), the `inputname` command returns the empty string ('').

**Examples** Suppose the function `myfun.m` is defined as

```
function c = myfun(a,b)
fprintf('First calling variable is "%s"\n.', inputname(1))
```

Then

```
x = 5; y = 3; myfun(x,y)
```

produces

```
First calling variable is "x".
```

But

```
myfun(pi+1, pi-1)
```

produces

```
First calling variable is "".
```

**See Also** `nargin` | `nargout` | `narginchk`

**Purpose** Parse function inputs

**Description** The `inputParser` object allows you to manage inputs to a function by creating an input scheme. To check the input, you can define validation functions for required arguments, optional arguments, and name-value pair arguments. Optionally, you can set properties to adjust the parsing behavior, such as handling case sensitivity, structure array inputs, and inputs that are not in the input scheme.

After calling the `parse` method to parse the inputs, the `inputParser` saves names and values of inputs that match the input scheme (stored in `Results`), names of inputs that are not passed to the function and, therefore, are assigned default values (stored in `UsingDefaults`), and names and values of inputs that do not match the input scheme (stored in `Unmatched`).

**Construction** `p = inputParser` creates `inputParser` object `p`.

**Properties** **CaseSensitive**

Scalar logical value that indicates whether to match case when checking argument names.

Possible values:

|                        |                                                   |
|------------------------|---------------------------------------------------|
| <code>false</code> (0) | Names are not sensitive to case: 'a' matches 'A'. |
| <code>true</code> (1)  | Names are case sensitive: 'a' does not match 'A'. |

**Default:** `false`

**FunctionName**

String that specifies the name of the function to include in error messages. By specifying the `FunctionName`, the `parse` method of the `inputParser` will throw error messages as if it were that

function. This allows the error to be attributed to the correct function and allows easy access to function documentation through the error message.

**Default:** The default value is an empty string, ''.

## **KeepUnmatched**

Scalar logical value that indicates how to handle parameter name and value inputs that are not in the input scheme.

Possible values:

|           |                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| false (0) | Throw an error whenever inputs are not in the scheme.                                                                                                           |
| true (1)  | Store the parameter names and values of unmatched inputs in the <code>Unmatched</code> property of the <code>inputParser</code> object, and suppress the error. |

**Default:** false

## **PartialMatching**

Scalar logical value that indicates whether partial matching of parameter names will be accepted. Partial parameter matching is supported by the `addParameter` method.

Possible values:

|           |                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| true (1)  | Inputs that are leading substrings of parameter names will be accepted and the value matched to that parameter. If there are multiple possible matches to the input string, MATLAB throws an error. |
| false (0) | Input names are required to match a parameter name exactly (with respect to the CaseSensitive property.)                                                                                            |

**Default:** true

## **StructExpand**

Scalar logical value that specifies whether to interpret a structure array as a single input or as a set of parameter name and value pairs.

|           |                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------|
| true (1)  | Expand structures into separate inputs. Each field name corresponds to an input parameter name. |
| false (0) | Regard a structure array as a single input argument.                                            |

**Default:** true

## **Read Only Properties**

### **Parameters**

Cell array of strings that contains the names of arguments currently defined in the input scheme.

Each method that adds an input argument to the scheme (addRequired, addOptional, addParameter) updates the Parameters property.

### **Results**

# inputParser

---

Structure containing names and values of inputs that match the function input scheme, populated by the `parse` method.

Each field of the `Results` structure corresponds to the name of an input.

## Unmatched

Structure array containing the names and values of inputs that do not match the function input scheme, populated by the `parse` method.

If `KeepUnmatched` is `false` (default) or all inputs match the scheme, then `Unmatched` is a 1-by-1 structure with no fields. Otherwise, each field of the structure corresponds to the name of an input that did not match the scheme.

## UsingDefaults

Cell array containing the names of inputs not passed explicitly to the function and assigned default values, populated by the `parse` method.

## Methods

|                            |                                                                                |
|----------------------------|--------------------------------------------------------------------------------|
| <code>addOptional</code>   | Add optional positional argument to input parser scheme                        |
| <code>addParameter</code>  | Add optional parameter name-value pair argument to input parser scheme         |
| <code>addParamValue</code> | (Not recommended) Add parameter name and value argument to Input Parser scheme |
| <code>addRequired</code>   | Add required positional argument to input parser scheme                        |
| <code>createCopy</code>    | Create copy of <code>inputParser</code> object (to be removed)                 |
| <code>parse</code>         | Parse function inputs                                                          |

You can define your scheme by calling `addRequired`, `addOptional`, and `addParameter` in any order, but when you call your function that uses the input parser, you should pass in required inputs first, followed by any optional positional inputs, and, finally, any name-value pairs.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

The copy method creates another scheme with the same properties as an existing `inputParser` object:

```
pNew = copy(pOld);
```

## Examples

### Input Validation

Check the validity of required and optional function inputs.

Create a custom function with required and optional inputs in the file `findArea.m`.

```
function a = findArea(width,varargin)
    p = inputParser;
    defaultHeight = 1;
    defaultUnits = 'inches';
    defaultShape = 'rectangle';
    expectedShapes = {'square','rectangle','parallelogram'};

    addRequired(p,'width',@isnumeric);
    addOptional(p,'height',defaultHeight,@isnumeric);
    addParameter(p,'units',defaultUnits);
    addParameter(p,'shape',defaultShape,...
        @(x) any(validatestring(x,expectedShapes)));

    parse(p,width,varargin{:});
    a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the shape matches a string in cell array `expectedShapes`. @

# inputParser

---

indicates a function handle, and the syntax @(x) creates an anonymous function with input x.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the width input:

```
findArea('text')
```

```
Error using findArea (line 14)  
The value of 'width' is invalid. It must satisfy the function: isnumeric.
```

Specify an unsupported value for shape:

```
findArea(4,'shape','circle')
```

```
Error using findArea (line 14)  
The value of 'shape' is invalid. Expected input to match one of these strings:
```

```
square, rectangle, parallelogram
```

The input, 'circle', did not match any of the valid strings.

## Extra Parameter Value Inputs

Store parameter name and value inputs that are not in the input scheme instead of throwing an error.

```
default = 0;  
value = 1;  
  
p = inputParser;  
p.KeepUnmatched = true;  
addOptional(p,'expectedInputName',default);  
parse(p,'extraInput',value);
```

View the unmatched parameter name and value:

```
p.Unmatched
```

```
ans =
```

```
extraInput: 1
```

## Case Sensitivity

Enforce case sensitivity when checking function inputs.

```
p = inputParser;  
p.CaseSensitive = true;  
defaultValue = 0;  
addParameter(p, 'InputName', defaultValue);  
  
parse(p, 'inputname', 10)
```

```
'inputname' is not a recognized parameter. For a list of valid name-value
```

## Structure Array Inputs

Parse structure array inputs with the `StructExpand` property set to `true` (default) or `false`.

Expand a structure array input into parameter name and value pairs using the default `true` value of the `StructExpand` property.

```
s.input1 = 10;  
s.input2 = 20;  
default = 0;  
  
p = inputParser;  
addParameter(p, 'input1', default);  
addParameter(p, 'input2', default);  
parse(p, s);
```

```
p.Results
```

```
ans =  
    input1: 10  
    input2: 20
```

Explicitly specifying a parameter name and value pair overrides values in the structure.

# inputParser

---

```
parse(p,s,'input2',300);  
p.Results
```

```
ans =  
    input1: 10  
    input2: 300
```

Accept a structure array input as a single argument by setting the StructExpand property to false.

```
s2.first = 1;  
s2.random = rand(3,4,2);  
s2.mytext = 'some text';
```

```
p = inputParser;  
p.StructExpand = false;  
addRequired(p,'structInput');  
parse(p,s2);
```

```
results = p.Results  
fieldList = fieldnames(p.Results.structInput)
```

```
results =  
    structInput: [1x1 struct]
```

```
fieldList =  
    'first'  
    'random'  
    'mytext'
```

## Parse Inputs Using validateattributes

Create a function that parses information about people and, if parsing passes, adds the information to a cell array.

Create a function, addPerson, that sets up an inputParser scheme using validateAttributes. The function should accept the list of people, modify the list if necessary and return the list. Use a persistent inputParser to avoid construction of a new object with every function

call. If this is the first call to the function, add a titles row to the cell array.

```
function mList = addPerson(mList,name,id,varargin)

persistent p
if isempty(p)
    p = inputParser;
    p.FunctionName = 'addPerson';
    addRequired(p,'mList',@(x)validateattributes(x',{'cell'},...
        {'ndims',2}));
    addRequired(p,'name',@(x)validateattributes(x',{'char'},...
        {'nonempty'}));
    addRequired(p,'id',@(x)validateattributes(x',{'numeric'},...
        {'nonempty','integer','positive'}));
    addOptional(p,'birthyear',9999,@(x)validateattributes(x,...
        {'numeric'},{'nonempty'}));
    addParamValue(p,'nickname','- ',@(x)validateattributes(x,...
        {'char'},{'nonempty'}));
    addParamValue(p,'favColor','- ',@(x)validateattributes(x,...
        {'char'},{'nonempty'}));
end

parse(p,mList,name,id,varargin{:});

if isempty(mList)
    mList = fieldnames(rmfield(p.Results,'mList'))';
end
mList = [mList; struct2cell(rmfield(p.Results,'mList'))]';

end
```

Create an empty list, and add a person to it.

```
pList = {};
pList = addPerson(pList,78,'Joe');
```

Error using addPerson

# inputParser

---

The value of 'name' is invalid. Expected input to be one of these types:

char

Instead its type was double.

Error in addPerson (line 17)

```
parse(p,mList,name,id,varargin{:});
```

The parsing failed because the function received the inputs in the incorrect order and tried to assign name a value of 78. This entry was not added to pList.

Add several more people to the list.

```
pList = addPerson(pList,'Joe',78);  
pList = addPerson(pList,'Mary',3,1942,'favColor','red');  
pList = addPerson(pList,'James',182,1970,'nickname','Jimmy')
```

pList =

| 'birthyear' | 'favColor' | 'id'  | 'mList'    | 'name'  | 'nickn  |
|-------------|------------|-------|------------|---------|---------|
| [ 9999]     | '-'        | [ 78] | {}         | 'Joe'   | '-'     |
| [ 1942]     | 'red'      | [ 3]  | {2x6 cell} | 'Mary'  | '-'     |
| [ 1970]     | '-'        | [182] | {3x6 cell} | 'James' | 'Jimmy' |

## Concepts

- “Input Parser Validation Functions”

**Purpose** Open Property Inspector

**Syntax**  
`inspect`  
`inspect(h)`  
`inspect([h1,h2,...])`

**Description** `inspect` creates a separate Property Inspector window to enable the display and modification of the properties of any object you select in the figure window or Layout Editor. If no object is selected, the Property Inspector is blank.

`inspect(h)` creates a Property Inspector window for the object whose handle is `h`.

`inspect([h1,h2,...])` displays properties that objects `h1` and `h2` have in common, or a blank window if there are no such properties; any number of objects can be inspected and edited in this way (for example, handles returned by the `bar` command).

The Property Inspector has the following behaviors:

- Only one Property Inspector window is active at any given time; when you inspect a new object, its properties replace those of the object last inspected.
- When the Property Inspector is open and plot edit mode is on, clicking any object in the figure window displays the properties of that object (or set of objects) in the Property Inspector.
- When you select and inspect two or more objects of different types, the Property Inspector only shows the properties that all objects have in common.
- To change the value of any property, click on the property name shown at the left side of the window, and then enter the new value in the field at the right.

The Property Inspector provides two different views:

- List view — properties are ordered alphabetically (default); this is the only view available for annotation objects.

- Group view — properties are grouped under classified headings (Handle Graphics objects only)

To view alphabetically, click the “AZ” Icon  in the Property Inspector toolbar. To see properties in groups, click

the “++” icon . When properties are grouped, the “-” and “+” icons are enabled; click  to expand all categories and click  to collapse all categories. You can also expand and collapse individual categories by clicking on the “+” next to the category name. Some properties expand and collapse

---

**Notes** To see a complete description of any property, right-click on its name or value and select **What’s This**; a help window opens that displays the reference page entry for it.

The Property Inspector displays most, but not all, properties of Handle Graphics objects. For example, the `parent` and `children` of HG objects are not shown.

`inspect h` displays a Property Inspector window that enables modification of the string 'h', not the object whose handle is h.

If you modify properties at the MATLAB command line, you must refresh the Property Inspector window to see the change reflected there. Refresh the Property Inspector by reinvoking `inspect` on the object.

---

## Examples

### Example 1

Create a surface mesh plot and view its properties with the Property Inspector:

```
Z = peaks(30);  
h = surf(Z)  
inspect(h)
```

Use the Property Inspector to change the `FaceAlpha` property from 1.0 to 0.4 (equivalent to the command `set(h,'FaceAlpha',0.4)`). `FaceAlpha` controls the transparency of patch faces.

# inspect

When you press **Enter** or click a different field, the FaceAlpha property of the surface object is updated:

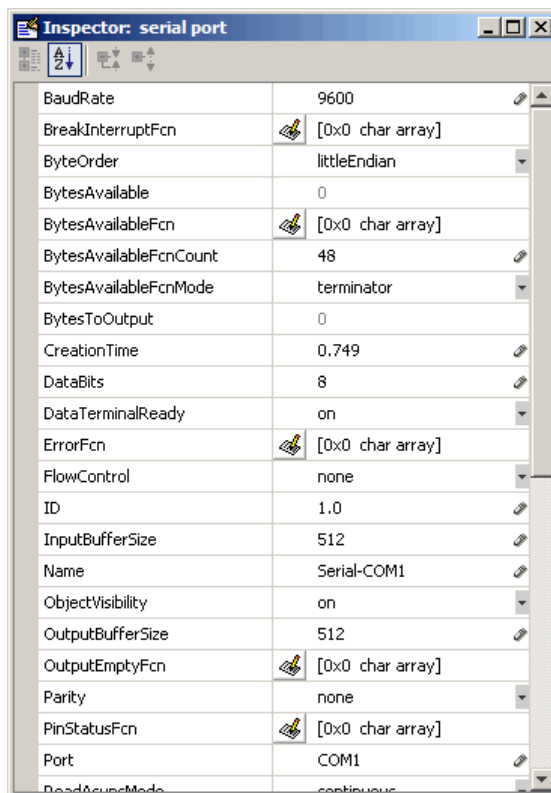

### Example 2

Create a serial port object for COM1 on a Windows platform and use the Property Inspector to peruse its properties:

```
s = serial('COM1');  
inspect(s)
```

Because COM objects do not define property groupings, only the alphabetical list view of their properties is available.

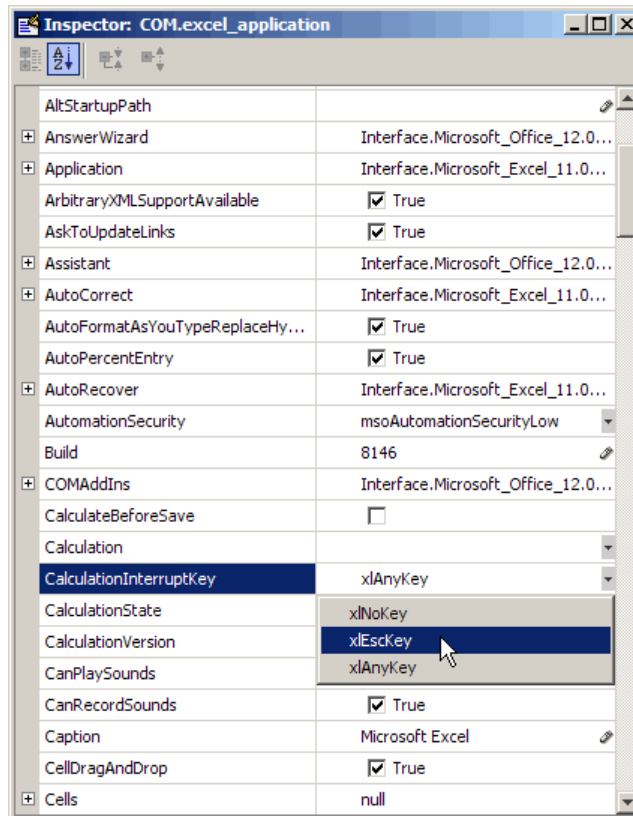

### Example 3

Create a COM Excel server and open a Property Inspector window with `inspect`:

```
h = actxserver('excel.application');  
inspect(h)
```

Scroll down until you see the `CalculationInterruptKey` property, which by default is `xlAnyKey`. Click on the down-arrow in the right

margin of the property inspector and select `xlEscKey` from the drop-down menu, as shown below:

Check this field in the MATLAB Command Window using `get` to confirm that it has changed:

```
get(h, 'CalculationInterruptKey')
```

```
ans =  
xlEscKey
```

# inspect

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Event information when event occurs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Syntax</b>      | <code>instrcallback(obj,event)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p><code>instrcallback(obj,event)</code> displays a message that contains the event type, event, the time the event occurred, and the name of the serial port object, <code>obj</code>, that caused the event to occur.</p> <p>For error events, the error message is also displayed. For pin status events, the pin that changed value and its value are also displayed.</p>                                                                                                                                                                                                                                                                                                                                                     |
| <b>Tips</b>        | You should use <code>instrcallback</code> as a template from which you create callback functions that suit your specific application needs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Examples</b>    | <p>The following example creates the serial port objects <code>s</code>, on a Windows platform. It configures <code>s</code> to execute <code>instrcallback</code> when an output-empty event occurs. The event occurs after the <code>*IDN?</code> command is written to the instrument.</p> <pre>s = serial('COM1'); set(s, 'OutputEmptyFcn', @instrcallback) fopen(s) fprintf(s, '*IDN?', 'async')</pre> <p>The resulting display from <code>instrcallback</code> is shown below.</p> <pre>OutputEmpty event occurred at 08:37:49 for the object: Serial-COM1.</pre> <p>Read the identification information from the input buffer and end the serial port session.</p> <pre>idn = fscanf(s); fclose(s) delete(s) clear s</pre> |

# instrfind

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Read serial port objects from memory to MATLAB workspace                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <pre>out = instrfind out = instrfind('PropertyName',PropertyValue,...) out = instrfind(S) out = instrfind(obj,'PropertyName',PropertyValue,...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p><code>out = instrfind</code> returns all valid serial port objects as an array to <code>out</code>.</p> <p><code>out = instrfind('PropertyName',PropertyValue,...)</code> returns an array of serial port objects whose property names and property values match those specified.</p> <p><code>out = instrfind(S)</code> returns an array of serial port objects whose property names and property values match those defined in the structure <code>S</code>. The field names of <code>S</code> are the property names, while the field values are the associated property values.</p> <p><code>out = instrfind(obj,'PropertyName',PropertyValue,...)</code> restricts the search for matching property name/property value pairs to the serial port objects listed in <code>obj</code>.</p>                                                                         |
| <b>Tips</b>        | <p>Refer to “Displaying Property Names and Property Values” for a list of serial port object properties that you can use with <code>instrfind</code>.</p> <p>You must specify property values using the same format as the <code>get</code> function returns. For example, if <code>get</code> returns the <code>Name</code> property value as <code>MyObject</code>, <code>instrfind</code> will not find an object with a <code>Name</code> property value of <code>myobject</code>. However, this is not the case for properties that have a finite set of string values. For example, <code>instrfind</code> will find an object with a <code>Parity</code> property value of <code>Even</code> or <code>even</code>.</p> <p>You can use property name/property value string pairs, structures, and cell array pairs in the same call to <code>instrfind</code>.</p> |
| <b>Examples</b>    | <p>Suppose you create the following two serial port objects on a Windows platform.</p> <pre>s1 = serial('COM1');</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

```
s2 = serial('COM2');  
set(s2, 'BaudRate', 4800)  
fopen([s1 s2])
```

You can use `instrfind` to return serial port objects based on property values.

```
out1 = instrfind('Port', 'COM1');  
out2 = instrfind({'Port', 'BaudRate'}, {'COM2', 4800});
```

You can also use `instrfind` to return cleared serial port objects to the MATLAB workspace.

```
clear s1 s2  
newobjs = instrfind
```

```
Instrument Object Array  
Index:   Type:      Status:   Name:  
1        serial    open     Serial-COM1  
2        serial    open     Serial-COM2
```

To close both `s1` and `s2`

```
fclose(newobjs)
```

```

# instrfindall

---

**Purpose** Find visible and hidden serial port objects

**Syntax**

```
out = instrfindall
out = instrfindall('P1',V1,...)
out = instrfindall(s)
out = instrfindall(objs,'P1',V1,...)
```

**Description** `out = instrfindall` finds all serial port objects, regardless of the value of the objects' `ObjectVisibility` property. The object or objects are returned to `out`.

`out = instrfindall('P1',V1,...)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified as arguments.

`out = instrfindall(s)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified in the structure `s`, where the field names correspond to property names and the field values correspond to the current value of the respective property.

`out = instrfindall(objs,'P1',V1,...)` restricts the search for objects with matching property name/value pairs to the serial port objects listed in `objs`.

Note that you can use string property name/property value pairs, structures, and cell array property name/property value pairs in the same call to `instrfindall`.

**Tips** `instrfindall` differs from `instrfind` in that it finds objects whose `ObjectVisibility` property is set to `off`.

Property values are case sensitive. You must specify property values using the same format as that returned by the `get` function. For example, if `get` returns the `Name` property value as `'MyObject'`, `instrfindall` will not find an object with a `Name` property value of `'myobject'`. However, this is not the case for properties that have a finite set of string values. For example, `instrfindall` will find an object with a `Parity` property value of `'Even'` or `'even'`.

## Examples

Suppose you create the following serial port objects on a Windows platform:

```
s1 = serial('COM1');  
s2 = serial('COM2');  
set(s2,'ObjectVisibility','off')
```

Because object `s2` has its `ObjectVisibility` set to `'off'`, it is not visible to commands like `instrfind`:

```
instrfind  
  
Serial Port Object : Serial-COM1
```

However, `instrfindall` finds all objects regardless of the value of `ObjectVisibility`:

```
instrfindall  
  
Instrument Object Array  
Index:   Type:           Status:      Name:  
1        serial          closed      Serial-COM1  
2        serial          closed      Serial-COM2
```

The following statements use `instrfindall` to return objects with specific property settings, which are passed as cell arrays:

```
props = {'PrimaryAddress','SecondaryAddress'};  
vals = {2,0};  
obj = instrfindall(props,vals);
```

You can use `instrfindall` as an argument when you want to apply the command to all objects, visible and invisible. For example, the following statement makes all objects visible:

```
set(instrfindall,'ObjectVisibility','on')
```

# int2str

---

**Purpose** Convert integer to string

**Syntax** `str = int2str(N)`

**Description** `str = int2str(N)` converts an integer to a string with integer format. The input `N` can be a single integer or a vector or matrix of integers. Noninteger inputs are rounded before conversion.

**Examples** `int2str(2+3)` is the string '5'.

One way to label a plot is

```
title(['case number ' int2str(n)])
```

For matrix or vector inputs, `int2str` returns a string matrix:

```
int2str(eye(3))
```

```
ans =
```

```
1 0 0
0 1 0
0 0 1
```

| <b>Purpose</b>          | Convert to 64-bit signed integer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Syntax</b>           | <code>intArray = int64(array)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>      | <code>intArray = int64(array)</code> converts the elements of an array into signed 64-bit (8-byte) integers of class <code>int64</code> .                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Tips</b>             | <p>Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, <code>double</code> values cannot represent all integers greater than <math>2^{53}</math> correctly. Before performing arithmetic operations on values larger than <math>2^{53}</math> in magnitude, convert the values to 64-bit integers. For example,</p> <pre>x = int64(2^53+1);    % Floating-point arithmetic, loses precision</pre> <p>is not as accurate as the 64-bit integer arithmetic operation:</p> <pre>x = int64(2^53) + 1;    % Preferred</pre> |
| <b>Input Arguments</b>  | <p><b>array</b></p> <p>Array of any numeric class, such as <code>single</code> or <code>double</code>. If <code>array</code> is already of class <code>int64</code>, the <code>int64</code> function has no effect.</p>                                                                                                                                                                                                                                                                                                                                  |
| <b>Output Arguments</b> | <p><b>intArray</b></p> <p>Array of class <code>int64</code>. Values range from <math>-2^{63}</math> to <math>2^{63} - 1</math>.</p> <p>The <code>int64</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example,</p> <pre>int64(2^63)    % 2^63 = 9223372036854775808</pre> <p>returns</p> <pre>ans =<br/>    9223372036854775807</pre>                                                                                                                                                     |

# int64

---

## Examples

Convert a literal value to int64:

```
x = int64(9007199254740993);
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int64(zeros(100));    % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int64'); % Preferred
```

## Tutorials

- “Integers”
- “Arithmetic Operations on Integer Classes”

## Purpose

Numerically evaluate integral

## Syntax

```
q = integral(fun,xmin,xmax)
q = integral(fun,xmin,xmax,Name,Value)
```

## Description

`q = integral(fun,xmin,xmax)` approximates the integral of function `fun` from `xmin` to `xmax` using global adaptive quadrature and default error tolerances.

`q = integral(fun,xmin,xmax,Name,Value)` specifies additional options with one or more `Name, Value` pair arguments.

## Input Arguments

### **fun - Integrand**

function handle

Integrand, specified as a function handle, defines the function to be integrated from `xmin` to `xmax`. For scalar-valued problems, the function `y = fun(x)` must accept a vector argument, `x`, and return a vector result, `y`. This generally means that `fun` must use array operators instead of matrix operators. For example, use `.*` (times) rather than `*` (mtimes). If you set the 'ArrayValued' option to true, `fun` must accept a scalar and return an array of fixed size.

### **xmin - Lower limit of x**

real number | complex number

Lower limit of `x`, specified as a real (finite or infinite) scalar value or a complex (finite) scalar value. If either `xmin` or `xmax` are complex, `integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

### **Data Types**

double | single

**Complex Number Support:** Yes

### **xmax - Upper limit of x**

real number | complex number

Upper limit of  $x$ , specified as a real (finite or infinite) scalar value or a complex (finite) scalar value. If either `xmin` or `xmax` are complex, `integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

### Data Types

double | single

**Complex Number Support:** Yes

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

### 'AbsTol' - Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

---

**Note** `AbsTol` and `RelTol` work together. `integral` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-3084 section.

---

**Example:** 'AbsTol', 1e-12 sets the absolute error tolerance to approximately 12 decimal places of accuracy.

**Data Types**

single | double

**'RelTol' - Relative error tolerance**

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of 'RelTol' and a nonnegative real number. `integral` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is 1e-6.

---

**Note** RelTol and AbsTol work together. `integral` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the Tips section.

---

**Example:** 'RelTol', 1e-9 sets the relative error tolerance to approximately 9 significant digits.

**Data Types**

single | double

**'ArrayValued' - Array-valued function flag**

false (default) | true | 0 | 1

Array-valued function flag, specified as the comma-separated pair consisting of 'ArrayValued' and either false, true, 0, or 1. Set this flag to true when you want to integrate over an array-valued function. The shape of `fun(x)` can be a vector, matrix, or N-D array.

**Example:** 'ArrayValued', true indicates that the integrand is an array-valued function.

## 'Waypoints' - Integration waypoints

vector

Integration waypoints, specified as the comma-separated pair consisting of 'Waypoints' and a vector of real or complex numbers. Use waypoints to indicate any points in the integration interval you would like the integrator to use. You can use waypoints to integrate efficiently across discontinuities of the integrand. Specify the locations of the discontinuities in the vector you supply.

You can specify waypoints when you want to perform complex contour integration. If `xmin`, `xmax`, or any entry of the waypoints vector is complex, the integration is performed over a sequence of straight line paths in the complex plane.

**Example:** 'Waypoints', [1+1i, 1-1i] specifies two complex waypoints along the interval of integration.

## Data Types

single | double

**Complex Number Support:** Yes

## Output Arguments

### q - Computed integral

numeric value | numeric array

Computed integral of `fun(x)` between the limits `xmin` and `xmax`, returned as a numeric value or numeric array.

## Tips

- Do not use waypoints to specify singularities. Instead, split the interval and add the results of separate integrations with the singularities at the endpoints.
- The integral function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if  $\text{abs}(q)$  is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- If you specify a complex value for  $x_{\min}$ ,  $x_{\max}$ , or any waypoint, all of your limits and waypoints must be finite.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.

## Examples

### Evaluate Improper Integral

Create the anonymous function  $f(x) = e^{-x_2}(\ln x)^2$ .

```
fun = @(x) exp(-x.^2).*log(x).^2;
```

Evaluate the integral from  $x=0$  to  $x=\text{Inf}$ .

```
q = integral(fun,0,Inf)
```

```
q =
```

```
1.9475
```

### Integrate Parameterized Function

Create the anonymous function  $f(x) = 1/(x^3 - 2x - c)$  with one parameter,  $c$ .

```
fun = @(x,c) 1./(x.^3-2*x-c);
```

Evaluate the integral from  $x=0$  to  $x=2$  at  $c=5$ .

```
q = integral(@(x)fun(x,5),0,2)
```

```
q =
```

```
-0.4605
```

## Evaluate Integral with Singularity at the Lower Limit of Integration

Create the anonymous function  $f(x) = \ln(x)$ .

```
fun = @(x)log(x);
```

Evaluate the integral from  $x=0$  to  $x=1$  with the default error tolerances.

```
format long
```

```
q1 = integral(fun,0,1)
```

```
q1 =
```

```
-1.000000010959678
```

Evaluate the integral again, specifying approximately 12 decimal places of accuracy.

```
q2 = integral(fun,0,1,'RelTol',0,'AbsTol',1e-12)
```

```
q2 =
```

```
-1.000000000000010
```

## Complex Contour Integration Using Waypoints

Specify waypoints  $[1+1i, 1-1i]$  to integrate over the triangular path:  $0$  to  $1+1i$  to  $1-1i$  to  $0$ .

Create the anonymous function  $f(z) = 1/(2z - 1)$ .

```
fun = @(z) 1./(2*z-1);
```

Integrate in the complex plane over the triangular path from 0 to 1+1i to 1-1i to 0.

```
q = integral(fun,0,0,'Waypoints',[1+1i,1-1i])
```

```
q =
```

```
0 - 3.1416i
```

## Integrate Vector-Valued Function

Specify 'ArrayValued', true to evaluate the integral of an array-valued or vector-valued function.

Create the anonymous vector-valued function  $f(x) = [\sin x, \sin 2x, \sin 3x, \sin 4x, \sin 5x]$  and integrate from  $x=0$  to  $x=1$ .

```
fun = @(x)sin((1:5)*x);
```

```
q = integral(fun,0,1,'ArrayValued',true)
```

```
q =
```

```
0.4597    0.7081    0.6633    0.4134    0.1433
```

## Improper Integral of an Oscillatory Function

Create the anonymous function  $f(x) = x^5 e^{-x} \sin x$ .

```
fun = @(x)x.^5.*exp(-x).*sin(x);
```

Evaluate the integral from  $x=0$  to  $x=Inf$ , adjusting the absolute and relative tolerances.

```
format long
```

```
q = integral(fun,0,Inf,'RelTol',1e-8,'AbsTol',1e-13)
```

```
q =
```

```
-14.999999999998364
```

**Concepts**

- “Parameterizing Functions”

## Purpose

Numerically evaluate double integral

## Syntax

```
q = integral2(fun,xmin,xmax,ymin,ymax)
q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)
```

## Description

`q = integral2(fun,xmin,xmax,ymin,ymax)` approximates the integral of the function  $z = \text{fun}(x,y)$  over the planar region  $x_{\min} \leq x \leq x_{\max}$  and  $y_{\min}(x) \leq y \leq y_{\max}(x)$ .

`q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)` specifies additional options with one or more `Name, Value` pair arguments.

## Input Arguments

### **fun** - Integrand

function handle

Integrand, specified as a function handle, defines the function to be integrated over the planar region  $x_{\min} \leq x \leq x_{\max}$  and  $y_{\min}(x) \leq y \leq y_{\max}(x)$ . The function `fun` must accept two arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

### **Data Types**

function\_handle

### **xmin** - Lower limit of *x*

real number

Lower limit of  $x$ , specified as a real scalar value that is either finite or infinite.

### **Data Types**

double | single

### **xmax** - Upper limit of *x*

real number

Upper limit of  $x$ , specified as a real scalar value that is either finite or infinite.

## Data Types

double | single

## **ymin - Lower limit of y**

real number | function handle

Lower limit of  $y$ , specified as a real scalar value that is either finite or infinite. You can specify `ymin` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

## Data Types

double | function\_handle | single

## **ymax - Upper limit of y**

real number | function handle

Upper limit of  $y$ , specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

## Data Types

double | function\_handle | single

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

## **'AbsTol' - Absolute error tolerance**

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral2` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is

the (unknown) exact value. `integral2` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is  $1e-10$ .

---

**Note** `AbsTol` and `RelTol` work together. `integral2` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-3093 section.

---

**Example:** `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

### Data Types

`double` | `single`

### 'RelTol' - Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of `'RelTol'` and a nonnegative real number. `integral2` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral2` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is  $1e-6$ .

---

**Note** `RelTol` and `AbsTol` work together. `integral2` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-3093 section.

---

**Example:** `'RelTol', 1e-9` sets the relative error tolerance to approximately 9 significant digits.

# integral2

## Data Types

double | single

## 'Method' - Integration method

'auto' (default) | 'tiled' | 'iterated'

Integration method, specified as the comma-separated pair consisting of 'Method' and one of the methods described below.

| Integration Method | Description                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'             | For most cases, <code>integral2</code> uses the 'tiled' method. It uses the 'iterated' method when any of the integration limits are infinite. This is the default method.                                                                                                      |
| 'tiled'            | <code>integral2</code> transforms the region of integration to a rectangular shape and subdivides it into smaller rectangular regions as needed. The integration limits must be finite.                                                                                         |
| 'iterated'         | <code>integral2</code> calls <code>integral</code> to perform an iterated integral. The outer integral is evaluated over $x_{\min} \leq x \leq x_{\max}$ . The inner integral is evaluated over $y_{\min}(x) \leq y \leq y_{\max}(x)$ . The integration limits can be infinite. |

**Example:** 'Method', 'tiled' specifies the tiled integration method.

## Output Arguments

### q - Computed integral

numeric value

Computed integral of `fun(x,y)` over the specified region, returned as a numeric value.

## Tips

- The `integral2` function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if  $\text{abs}(q)$  is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- The `'iterated'` method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integral at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when `ymin`, `ymax`, (or both) are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify `'iterated'` method.
- Use the `'iterated'` method when `ymin`, `ymax`, (or both) are unbounded functions.
- When parameterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y) x + y + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.

## Examples

### Integrate Triangular Region with Singularity at the Boundary

The function

# integral2

---

$$f(x,y) = \frac{1}{(\sqrt{x+y})(1+x+y)}$$

is undefined when  $x$  and  $y$  are zero. `integral2` performs best when singularities are on the integration boundary.

Create the anonymous function.

```
fun = @(x,y) 1./ ( sqrt(x + y) .* (1 + x + y).^2 )
```

Integrate over the triangular region bounded by  $0 \leq x \leq 1$  and  $0 \leq y \leq 1 - x$ .

```
ymax = @(x) 1 - x  
q = integral2(fun,0,1,0,ymax)
```

```
q =
```

```
0.2854
```

## Evaluate Double Integral in Polar Coordinates

Define the function

$$f(\theta,r) = \frac{r}{\sqrt{r \cos \theta + r \sin \theta} (1 + r \cos \theta + r \sin \theta)^2}$$

```
fun = @(x,y) 1./ ( sqrt(x + y) .* (1 + x + y).^2 );  
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
```

Define a function for the upper limit of  $r$ .

```
rmax = @(theta) 1./(sin(theta) + cos(theta));
```

Integrate over the region bounded by  $0 \leq \theta \leq \pi/2$  and  $0 \leq r \leq r_{\max}$ .

```
q = integral2(polarfun,0,pi/2,0,rmax)
```

```
q =
```

```
0.2854
```

### Evaluate Double Integral of Parameterized Function with Specific Method and Error Tolerance

Create the anonymous parameterized function  $f(x,y) = ax^2 + by^2$  with parameters  $a=3$  and  $b=5$ .

```
a = 3; b = 5;  
fun = @(x,y) a*x.^2 + b*y.^2;
```

Evaluate the integral over the region  $0 \leq x \leq 5$  and  $-5 \leq y \leq 0$ . Specify the 'iterated' method and approximately 10 significant digits of accuracy.

```
format long  
q = integral2(fun,0,5,-5,0,'Method','iterated',...  
'AbsTol',0,'RelTol',1e-10)
```

```
q =
```

```
1.666666666666666e+03
```

### Concepts

- “Parameterizing Functions”

# integral3

---

**Purpose** Numerically evaluate triple integral

**Syntax**  
`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)`  
`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)`

**Description** `q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)` approximates the integral of the function  $z = \text{fun}(x,y,z)$  over the region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min}(x) \leq y \leq y_{\max}(x)$  and  $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ .

`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)` specifies additional options with one or more Name,Value pair arguments.

## Input Arguments

**fun - Integrand**  
function handle

Integrand, specified as a function handle, defines the function to be integrated over the region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min}(x) \leq y \leq y_{\max}(x)$ , and  $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ . The function `fun` must accept three arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

**Data Types**  
function\_handle

**xmin - Lower limit of x**  
real number

Lower limit of  $x$ , specified as a real scalar value that is either finite or infinite.

**Example:**

**Data Types**  
double | single

**xmax - Upper limit of x**  
real number

Upper limit of  $x$ , specified as a real scalar value that is either finite or infinite.

**Data Types**

double | single

**ymin - Lower limit of y**

real number | function handle

Lower limit of  $y$ , specified as a real scalar value that is either finite or infinite. You also can specify `ymin` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

**Example:****Data Types**

double | function\_handle | single

**ymax - Upper limit of y**

real number | function handle

Upper limit of  $y$ , specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

**Example:****Data Types**

double | function\_handle | single

**zmin - Lower limit of z**

real number | function handle

Lower limit of  $z$ , specified as a real scalar value that is either finite or infinite. You also can specify `zmin` to be a function handle (a function of  $x,y$ ) when integrating over a nonrectangular region.

**Data Types**

double | function\_handle | single

**zmax - Upper limit of z**

real number | function handle

Upper limit of  $z$ , specified as a real scalar value that is either finite or infinite. You also can specify `zmax` to be a function handle (a function of  $x,y$ ) when integrating over a nonrectangular region.

### Data Types

double | function\_handle | single

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

### 'AbsTol' - Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral3` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral3` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

---

**Note** `AbsTol` and `RelTol` work together. `integral3` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-3100 section.

---

**Example:** `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

**Data Types**

double | single

**'RelTol' - Relative error tolerance**

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of 'RelTol' and a nonnegative real number. `integral3` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral3` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is  $1e-6$ .

---

**Note** `RelTol` and `AbsTol` work together. `integral3` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-3100 section.

---

**Example:** `'RelTol', 1e-9` sets the relative error tolerance to approximately 9 significant digits.

**Data Types**

double | single

**'Method' - Integration method**

'auto' (default) | 'tiled' | 'iterated'

Integration method, specified as the comma-separated pair consisting of 'Method' and one of the methods described below.

# integral3

| Integration Method | Description                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'             | For most cases, <code>integral3</code> uses the 'tiled' method. It uses the 'iterated' method when any of the integration limits are infinite. This is the default method.                                                                                                                                                           |
| 'tiled'            | <code>integral3</code> calls <code>integral</code> to integrate over $x_{\min} \leq x \leq x_{\max}$ . It calls <code>integral2</code> with the 'tiled' method to evaluate the double integral over $y_{\min}(x) \leq y \leq y_{\max}(x)$ and $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ .                                            |
| 'iterated'         | <code>integral3</code> calls <code>integral</code> to integrate over $x_{\min} \leq x \leq x_{\max}$ . It calls <code>integral2</code> with the 'iterated' method to evaluate the double integral over $y_{\min}(x) \leq y \leq y_{\max}(x)$ and $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ . The integration limits can be infinite. |

**Example:** 'Method', 'tiled' specifies the tiled integration method.

## Output Arguments

### q - Computed integral

numeric value

Computed integral of `fun(x,y,z)` over the specified region, returned as a numeric value.

## Tips

- The `integral3` function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where `q` is the computed value of the integral and `Q` is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines

the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- The 'iterated' method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integral at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when any or all of the limits: `ymin`, `ymax`, `zmin`, `zmax` are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify 'iterated' method.
- Use the 'iterated' method when any or all of the limits: `ymin(x)`, `ymax(x)`, `zmin(x,y)`, `zmax(x,y)` are unbounded functions.
- When parameterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y,z) x + y + z + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you may need to specify larger absolute and relative error tolerances.

## Examples

### Triple Integral with Finite Limits

Define the anonymous function  $f(x,y,z) = y \sin x + z \cos x$ .

```
fun = @(x,y,z) y.*sin(x)+z.*cos(x)
```

Integrate over the region  $0 \leq x \leq \pi$ ,  $0 \leq y \leq 1$ , and  $-1 \leq z \leq 1$ .

```
q = integral3(fun,0,pi,0,1,-1,1)
```

```
q =
```

```
2.0000
```

# integral3

---

## Integral Over the Unit Sphere in Cartesian Coordinates

Define the anonymous function  $f(x,y,z) = x \cos y + x^2 \cos z$ .

```
fun = @(x,y,z) x.*cos(y) + x.^2.*cos(z)
```

Define the limits of integration.

```
xmin = -1;  
xmax = 1;  
ymin = @(x)-sqrt(1 - x.^2);  
ymax = @(x) sqrt(1 - x.^2);  
zmin = @(x,y)-sqrt(1 - x.^2 - y.^2);  
zmax = @(x,y) sqrt(1 - x.^2 - y.^2);
```

Evaluate the definite integral with the 'tiled' method.

```
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,'Method','tiled')
```

```
q =
```

```
0.7796
```

## Evaluate Improper Triple Integral of Parameterized Function

Define the anonymous parameterized function  $f(x,y,z) = 10/(x^2 + y^2 + z^2 + a)$ .

```
a = 2;  
f = @(x,y,z) 10./(x.^2 + y.^2 + z.^2 + a);
```

Evaluate the triple integral over the region  $-\infty \leq x \leq 0$ ,  $-100 \leq y \leq 0$ , and  $-100 \leq z \leq 0$ .

```
format long  
q1 = integral3(f,-Inf,0,-100,0,-100,0)
```

```
q1 =
```

```
2.734244598320928e+03
```

Evaluate the integral again and specify accuracy to approximately 9 significant digits.

```
q2 = integral3(f,-Inf,0,-100,0,-100,0,'AbsTol', 0,'RelTol',1e-9)
```

```
q2 =
```

```
2.734244599944285e+03
```

## Concepts

- “Parameterizing Functions”

# interfaces

---

**Purpose** List custom interfaces exposed by COM server object

**Syntax**  
`customlist = h.interfaces`  
`customlist = interfaces(h)`

**Description** `customlist = h.interfaces` returns cell array of strings `customlist` listing all custom interfaces implemented by the component in a specific COM server object. The server is designated by input argument `h`, the handle returned by the `actxcontrol` or `actxserver` function when creating that server.

`customlist = interfaces(h)` is an alternate syntax.

The `interfaces` function only lists the custom interfaces exposed by the object; it does not return interfaces. Use the `invoke` function to return a handle to a specific custom interface.

COM functions are available on Microsoft Windows systems only.

**See Also** `actxcontrol` | `actxserver` | `invoke` | `get` (COM)

**How To**

- “Custom Interfaces”

**Purpose**

1-D data interpolation (table lookup)

If you pass nonuniformly spaced points and specify the 'v5cubic' method, `interp1` issues a warning. In addition, the following syntaxes will be removed or changed in a future release:

- `interp1(..., 'cubic')`
- `pp = interp1(... 'pp')`
- `interp1(X,Y,Xq,[],...)`

For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

**Syntax**

```
vq = interp1(x,v,xq)
vq = interp1(x,v,xq,method)
vq = interp1(x,v,xq,method,extrapolation)
```

```
vq = interp1(v,xq)
vq = interp1(v,xq,method)
vq = interp1(v,xq,method,extrapolation)
```

```
pp = interp1(x,v,method,'pp')
```

**Description**

`vq = interp1(x,v,xq)` returns interpolated values of a 1-D function at specific query points using linear interpolation. Vector `x` contains the sample points, and `v` contains the corresponding values,  $v(x)$ . Vector `xq` contains the coordinates of the query points.

If you have multiple sets of data that are sampled at the same point coordinates, then you can pass `v` as an array. Each column of array `v` contains a different set of 1-D sample values.

`vq = interp1(x,v,xq,method)` specifies any of five strings for choosing an alternative interpolation method: 'nearest', 'linear', 'spline', 'pchip', or 'cubic'. The default method is 'linear'.

# interp1

---

`vq = interp1(x,v,xq,method,extrapolation)` specifies a strategy for evaluating points that lie outside the domain of `x`. Set `extrapolation` to the string, 'extrap', when you want to use the `method` algorithm for extrapolation. Alternatively, you can specify a scalar value, in which case, `interp1` returns that value for all points outside the domain of `x`.

`vq = interp1(v,xq)` returns interpolated values and assumes a default set of sample point coordinates. The default points are the sequence of numbers from 1 to `n`, where `n` depends on the shape of `v`:

- When `v` is a vector, the default points are `1:length(v)`.
- When `v` is an array, the default points are `1:size(v,1)`.

Use this syntax when you are not concerned about the absolute distances between points.

`vq = interp1(v,xq,method)` specifies any of the five alternative interpolation methods and uses the default sample points.

`vq = interp1(v,xq,method,extrapolation)` specifies an extrapolation strategy and uses the default sample points.

`pp = interp1(x,v,method,'pp')` returns the piece-wise polynomial form of  $v(x)$  using the `method` algorithm.

## Input Arguments

### **x** - Sample points

vector

Sample points, specified as a row or column vector of real numbers. The values in `x` must be strictly monotonic and increasing. Furthermore, the length of `x` must conform to one of the following requirements:

- If `v` is a vector, then `length(x)` must equal `length(v)`.
- If `v` is an array, then `length(x)` must equal `size(v,1)`.

**Example:** `[1 2 3 4 5 6 7 8 9 10]`

**Example:** 1:10

**Example:** [3 7 11 15 19 23 27 31]'

## Data Types

single | double

## v - Sample values

vector | matrix | array

Sample values, specified as a vector, matrix, or array of real or complex numbers. If *v* is a matrix or an array, then each column contains a separate set of 1-D values.

**Example:** rand(1,10)

**Example:** rand(10,1)

**Example:** rand(10,3)

## Data Types

single | double

**Complex Number Support:** Yes

## xq - Query points

scalar | vector | matrix | array

Query points, specified as a scalar, vector, matrix, or array of real numbers.

**Example:** 5

**Example:** 1:0.05:10

**Example:** (1:0.05:10)'

**Example:** [0 1 2 7.5 10]

## Data Types

single | double

## method - Interpolation method

'linear' (default) | 'nearest' | 'spline' | 'pchip' | 'cubic'

# interp1

Interpolation method, specified as a string from the table below.

| method string | Description                                                                                                                                                                                    | Continuity    | Comments                                                                                                                                                                                                           |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear'      | Linear interpolation. The interpolated value at a query point is the value at the nearest sample grid point.                                                                                   | Discontinuous | <ul style="list-style-type: none"><li>• Requires a minimum of 2 points.</li><li>• Requires more memory than nearest neighbor.</li><li>• Requires more memory and computation time than nearest neighbor.</li></ul> |
| 'nearest'     | Nearest neighbor interpolation. The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension.                | $C^0$         | <ul style="list-style-type: none"><li>• Requires a minimum of 2 points.</li><li>• Modest memory requirements</li><li>• Fastest computation time</li></ul>                                                          |
| 'pchip'       | Shape-preserving piecewise cubic interpolation. The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points. | $C^1$         | <ul style="list-style-type: none"><li>• Requires at least 4 points.</li><li>• Requires more memory and computation time than linear.</li></ul>                                                                     |

| method string | Description                                                                                                                                                            | Continuity | Comments                                                                                                                                           |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 'cubic'       | Same as 'pchip'.                                                                                                                                                       | $C^1$      | This method currently returns the same result as 'pchip'. In a future release, this method will perform cubic convolution.                         |
| 'v5cubic'     | Cubic convolution used in MATLAB 5.                                                                                                                                    | $C^1$      | Points must be uniformly spaced. 'cubic' will replace 'v5cubic' in a future release.                                                               |
| 'spline'      | Spline interpolation. The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. | $C^2$      | <ul style="list-style-type: none"> <li>• Requires at least 4 points.</li> <li>• Requires more memory and computation time than 'pchip'.</li> </ul> |

## extrapolation - Extrapolation strategy

'extrap' | scalar value

Extrapolation strategy, specified as the string, 'extrap', or a real scalar value.

- Specify 'extrap' when you want `interp1` to evaluate points outside the domain using the same method it uses for interpolation.
- Specify a scalar value when you want `interp1` to return a specific constant value for points outside the domain.

The default behavior depends on the input arguments:

# interp1

- If you specify the 'pchip' or 'spline' interpolation methods, then the default behavior is 'extrap'.
- All other interpolation methods return NaN by default for query points outside the domain.

**Example:** 'extrap'

**Example:** 5

## Data Types

char | single | double

## Output Arguments

### vq - Interpolated values

scalar | vector | matrix | array

Interpolated values, returned as a scalar, vector, matrix, or array. The size of vq depends on the shape of v and xq.

| Shape of v | Shape of xq         | Size of Vq | Example                                                               |
|------------|---------------------|------------|-----------------------------------------------------------------------|
| Vector     | Vector              | size(xq)   | If size(v) = [1 100] and size(xq) = [1 500], then size(vq) = [1 500]. |
| Vector     | Matrix or N-D Array | size(xq)   | If size(v) = [1 100] and size(xq) = [50 30], then size(vq) = [50 30]. |

| Shape of <b>v</b>   | Shape of <b>xq</b>  | Size of <b>Vq</b>                                                                          | Example                                                                                                                |
|---------------------|---------------------|--------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Matrix or N-D Array | Vector              | $[\text{length}(xq) \text{ size}(v,2), \dots, \text{size}(v,3)]$                           | If $\text{size}(v) = [100 \ 3]$ and $\text{size}(xq) = [1 \ 500]$ , then $\text{size}(vq) = [500 \ 3]$ .               |
| Matrix or N-D Array | Matrix or N-D Array | $[\text{size}(xq,1), \dots, \text{size}(xq,2), \text{size}(v,2), \dots, \text{size}(v,3)]$ | If $\text{size}(v) = [4 \ 5 \ 6]$ and $\text{size}(xq) = [2 \ 3 \ 7]$ , then $\text{size}(vq) = [2 \ 3 \ 7 \ 5 \ 6]$ . |

## pp - Piecewise polynomial

structure

Piecewise polynomial, returned as a structure that you can pass to the `ppval` function for evaluation.

## Definitions

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2 \ 4 \ 6 \ 8]$  is strictly monotonic and increasing. The sequence,  $b = [2 \ 4 \ 4 \ 6 \ 8]$  is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2 \ 4 \ 6 \ 8 \ 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

## Examples

### Interpolation of Coarsely Sampled Sine Function

Define the sample points,  $x$ , and corresponding sample values,  $v$ .

```
x = 0:pi/4:2*pi;
v = sin(x);
```

# interp1

---

Define the query points to be a finer sampling over the range of  $x$ .

```
xq = 0:pi/16:2*pi;
```

Interpolate the function at the query points and plot the result.

```
figure
vq1 = interp1(x,v,xq);
plot(x,v,'o',xq,vq1);
xlim([0 2*pi]);
title('(Default) Linear Interpolation');
```

Now evaluate  $v$  at the same points using the 'spline' method.

```
figure
vq2 = interp1(x,v,xq,'spline');
plot(x,v,'o',xq,vq2);
```

# interp1

---

```
xlim([0 2*pi]);  
title('Spline Interpolation');
```

## Interpolation Without Specifying Points

Define a set of function values.

```
v = [0 1.41 2 1.41 0 -1.41 -2 -1.41 0];
```

Define a set of query points that fall between the default points, 1:9. In this case, the default points are 1:9 because v contains 9 values.

```
xq = 1.5:8.5;
```

Evaluate v at xq.

```
vq = interp1(v,xq);
```

Plot the result.

```
figure  
plot((1:9),v,'o',xq,vq,'*');  
legend('v','vq');
```

# interp1

## Interpolation of Complex Values

Define a set of sample points.

```
x = 1:10;
```

Define the values of the function,  $v(x) = 5x + x^2i$ , at the sample points.

```
v = (5*x)+(x.^2*1i);
```

Define the query points to be a finer sampling over the range of  $x$ .

```
xq = 1:0.25:10;
```

Interpolate  $v$  at the query points.

```
vq = interp1(x,v,xq);
```

Plot the real part of the result in red and the imaginary part in blue.

```
figure  
plot(x,real(v),'*r',xq,real(vq),'-r');  
hold on  
plot(x,imag(v),'*b',xq,imag(vq),'-b');
```

# interp1

---

## Extrapolation Using Two Different Methods

Define the sample points,  $x$ , and corresponding sample values,  $v$ .

```
x = [1 2 3 4 5];  
v = [12 16 31 10 6];
```

Specify the query points,  $xq$ , that extend beyond the domain of  $x$ .

```
xq = [0 0.5 1.5 5.5 6];
```

Evaluate  $v$  at  $xq$  using the 'pchip' method.

```
vq1 = interp1(x,v,xq,'pchip')
vq1 =
    19.3684    13.6316    13.2105     7.4800    12.5600
```

Next, evaluate  $v$  at  $xq$  using the 'linear' method.

```
vq2 = interp1(x,v,xq,'linear')
vq2 =
    NaN    NaN    14    NaN    NaN
```

Now, use the 'linear' method with the 'extrap' option.

```
vq3 = interp1(x,v,xq,'linear','extrap')
vq3 =
     8     10     14     4     2
```

'pchip' extrapolates by default, but 'linear' does not.

## Designate Constant Value for All Queries Outside the Domain of $x$

Define the sample points,  $x$ , and corresponding sample values,  $v$ .

```
x = [-3 -2 -1 0 1 2 3];
v = 3*x.^2;
```

Specify the query points,  $xq$ , that extend beyond the domain of  $x$ .

```
xq = [-4 -2.5 -0.5 0.5 2.5 4];
```

Now evaluate  $v$  at  $xq$  using the 'pchip' method and assign any values outside the domain of  $x$  to the value, 27.

# interp1

---

```
vq = interp1(x,v,xq,'pchip',27)
```

```
vq =
```

```
27.0000 18.6563 0.9375 0.9375 18.6563 27.0000
```

## Interpolate Multiple Sets of Data in One Pass

Define the sample points.

```
x = (-5:5)';
```

Sample three different parabolic functions at the points defined in x.

```
v1 = x.^2;  
v2 = 2*x.^2 + 2;  
v3 = 3*x.^2 + 4;
```

Create matrix v, whose columns are the vectors, v1, v2, and v3.

```
v = [v1 v2 v3];
```

Define a set of query points, xq, to be a finer sampling over the range of x.

```
xq = -5:0.1:5;
```

Evaluate all three functions at xq and plot the results.

```
vq = interp1(x,v,xq,'pchip');  
figure  
plot(x,v,'o',xq,vq);  
set(gca,'XTick',-5:5);
```

The circles in the plot represent  $v$ , and the solid lines represent  $vq$ .

[interp2](#) | [interp3](#) | [interpgriddedInterpolant](#) |

# interp1q

---

**Purpose** Quick 1-D linear interpolation

---

**Note** `interp1q` is not recommended. Use `interp1` instead.

---

**Syntax** `yi = interp1q(x,Y,xi)`

**Description** `yi = interp1q(x,Y,xi)` returns the value of the 1-D function `Y` at the points of column vector `xi` using linear interpolation. The vector `x` specifies the coordinates of the underlying interval. The length of output `yi` is equal to the length of `xi`.

`interp1q` is quicker than `interp1` on non-uniformly spaced data because it does no input checking.

For `interp1q` to work properly,

- `x` must be a monotonically increasing column vector.
- `Y` must be a column vector or matrix with `length(x)` rows.
- `xi` must be a column vector

`interp1q` returns NaN for any values of `xi` that lie outside the coordinates in `x`. If `Y` is a matrix, then the interpolation is performed for each column of `Y`, in which case `yi` is `length(xi)-by-size(Y,2)`.

**Examples** Generate a coarse sine curve and interpolate over a finer abscissa.

```
x = (0:10)';  
y = sin(x);  
xi = (0:.25:10)';  
yi = interp1q(x,y,xi);  
plot(x,y,'o',xi,yi)
```

**See Also**

[interp1](#) | [interp2](#) | [interp3](#) | [interpn](#)

# interp2

---

## Purpose

Interpolation for 2-D gridded data in meshgrid format

In a future release, `interp2` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

## Syntax

```
Vq = interp2(X,Y,V,Xq,Yq)
```

```
Vq = interp2(V,Xq,Yq)
```

```
Vq = interp2(V,ntimes)
```

```
Vq = interp2(__,method)
```

```
Vq = interp2(__,method,extrapval)
```

## Description

`Vq = interp2(X,Y,V,Xq,Yq)` returns interpolated values of a function of two variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X` and `Y` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq` and `Yq` contain the coordinates of the query points.

`Vq = interp2(V,Xq,Yq)` assumes a default grid of sample points. The default grid points cover the rectangular region, `X=1:n` and `Y=1:m`, where `[m,n] = size(V)`. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp2(V,ntimes)` returns the sample values with `ntimes` interpolated values inserted between adjacent sample values in each dimension.

`Vq = interp2(__,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: 'linear', 'nearest', 'cubic', or 'spline'. The default method is 'linear'.

`Vq = interp2( ___, method, extrapolval)` also specifies `extrapolval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points. If you omit the `extrapolval` argument, then `interp2` returns NaN values for queries outside the domain of the sample points.

## Input Arguments

### **X,Y - Sample grid points**

matrices | vectors

Sample grid points, specified as real matrices or vectors.

- If `X` and `Y` are matrices, then they contain the coordinates of a full grid (in `meshgrid` format). Use the `meshgrid` function to create the `X` and `Y` matrices together. Both matrices must be the same size.
- If `X` and `Y` are vectors, then they are treated as a grid vectors. The values in both vectors must be strictly monotonic and increasing.

**Example:** `[X,Y] = meshgrid(1:30,-10:10)`

### **Data Types**

single | double

### **V - Sample values**

matrix

Sample values, specified as a real or complex matrix. The size requirements for `V` depend on the size of `X` and `Y`.

- If `X` and `Y` are matrices representing a full grid (in `meshgrid` format), then `V` must be the same size as `X` and `Y`.
- If `X` and `Y` are grid vectors, then `V` must be a matrix containing `length(Y)` rows and `length(X)` columns.

**Example:** `rand(10,10)`

### **Data Types**

single | double

**Complex Number Support:** Yes

### **Xq,Yq - Query points**

scalars | vectors | matrices | arrays

Query points, specified as a real scalars, vectors, matrices, or arrays.

- If  $Xq$  and  $Yq$  are scalars, then they are the coordinates of a single query point.
- If  $Xq$  and  $Yq$  are vectors of different orientations, then  $Xq$  and  $Yq$  are treated as grid vectors.
- If  $Xq$  and  $Yq$  are vectors of the same size and orientation, then  $Xq$  and  $Yq$  are treated as scattered points in 2-D space.
- If  $Xq$  and  $Yq$  are matrices, then they represent either a full grid of query points (in `meshgrid` format) or scattered points.
- If  $Xq$  and  $Yq$  are N-D arrays, then they represent scattered points in 2-D space.

**Example:** `[Xq,Yq] = meshgrid((1:0.1:10),(-5:0.1:0))`

## Data Types

single | double

## **ntimes - Refinement factor**

real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of interpolated values to insert between original sample values in each dimension. If `ntimes` is 0, then  $Vq$  is the same as  $V$ . The following illustration shows the placement of interpolated values (in red) among nine sample values (in black) for `ntimes=3`.

Example: 3

### Data Types

single | double

### method - Interpolation method

'linear' (default) | 'nearest' | 'cubic' | 'spline'

Interpolation method, specified as a string from this table.

| Method    | Description                                                                                                                                                                               | Continuity    | Comments                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear'  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method. | $C^0$         | <ul style="list-style-type: none"> <li>Requires at least two grid points in each dimension</li> <li>Requires more memory than 'nearest'</li> </ul> |
| 'nearest' | The interpolated value at a query point is the value                                                                                                                                      | Discontinuous | <ul style="list-style-type: none"> <li>Requires two grid points in each dimension.</li> </ul>                                                      |

# interp2

| 'spline' | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline.      | $C^2$      | <ul style="list-style-type: none"><li>• Requires four points in each dimension</li><li>• Requires more memory and computation time than 'cubic'</li></ul>                                                                                                                                       |

**extrapval - Function value outside domain of X and Y**  
scalar

Function value outside domain of X and Y, specified as a real or complex scalar. `interp2` returns this constant value for all points outside the domain of X and Y.

**Example:** 5

**Example:** 5+1i

### Data Types

single | double

**Complex Number Support:** Yes

## Output Arguments

### Vq - Interpolated values

scalar | vector | matrix

Interpolated values, returned as a real or complex scalar, vector, or matrix. The size and shape of Vq depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                                                                          | Special Conditions                                  | Size of Vq                                                                                                           | Example                                                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>interp2(X,Y,V,Xq,Yq)</code><br><code>interp2(V,Xq,Yq)</code><br>and variations of these syntaxes that include <code>method</code> or <code>extrapval</code> | Xq, Yq are scalars                                  | Scalar                                                                                                               | <code>size(Vq) = [1 1]</code> when you pass Xq and Yq as scalars.                                               |

## Definitions

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2 \ 4 \ 6 \ 8]$  is strictly monotonic and increasing. The sequence,  $b = [2 \ 4 \ 4 \ 6 \ 8]$  is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2 \ 4 \ 6 \ 8 \ 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

### Full Grid (in meshgrid Format)

For `interp2`, the full grid is a pair of matrices whose elements represent a grid of points over a rectangular region. One matrix contains the  $x$ -coordinates, and the other matrix contains the  $y$ -coordinates. The values in the  $x$ -matrix are strictly monotonic and increasing along the rows. The values along its columns are constant. The values in the  $y$ -matrix are strictly monotonic and increasing along the columns. The values along its rows are constant. Use the `meshgrid` function to create a full grid that you can pass to `interp2`.

For example, the following code creates a full grid for the region,  $-1 \leq x \leq 3$  and  $1 \leq y \leq 4$ :

```
[X,Y] = meshgrid(-1:3,(1:4))
```

X =

```

-1    0    1    2    3
-1    0    1    2    3
-1    0    1    2    3
-1    0    1    2    3

```

Y =

```

1     1     1     1     1
2     2     2     2     2
3     3     3     3     3
4     4     4     4     4

```

## Grid Vectors

For `interp2`, grid vectors consist of a pair of mixed-orientation vectors that define the  $x$ - and  $y$ -coordinates in a grid. One vector is a row vector, and the other is a column vector.

For example, the following code creates the grid vectors that specify the region,  $-1 \leq x \leq 3$  and  $1 \leq y \leq 4$ :

```
x = -1:3;
y = (1:4)';
```

## Scattered Points

For `interp2`, scattered points consist of a pair of arrays that define a collection of points scattered in 2-D space. One array contains the  $x$ -coordinates, and the other contains the  $y$ -coordinates.

For example, the following code specifies the points, (2,7), (5,3), (4,1), and (10,9):

```
x = [2 5; 4 10];
```

```
y = [7 3; 1 9];
```

## Examples

### Interpolate Over a Grid Using Default Method

Coarsely sample the peaks function.

```
[X,Y] = meshgrid(-3:3);  
V = peaks(X,Y);
```

Plot the coarse sampling.

```
figure  
surf(X,Y,V)  
title('Original Sampling');
```

Create the query grid with spacing of 0.25.

```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points.

## interp2

---

```
Vq = interp2(X,Y,V,Xq,Yq);
```

Plot the result.

```
figure  
surf(Xq,Yq,Vq);  
title('Linear Interpolation Using Finer Grid');
```

Linear Interpolation Using Finer Grid

### Interpolate Over a Grid Using Cubic Method

Coarsely sample the peaks function.

```
[X,Y] = meshgrid(-3:3);
```

## interp2

---

```
V = peaks(7);
```

Plot the coarse sampling.

```
figure  
surf(X,Y,V)  
title('Original Sampling');
```

Create the query grid with spacing of 0.25.

```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points, and specify cubic interpolation.

## interp2

---

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic');
```

Plot the result.

```
figure  
surf(Xq,Yq,Vq);  
title('Cubic Interpolation Over Finer Grid');
```

### Evaluate Outside the Domain of X and Y

Coarsely sample a function over the range,  $[-2, 2]$  in both dimensions.

```
[X,Y] = meshgrid(-2:0.75:2);
```

## interp2

---

```
R = sqrt(X.^2 + Y.^2)+ eps;  
V = sin(R)./(R);
```

Plot the coarse sampling.

```
figure  
surf(X,Y,V)  
xlim([-4 4]);  
ylim([-4 4]);  
title('Original Sampling');
```

Create the query grid that extends beyond the domain of X and Y.

```
[Xq,Yq] = meshgrid(-3:0.2:3);
```

## interp2

---

Perform cubic interpolation within the domain of X and Y, and assign all queries that fall outside to zero.

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic',0);
```

Plot the result.

```
figure  
surf(Xq,Yq,Vq);  
title('Cubic Interpolation with Vq=0 Outside Domain of X and Y');
```

Cubic Interpolation with  $V_q=0$  Outside Domain of X and Y

# interp3

---

## Purpose

Interpolation for 3-D gridded data in meshgrid format

In a future release, `interp3` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

## Syntax

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)
```

```
Vq = interp3(V,Xq,Yq,Zq)
```

```
Vq = interp3(V,ntimes)
```

```
Vq = interp3(__,method)
```

```
Vq = interp3(__,method,extrapval)
```

## Description

`Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)` returns interpolated values of a function of three variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X`, `Y`, and `Z` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq`, `Yq`, and `Zq` contain the coordinates of the query points.

`Vq = interp3(V,Xq,Yq,Zq)` assumes a default grid of sample points. The default grid points cover the region, `X=1:n`, `Y=1:m`, `Z=1:p`, where `[m,n,p] = size(V)`. Use this syntax when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp3(V,ntimes)` returns the sample values with `ntimes` interpolated values inserted between adjacent sample values in each dimension.

`Vq = interp3(__,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interp3( ____, method, extrapolval)` also specifies `extrapolval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points. If you omit the `extrapolval` argument, then `interp3` returns NaN values for queries outside the domain of the sample points.

## Input Arguments

### **X,Y,Z - Sample grid points**

arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If X, Y, and Z are arrays, then they contain the coordinates of a full grid (in `meshgrid` format). Use the `meshgrid` function to create the X, Y, and Z arrays together. These arrays must be the same size.
- If X, Y, and Z are vectors, then they are treated as a grid vectors. The values in these vectors must be strictly monotonic and increasing.

**Example:** `[X,Y,Z] = meshgrid(1:30, -10:10, 1:5)`

### **Data Types**

single | double

### **V - Sample values**

array

Sample values, specified as a real or complex array. The size requirements for V depend on the size of X, Y, and Z.

- If X, Y, and Z are arrays representing a full grid (in `meshgrid` format), then the size of V matches the size of X, Y, or Z.
- If X, Y, and Z are grid vectors, then `size(V) = [length(Y) length(X) length(Z)]`.

**Example:** `rand(10,10,10)`

### **Data Types**

single | double

**Complex Number Support:** Yes

### **Xq,Yq,Zq - Query points**

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If  $Xq$ ,  $Yq$ , and  $Zq$  are scalars, then they are the coordinates of a single query point in  $R^3$ .
- If  $Xq$ ,  $Yq$ , and  $Zq$  are vectors of different orientations, then  $Xq$ ,  $Yq$ , and  $Zq$  are treated as grid vectors in  $R^3$ .
- If  $Xq$ ,  $Yq$ , and  $Zq$  are vectors of the same size and orientation, then  $Xq$ ,  $Yq$ , and  $Zq$  are treated as scattered points in  $R^3$ .
- If  $Xq$ ,  $Yq$ , and  $Zq$  are arrays of the same size, then they represent either a full grid of query points (in `meshgrid` format) or scattered points in  $R^3$ .

**Example:** `[Xq,Yq,Zq] = meshgrid((1:0.1:10),(-5:0.1:0),3:5)`

## Data Types

single | double

## **ntimes** - Refinement factor

real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of interpolated values that `interp3` inserts between original sample values in each dimension. If `ntimes` is 0, then  $Vq$  is the same as  $V$ . The illustration below depicts `ntimes=3` in one plane of  $R^3$ . There are 72 interpolated values in red and 9 sample values in black.

Example: 3

**Data Types**

single | double

**method - Interpolation method**

'linear' (default) | 'nearest' | 'cubic' | 'spline'

Interpolation method, specified as a string from this table.

| Method    | Description                                                                                                                                                                               | Continuity    | Comments                                                                                                                                                  |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear'  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method. | $C^0$         | <ul style="list-style-type: none"> <li>Requires at least two grid points in each dimension</li> <li>Requires more memory than 'nearest'</li> </ul>        |
| 'nearest' | The interpolated value at a query point is the value at the nearest sample grid point.                                                                                                    | Discontinuous | <ul style="list-style-type: none"> <li>Requires two grid points in each dimension</li> <li>Fastest computation with modest memory requirements</li> </ul> |

# interp3

| Method   | Description                                                                                                                                                                                         | Continuity | Comments                                                                                                                                                                                                                                                                                        |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'cubic'  | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution. | $C^1$      | <ul style="list-style-type: none"><li>• Grid must have uniform spacing in each dimension, but the spacing does not have to be the same for all dimensions</li><li>• Requires at least four points in each dimension</li><li>• Requires more memory and computation time than 'linear'</li></ul> |
| 'spline' | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline.      | $C^2$      | <ul style="list-style-type: none"><li>• Requires four points in each dimension</li><li>• Requires more memory and computation time than 'cubic'</li></ul>                                                                                                                                       |

**extrapval - Function value outside domain of X, Y, and Z**  
scalar

Function value outside domain of X, Y, and Z, specified as a real or complex scalar. `interp3` returns this constant value for all points outside the domain of X, Y, and Z.

**Example:** 5

**Example:** 5+1i

**Data Types**

single | double

**Complex Number Support:** Yes

## Output Arguments

### Vq - Interpolated values

scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of Vq depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                                     | Special Conditions                                                          | Size of Vq                                                  | Example                                                                                                           |

## Definitions

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2\ 4\ 6\ 8]$  is strictly monotonic and increasing. The sequence,  $b = [2\ 4\ 4\ 6\ 8]$  is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2\ 4\ 6\ 8\ 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

### Full Grid (in meshgrid Format)

For interp3, a full grid consists of three arrays whose elements represent a grid of points that define a region in  $R^3$ . The first array contains the  $x$ -coordinates, the second array contains the  $y$ -coordinates, and the third array contains the  $z$ -coordinates.

The values in the  $x$ -array are strictly monotonic, increasing, and vary along the second dimension. The values in the  $y$ -array are strictly monotonic, increasing, and vary along the first dimension. The values in the  $z$ -array are strictly monotonic, increasing, and vary along the third dimension. Use the meshgrid function to create a full grid that you can pass to interp3.

### Grid Vectors

For `interp3`, grid vectors consist of three vectors of mixed-orientation that define the points on a grid in  $R^3$ .

For example, the following code creates the grid vectors for the region,  $1 \leq x \leq 3$ ,  $4 \leq y \leq 5$ , and  $6 \leq z \leq 8$ :

```
x = 1:3;
y = (4:5)';
z = 6:8;
```

### Scattered Points

For `interp3`, scattered points consist of three arrays or vectors,  $Xq$ ,  $Yq$ , and  $Zq$ , that define a collection of points scattered in  $R^3$ . The  $i$ th array contains the coordinates in the  $i$ th dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13).

```
Xq = [1 6; 15 0];
Yq = [19 40; 33 61];
Zq = [10 1; 22 13];
```

## Examples

### Interpolate Using Default Method

Load the points and values of the flow function, sampled at 10 points in each dimension.

```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays,  $X$ ,  $Y$ ,  $Z$ . The grid covers the region,  $0.1 \leq X \leq 10$ ,  $-3 \leq Y \leq 3$ ,  $-3 \leq Z \leq 3$ , and the spacing is  $\Delta X = 0.5$ ,  $\Delta Y = 0.7$ , and  $\Delta Z = 0.7$ .

Now, plot slices through the volume of the sample at:  $X=6$ ,  $X=9$ ,  $Y=2$ , and  $Z=0$ .

```
figure
slice(X,Y,Z,V,[6 9],2,0);
```

# interp3

shading flat

Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10,-3:.25:3,-3:.25:3);
```

Interpolate at the points in the query grid and plot the results using the same slice planes.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq);  
figure  
slice(Xq,Yq,Zq,Vq,[6 9],2,0);  
shading flat
```

## Interpolate Using Cubic Method

Load the points and values of the flow function, sampled at 10 points in each dimension.

```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays, `X`, `Y`, `Z`. The grid covers the region,  $0.1 \leq X \leq 10$ ,  $-3 \leq Y \leq 3$ ,  $-3 \leq Z \leq 3$ , and the spacing is  $\Delta X = 0.5$ ,  $\Delta Y = 0.7$ , and  $\Delta Z = 0.7$ .

Plot slices through the volume of the sample at: `X=6`, `X=9`, `Y=2`, and `Z =0`.

```
figure  
slice(X,Y,Z,V,[6 9],2,0);  
shading flat
```

# interp3

---

Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10,-3:.25:3,-3:.25:3);
```

Interpolate at the points in the query grid using the 'cubic' interpolation method. Then plot the results.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq,'cubic');  
figure  
slice(Xq,Yq,Zq,Vq,[6 9],2,0);  
shading flat
```

# interp3

---

## Evaluate Outside the Domain of X, Y, and Z

Create the grid vectors,  $x$ ,  $y$ , and  $z$ . These vectors define the points associated with values in  $V$ .

```
x = 1:100;  
y = (1:50)';  
z = 1:30;
```

Define the sample values to be a 50-by-100-by-30 random number array, *V*. Use the `gallery` function to create the array.

```
V = gallery('uniformdata',50,100,30,0);
```

Evaluate *V* at three points outside the domain of *x*, *y*, and *z*. Specify `extrapval = -1`.

```
xq = [0 0 0];  
yq = [0 0 51];  
zq = [0 101 102];  
vq = interp3(x,y,z,V,xq,yq,zq,'linear',-1)
```

```
vq =
```

```
    -1    -1    -1
```

All three points evaluate to -1 because they are outside the domain of *x*, *y*, and *z*.

## See Also

[interp1](#) | [interp2](#) | [interp3](#) | [interp](#) | [meshgrid](#)

# interpft

---

**Purpose** 1-D interpolation using FFT method

**Syntax**  
`y = interpft(x,n)`  
`y = interpft(x,n,dim)`

**Description** `y = interpft(x,n)` returns the vector `y` that contains the value of the periodic function `x` resampled to `n` equally spaced points.

If `length(x) = m`, and `x` has sample interval `dx`, then the new sample interval for `y` is `dy = dx*m/n`. Note that `n` cannot be smaller than `m`.

If `X` is a matrix, `interpft` operates on the columns of `X`, returning a matrix `Y` with the same number of columns as `X`, but with `n` rows.

`y = interpft(x,n,dim)` operates along the specified dimension.

**Algorithms** The `interpft` command uses the FFT method. The original vector `x` is transformed to the Fourier domain using `fft` and then transformed back with more points.

**Examples** Interpolate a triangle-like signal using an interpolation factor of 5. First, set up signal to be interpolated:

```
y = [0 .5 1 1.5 2 1.5 1 .5 0 -.5 -1 -1.5 -2 -1.5 -1 -.5 0];  
N = length(y);
```

Perform the interpolation:

```
L = 5;  
M = N*L;  
x = 0:L:L*N-1;  
xi = 0:M-1;  
yi = interpft(y,M);  
plot(x,y,'o',xi,yi,'*')  
legend('Original data','Interpolated data')
```

**See Also** `interp1`

**Purpose**

Interpolation for 1-D, 2-D, 3-D, and N-D gridded data in ndgrid format

In a future release, `interpn` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

**Syntax**

```
Vq = interpn(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)
```

```
Vq = interpn(V,Xq1,Xq2,...,Xqn)
```

```
Vq = interpn(V,ntimes)
```

```
Vq = interpn( __ ,method)
```

```
Vq = interpn( __ ,method,extrapval)
```

**Description**

`Vq = interpn(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)` returns interpolated values of a function of  $n$  variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `Xq1,Xq2,...,Xqn` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq1,Xq2,...,Xqn` contain the coordinates of the query points.

`Vq = interpn(V,Xq1,Xq2,...,Xqn)` assumes a default grid of sample points. The default grid consists of the points,  $1,2,3,\dots,n_i$  in each dimension. The value of  $n_i$  is the length of the  $i$ th dimension in `V`. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interpn(V,ntimes)` returns the sample values with `ntimes` interpolated values inserted between adjacent sample values in each dimension.

`Vq = interpn( __ ,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that

# interp

---

specify alternative interpolation methods: 'linear', 'nearest', 'pchip', 'cubic', or 'spline'. The default method is 'linear'.

`Vq = interp( ___, method, extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points. If you omit the `extrapval` argument, then `interp` returns NaN values for queries outside the domain of the sample points.

## Input Arguments

### **X1,X2,...,Xn - Sample grid points**

arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If  $X_1, X_2, \dots, X_n$  are arrays, then they contain the coordinates of a full grid (in `ndgrid` format). Use the `ndgrid` function to create the  $X_1, X_2, \dots, X_n$  arrays together. These arrays must be the same size.
- If  $X_1, X_2, \dots, X_n$  are vectors, then they are treated as grid vectors. The values in these vectors must be strictly monotonic and increasing.

**Example:** `[X1,X2,X3] = ndgrid(1:30,-10:10,1:5)`

### **Data Types**

single | double

### **V - Sample values**

array

Sample values, specified as a real or complex array. The size requirements for  $V$  depend on the size of  $X_1, X_2, \dots, X_n$ .

- If  $X_1, X_2, \dots, X_n$  are arrays representing a full grid (in `ndgrid` format), then the size of  $V$  matches the size of any array,  $X_1, X_2, \dots, X_n$ .
- If  $X_1, X_2, \dots, X_n$  are grid vectors, then  $V$  is an array whose  $i$ th dimension is the same length as grid vector  $X_i$ , where  $i = 1, 2, \dots, n$ .

**Example:** `rand(10,5,3,2)`

**Data Types**

single | double

**Complex Number Support:** Yes**Xq1,Xq2,...,Xqn - Query points**

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If  $Xq_1, Xq_2, \dots, Xq_n$  are scalars, then they are the coordinates of a single query point in  $R^n$ .
- If  $Xq_1, Xq_2, \dots, Xq_n$  are vectors of different orientations, then  $Xq_1, Xq_2, \dots, Xq_n$  are treated as grid vectors in  $R^n$ .
- If  $Xq_1, Xq_2, \dots, Xq_n$  are vectors of the same size and orientation, then  $Xq_1, Xq_2, \dots, Xq_n$  are treated as scattered points in  $R^n$ .
- If  $Xq_1, Xq_2, \dots, Xq_n$  are arrays of the same size, then they represent either a full grid of query points (in `ndgrid` format) or scattered points in  $R^n$ .

**Example:** `[X1,X2,X3,X4] = ndgrid(1:10,1:5,7:9,10:11)`**Data Types**

single | double

**ntimes - Refinement factor**

real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of interpolated values that `interpn` inserts between original sample values in each dimension. If `ntimes` is 0, then  $V_q$  is the same as  $V$ . The illustration below depicts `ntimes=3` in  $R^2$ . There are 72 interpolated values in red and 9 sample values in black.

# interp

Example: 3

### Data Types

single | double

### method - Interpolation method

'linear' (default) | 'nearest' | 'pchip' | 'cubic' | 'spline'

Interpolation method, specified as a string from this table.

| Method    | Description                                                                                                                                                                               | Continuity    | Comments                                                                                                                                            |

**Vq - Interpolated values**

scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of  $V_q$  depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                                                                                                   | Special Conditions                                             | Size of Vq                                               | Example                                                                                                                                                            |

## Definitions **Strictly Monotonic**

A set of values that are always increasing or decreasing, without reversals. For example, the sequence, `a = [2 4 6 8]` is strictly monotonic and increasing. The sequence, `b = [2 4 4 6 8]` is not strictly monotonic because there is no change in value between `b(2)` and `b(3)`. The sequence, `c = [2 4 6 8 6]` contains a reversal between `c(4)` and `c(5)`, so it is not monotonic at all.

## Full Grid (in ndgrid Format)

For `interp`, the full grid consists of  $n$  arrays, `X1, X2, ..., Xn`, whose elements represent a grid of points in  $R^n$ . The  $i$ th array, `Xi`, contains strictly monotonic, increasing values that vary most rapidly along the  $i$ th dimension.

Use the `ndgrid` function to create a full grid that you can pass to `interp`. For example, the following code creates a full grid in  $R^2$  for the region,  $1 \leq X1 \leq 3$ ,  $1 \leq X2 \leq 4$ .

```
[X1,X2] = ndgrid(-1:3, (1:4))
```

X1 =

```
-1    -1    -1    -1
 0     0     0     0
 1     1     1     1
 2     2     2     2
 3     3     3     3
```

X2 =

```

1     2     3     4
1     2     3     4
1     2     3     4
1     2     3     4
1     2     3     4

```

## Grid Vectors

For `interpn`, grid vectors consist of  $n$  vectors of mixed-orientation that define the points of a grid in  $R^n$ .

For example, the following code creates the grid vectors in  $R^3$  for the region,  $1 \leq x_1 \leq 3$ ,  $4 \leq x_2 \leq 5$ , and  $6 \leq x_3 \leq 8$ :

```

x1 = 1:3;
x2 = (4:5)';
x3 = 6:8;

```

## Scattered Points

For `interpn`, scattered points consist of  $n$  arrays or vectors,  $X_{q1}, X_{q2}, \dots, X_{qn}$ , that define a collection of points scattered in  $R^n$ . The  $i$ th array,  $X_i$ , contains the coordinates in the  $i$ th dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13) in  $R^3$ .

```

Xq1 = [1 6; 15 0];
Xq2 = [19 40; 33 61];
Xq3 = [10 1; 22 13];

```

## Examples

### 1-D Interpolation

Define the sample points and values.

```

x = [1 2 3 4 5];
v = [12 16 31 10 6];

```

Define the query points, `xq`, and interpolate.

# interp

```
xq = (1:0.1:5);  
vq = interp(x,v,xq,'cubic');
```

Plot the result.

```
figure  
plot(x,v,'o',xq,vq,'-');  
legend('Samples','Cubic Interpolation');
```

## 2-D Interpolation

Create a set of grid points and corresponding sample values.

```
[X1,X2] = ndgrid((-5:1:5));  
R = sqrt(X1.^2 + X2.^2)+ eps;  
V = sin(R)./(R);
```

Interpolate over a finer grid using `ntimes=1`.

```
Vq = interpn(V,1,'cubic');  
mesh(Vq);
```

## Evaluate Outside Domain of 3-D Function

Create the grid vectors,  $x_1$ ,  $x_2$ , and  $x_3$ . These vectors define the points associated with the values in  $V$ .

```
x1 = 1:100;
x2 = (1:50)';
x3 = 1:30;
```

Define the sample values to be a 100-by-50-by-30 random number array, *V*. Use the `gallery` function to create the array.

```
V = gallery('uniformdata',100,50,30,0);
```

Evaluate *V* at three points outside the domain of *x1*, *x2*, and *x3*. Specify `extrapval = -1`.

```
xq1 = [0 0 0];
xq2 = [0 0 51];
xq3 = [0 101 102];
vq = interpn(x1,x2,x3,V,xq1,xq2,xq3,'linear',-1)
```

```
vq =
```

```
    -1    -1    -1
```

All three points evaluate to -1 because they are outside the domain of *x1*, *x2*, and *x3*.

## 4-D Interpolation

Define an anonymous function that represents  $f = te^{-x^2-y^2-z^2}$ .

```
f = @(x,y,z,t) t.*exp(-x.^2 - y.^2 - z.^2);
```

Create a grid of points in  $R^4$ . Then, pass the points through the function to create the sample values, *V*.

```
[x,y,z,t] = ndgrid(-1:0.2:1,-1:0.2:1,-1:0.2:1,0:2:10);
V = f(x,y,z,t);
```

Now, create the query grid.

```
[xq,yq,zq,tq] = ...
```

# interp

---

```
ndgrid(-1:0.05:1, -1:0.08:1, -1:0.05:1, 0:0.5:10);
```

Interpolate V at the query points.

```
Vq = interpn(x,y,z,t,V,xq,yq,zq,tq);
```

Create a movie to show the results.

```
figure('renderer','zbuffer');
nframes = size(tq, 4);
for j = 1:nframes
    slice(yq(:,:,:,j),xq(:,:,:,j),zq(:,:,:,j),...
        Vq(:,:,:,j),0,0,0);
    caxis([0 10]);
    M(j) = getframe;
end
movie(M);
```

## See Also

[interp1](#) | [interp2](#) | [interp3](#) | [ndgrid](#)

# interpstreamspeed

---

**Purpose** Interpolate stream-line vertices from flow speed

**Syntax**

```
interpstreamspeed(X,Y,Z,U,V,W,vertices)
interpstreamspeed(U,V,W,vertices)
interpstreamspeed(X,Y,Z,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(X,Y,U,V,vertices)
interpstreamspeed(U,V,vertices)
interpstreamspeed(X,Y,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(...,sf)
vertsout = interpstreamspeed(...)
```

**Description** `interpstreamspeed(X,Y,Z,U,V,W,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U, V, W`.

The arrays `X, Y, and Z`, which define the coordinates for `U, V, and W`, must be monotonic, but do not need to be uniformly spaced. `X, Y, and Z` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,W,vertices)` assumes `X, Y, and Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(U)`.

`interpstreamspeed(X,Y,Z,speed,vertices)` uses the 3-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X, Y, and Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p]=size(speed)`.

`interpstreamspeed(X,Y,U,V,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M N]=size(U)`.

`interpstreamspeed(X,Y,speed,vertices)` uses the 2-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M,N]= size(speed)`.

`interpstreamspeed(...,sf)` uses `sf` to scale the magnitude of the vector data and therefore controls the number of interpolated vertices. For example, if `sf` is 3, then `interpstreamspeed` creates only one-third of the vertices.

`vertsout = interpstreamspeed(...)` returns a cell array of vertex arrays.

## Examples

This example draws streamlines using the vertices returned by `interpstreamspeed`. Dot markers indicate the location of each vertex. This example enables you to visualize the relative speeds of the flow data. Streamlines having widely spaced vertices indicate faster flow; those with closely spaced vertices indicate slower flow.

```
load wind
[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.2);
sl = streamline(iverts);
```

# interpstreamspeed

---

```
set(sl,'Marker','.')  
axis tight; view(2); daspect([1 1 1])
```

This example plots streamlines whose vertex spacing indicates the value of the gradient along the streamline.

```
figure  
z = membrane(6,30);  
[u v] = gradient(z);  
pcolor(z)  
hold on  
[verts averts] = streamslice(u,v);  
iverts = interpstreamspeed(u,v,verts,15);  
sl = streamline(iverts);  
set(sl,'Marker','.')  
shading interp  
axis tight  
view(2)
```

```
daspect([1,1,1])  
hold off
```

## See Also

[stream2](#) | [stream3](#) | [streamline](#) | [streamslice](#) | [streamparticles](#)

# intersect

---

## Purpose

Set intersection of two arrays

## Syntax

```
C = intersect(A,B)
C = intersect(A,B,'rows')
[C,ia,ib] = intersect(A,B)
[C,ia,ib] = intersect(A,B,'rows')

[C,ia,ib] = intersect(__,setOrder)

[C,ia,ib] = intersect(A,B,'legacy')

[C,ia,ib] = intersect(A,B,'rows','legacy')
```

## Description

`C = intersect(A,B)` returns the data common to both A and B with no repetitions.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `intersect` returns the values common to both A and B. The values of C are in sorted order.
- If A and B are tables, then `intersect` returns the set of rows common to both tables. The rows of table C are in sorted order.

`C = intersect(A,B,'rows')` treats each row of A and each row of B as single entities and returns the rows common to both A and B. The rows of C are in sorted order.

The 'rows' option does not support cell arrays.

`[C,ia,ib] = intersect(A,B)` also returns index vectors `ia` and `ib`.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `C = A(ia)` and `C = B(ib)`.
- If A and B are tables, then `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect(A,B,'rows')` also returns index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect(___,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`, and then `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = intersect(A,B,'legacy')` and `[C,ia,ib] = intersect(A,B,'rows','legacy')` preserve the behavior of the `intersect` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

## Input Arguments

### **A,B - Input arrays**

numeric arrays | logical arrays | character arrays | categorical arrays  
| cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, cell arrays of strings, or tables.

`A` and `B` must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of `C` are the sorted union of the categories from `A` and `B`.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

# intersect

---

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, A and B can be objects with the following class methods:

- sort (or sortrows for the 'rows' option)
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

## setOrder - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

| Order Flag | Meaning                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'sorted'   | The values (or rows) in C return in sorted order. For example:<br><code>C = intersect([7 0 5],[7 1 5],'sorted')</code> returns<br><code>C = [5 7]</code> .                             |
| 'stable'   | The values (or rows) in C return in the same order as they appear in A and B. For example:<br><code>C = intersect([7 0 5],[7 1 5],'stable')</code> returns<br><code>C = [7 5]</code> . |

## Output Arguments

### C - Data common to A and B

vector | matrix | table

Data common to A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of **C** when the inputs are vectors or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then **C** is a column vector unless both **A** and **B** are row vectors.
- If the 'rows' flag is not specified and both **A** and **B** are row vectors, then **C** is a row vector.
- If the 'rows' flag is specified, then **C** is a matrix containing the rows in common from **A** and **B**.
- If **A** and **B** have no values (or rows) in common, then **C** is an empty matrix.

The class of the inputs **A** and **B** determines the class of **C**:

- If the class of **A** and **B** are the same, then **C** is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then **C** is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then **C** is `double`.
- If you combine a cell array of strings with `char`, then **C** is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then **C** is a categorical array.

### **ia - Index to A**

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** identifies the values (or rows) in **A** that are common to **B**. If there is a repeated value (or row) in **A**, then **ia** contains the index to the first occurrence of the value (or row).

### **ib - Index to B**

column vector

Index to **B**, returned as a column vector when the 'legacy' flag is not specified. **ib** identifies the values (or rows) in **B** that are common to **A**. If

# intersect

---

there is a repeated value (or row) in B, then `ib` contains the index to the first occurrence of the value (or row).

## Examples

### Intersection of Two Vectors

Define two vectors with values in common.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
```

Find the values common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```
     4     7
```

### Intersection of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 2    | B    | true  |
| 3    | C    | false |
| 4    | D    | true  |
| 5    | E    | false |

```
B =
```

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 3    | C    | false |
| 5    | E    | false |
| 7    | G    | false |
| 9    | I    | false |

```

1      A      false
3      C      false
5      E      false
7      G      false
9      I      false

```

Find the rows common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```

3      C      false
5      E      false

```

### **Intersection of Two Vectors and Their Indices**

Define two vectors with values in common.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
```

Find the values common to both A and B, as well as the index vectors *ia* and *ib*, such that  $C = A(ia)$  and  $C = B(ib)$ .

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```

4      7

```

```
ia =
```

```

5
1

```

# intersect

---

```
ib =
```

```
  3  
  1
```

## Intersection of Two Tables and Their Indices

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...  
'VariableNames',{'Gender' 'Age' 'Height'},...  
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =
```

|       | Gender | Age | Height |
|-------|--------|-----|--------|
|       | -----  | --- | -----  |
| Ted   | M      | 27  | 74     |
| Fred  | M      | 52  | 68     |
| Betty | F      | 31  | 64     |
| Bob   | M      | 46  | 61     |
| Judy  | F      | 35  | 64     |

Define a table, B, with rows in common with A.

```
B = table(['F';'M';'F';'F'],[31;47;35;23],[64;68;62;58],...  
'VariableNames',{'Gender' 'Age' 'Height'},...  
'RowNames',{'Meg' 'Joe' 'Beth' 'Amy'})
```

```
B =
```

|      | Gender | Age | Height |
|------|--------|-----|--------|
|      | -----  | --- | -----  |
| Meg  | F      | 31  | 64     |
| Joe  | M      | 47  | 68     |
| Beth | F      | 35  | 62     |
| Amy  | F      | 23  | 58     |

Find the rows common to both A and B, as well as the index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

|       | Gender | Age | Height |
|-------|--------|-----|--------|
|       | -----  | --- | -----  |
| Betty | F      | 31  | 64     |

```
ia =
```

```
3
```

```
ib =
```

```
1
```

Two rows that have the same values, but different names, are considered equal. Therefore, we discover that Betty, `A(3,:)`, and Meg, `B(1,:)` have the same gender, age, and height.

## Intersection of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [2 2 2; 0 0 1; 1 2 3; 1 1 1];
```

```
B = [1 2 3; 2 2 2; 2 2 0];
```

Find the rows common to both A and B as well as the index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

```
[C,ia,ib] = intersect(A,B,'rows')
```

```
C =
```

# intersect

---

```
      1     2     3
      2     2     2
```

```
ia =
```

```
      3
      1
```

```
ib =
```

```
      1
      2
```

A and B do not need to have the same number of rows, but they must have the same number of columns.

## Intersection with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as in A.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C,ia,ib] = intersect(A,B,'stable')
```

```
C =
```

```
      7     4
```

```
ia =
```

```
      1
      5
```

```
ib =
```

```
    1  
    3
```

Alternatively, you can specify 'sorted' order.

```
[C,ia,ib] = intersect(A,B,'sorted')
```

```
C =
```

```
    4    7
```

```
ia =
```

```
    5  
    1
```

```
ib =
```

```
    3  
    1
```

## Intersection of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the values common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```
    5
```

# intersect

---

`intersect` treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Find the strings common to both A and B.

```
[C,ia,ib] = intersect(A,B)
```

```
C =  
    'cat'    'horse'
```

```
ia =
```

```
    2  
    4
```

```
ib =
```

```
    2  
    4
```

`intersect` treats trailing white space in cell arrays of strings as distinct characters.

## Intersection of Arrays of Different Classes and Shapes

Create a column vector character array.

```
A = ['A';'B';'C'], class(A)
```

```
A =
```

```
A  
B  
C
```

```
ans =
```

```
char
```

Create a 2-by-3 matrix containing elements of numeric type double.

```
B = [65 66 67;68 69 70], class(B)
```

```
B =
```

```
    65    66    67  
    68    69    70
```

```
ans =
```

```
double
```

Find the values common to both A and B.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
A
```

# intersect

---

```
B  
C
```

```
ia =
```

```
1  
2  
3
```

```
ib =
```

```
1  
3  
5
```

`intersect` interprets `B` as a character array and returns a character array, `C`.

```
class(C)
```

```
ans =
```

```
char
```

## Intersection of Char and Cell Array of Strings

Create a character array containing animal names that have three letters.

```
A = ['dog'; 'cat'; 'fox'; 'pig'];  
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings containing animal names of varying lengths.

```
B = {'cat','dog','fish','horse'};  
class(B)
```

```
ans =
```

```
cell
```

Find the strings common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```
    'cat'  
    'dog'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

### **Preserve Legacy Behavior of intersect**

Use the 'legacy' flag to preserve the behavior of `intersect` from R2012b and prior releases in your code.

Find the intersection of A and B with the current behavior.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];  
[C1,ia1,ib1] = intersect(A,B)
```

```
C1 =
```

# intersect

---

```
4      7
```

```
ia1 =
```

```
5  
1
```

```
ib1 =
```

```
3  
1
```

Find the unique elements of A and preserve the legacy behavior.

```
[C2,ia2,ib2] = intersect(A,B,'legacy')
```

```
C2 =
```

```
4      7
```

```
ia2 =
```

```
5      4
```

```
ib2 =
```

```
4      1
```

## Tips

- To find the intersection with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `intersect(A(:,vars),B(:,vars))`, where *vars* is a positive integer,

a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

## Concepts

- “Combine Categorical Arrays”

# intmax

---

**Purpose** Largest value of specified integer type

**Syntax**

```
v = intmax
v = intmax('classname')
```

**Description** `v = intmax` is the largest positive value that can be represented in the MATLAB software with a 32-bit integer. Any value larger than the value returned by `intmax` saturates to the `intmax` value when cast to a 32-bit integer.

`v = intmax('classname')` is the largest positive value in the integer class `classname`. Valid values for the string `classname` are

|         |          |          |          |
|---------|----------|----------|----------|
| 'int8'  | 'int16'  | 'int32'  | 'int64'  |
| 'uint8' | 'uint16' | 'uint32' | 'uint64' |

`intmax('int32')` is the same as `intmax` with no arguments.

**Examples** Find the maximum value for a 64-bit signed integer:

```
v = intmax('int64')
v =
    9223372036854775807
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
    2147483647
```

Compare the result with the default value returned by `intmax`:

```
isequal(x, intmax)
ans =
     1
```

**See Also** `intmin` | `realmax` | `realmin` | `int8` | `uint8` | `isa` | `class`

**Purpose**            Smallest value of specified integer type

**Syntax**            `v = intmin`  
                       `v = intmin('classname')`

**Description**        `v = intmin` is the smallest value that can be represented in the MATLAB software with a 32-bit integer. Any value smaller than the value returned by `intmin` saturates to the `intmin` value when cast to a 32-bit integer.

`v = intmin('classname')` is the smallest positive value in the integer class `classname`. Valid values for the string `classname` are

|         |          |          |          |
|---------|----------|----------|----------|
| 'int8'  | 'int16'  | 'int32'  | 'int64'  |
| 'uint8' | 'uint16' | 'uint32' | 'uint64' |

`intmin('int32')` is the same as `intmin` with no arguments.

**Examples**            Find the minimum value for a 64-bit signed integer:

```
v = intmin('int64')
v =
-9223372036854775808
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
2147483647
```

Compare the result with the default value returned by `intmin`:

```
isequal(x, intmin)
ans =
1
```

**See Also**            `intmax` | `realmin` | `realmax` | `int8` | `uint8` | `isa` | `class`

**Purpose** Matrix inverse

**Syntax**  $Y = \text{inv}(X)$

**Description**  $Y = \text{inv}(X)$  returns the inverse of the square matrix  $X$ . A warning message is printed if  $X$  is badly scaled or nearly singular.

In practice, it is seldom necessary to form the explicit inverse of a matrix. A frequent misuse of `inv` arises when solving the system of linear equations  $Ax = b$ . One way to solve this is with  $x = \text{inv}(A)*b$ . A better way, from both an execution time and numerical accuracy standpoint, is to use the matrix division operator  $x = A \setminus b$ . This produces the solution using Gaussian elimination, without forming the inverse. See `mldivide (\)` for further information.

---

**Note** MATLAB computes  $X^{(-1)}$  and  $\text{inv}(X)$  in the same manner, and both are subject to the same limitations.

---

## Examples

Here is an example demonstrating the difference between solving a linear system by inverting the matrix with  $\text{inv}(A)*b$  and solving it directly with  $A \setminus b$ . A random matrix  $A$  of order 500 is constructed so that its condition number, `cond(A)`, is  $1.e10$ , and its norm, `norm(A)`, is 1. The exact solution  $x$  is a random vector of length 500 and the right-hand side is  $b = A*x$ . Thus the system of linear equations is badly conditioned, but consistent.

On a 300 MHz, laptop computer the statements

```
n = 500;
Q = orth(randn(n,n));
d = logspace(0, -10, n);
A = Q*diag(d)*Q';
x = randn(n,1);
b = A*x;
tic, y = inv(A)*b; toc
err = norm(y-x)
```

```
res = norm(A*y-b)
```

```
produce
```

```
elapsed_time =
```

```
    1.4320
```

```
err =
```

```
    7.3260e-006
```

```
res =
```

```
    4.7511e-007
```

```
while the statements
```

```
tic, z = A\b, toc
```

```
err = norm(z-x)
```

```
res = norm(A*z-b)
```

```
produce
```

```
elapsed_time =
```

```
    0.6410
```

```
err =
```

```
    7.1209e-006
```

```
res =
```

```
    4.4509e-015
```

It takes almost two and one half times as long to compute the solution with  $y = \text{inv}(A)*b$  as with  $z = A\b$ . Both produce computed solutions with about the same error,  $1.e-6$ , reflecting the condition number of the matrix. But the size of the residuals, obtained by plugging the computed solution back into the original equations, differs by several orders of magnitude. The direct solution produces residuals on the order of the machine accuracy, even though the system is badly conditioned.

The behavior of this example is typical. Using  $A\b$  instead of  $\text{inv}(A)*b$  is two to three times as fast and produces residuals on the order of machine accuracy, relative to the magnitude of the data.

# invhilb

---

**Purpose** Inverse of Hilbert matrix

**Syntax** `H = invhilb(n)`

**Description** `H = invhilb(n)` generates the exact inverse of the exact Hilbert matrix for  $n$  less than about 15. For larger  $n$ , `invhilb(n)` generates an approximation to the inverse Hilbert matrix.

**Limitations** The exact inverse of the exact Hilbert matrix is a matrix whose elements are large integers. These integers may be represented as floating-point numbers without roundoff error as long as the order of the matrix,  $n$ , is less than 15.

Comparing `invhilb(n)` with `inv(hilb(n))` involves the effects of two or three sets of roundoff errors:

- The errors caused by representing `hilb(n)`
- The errors in the matrix inversion process
- The errors, if any, in representing `invhilb(n)`

It turns out that the first of these, which involves representing fractions like  $1/3$  and  $1/5$  in floating-point, is the most significant.

**Examples** `invhilb(4)` is

|      |       |       |       |
|------|-------|-------|-------|
| 16   | -120  | 240   | -140  |
| -120 | 1200  | -2700 | 1680  |
| 240  | -2700 | 6480  | -4200 |
| -140 | 1680  | -4200 | 2800  |

**References** [1] Forsythe, G. E. and C. B. Moler, *Computer Solution of Linear Algebraic Systems*, Prentice-Hall, 1967, Chapter 19.

**See Also** `hilb`

**Purpose** Invoke method on COM object or interface, or display methods

**Syntax**

```
S = h.invoke
S = h.invoke('methodname')
S = h.invoke('methodname',arg1,arg2, ...)
S = h.invoke('custominterfacename')
S = invoke(h,...)
```

**Description** `S = h.invoke` returns structure array `S` containing a list of all methods supported by the object or interface, `h`, along with the prototypes for these methods. If `S` is empty, either there are no properties or methods in the object, or the MATLAB software cannot read the object's type library. Refer to the COM vendor's documentation.

`S = h.invoke('methodname')` invokes the method specified in the string `methodname`, and returns an output value, if any, in `S`. The data type of the return value depends on the invoked method, which is determined by the control or server.

`S = h.invoke('methodname',arg1,arg2, ...)` invokes the method specified in the string `methodname` with input arguments `arg1`, `arg2`, etc.

`S = h.invoke('custominterfacename')` returns an `Interface` object `S`, which is a handle to a custom interface implemented by the COM component. The `h` argument is a handle to the COM object. The `custominterfacename` argument is a string returned by the `interfaces` function.

`S = invoke(h,...)` is an alternate syntax. For Automation objects, if the vendor provides documentation for specific properties or methods, use the `S = invoke(h, ...)` syntax to call them.

If the method returns a COM interface, then `invoke` returns a new MATLAB COM object that represents the interface returned. For a description of how MATLAB converts COM types, see "Handling COM Data in MATLAB Software".

COM functions are available on Microsoft Windows systems only.

## Examples

Invoke the Redraw method in the mwsamp control:

```
f = figure ('position', [100 200 200 200]);  
h = actxcontrol ('mwsamp.mwsampctrl.1', [0 0 200 200], f);  
h.Radius = 100;  
h.invoke('Redraw');
```

---

Call the method directly:

```
h.Redraw;
```

---

Display all mwsamp methods:

```
h.invoke
```

MATLAB displays (in part):

```
ans =  
  AboutBox = void AboutBox(handle)  
  Beep = void Beep(handle)  
  FireClickEvent = void FireClickEvent(handle)  
  .  
  .
```

## Getting a Custom Interface Example

Once you have created a COM server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces:

```
h = actxserver('mytestenv.calculator');  
customlist = h.interfaces
```

MATLAB displays:

```
customlist =  
  ICalc1
```

```
ICalc2  
ICalc3
```

To get a handle to the custom interface you want, use the `invoke` function, specifying the handle returned by `actxcontrol` or `actxserver` and also the name of the custom interface:

```
c1 = h.invoke('ICalc1')
```

MATLAB displays:

```
c1 =  
    Interface.Calc_1.0_Type_Library.ICalc_Interface
```

You can now use this handle with most of the COM client functions to access the properties and methods of the object through the selected custom interface.

## How To

- “Handling COM Data in MATLAB Software”
- “Custom Interfaces”

# ipermute

---

**Purpose** Inverse permute dimensions of N-D array

**Syntax** `A = ipermute(B,order)`

**Description** `A = ipermute(B,order)` is the inverse of `permute`. `ipermute` rearranges the dimensions of `B` so that `permute(A,order)` will produce `B`. `B` has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. All the elements of `order` must be unique.

**Tips** `permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

**Examples** Consider the 2-by-2-by-3 array `a`:

```
a = cat(3,eye(2),2*eye(2),3*eye(2))
```

```
a(:,:,1) =          a(:,:,2) =
    1     0          2     0
    0     1          0     2
```

```
a(:,:,3) =
    3     0
    0     3
```

Permuting and inverse permuting `a` in the same fashion restores the array to its original form:

```
B = permute(a,[3 2 1]);
C = ipermute(B,[3 2 1]);
isequal(a,C)
ans=
```

```
1
```

**See Also** `permute`

**Purpose** Detect state

**Description** These functions detect the state of MATLAB entities:

|               |                                                                   |
|---------------|-------------------------------------------------------------------|
| isa           | Detect object of given MATLAB class or Java class                 |
| isappdata     | Determine if object has specific application-defined data         |
| iscategorical | Determine whether input is categorical array                      |
| iscategory    | Test for categorical array categories                             |
| iscell        | Determine if input is cell array                                  |
| iscellstr     | Determine if input is cell array of strings                       |
| ischar        | Determine if input is character array                             |
| iscolumn      | Determine whether input is column vector                          |
| iscom         | Determine if input is Component Object Model (COM) object         |
| isdir         | Determine if input is folder                                      |
| isempty       | Determine if input is empty array                                 |
| isequal       | Determine if arrays are numerically equal                         |
| isequaln      | Determine if arrays are numerically equal, treating NaNs as equal |
| isevent       | Determine if input is Component Object Model (COM) object event   |
| isfield       | Determine if input is MATLAB structure array field                |
| isfinite      | Detect finite elements of array                                   |
| isfloat       | Determine if input is floating-point array                        |
| isglobal      | Determine if input is global variable                             |
| ishandle      | Detect valid graphics object handles                              |
| ishold        | Determine if graphics hold state is on                            |

|                          |                                                                 |
|--------------------------|-----------------------------------------------------------------|
| <code>isinf</code>       | Detect infinite elements of array                               |
| <code>isinteger</code>   | Determine if input is integer array                             |
| <code>isinterface</code> | Determine if input is Component Object Model (COM) interface    |

### See Also

isa | exist

5. UNIX is a registered trademark of The Open Group in the United States and other countries.

**Purpose** Determine if input is object of specified class

**Syntax**

```
tf = isa(obj,ClassName)
tf = isa(obj,classCategory)
```

**Description** `tf = isa(obj,ClassName)` returns true if `obj` is an instance of the class specified by `ClassName`, and false otherwise. `isa` also returns true if `obj` is an instance of a class that is derived from `ClassName`.

`obj` can be any MATLAB variable.

`ClassName` can be any of the following:

- Name of any MATLAB class or fundamental type
- Name of a Java, or .NET class

### **MATLAB Fundamental Types**

|           |                         |
|-----------|-------------------------|
| 'single'  | Single-precision number |
| 'double'  | Double-precision number |
| 'int8'    | Signed 8-bit integer    |
| 'int16'   | Signed 16-bit integer   |
| 'int32'   | Signed 32-bit integer   |
| 'int64'   | Signed 64-bit integer   |
| 'uint8'   | Unsigned 8-bit integer  |
| 'uint16'  | Unsigned 16-bit integer |
| 'uint32'  | Unsigned 32-bit integer |
| 'uint64'  | Unsigned 64-bit integer |
| 'logical' | Logical true or false   |
| 'char'    | Character or string     |
| 'struct'  | Structure array         |

```
'cell'           Cell array
'function_handle' function handle
```

`tf = isa(obj, classCategory)` returns true if `obj` is an instance of any of the classes in the specified `classCategory`, and false otherwise. `isa` also returns true if `obj` is an instance of a class that is derived from any of the classes in `classCategory`.

`classCategory` can be 'numeric', 'float', or 'integer', representing a category of numeric types:

## Categories of Numeric Types

```
'numeric'       Integer or floating-point array (double, single,
                int8, uint8, int16, uint16, int32, uint32,
                int64, uint64)
'float'         Single- or double-precision floating-point array
                (double, single)
'integer'       Signed or unsigned integer array (int8, uint8,
                int16, uint16, int32, uint32, int64, uint64)
```

To test for a sparse array, use `issparse`. To test for a complex array, use `~isreal`.

## Examples

These examples show the values returned by `isa` when passed different types:

Determine if the value returned by the `pi` function is of class `double`:

```
isa(pi, 'double')
ans =
     1
```

More generally, determine if the value returned by the `pi` function is a numeric value:

```
isa(pi, 'numeric')
```

```
ans =
     1
```

`isa` also returns `true` for the `float` category because the class `double` is a floating-point type. However, `pi` does not return an integer type:

```
isa(pi,'integer')
ans =
     0
```

Determine if the 2-by-3 array returned by `true` is of type `logical`:

```
isa(true(2,3),'logical')
ans =
     1
```

Identify an instance of the MATLAB `containers.Map` class:

```
mapObj = containers.Map({'Color','RGB'},...
    {'Yellow',uint8([255,255,0])});
isa(mapObj,'containers.Map')
ans =
     1
```

The map key, `RGB`, references a `uint8` array:

```
isa(mapObj('RGB'),'integer')
ans =
     1
```

Specifying a particular integer class provides more specific testing:

```
if strcmp(mapObj('Color'),'Yellow') && isa(mapObj('RGB'),'uint8')
    % The Color is Yellow and the RGB numbers are uint8 values
    ...
end
```

## See Also

`class` | `is*` | `isnumeric` | `isfloat` | `isinteger` | `exist`

# isappdata

---

**Purpose** True if application-defined data exists

**Syntax** `isappdata(h,name)`

**Description** `isappdata(h,name)` returns 1 if application-defined data with the specified name exists on the object specified by handle `h`, and returns 0 otherwise.

**Tips** Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

**See Also** `getappdata` | `rmappdata` | `setappdata`

**Purpose** Determine whether input is categorical array

**Syntax** `tf = iscategorical(A)`

**Description** `tf = iscategorical(A)` returns logical 1 (true) if *A* is a categorical array. Otherwise, `iscategorical` returns logical 0 (false).

**Input Arguments** **A - Input variable**  
workspace variable

Input variable, specified as a workspace variable. *A* can be any data type.

**Examples** **Determine Whether Workspace Variable Is Categorical Array**

Create a workspace variable, *A*.

```
A = categorical({'red' 'green' 'violet'; 'orange' 'red' 'yellow'})
```

```
A =
```

```
      red      green      violet  
orange      red      yellow
```

Verify that the workspace variable, *A*, is a categorical array.

```
tf = iscategorical(A)
```

```
tf =
```

```
      1
```

*A* is a 2-by-3 categorical array.

**See Also** `categorical` | `isnumeric` | `isobject` | `islogical` | `istable` | `iscell` | `isstruct`

# iscategory

---

**Purpose** Test for categorical array categories

**Syntax** `tf = iscategory(A,catnames)`

**Description** `tf = iscategory(A,catnames)` returns an array containing logical 1 (true) where the data in `catnames` is a category of `A`. Otherwise, `iscategory` returns logical 0 (false).

`tf` is the same size as `catnames`.

## Input Arguments

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### **catnames - Category names**

string | cell array of strings | categorical array

Category names, specified as a string, cell array of strings, or categorical array.

## Examples

### **Test for Categories**

Create an ordinal categorical array, `A`.

```
A = categorical({'shirt' 'pants'; 'pants' 'hat'; 'shirt' 'pants'})
```

```
A =
```

```
    shirt    pants
    pants    hat
    shirt    pants
```

`A` is a 1-by-5 categorical array.

Test if the articles of clothing, `shirt`, `pants`, `socks`, and `shoes`, are categories of `A`.

```
catnames = {'shirt' 'pants' 'socks' 'shoes'};
tf = iscategory(A,catnames)
```

```
tf =
```

```
     1     1     0     0
```

shirt and pants are categories of A, but socks, and shoes are not.

iscategory does not tell us anything about the category, hat, which we did not include in catnames.

### Test for Category with No Corresponding Data

Create a categorical array, A.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'},...
               {'boat' 'car' 'plane' 'train'})
```

```
A =
```

```
     plane     car     train     car     plane
```

A is a 1-by-5 categorical array.

Test to see if boat is a category in A.

```
tf = iscategory(A,'boat')
```

```
tf =
```

```
     1
```

iscategory returns true, even though A does not contain any values from the category boat.

# iscell

---

**Purpose** Determine whether input is cell array

**Syntax** `tf = iscell(A)`

**Description** `tf = iscell(A)` returns logical 1 (true) if A is a cell array and logical 0 (false) otherwise.

**Examples**

```
A{1,1} = [1 4 3; 0 5 8; 7 2 9];  
A{1,2} = 'Anne Smith';  
A{2,1} = 3+7i;  
A{2,2} = -pi:pi/10:pi;
```

```
iscell(A)
```

```
ans =
```

```
1
```

**See Also** `cell` | `iscellstr` | `isstruct` | `isnumeric` | `islogical` | `isobject`  
| `isa` | `is*`

**Purpose** Determine whether input is cell array of strings

**Syntax** `tf = iscellstr(A)`

**Description** `tf = iscellstr(A)` returns logical 1 (true) if `A` is a cell array of strings (or an empty cell array), and logical 0 (false) otherwise. A cell array of strings is a cell array where every element is a character array.

**Examples**

```
A{1,1} = 'Thomas Lee';  
A{1,2} = 'Marketing';  
A{2,1} = 'Allison Jones';  
A{2,2} = 'Development';
```

```
iscellstr(A)
```

```
ans =
```

```
1
```

**See Also** `cellstr` | `iscell` | `isstrprop` | `strings` | `char` | `isstruct` | `isa` | `is*`

# ischar

---

**Purpose** Determine whether item is character array

**Syntax** `tf = ischar(A)`

**Description** `tf = ischar(A)` returns logical 1 (true) if A is a character array and logical 0 (false) otherwise.

**Examples** Given the following cell array,

```
C{1,1} = magic(3);           % double array
C{1,2} = 'John Doe';       % char array
C{1,3} = 2 + 4i            % complex double
```

```
C =
```

```
    [3x3 double]    'John Doe'    [2.0000+ 4.0000i]
```

`ischar` shows that only `C{1,2}` is a character array.

```
for k = 1:3
x(k) = ischar(C{1,k});
end
```

```
x
```

```
x =
```

```
    0    1    0
```

**See Also** `char` | `strings` | `isletter` | `isspace` | `isstrprop` | `iscellstr` | `isnumeric` | `isa` | `is*`

**Purpose** Determine whether input is column vector

**Syntax** `iscolumn(V)`

**Description** `iscolumn(V)` returns logical 1 (true) if `size(V)` returns `[n 1]` with a nonnegative integer value `n`, and logical 0 (false) otherwise.

**Examples** Determine if a vector is a column. This example is a row so `iscolumn` returns 0:

```
V = rand(1,5);  
iscolumn(V)  
ans =  
    0
```

Transpose the vector to make it a column. `iscolumn` returns 1:

```
V1 = V';  
iscolumn(V1)  
ans =  
    1
```

**See Also** `ismatrix` | `isrow` | `isscalar` | `isvector`

**Purpose** Determine whether input is COM or ActiveX object

**Syntax**

```
tf = h.iscom
tf = iscom(h)
```

**Description** `tf = h.iscom` returns logical 1 (true) if handle `h` is a COM or Microsoft ActiveX object. Otherwise, returns logical 0 (false).

`tf = iscom(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Test an instance of a Microsoft Excel application:

```
h = actxserver('Excel.Application');
h.iscom
```

MATLAB displays `true`, indicating object `h` is a COM object.

---

Test an Excel interface:

```
h = actxserver('Excel.Application');
%Create a workbooks object
w = h.get('workbooks');
w.iscom
```

MATLAB displays `false`, indicating object `w` is not a COM object.

**How To**

- “MATLAB COM Integration”

**Purpose** Determine whether input is folder

**Syntax** `tf = isdir('A')`

**Description** `tf = isdir('A')` returns logical 1 (true) if A is a folder. Otherwise, it returns logical 0 (false).

**Examples** Run:

```
tf=isdir('myfiles/results')
```

MATLAB returns

```
tf =  
1
```

indicating that `myfiles/results` is a folder.

**See Also** `dir` | `is*`

# TriRep.isEdge

---

**Purpose** (Will be removed) Test if vertices are joined by edge

---

**Note** `isEdge(TriRep)` will be removed in a future release. Use `isConnected(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax**  
`TF = isEdge(TR, V1, V2)`  
`TF = isEdge(TR, EDGE)`

**Description**  
`TF = isEdge(TR, V1, V2)` returns an array of 1/0 (true/false) flags, where each entry `TF(i)` is true if `V1(i), V2(i)` is an edge in the triangulation. `V1, V2` are column vectors representing the indices of the vertices in the mesh, that is, indices into the vertex coordinate arrays.  
`TF = isEdge(TR, EDGE)` specifies the edge start and end indices in matrix format.

**Input Arguments**

|        |                                                             |
|--------|-------------------------------------------------------------|
| TR     | Triangulation representation.                               |
| V1, V2 | Column vectors of mesh vertices.                            |
| EDGE   | Matrix of size n-by-2 where n is the number of query edges. |

**Output Arguments**

|    |                                                                                                                                            |
|----|--------------------------------------------------------------------------------------------------------------------------------------------|
| TF | Array of 1/0 (true/false) flags, where each entry <code>TF(i)</code> is true if <code>V1(i), V2(i)</code> is an edge in the triangulation. |
|----|--------------------------------------------------------------------------------------------------------------------------------------------|

**Examples**      **Example 1**

Load a 2-D triangulation and use `TriRep` to query the presence of an edge between pairs of points.

```
load trimesh2d  
trep = TriRep(tri, x,y);
```

Test if vertices 3 and 117 are connected by an edge

```
isEdge(trep, 3, 117)
```

Test if vertices 3 and 164 are connected by an edge

```
isEdge(trep, 3, 164)
```

## Example 2

Direct query of a 3-D Delaunay triangulation created using DelaunayTri.

```
X = rand(10,3)  
dt = DelaunayTri(X)
```

Test if vertices 2 and 7 are connected by an edge

```
isEdge(dt, 2, 7);
```

## See Also

[delaunayTriangulation](#) | [triangulation](#)

# isempty

---

**Purpose** Determine whether array is empty

**Syntax** TF = isempty(A)

**Description** TF = isempty(A) returns logical 1 (true) if A is an empty array and logical 0 (false) otherwise. An empty array has at least one dimension of size zero, for example, 0-by-0 or 0-by-5.

**Examples**

```
B = rand(2,2,2);  
B(:,:,:) = [];
```

```
isempty(B)
```

```
ans = 1
```

**See Also** is\*

**Purpose**

Determine whether `tscollection` object is empty

**Syntax**

```
isempty(tsc)
```

**Description**

`isempty(tsc)` returns a logical value for `tscollection` object `tsc`, as follows:

- 1 — When `tsc` contains neither `timeseries` members nor a time vector
- 0 — When `tsc` contains either `timeseries` members or a time vector

**See Also**

`timeseries` | `tscollection` | `length (tscollection)` | `size (tscollection)`

# isequal

---

**Purpose** Determine array equality

**Syntax**  
`tf = isequal(A,B)`  
`tf = isequal(A1,A2,...,An)`

**Description** `tf = isequal(A,B)` returns logical 1 (true) if A and B are the same size and their contents are of equal value; otherwise, it returns logical 0 (false). The test compares both real and imaginary parts of numeric arrays. `isequal` ignores the data type of the values in determining whether they are equal. For cell arrays, categorical arrays, tables, or structures, the function returns logical 1 (true) only when all elements and properties are numerically equal. Undefined categorical elements or NaN (not a number) values are considered to be unequal to other elements, as well as themselves.

`tf = isequal(A1,A2,...,An)` returns logical 1 (true) if all the inputs are numerically equal.

## Input Arguments

### A,B - Inputs to be compared

numeric arrays | categorical arrays | cell arrays | tables | structures  
| ...

Inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, or objects. The numeric types of A and B do not have to match.

You can compare a categorical array to a cell array of strings of the same size, or a single categorical element to a single string.

If inputs A and B are *both*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.

- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Objects of different classes -- `isequal` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

### **A1,A2,...,An - Series of inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures  
| ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Objects of different classes -- `isequal` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

## **Examples**

### **Compare Two Numeric Matrices**

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
```

# isequal

---

```
B = zeros(3,3);  
tf = isequal(A,B)
```

```
tf =
```

```
0
```

The function returns logical 0 (false) because the matrices differ by a very small amount and are not *exactly* equal.

## Compare Two Structures

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);  
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)
```

```
tf =
```

```
1
```

Even though the ordering of the fields in each structure is different, `isequal` treats them as the same because the values are equal.

## Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value `true` to the double integer 1.

```
isequal(true,1)
```

```
ans =
```

```
1
```

Notice that `isequal` does not consider data type when it tests for equality.

Similarly, compare 'A' to the ASCII-equivalent integer, 65.

```
isequal('A',65)
```

```
ans =
```

```
1
```

The result is logical 1 (true) since `double('A')` equals 65.

### Compare Vectors Containing NaN Values

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
```

```
A2 = [1 NaN NaN];
```

```
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequal(A1,A2,A3)
```

```
tf =
```

```
0
```

The result is logical 0 (false) because `isequal` does not treat NaN values as equal to each other.

### Tips

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.
- Use `isequaln` if you want to test for equality and treat NaN values as equal.

# isequal

---

# isequaln

---

- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Objects of different classes -- `isequaln` returns logical 0 (false). This applies even when the objects have the same properties and their values match.

## **A1,A2,...,An - Series of inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures  
| ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Objects of different classes -- `isequaln` returns logical 0 (false). This applies even when the objects have the same properties and their values match.

## **Examples**

### **Compare Two Numeric Matrices**

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
```

```
B = zeros(3,3);  
tf = isequaln(A,B)
```

```
tf =  
  
    0
```

The function returns logical 0 (false) because the matrices differ by a very small amount and are not *exactly* equal.

### Compare Two Structures

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);  
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)  
  
tf =  
  
    1
```

Even though the ordering of the fields in each structure is different, `isequaln` treats them as the same because the values are equal.

### Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value true to the double integer 1.

```
isequaln(true,1)  
  
ans =  
  
    1
```

# isequaln

---

Notice that `isequaln` does not consider data type when it tests for equality.

Similarly, compare 'A' to the ASCII-equivalent integer, 65.

```
isequaln('A',65)
```

```
ans =
```

```
1
```

The result is logical 1 (true) since `double('A')` equals 65.

## Compare Vectors Containing NaN Values

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
```

```
A2 = [1 NaN NaN];
```

```
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequaln(A1,A2,A3)
```

```
tf =
```

```
1
```

The result is logical 1 (true) because `isequaln` treats the NaN values as equal to each other.

## Tips

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequaln` to treat NaN values as equal and determine if objects with different handles have equal property values.
- Use `isequal` if you want to test for equality and treat NaN values as unequal.

**See Also**      `isequaleq` | `is*` | `isa*` | `strcmp` | relational operators

# isequal (MException)

---

**Purpose** Compare scalar MException objects for equality

**Syntax** TF = isequal(eObj1, eObj2)

**Description** TF = isequal(eObj1, eObj2) tests MException objects eObj1 and eObj2 for equality, returning logical 1 (true) if the two objects are identical, otherwise returning logical 0 (false).

**See Also** try | catch | error | assert | MException | eq(MException) | ne(MException) | getReport(MException) | disp(MException) | throw(MException) | rethrow(MException) | throwAsCaller(MException) | addCause(MException) | last(MException)

**Purpose** Test arrays for equality, treating NaNs as equal

---

**Note** `isequalwithequalnans` is not recommended. Use `isequaln` instead.

---

**Syntax** `tf = isequalwithequalnans(A, B, ...)`

**Description** `tf = isequalwithequalnans(A, B, ...)` returns logical 1 (true) if the input arrays are the same type and size and hold the same contents, and logical 0 (false) otherwise. NaN (Not a Number) values are considered to be equal to each other. Numeric data types and structure field order do not have to match.

**Tips** `isequalwithequalnans` is the same as `isequal`, except `isequalwithequalnans` considers NaN (Not a Number) values to be equal, and `isequal` does not.

`isequalwithequalnans` recursively compares the contents of cell arrays and structures. If all the elements of a cell array or structure are numerically equal, `isequalwithequalnans` returns logical 1.

**Examples** Arrays containing NaNs are handled differently by `isequal` and `isequalwithequalnans`. `isequal` does not consider NaNs to be equal, while `isequalwithequalnans` does.

```
A = [32 8 -29 NaN 0 5.7];
B = A;
isequal(A, B)
ans =
    0
```

```
isequalwithequalnans(A, B)
ans =
    1
```

# isequalwithequalnans

---

The position of NaN elements in the array does matter. If they are not in the same position in the arrays being compared, then `isequalwithequalnans` returns zero.

```
A = [2 4 6 NaN 8];    B = [2 4 NaN 6 8];  
isequalwithequalnans(A, B)  
ans =  
    0
```

## See Also

[isequal](#) | [strcmp](#) | [isa](#) | [is\\*](#) | [relational operators](#) | [isequaln](#)

**Purpose** Determine whether input is COM object event

**Syntax**

```
tf = h.isevent('eventname')  
tf = isevent(h, 'eventname')
```

**Description** `tf = h.isevent('eventname')` returns logical 1 (true) if `event_name` is an event recognized by COM object `h`. Otherwise, returns logical 0 (false). The `event_name` argument is not case sensitive.

`tf = isevent(h, 'eventname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Test events in a MATLAB sample control object:

**1** Create an instance of the `mwsamp` control and test `Db1Click`:

```
f = figure ('position', [100 200 200 200]);  
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.isevent('Db1Click')
```

MATLAB displays `true`, indicating `Db1Click` is an event.

**2** Try the same test on `Redraw`:

```
h.isevent('Redraw')
```

MATLAB displays `false`, indicating `Redraw` is not an event; it is a method.

---

Test events in a Microsoft Excel workbook object:

**1** Create a Workbook object `wb`:

```
myApp = actxserver('Excel.Application');  
wbs = myApp.Workbooks;  
wb = wbs.Add;
```

# isevent

---

## 2 Test Activate:

```
wb.isevent('Activate')
```

MATLAB displays `true`, indicating `Activate` is an event.

## 3 Test Save:

```
wb.isevent('Save')
```

MATLAB displays `false`, indicating `Save` is not an event; it is a method.

## See Also

## How To

- “Exploring Events”
- “Functions for Working with Events”

**Purpose**

Determine whether input is structure array field

**Syntax**

```
tf = isfield(S, 'fieldname')  
tf = isfield(S, C)
```

**Description**

`tf = isfield(S, 'fieldname')` examines structure `S` to see if it includes the field specified by the quoted string `'fieldname'`. Output `tf` is set to logical 1 (true) if `S` contains the field, or logical 0 (false) if not. If `S` is not a structure array, `isfield` returns false.

`tf = isfield(S, C)` examines structure `S` for multiple fieldnames as specified in cell array of strings `C`, and returns an array of logical values to indicate which of these fields are part of the structure. Elements of output array `tf` are set to a logical 1 (true) if the corresponding element of `C` holds a fieldname that belongs to structure `S`. Otherwise, logical 0 (false) is returned in that element. In other words, if structure `S` contains the field specified in `C{m,n}`, `isfield` returns a logical 1 (true) in `tf(m,n)`.

---

**Note** `isfield` returns false if the field or fieldnames input is empty.

---

**Examples****Example 1 – Single Fieldname Syntax**

Given the following MATLAB structure,

```
patient.name = 'John Doe';  
patient.billing = 127.00;  
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

`isfield` identifies `billing` as a field of that structure.

```
isfield(patient,'billing')  
ans =  
    1
```

# isfield

---

## Example 2 – Multiple Fieldname Syntax

Check structure S for any of four possible fieldnames. Only the first is found, so the first element of the return value is set to true:

```
S = struct('one', 1, 'two', 2);  
  
fields = isfield(S, {'two', 'pi', 'One', 3.14})  
fields =  
     1     0     0     0
```

| [isstruct](#) | [iscell](#) | [isa](#) | [is\\*](#)

## How To

- dynamic field names

**Purpose** Array elements that are finite

**Syntax** TF = isfinite(A)

**Description** TF = isfinite(A) returns an array the same size as A containing logical 1 (true) where the elements of the array A are finite and logical 0 (false) where they are infinite or NaN. For a complex number z, isfinite(z) returns 1 if both the real and imaginary parts of z are finite, and 0 if either the real or the imaginary part is infinite or NaN. For any real A, exactly one of the three quantities isfinite(A), isinf(A), and isnan(A) is equal to one.

**Examples**

```
a = [-2 -1 0 1 2];
isfinite(1./a)
ans =
     1     1     0     1     1
isfinite(0./a)
ans =
     1     1     0     1     1
```

**See Also** isinf | isnan | is\*

# isfloat

---

**Purpose** Determine if input is floating-point array

**Syntax** `tf = isfloat(A)`

**Description** `tf = isfloat(A)` returns true if A is a floating-point array and false otherwise. The floating-point types are `single` and `double`, and subclasses of `single` and `double`.

## Examples

These examples show the values `isfloat` returns when passed specific types:

```
% pi returns a floating-point value
isfloat(pi)
ans =
     1
% Complex numbers are floating-point values
isfloat(3+7i)
ans =
     1
% Single-precision numbers are floating-point values
isfloat(realmax('single'))
ans =
     1
% isfloat returns a logical value
isfloat(isfloat(pi))
ans =
     0
```

**See Also** `isa` | `isinteger` | `double` | `single` | `isnumeric`

**Purpose** Determine whether input is global variable

---

**Note** Support for the `isglobal` function will be removed in a future release of the MATLAB software. See “Tips” on page 1-3245 below.

---

**Syntax** `tf = isglobal(A)`

**Description** `tf = isglobal(A)` returns logical 1 (true) if `A` has been declared to be a global variable in the context from which `isglobal` is called, and logical 0 (false) otherwise.

**Tips** `isglobal` is most commonly used in conjunction with conditional global declaration. An alternate approach is to use a pair of variables, one local and one declared global.

Instead of using

```
if condition
    global x
end
```

```
x = some_value
```

```
if isglobal(x)
    do_something
end
```

You can use

```
global gx
if condition
    gx = some_value
else
    x = some_value
end
```

# isglobal

---

```
if condition
    do_something
end
```

If no other workaround is possible, you can replace the command

```
isglobal(variable)
```

with

```
~isempty(whos('global', 'variable'))
```

## See Also

```
global | isvarname | isa | is*
```

**Purpose** Test for valid graphics or Java object handle

**Syntax** `ishandle(H)`

**Description** `ishandle(H)` returns an array whose elements are 1 where the elements of `H` are graphics or Java object handles, and 0 where they are not.

---

**Note** You should use the most specific function for your application instead of `ishandle`, as described in the following sections.

---

### **MATLAB Object Handles**

Use the `isa` function to determine the class of MATLAB objects and use the `isvalid handle` class method to determine the validity of handle objects. See “Testing Handle Validity” for information on testing for MATLAB handle objects.

### **Graphics Object Handles**

Use `ishghandle` for graphics objects.

### **Java Object Handles**

Use `isjava` for Java objects.

**See Also** `isa` | `isjava` | `ishghandle`

# ishghandle

---

**Purpose** True for Handle Graphics object handles

**Syntax** `ishghandle(h)`

**Description** `ishghandle(h)` returns an array that contains 1's where the elements of `h` are handles to existing graphic objects and 0's where they are not. Differs from `ishandle` in that Simulink objects handles return false.

**Examples** Create a plot and find the valid handles:

```
x = [1:10];  
y = [1:10];  
p=plot(x,y);  
ishghandle([x y p])  
% This returns a 1-by-21 array of values with ones at the first,  
% eleventh, and last values, if the figure handle is 1.
```

**See Also** `isa` | `ishandle` | `findobj` | `gca` | `gcf` | `set`

**How To** • “Accessing Object Handles”

**Purpose** Current hold state

**Syntax** `tf = ishold`

**Description** `tf = ishold` returns 1 if hold is on, and 0 if it is off. When hold is on, the current plot and most axis properties are held so that subsequent graphing commands add to the existing graph.

A state of hold on implies that both figure and axes NextPlot properties are set to add.

**See Also** `hold` | `newplot`

**How To** • “Controlling Graphics Output”

# isinf

---

**Purpose** Array elements that are infinite

**Syntax** TF = isinf(A)

**Description** TF = isinf(A) returns an array the same size as A containing logical 1 (true) where the elements of A are +Inf or -Inf and logical 0 (false) where they are not. For a complex number z, isinf(z) returns 1 if either the real or imaginary part of z is infinite, and 0 if both the real and imaginary parts are finite or NaN.

For any real A, exactly one of the three quantities isfinite(A), isinf(A), and isnan(A) is equal to one.

## Examples

```
a = [-2 -1 0 1 2];  
  
isinf(1./a)  
  
ans =  
     0     0     1     0     0  
  
isinf(0./a)  
  
ans =  
     0     0     0     0     0
```

**See Also** isfinite | isnan | is\*

**Purpose** Determine if input is integer array

**Syntax** `tf = isinteger(A)`

**Description** `tf = isinteger(A)` returns true if the array A is an integer type and false otherwise.

An integer array is any of the following integer types and any subclasses of those types:

### **MATLAB Integer Types**

|                     |                               |
|---------------------|-------------------------------|
| <code>int8</code>   | 8-bit signed integer array    |
| <code>uint8</code>  | 8-bit unsigned integer array  |
| <code>int16</code>  | 16-bit signed integer array   |
| <code>uint16</code> | 16-bit unsigned integer array |
| <code>int32</code>  | 32-bit signed integer array   |
| <code>uint32</code> | 32-bit unsigned integer array |
| <code>int64</code>  | 64-bit signed integer array   |
| <code>uint64</code> | 64-bit unsigned integer array |

**Examples** These examples show the values `isinteger` returns when passed specific types:

```
% uint8 is one of the integer types
isinteger(uint8(1:255))
ans =
     1
% pi returns a double-precision value
isinteger(pi)
ans =
     0
% Constants are double-precision by default
isinteger(3)
```

# isinteger

---

```
ans =  
    0  
% isinteger returns a logical value  
isinteger(isinteger(uint8(3)))  
ans =  
    0
```

# isjava

---

**Purpose** Determine if input is Java object

**Syntax** `tf = isjava(A)`

**Description** `tf = isjava(A)` returns logical 1 (true) if object A is a Java object. Otherwise, it returns logical 0 (false).

**Examples** **Test if java.util.Date Is Java Object**

Create an instance of the Java Date class.

```
myDate = java.util.Date;  
isjava(myDate)
```

```
ans =
```

```
1
```

myDate is a Java object.

However, myDate is not a MATLAB object.

```
isobject(myDate)
```

```
ans =
```

```
0
```

# containers.Map.isKey

---

## Find a Single Key

Determine if `mapObj` from the previous example contains key `Feb`:

```
keySet = 'Feb';  
tf = isKey(mapObj, keySet)
```

This code returns scalar `tf`:

```
tf =  
    1
```

## See Also

[containers.Map](#) | [keys](#) | [values](#) | [remove](#)

**Purpose** Determine whether input is MATLAB keyword

**Syntax**

```
tf = iskeyword('str')
iskeyword str
iskeyword
```

**Description** `tf = iskeyword('str')` returns logical 1 (true) if the string `str` is a keyword in the MATLAB language and logical 0 (false) otherwise. MATLAB keywords cannot be used as variable names.

`iskeyword str` uses the MATLAB command format.

`iskeyword` returns a list of all MATLAB keywords.

**Examples** To test if the word `while` is a MATLAB keyword,

```
iskeyword while
ans =
     1
```

To obtain a list of all MATLAB keywords,

```
iskeyword
'break'
'case'
'catch'
'classdef'
'continue'
'else'
'elseif'
'end'
'for'
'function'
'global'
'if'
'otherwise'
'parfor'
'persistent'
```

# iskeyword

---

```
'return'  
'spmd'  
'switch'  
'try'  
'while'
```

## See Also

**Purpose** Array elements that are alphabetic letters

**Syntax** `tf = isletter('str')`

**Description** `tf = isletter('str')` returns an array the same size as `str` containing logical 1 (true) where the elements of `str` are letters of the alphabet and logical 0 (false) where they are not.

**Examples** Find the letters in character array `s`.

```
s = 'A1,B2,C3';
```

```
isletter(s)
```

```
ans =
```

```
     1     0     0     1     0     0     1     0
```

# islogical

---

**Purpose** Determine if input is logical array

**Syntax** `tf = islogical(A)`

**Description** `tf = islogical(A)` returns true if A is a logical array and false otherwise. `islogical` also returns true if A is an instance of a class that is derived from the `logical` class.

**Examples** These examples show the values `islogical` returns when passed specific types:

```
% Relational operators return logical values
islogical(5<7)
ans =
     1
```

```
% true and false return logical values
islogical(true) & islogical(false)
ans =
     1
```

```
% Constants are double-precision by default
islogical(1)
ans =
     0
```

```
% logical creates logical values
islogical(logical(1))
ans =
     1
```

# ismatrix

---

**Purpose** Determine whether input is matrix

**Syntax** `ismatrix(V)`

**Description** `ismatrix(V)` returns logical 1 (true) if `size(V)` returns `[m n]` with nonnegative integer values `m` and `n`, and logical 0 (false) otherwise.

**Examples** Create three vectors:

```
V1 = rand(5,1);  
V2 = rand(5,1);  
V3 = rand(5,1);
```

Concatenate the vectors and check that the result is a matrix. `ismatrix` returns 1:

```
M = cat(2,V1,V2,V3);  
ismatrix(M)  
ans =  
     1
```

**See Also** `iscolumn` | `isrow` | `isscalar` | `isvector`

## Purpose

Array elements that are members of set array

## Syntax

```
Lia = ismember(A,B)
Lia = ismember(A,B,'rows')
[Lia,Locb] = ismember(A,B)
[Lia,Locb] = ismember(A,B,'rows')

[Lia,Locb] = ismember( __ , 'legacy')
```

## Description

`Lia = ismember(A,B)` returns an array containing 1 (true) where the data in `A` is found in `B`. Elsewhere, it returns 0 (false).

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `ismember` returns a logical value for each element of `A`. The output, `Lia`, is an array of the same size as `A`.
- If `A` and `B` are tables, then `ismember` returns a logical value for each row of `A`. The output, `Lia`, is a column vector with the same number of rows as `A`.

`Lia = ismember(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns a column vector containing 1 (true) where the rows of `A` are also rows of `B`. Elsewhere, it returns 0 (false).

`A` and `B` must have the same number of columns when you use the 'rows' option. Furthermore, the 'rows' option does not support cell arrays.

`[Lia,Locb] = ismember(A,B)` also returns an array, `Locb`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `Locb` contains the lowest index in `B` for each value in `A` that is a member of `B`. The output array, `Locb`, contains 0 wherever `A` is not a member of `B`.

# ismember

---

- If A and B are tables, then Locb contains the lowest index in B for each row in A that is also a row in B. The output vector, Locb, contains 0 whenever A is not a row of B.

[Lia,Locb] = ismember(A,B, 'rows') also returns a column vector, Locb, containing the lowest index in B for each row in A that is also a row in B. The output vector, Locb, contains 0 wherever A is not a row of B.

[Lia,Locb] = ismember( \_\_ , 'legacy') preserves the behavior of the ismember function from R2012b and prior releases using any of the input arguments in previous syntaxes.

The 'legacy' option does not support categorical arrays or tables.

## Input Arguments

### A - Query array

numeric array | logical array | character array | categorical array | cell array of strings | table

Query array, specified as a numeric array, logical array, character array, categorical array, cell array of strings, or a table.

A must belong to the same class as B with the following exceptions:

- logical, char, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with char arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the 'rows' option, A must have the same number of columns as B.

If A is a table, it must have the same variable names as B. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, A can be an object with the following class methods:

- `sort` (or `sortrows` for the 'rows' option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### **B - Set array**

numeric array | logical array | character array | categorical array | cell array of strings | table

Set array, specified as a numeric array, logical array, character array, categorical array, cell array of strings, or a table.

B must belong to the same class as A with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the 'rows' option, B must have the same number of columns as A.

If B is a table, it must have the same variable names as A. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, B can be an object with the following class methods:

- `sort` (or `sortrows` for the 'rows' option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

## Output Arguments

### **Lia** - Logical index to A

vector | matrix | N-D array

Logical index to A, returned as a vector, matrix or N-D array containing 1 (true) wherever the values (or rows) in A are members of B. Elsewhere, it returns 0 (false).

Lia is an array of the same size as A, unless you specify the 'rows' flag.

If the 'rows' flag is specified or if A is a table, Lia is a column vector with the same number of rows as A.

### **Locb** - Locations in B

vector | matrix | N-D array

Locations in B, returned as a vector, matrix, or N-D array. If the 'legacy' flag is not specified, Locb contains the lowest indices to the values (or rows) in B that are found in A. Locb contains 0 wherever A is not a member of B.

Locb is an array of the same size as A unless you specify the 'rows' flag.

If the 'rows' flag is specified or if A is a table, Locb is a column vector with the same number of rows as A.

## Examples

### **Values That Are Members of Set**

Define two vectors with values in common.

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];
```

Determine which elements of A are also in B.

```
Lia = ismember(A,B)
```

```
Lia =
```

```
    0    0    1    1
```

A(3) and A(4) are found in B.

### Table Rows Found in Another Table

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 2    | B    | true  |
| 3    | C    | false |
| 4    | D    | true  |
| 5    | E    | false |

```
B =
```

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 3    | C    | false |
| 5    | E    | false |
| 7    | G    | false |
| 9    | I    | false |

# ismember

---

Determine which rows of A are also in B.

```
Lia = ismember(A,B)
```

```
Lia =
```

```
1  
0  
1  
0  
1
```

A(1,:), A(3,:), and A(5,:) are found in B.

## Members of Set and Indices to Values

Define two vectors with values in common.

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];
```

Determine which elements of A are also in B as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
0    0    1    1
```

```
Locb =
```

```
0    0    2    1
```

The lowest index to A(3) is B(2).

A(4) is found in B(1).

## Rows of Another Table and Their Location

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =
```

|       | Gender | Age | Height |
|-------|--------|-----|--------|
|       | -----  | --- | -----  |
| Ted   | M      | 27  | 74     |
| Fred  | M      | 52  | 68     |
| Betty | F      | 31  | 64     |
| Bob   | M      | 46  | 61     |
| Judy  | F      | 35  | 64     |

Define a table, B, with rows in common with A.

```
B = table(['M';'F';'F';'F'],[47;31;35;23],[68;64;62;58],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Joe' 'Meg' 'Beth' 'Amy'})
```

```
B =
```

|      | Gender | Age | Height |
|------|--------|-----|--------|
|      | -----  | --- | -----  |
| Meg  | F      | 31  | 64     |
| Joe  | M      | 47  | 68     |
| Beth | F      | 35  | 62     |
| Amy  | F      | 23  | 58     |

Determine which rows of A are also in B, as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
0
0
```

# ismember

---

```
1  
0  
0
```

```
Locb =
```

```
0  
0  
2  
0  
0
```

Two rows that have the same values, but different names, are considered equal. The same data for Betty is found in `B(2,:)`, which corresponds to Meg.

## Rows That Belong to a Set

Define two matrices with a row in common.

```
A = [1 3 5 6; 2 4 6 8];  
B = [2 4 6 8; 1 3 5 7; 2 4 6 8];
```

Determine which rows of `A` are also in `B` as well as their corresponding locations in `B`.

```
[Lia, Locb] = ismember(A,B, 'rows')
```

```
Lia =
```

```
0  
1
```

```
Locb =
```

```
0
```

1

The lowest index to A(2,:) is B(1,:).

### Members of Set Containing NaN Values

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Determine which elements of A are also in B as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
1 0 0
```

```
Locb =
```

```
1 0 0
```

ismember treats NaN values as distinct.

### Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Determine which strings of A can be found in B.

```
[Lia,Locb] = ismember(A,B)
```

# ismember

---

```
Lia =  
  
     0     1     0     1
```

```
Locb =  
  
     0     2     0     4
```

ismember treats trailing white space in cell arrays of strings as distinct characters.

## Members of Char and Cell Array of Strings

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
```

Create a cell array of strings, B.

```
B = {'dog', 'cat', 'fish', 'horse'};
```

Determine which strings of A can be found in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =  
  
     1  
     1  
     0  
     0
```

```
Locb =  
  
     2  
     1  
     0
```

0

**Preserve Legacy Behavior of ismember**

Use the 'legacy' flag to preserve the behavior of `ismember` from R2012b and prior releases in your code.

Find the members of B with the current behavior.

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];
[Lia1,Locb1] = ismember(A,B)
```

```
Lia1 =
     0     0     1     1
```

```
Locb1 =
     0     0     2     1
```

Find the members of B, and preserve the legacy behavior.

```
[Lia2,Locb2] = ismember(A,B,'legacy')
```

```
Lia2 =
     0     0     1     1
```

```
Locb2 =
     0     0     4     1
```

**Tips**

- To find the rows from table A that are found in B with respect to a subset of variables, you can use column subscripting. For example, you can use `ismember(A(:,vars),B(:,vars))`, where `vars` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

# ismember

---

`sort`

**Purpose** Determine if method of object

**Syntax** `tf = ismethod(h, 'methodName')`

**Description** `tf = ismethod(h, 'methodName')` returns logical 1 (true) if the specified `methodName` is a public method of object `obj`. Otherwise, returns logical 0 (false).

**Examples** Determine if objects support equality testing:

```
if ismethod(obj1,'eq') && ismethod(obj2,'eq')
    tf = obj1 == obj2;
end
```

**See Also** `methods` | `isprop` | `isobject` | `class`

**Tutorials**

- “Methods”

# ismethod (COM)

---

**Purpose** Determine whether input is COM object method

**Syntax**

```
tf = h.ismethod('methodname')  
tf = ismethod(h,'methodname')
```

**Description** `tf = h.ismethod('methodname')` returns logical 1 (true) if the specified `methodname` is a method you can call on COM object `h`. Otherwise, returns logical 0 (false).

`tf = ismethod(h,'methodname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Test members of an instance of a Microsoft Excel application:

```
h = actxserver ('Excel.Application');  
ismethod(h, 'SaveWorkspace')
```

MATLAB returns true, `SaveWorkspace` is a method.

---

Try the same test on `UsableWidth`:

```
ismethod(h, 'UsableWidth')
```

MATLAB returns false, `UsableWidth` is not a method; it is a property.

| <b>Purpose</b>         | Find table elements with missing values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>          | <pre>TF = ismissing(A) TF = ismissing(A,id)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>     | <p><code>TF = ismissing(A)</code> returns a logical array, <code>TF</code>, that indicates which elements in the table <code>A</code> contain a missing value. The size of <code>TF</code> is the same as the size of <code>A</code>.</p> <p>Indicators for missing data depend on the data type:</p> <ul style="list-style-type: none"><li>• NaN for numeric arrays</li><li>• &lt;undefined&gt; for categorical arrays</li><li>• empty string, { ' ' }, for cell arrays of strings</li><li>• blank string, [ ' ' ], for character arrays</li></ul> <p><code>ismissing</code> ignores other data types.</p> <p><code>TF = ismissing(A,id)</code> treats the values in <code>id</code> as missing value indicators. You must include NaN (for floating-point variables), the empty string (for variables that are cell arrays of strings or character arrays), or the string '&lt;undefined&gt;' (for categorical variables) to have <code>ismissing</code> recognize them as missing value indicators.</p> |
| <b>Input Arguments</b> | <p><b>A - Input table</b><br/>table<br/>Input table, specified as a table.</p> <p><b>id - Missing value indicators</b><br/>numeric vector   string   cell array containing numeric values and strings<br/>Missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings. Use strings to identify categories in categorical variables that you want to treat as missing values.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# ismissing

---

You must include NaN (for floating-point variables), the empty string (for variables that are cell arrays of strings or character arrays), or the string '<undefined>' (for categorical variables) to have `ismissing` recognize them as missing value indicators.

**Example:** `TF = ismissing(A, -99)` recognizes only -99 as a missing value.

## Data Types

double | char | cell

## Examples

### Missing Values in Table with Various Data Types

Create a table with variables of different data types where each contains a missing value.

```
dblVar = [NaN;3;5;7;9];
singleVar = single([1;NaN;5;7;9]);
cellstrVar = {'one';'three';'';'seven';'nine'};
charVar = ['A';'C';'E';' ';'I'];
categoryVar = categorical({'red';'yellow';'blue';'violet';''});

A = table(dblVar,singleVar,cellstrVar,charVar,categoryVar)
```

A =

| dblVar | singleVar | cellstrVar | charVar | categoryVar |
|--------|-----------|------------|---------|-------------|
| NaN    | 1         | 'one'      | A       | red         |
| 3      | NaN       | 'three'    | C       | yellow      |
| 5      | 5         | ' '        | E       | blue        |
| 7      | 7         | 'seven'    |         | violet      |
| 9      | 9         | 'nine'     | I       | <undefined> |

Find the table elements with missing values.

```
TF = ismissing(A)
```

TF =

```

     1     0     0     0     0
     0     1     0     0     0
     0     0     1     0     0
     0     0     0     1     0
     0     0     0     0     1

```

The size of TF is the same as the size of A.

### Specify Indicators for Missing Values in Table

Create a table where 'NA', '' -99, NaN, and Inf represent missing values.

```

dblVar = [NaN;3;Inf;7;9];
int8Var = int8([1;3;5;7;-99]);
cellstrVar = {'one';'three';'';'NA';'nine'};
charVar = ['A';'C';'E';' ';'I'];

```

```
A = table(dblVar,int8Var,cellstrVar,charVar)
```

A =

| dblVar | int8Var | cellstrVar | charVar |
|--------|---------|------------|---------|
| NaN    | 1       | 'one'      | A       |
| 3      | 3       | 'three'    | C       |
| Inf    | 5       | ''         | E       |
| 7      | 7       | 'NA'       |         |
| 9      | -99     | 'nine'     | I       |

Find the missing values in the table A.

```

id = {'NA' '' -99 NaN Inf};
TF = ismissing(A,id)

```

TF =

# ismissing

---

```
1    0    0    0
0    0    0    0
1    0    1    0
0    0    1    1
0    1    0    0
```

`ismissing` recognizes data in the each variable of the table, `A` as missing values. `ismissing` ignores trailing white space in character arrays. Therefore, since the empty string, `''`, is specified as a missing value indicator, `ismissing` identifies the empty string in the cell arrays of strings, `A.cellstrVar`, as well as the blank space in character array, `A.charVar` as missing values.

## Algorithms

`ismissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `ismissing` does not ignore white space. All strings must match exactly.
- For character arrays, `ismissing` ignores trailing white space. Therefore, when you specify the empty string, `''`, as a missing value indicator, `ismissing` identifies the empty string in cell arrays of strings, `''`, and the blank space in character arrays, `' '`, as missing values.
- For categorical arrays, `ismissing` ignores leading and trailing white space.

## Tips

- You can use `A(~any(TF,2),:)` to return only complete rows from `A` and `A(:,~any(TF,1))` to return only the variables from `A` with no missing values.
- Integer variables cannot store NaN; therefore, you must use a special integer value (otherwise unused) to indicate missing integer data. For example, `-99`.

## See Also

`standardizeMissing` | `isnan` | `isempty` | `isundefined` | `table`

**Purpose** Array elements that are NaN

**Syntax** TF = isnan(A)

**Description** TF = isnan(A) returns an array the same size as A containing logical 1 (true) where the elements of A are NaNs and logical 0 (false) where they are not. For a complex number z, isnan(z) returns 1 if either the real or imaginary part of z is NaN, and 0 if both the real and imaginary parts are finite or Inf.

For any real A, exactly one of the three quantities isfinite(A), isinf(A), and isnan(A) is equal to one.

**Examples**

```
A = [-2 -1 0 1 2];

isnan(1./A)
ans =
     0     0     0     0     0

isnan(0./A)
ans =
     0     0     1     0     0
```

**See Also** isfinite | isinf | is\*

# isnumeric

---

**Purpose** Determine if input is numeric array

**Syntax** `tf = isnumeric(A)`

**Description** `tf = isnumeric(A)` returns true if A is a numeric array and false otherwise.

A numeric array is any of the following numeric types and any subclasses of those types:

## **MATLAB Numeric Types**

|                     |                                       |
|---------------------|---------------------------------------|
| <code>single</code> | Single-precision floating-point array |
| <code>double</code> | Double-precision floating-point array |
| <code>int8</code>   | 8-bit signed integer array            |
| <code>uint8</code>  | 8-bit unsigned integer array          |
| <code>int16</code>  | 16-bit signed integer array           |
| <code>uint16</code> | 16-bit unsigned integer array         |
| <code>int32</code>  | 32-bit signed integer array           |
| <code>uint32</code> | 32-bit unsigned integer array         |
| <code>int64</code>  | 64-bit signed integer array           |
| <code>uint64</code> | 64-bit unsigned integer array         |

**Examples** These examples show the values `isnumeric` returns when passed specific types:

```
% pi returns a numeric value
isnumeric(pi)
ans =
     1
% Complex numbers are numeric
isnumeric(3+7i)
ans =
```

```
    1
% Integers are numeric
isnumeric(uint8(1:255))
ans =
    1
% isnumeric returns a logical value
isnumeric(isnumeric(pi))
ans =
    0
```

| [isa](#) | [is\\*](#)

# isobject

---

**Purpose** Determine if input is MATLAB object

**Syntax** `tf = isobject(A)`

**Description** `tf = isobject(A)` returns true if `A` is an object of a MATLAB class. Otherwise, it returns false.

Handle Graphics objects return false. Use `ishandle` to test for Handle Graphics objects.

Instances of MATLAB fundamental classes return false. Use `isa` to test for any of these types. See “Fundamental MATLAB Classes” for more on these classes.

**Examples** These examples show the values `isobject` returns when passed specific types:

Define the following MATLAB class:

```
classdef button < handle
    properties
        UiHandle
    end
    methods
        function obj = button(pos)
            obj.UiHandle = uicontrol('Position',pos,...
                'Style','pushbutton');
        end
    end
end
```

Determine which objects are MATLAB objects. For example:

```
h = button([20 20 60 60]);
isobject(h)
ans =
     1
isobject(h.UiHandle)
```

```
ans =  
    0
```

---

Use `isjava` to test for Java objects in MATLAB, where it returns `false` for MATLAB objects:

```
isjava(h)  
ans =  
    0
```

---

Create an object that is a MATLAB numeric type:

```
a = pi;  
isa(a, 'double')  
ans =  
    1  
isobject(a)  
ans =  
    0
```

- “Class Syntax Fundamentals”

# isocaps

---

**Purpose** Compute isosurface end-cap geometry

**Syntax**

```
fvc = isocaps(X,Y,Z,V,isovalue)
fvc = isocaps(V,isovalue)
fvc = isocaps(...,'enclose')
fvc = isocaps(...,'whichplane')
[f,v,c] = isocaps(...)
isocaps(...)
```

**Description** `fvc = isocaps(X,Y,Z,V,isovalue)` computes isosurface end-cap geometry for the volume data `V` at isosurface value `isovalue`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`.

The struct `fvc` contains the face, vertex, and color data for the end-caps and can be passed directly to the `patch` command.

`fvc = isocaps(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isocaps(...,'enclose')` specifies whether the end-caps enclose data values above or below the value specified in `isovalue`. The string `enclose` can be either `above` (default) or `below`.

`fvc = isocaps(...,'whichplane')` specifies on which planes to draw the end-caps. Possible values for `whichplane` are `all` (default), `xmin`, `xmax`, `ymin`, `ymax`, `zmin`, or `zmax`.

`[f,v,c] = isocaps(...)` returns the face, vertex, and color data for the end-caps in three arrays instead of the struct `fvc`.

`isocaps(...)` without output arguments draws a patch with the computed faces, vertices, and colors.

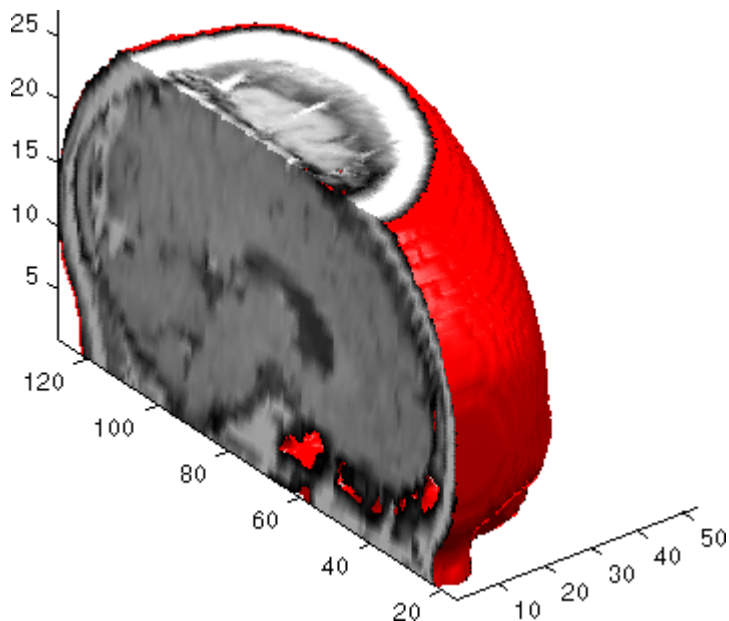

**Examples** This example uses a data set that is a collection of MRI slices of a human skull. It illustrates the use of `isocaps` to draw the end-caps on this cutaway volume.

The red isosurface shows the outline of the volume (skull) and the end-caps show what is inside of the volume.

The patch created from the end-cap data (p2) uses interpolated face coloring, which means the gray colormap and the light sources determine how it is colored. The isosurface patch (p1) used a flat red face color, which is affected by the lights, but does not use the colormap.

```
load mri
D = squeeze(D);
D(:,1:60,:) = [];
p1 = patch(isosurface(D, 5), 'FaceColor', 'red', ...
    'EdgeColor', 'none');
p2 = patch(isocaps(D, 5), 'FaceColor', 'interp', ...
    'EdgeColor', 'none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight left; camlight; lighting gouraud
isonormals(D,p1)
```

# isocaps

---

## How To

- “Isocaps Add Context to Visualizations”

**Purpose**

Calculate isosurface and patch colors

**Syntax**

```
nc = isocolors(X,Y,Z,C,vertices)
nc = isocolors(X,Y,Z,R,G,B,vertices)
nc = isocolors(C,vertices)
nc = isocolors(R,G,B,vertices)
nc = isocolors(...,PatchHandle)
isocolors(...,PatchHandle)
```

**Description**

`nc = isocolors(X,Y,Z,C,vertices)` computes the colors of isosurface (patch object) vertices (`vertices`) using color values `C`. Arrays `X`, `Y`, `Z` define the coordinates for the color data in `C` and must be monotonic vectors that represent a Cartesian, axis-aligned grid (as if produced by `meshgrid`). The colors are returned in `nc`. `C` must be 3-D (index colors).

`nc = isocolors(X,Y,Z,R,G,B,vertices)` uses `R`, `G`, `B` as the red, green, and blue color arrays (true color).

`nc = isocolors(C,vertices)`, and `nc = isocolors(R,G,B,vertices)` assume `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(C)`.

`nc = isocolors(...,PatchHandle)` uses the vertices from the patch identified by `PatchHandle`.

`isocolors(...,PatchHandle)` sets the `FaceVertexCData` property of the patch specified by `PatchHandle` to the computed colors.

**Examples****Indexed Color Data**

This example displays an isosurface and colors it with random data using indexed color. (See “Interpolating in Indexed Color Versus Truecolor” for information on how patch objects interpret color data.)

```
[x y z] = meshgrid(1:20,1:20,1:20);
```

# isocolors

---

```
data = sqrt(x.^2 + y.^2 + z.^2);
cdata = smooth3(rand(size(data)), 'box', 7);
p = patch(isosurface(x,y,z,data,10));
isonormals(x,y,z,data,p);
isocolors(x,y,z,cdata,p);
set(p, 'FaceColor', 'interp', 'EdgeColor', 'none')
view(150,30); daspect([1 1 1]); axis tight
camlight; lighting phong;
```

## True Color Data

This example displays an isosurface and colors it with true color (RGB) data.

```
[x y z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(x,y,z,data,20));
isonormals(x,y,z,data,p);
[r g b] = meshgrid(20:-1:1,1:20,1:20);
```

```

isocolors(x,y,z,r/20,g/20,b/20,p);
set(p,'FaceColor','interp','EdgeColor','none')
view(150,30); daspect([1 1 1]);
camlight; lighting phong;

```

### Modified True Color Data

This example uses `isocolors` to calculate the true color data using the `isosurface`'s (patch object's) vertices, but then returns the color data in a variable (`c`) in order to modify the values. It then explicitly sets the `isosurface`'s `FaceVertexCData` to the new data (`1-c`).

```

[x y z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(data,20));
isonormals(data,p);
[r g b] = meshgrid(20:-1:1,1:20,1:20);
c = isocolors(r/20,g/20,b/20,p);
set(p,'FaceVertexCData',1-c)

```

# isocolors

---

```
set(p,'FaceColor','interp','EdgeColor','none')  
view(150,30); daspect([1 1 1]);  
camlight; lighting phong;
```

## See Also

[isosurface](#) | [isocaps](#) | [smooth3](#) | [subvolume](#) | [reducevolume](#) | [reducepatch](#) | [isonormals](#)

**Purpose**

Compute normals of isosurface vertices

**Syntax**

```
n = isonormals(X,Y,Z,V,vertices)
n = isonormals(V,vertices)
n = isonormals(V,p) and n = isonormals(X,Y,Z,V,p)
n = isonormals(...,'negate')
isonormals(V,p) and isonormals(X,Y,Z,V,p)
```

**Description**

`n = isonormals(X,Y,Z,V,vertices)` computes the normals of the isosurface vertices from the vertex list, `vertices`, using the gradient of the data `V`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The computed normals are returned in `n`.

`n = isonormals(V,vertices)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`n = isonormals(V,p)` and `n = isonormals(X,Y,Z,V,p)` compute normals from the vertices of the patch identified by the handle `p`.

`n = isonormals(...,'negate')` negates (reverses the direction of) the normals.

`isonormals(V,p)` and `isonormals(X,Y,Z,V,p)` set the `VertexNormals` property of the patch identified by the handle `p` to the computed normals rather than returning the values.

**Examples**

This example compares the effect of different surface normals on the visual appearance of lit isosurfaces. In one case, the triangles used to draw the isosurface define the normals. In the other, the `isonormals` function uses the volume data to calculate the vertex normals based on the gradient of the data points. The latter approach generally produces a smoother-appearing isosurface.

Define a 3-D array of volume data (`cat`, `interp3`):

```
data = cat(3, [0 .2 0; 0 .3 0; 0 0 0], ...
             [.1 .2 0; 0 1 0; .2 .7 0], ...
             [0 .4 .2; .2 .4 0;.1 .1 0]);
```

# isonormals

---

```
data = interp3(data,3,'cubic');
```

Draw an isosurface from the volume data and add lights. This isosurface uses triangle normals (patch, isosurface, view, daspect, axis, camlight, lighting, title):

```
subplot(1,2,1)
p1 = patch(isosurface(data,.5),...
'FaceColor','red','EdgeColor','none');
view(3); daspect([1,1,1]); axis tight
camlight; camlight(-80,-10); lighting phong;
title('Triangle Normals')
```

Draw the same lit isosurface using normals calculated from the volume data:

```
subplot(1,2,2)
p2 = patch(isosurface(data,.5),...
'FaceColor','red','EdgeColor','none');
isonormals(data,p2)
view(3); daspect([1 1 1]); axis tight
camlight; camlight(-80,-10); lighting phong;
title('Data Normals')
```

These isosurfaces illustrate the difference between triangle and data normals:

Triangle Normals

Data Normals

`reducevolume` | `reducepatch`

# isordinal

---

**Purpose** Determine whether input is ordinal categorical array

**Syntax** `tf = isordinal(A)`

**Description** `tf = isordinal(A)` returns logical 1 (true) if A is an ordinal categorical array. Otherwise, `isordinal` returns logical 0 (false).

If a categorical array is ordinal, you can use relational operations for inequality comparisons, such as greater and less than, in addition to tests for equality.

**Input Arguments** **A - Categorical array**  
vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

## **Examples** Determine Whether Categorical Array Is Ordinal

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values 'S', 'M', and 'L'.

```
A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...  
              {'S','M','L'},{'small','medium','large'})
```

```
A =  
  
    medium  
    large  
    small  
    small  
    medium  
    large  
    medium  
    large  
    medium  
    small
```

Determine if the categories of A have a mathematical ordering.

```
isordinal(A)
```

```
ans =
```

```
0
```

A is not ordinal. You must use the 'Ordinal', true name-value pair argument in the function `categorical` to create an ordinal categorical array.

## Tips

- To convert a categorical array, A, from nonordinal to ordinal, use `A = categorical(A, 'Ordinal', true)`.
- To convert a categorical array, A, from ordinal to nonordinal, use `A = categorical(A, 'Ordinal', false)`.

## Concepts

- “Ordinal Categorical Arrays”

# isosurface

---

**Purpose** Extract isosurface data from volume data

**Syntax**

```
fv = isosurface(X,Y,Z,V,isovalue)
fv = isosurface(V,isovalue)
fvc = isosurface(...,colors)
fv = isosurface(...,'noshare')
fv = isosurface(...,'verbose')
[f,v] = isosurface(...)
[f,v,c] = isosurface(...)
isosurface(...)
```

**Description** `fv = isosurface(X,Y,Z,V,isovalue)` computes isosurface data from the volume data `V` at the isosurface value specified in `isovalue`. That is, the isosurface connects points that have the specified value much the way contour lines connect points of equal elevation.

The arrays `X`, `Y`, and `Z` represent a Cartesian, axis-aligned grid. `V` contains the corresponding values at these grid points. The coordinate arrays (`X`, `Y`, and `Z`) must be monotonic and conform to the format produced by `meshgrid`. `V` must be a 3D volume array of the same size as `X`, `Y`, and `Z`.

The struct `fv` contains the faces and vertices of the isosurface, which you can pass directly to the `patch` command.

`fv = isosurface(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isosurface(...,colors)` interpolates the array `colors` onto the scalar field and returns the interpolated values in the `facevertexcdata` field of the `fvc` structure. The size of the `colors` array must be the same as `V`. The `colors` argument enables you to control the color mapping of the isosurface with data different from that used to calculate the isosurface (e.g., temperature data superimposed on a wind current isosurface).

`fv = isosurface(..., 'noshare')` does not create shared vertices. This is faster, but produces a larger set of vertices.

`fv = isosurface(..., 'verbose')` prints progress messages to the command window as the computation progresses.

`[f,v] = isosurface(...)` or `[f,v,c] = isosurface(...)` returns the faces and vertices (and `faceVertexcCData`) in separate arrays instead of a struct.

`isosurface(...)` with no output arguments, creates a patch in the current axes with the computed faces and vertices. If no current axes exists, a new axes is created with a 3-D view and appropriate lighting.

## Special Case Behavior – isosurface Called with No Output Arguments

If there is no current axes and you call `isosurface` without assigning output arguments, MATLAB creates a new axes, sets it to a 3-D view, and adds lighting to the isosurface graph.

## Tips

You can pass the `fv` structure created by `isosurface` directly to the `patch` command, but you cannot pass the individual faces and vertices arrays (`f`, `v`) to `patch` without specifying property names. For example,

```
patch(isosurface(X,Y,Z,V,isovalue))
```

or

```
[f,v] = isosurface(X,Y,Z,V,isovalue);  
patch('Faces',f,'Vertices',v)
```

## Examples

### Example 1

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). The isosurface is drawn at the data value of -3. The statements that follow the `patch` command prepare the isosurface for lighting by

# isosurface

---

- Recalculating the isosurface normals based on the volume data (`isonormals`)
- Setting the face and edge color (`set`, `FaceColor`, `EdgeColor`)
- Specifying the view (`daspect`, `view`)
- Adding lights (`camlight`, `lighting`)

```
[x,y,z,v] = flow;  
p = patch(isosurface(x,y,z,v,-3));  
isonormals(x,y,z,v,p)  
set(p,'FaceColor','red','EdgeColor','none');  
daspect([1,1,1])  
view(3); axis tight  
camlight  
lighting gouraud
```

### Example 2

Visualize the same flow data as above, but color-code the surface to indicate magnitude along the X-axis. Use a sixth argument to `isosurface`, which provides a means to overlay another data set by coloring the resulting isosurface. The `colors` variable is a vector containing a scalar value for each vertex in the isosurface, to be portrayed with the current color map. In this case, it is one of the

# isosurface

---

variables that define the surface, but it could be entirely independent. You can apply a different color scheme by changing the current figure color map.

```
[x,y,z,v] = flow;  
[faces,verts,colors] = isosurface(x,y,z,v,-3,x);  
patch('Vertices', verts, 'Faces', faces, ...  
      'FaceVertexCData', colors, ...  
      'FaceColor', 'interp', ...  
      'edgecolor', 'interp');  
view(30,-15);  
axis vis3d;  
colormap copper
```

## How To

- “Connecting Equal Values with Isosurfaces”

**Purpose** Determine if version is for Windows (PC) platform

**Syntax** `tf = ispc`

**Description** `tf = ispc` returns logical 1 (true) if the version of MATLAB software is for the Microsoft Windows platform. Otherwise, it returns logical 0 (false).

**See Also** `isunix` | `ismac` | `computer` | `isstudent` | `is*`

# ispref

---

**Purpose** Test for existence of preference

**Syntax**

```
ispref('group','pref')
ispref('group')
ispref('group',{'pref1','pref2',... 'prefn'})
```

**Description**

`ispref('group','pref')` returns 1 if the preference specified by `group` and `pref` exists, and 0 otherwise.

`ispref('group')` returns 1 if the `GROUP` exists, and 0 otherwise.

`ispref('group',{'pref1','pref2',... 'prefn'})` returns a logical array the same length as the cell array of preference names, containing 1 where each preference exists, and 0 elsewhere.

**Examples**

```
addpref('mytoolbox','version','1.0')
ispref('mytoolbox','version')
```

ans =  
1.0

# isprime

---

0 1 0

71 is prime, but 333 and 99 are not.

## See Also

[is\\*](#) | [primes](#)

**Purpose** Determine if property of object

**Syntax** `tf = isprop(obj, 'PropertyName')`

**Description** `tf = isprop(obj, 'PropertyName')` returns true if the specified `PropertyName` is a property of object `obj`. Otherwise, returns logical false.

If `obj` is an array, `isprop` returns a logical array the same size as `obj`. Each true element of `tf` corresponds to an element of `obj` that has the property `PropertyName`

---

**Note** If `obj` is an empty object, `isprop` always returns false, even if the class of `obj` defines the property specified in `PropertyName`.

---

While `isprop` returns true if the class of an object defines a property of that name, classes can control access to property values by defining property attributes. Property access can be defined as:

- Readable and writable
- Read only
- Write only
- Accessible only to certain class methods

Therefore, `isprop` might indicate that a property exists, but you might not be able to access that property. See “Getting Information About Properties” for information about properties.

## Examples

This example uses `isprop` to determine if `XDataSource` is a property of object `h` before attempting to set the property value:

```
h = plot(1:10);  
if isprop(h, 'XDataSource')  
    set(h, 'XDataSource', 'x')  
else
```

# isprop

---

```
        error(['XDataSource is not a property of class ',class(h)])  
    end
```

## Tutorials

- “Properties”

**Purpose** Determine whether input is COM object property

**Syntax**

```
tf = h.isprop('propertyname')  
tf = isprop(h, 'propertyname')
```

**Description** `tf = h.isprop('propertyname')` returns logical 1 (true) if the specified name is a property of COM object `h`. Otherwise, returns logical 0 (false).

`tf = isprop(h, 'propertyname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Test a property of an instance of a Microsoft Excel application:

```
h = actxserver('Excel.Application');  
isprop(h, 'UsableWidth')
```

MATLAB returns true, `UsableWidth` is a property.

---

Try the same test on `SaveWorkspace`:

```
isprop(h, 'SaveWorkspace')
```

MATLAB returns false. `SaveWorkspace` is not a property; it is a method.

**See Also** `inspect` | `ismethod` | `isevent`

**How To**

- “Exploring Properties”

# isprotected

---

**Purpose** Determine whether categories of categorical array are protected

**Syntax** `tf = isprotected(A)`

**Description** `tf = isprotected(A)` returns logical 1 (true) if the categories of A are protected. Otherwise, `isprotected` returns logical 0 (false).

- **true** — When you assign new values to B, the values must belong to one of the existing categories. Therefore, you only can combine arrays that have the same categories. To add new categories to B, you must use the `addcats` function.
- **false** — When you assign new values to B, the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update to include the categories from both arrays.

## Input Arguments

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

The categories of ordinal categorical arrays are always protected.

## Examples

### **Determine Whether Categories Are Protected**

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values 'S', 'M', and 'L'.

```
valueset = {'S','M','L'};  
catnames = {'small','medium','large'};
```

```
A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...  
    valueset,catnames,'Ordinal',true)
```

```
A =
```

```
    medium
```

```
large
small
small
medium
large
medium
large
medium
small
```

A is a 10-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
 'small'
 'medium'
 'large'
```

Determine whether the categories of A are protected.

```
tf = isprotected(A)
```

```
tf =
```

```
1
```

Since A is an ordinal categorical array, the categories are protected. If you try to add a new value that does not belong to one of the existing categories, for example `A(11) = 'xlarge'`, then MATLAB returns an error.

First, use `addcats` to add a new category for `xlarge`.

```
A = addcats(A, 'xlarge', 'After', 'large');
```

# isprotected

---

Since A is protected, you can now add a value for `xlarge` since it has an existing category.

```
A(11) = 'xlarge'
```

```
A =
```

```
    medium  
    large  
    small  
    small  
    medium  
    large  
    medium  
    large  
    medium  
    small  
    xlarge
```

A is now a 11-by-1 categorical array with four categories, such that `small < medium < large < xlarge`.

|                    |                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Check if input is real array                                                                                                                                                                                                                                |
| <b>Syntax</b>      | <code>TF = isreal(A)</code>                                                                                                                                                                                                                                 |
| <b>Description</b> | <code>TF = isreal(A)</code> returns logical 1 (true) if <code>A</code> does not have an imaginary part. It returns logical 0 (false) otherwise. If <code>A</code> has a stored imaginary part of value 0, <code>isreal(A)</code> returns logical 0 (false). |

---

**Note** For logical and char data classes, `isreal` always returns true. For numeric data types, if `A` does not have an imaginary part `isreal` returns true; if `A` does have an imaginary part `isreal` returns false. For cell, struct, function\_handle, and object data types, `isreal` always returns false.

---

`~isreal(x)` returns true for arrays that have at least one element with an imaginary component. The value of that component can be 0.

**Tips** If `A` is real, `complex(A)` returns a complex number whose imaginary component is 0, and `isreal(complex(A))` returns false. In contrast, the addition `A + 0i` returns the real value `A`, and `isreal(A + 0i)` returns true.

If `B` is real and `A = complex(B)`, then `A` is a complex matrix and `isreal(A)` returns false, while `A(m:n)` returns a real matrix and `isreal(A(m:n))` returns true.

Because MATLAB software supports complex arithmetic, certain of its functions can introduce significant imaginary components during the course of calculations that appear to be limited to real numbers. Thus, you should use `isreal` with discretion.

## Examples

### Example 1

If a computation results in a zero-value imaginary component, `isreal` returns true.

# isreal

---

```
x=3+4i;  
y=5-4i;  
isreal(x+y)
```

```
ans =
```

```
1
```

## Example 2

These examples use `isreal` to detect the presence or absence of imaginary numbers in an array. Let

```
x = magic(3);  
y = complex(x);
```

`isreal(x)` returns `true` because no element of `x` has an imaginary component.

```
isreal(x)
```

```
ans =
```

```
1
```

`isreal(y)` returns `false`, because every element of `x` has an imaginary component, even though the value of the imaginary components is 0.

```
isreal(y)
```

```
ans =
```

```
0
```

This expression detects strictly real arrays, i.e., elements with 0-valued imaginary components are treated as real.

```
~any(imag(y(:)))
```

```
ans =
```

1

**Example 3**

Given the following cell array,

```
C{1} = pi;           % double
C{2} = 'John Doe';  % char array
C{3} = 2 + 4i;      % complex double
C{4} = ispc;        % logical
C{5} = magic(3);    % double array
C{6} = complex(5,0) % complex double
```

C =

```
    [3.1416]    'John Doe'    [2.0000 + 4.0000i]    [1]    [3x3 double]
```

isreal shows that all but C{1,3} and C{1,6} are real arrays.

```
for k = 1:6
x(k) = isreal(C{k});
end
```

x

x =

```
    1    1    0    1    1    0
```

**See Also**

complex | isnumeric | isnan | isprime | isfinite | isinf | isa | is\*

# isrow

---

**Purpose** Determine whether input is row vector

**Syntax** `isrow(V)`

**Description** `isrow(V)` returns logical 1 (true) if `size(V)` returns `[1 n]` with a nonnegative integer value `n`, and logical 0 (false) otherwise.

**Examples** Determine if a vector is a row. This example is a column so `isrow` returns 0:

```
V = rand(5,1);  
isrow(V)  
ans =  
    0
```

Transpose the vector to make it a row. `isrow` returns 1:

```
V1 = V';  
isrow(V1)  
ans =  
    1
```

**See Also** `iscolumn` | `ismatrix` | `isscalar` | `isvector`

**Purpose** Determine whether input is scalar

**Syntax** `isscalar(A)`

**Description** `isscalar(A)` returns logical 1 (true) if `size(A)` returns [1 1], and logical 0 (false) otherwise.

**Examples** Test matrix A and one element of the matrix:

```
A = rand(5);
```

```
isscalar(A)
ans =
     0
```

```
isscalar(A(3,2))
ans =
     1
```

# issorted

---

**Purpose** Determine whether set elements are in sorted order

**Syntax** TF = issorted(A)  
TF = issorted(A, 'rows')

**Description** TF = issorted(A) returns logical 1 (true) if the elements of A are in sorted order, and logical 0 (false) otherwise. Input A can be a vector or an N-by-1 or 1-by-N cell array of strings. A is considered to be sorted if A and the output of sort(A) are equal.

TF = issorted(A, 'rows') returns logical 1 (true) if the rows of two-dimensional matrix A are in sorted order, and logical 0 (false) otherwise. Matrix A is considered to be sorted if A and the output of sortrows(A) are equal.

---

**Note** Only the issorted(A) syntax supports A as a cell array of strings.

The issorted(A, 'rows') syntax supports A as a categorical array, but not as a cell array of strings.

---

**Tips** For character arrays, issorted uses ASCII, rather than alphabetical, order.

You cannot use issorted on arrays of greater than two dimensions.

**Examples** **Example 1 – Using issorted on a vector**

```
A = [5 12 33 39 78 90 95 107 128 131];
```

```
issorted(A)  
ans =  
     1
```

**Example 2 – Using issorted on a matrix**

```
A = magic(5)
```

```
A =
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

```
issorted(A, 'rows')
ans =
     0
```

```
B = sortrows(A)
B =
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
    17    24     1     8    15
    23     5     7    14    16
```

```
issorted(B)
ans =
     1
```

### Example 3 – Using issorted on a cell array

```
x = {'one'; 'two'; 'three'; 'four'; 'five'};
issorted(x)
ans =
     0
```

```
y = sort(x)
y =
    'five'
    'four'
    'one'
    'three'
    'two'
```

# issorted

---

`issorted(y)`

## **See Also**

`sort` | `sortrows` | `ismember` | `unique` | `intersect` | `union` | `setdiff`  
| `setxor` | `is*`

**Purpose** Array elements that are space characters

**Syntax** `tf = isspace('str')`

**Description** `tf = isspace('str')` returns an array the same size as 'str' containing logical 1 (true) where the elements of `str` are Unicode<sup>®</sup>-represented whitespace characters, and logical 0 (false) where they are not.

Whitespace characters for which `isspace` returns true include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which `isspace` returns true, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isspace(char(1):char(intmax('uint16'))))
```

## Examples

```
isspace(' Find spa ces ')
Columns 1 through 13
    1    1    0    0    0    0    1    0    0    0    1    0    0
Columns 14 through 15
    0    1
```

**See Also** `isletter` | `isstrprop` | `ischar` | `strings` | `isa` | `is*`

# issparse

---

**Purpose** Determine whether input is sparse

**Syntax** TF = issparse(S)

**Description** TF = issparse(S) returns logical 1 (true) if the storage class of S is sparse and logical 0 (false) otherwise.

**See Also** is\* | sparse | full

**Purpose** Determine whether input is character array

---

**Note** `isstr` is not recommended. Use `ischar` instead.

---

**See Also** `ischar` | `isa` | `is*`

# isstrprop

---

**Purpose** Determine whether string is of specified category

**Syntax** `tf = isstrprop('str', 'category')`

**Description** `tf = isstrprop('str', 'category')` returns a logical array the same size as `str` containing logical 1 (true) where the elements of `str` belong to the specified `category`, and logical 0 (false) where they do not.

The `str` input can be a character array, cell array, or any MATLAB numeric type. If `str` is a cell array, then the return value is a cell array of the same shape as `str`.

The `category` input can be any of the strings shown in the left column below:

| Category | Description                                                                                                                                                                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| alpha    | True for those elements of <code>str</code> that are alphabetic                                                                                                                                                                                                                                                                                                     |
| alphanum | True for those elements of <code>str</code> that are alphanumeric                                                                                                                                                                                                                                                                                                   |
| cntrl    | True for those elements of <code>str</code> that are control characters (for example, <code>char(0:20)</code> )                                                                                                                                                                                                                                                     |
| digit    | True for those elements of <code>str</code> that are numeric digits                                                                                                                                                                                                                                                                                                 |
| graphic  | True for those elements of <code>str</code> that are graphic characters. These are all values that represent any characters except for the following:<br><br>unassigned, space, line separator, paragraph separator, control characters, Unicode format control characters, private user-defined characters, Unicode surrogate characters, Unicode other characters |
| lower    | True for those elements of <code>str</code> that are lowercase letters                                                                                                                                                                                                                                                                                              |
| print    | True for those elements of <code>str</code> that are graphic characters, plus <code>char(32)</code>                                                                                                                                                                                                                                                                 |

| Category | Description                                                                                                                                                                                                                         |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| punct    | True for those elements of <code>str</code> that are punctuation characters                                                                                                                                                         |
| wspace   | True for those elements of <code>str</code> that are white-space characters. This range includes the ANSI® C definition of white space, { ' ', '\t', '\n', '\r', '\v', '\f' }, in addition to a number of other Unicode characters. |
| upper    | True for those elements of <code>str</code> that are uppercase letters                                                                                                                                                              |
| xdigit   | True for those elements of <code>str</code> that are valid hexadecimal digits                                                                                                                                                       |

## Tips

Numbers of type `double` are converted to `int32` according to MATLAB rules of double-to-integer conversion. Numbers of type `int64` and `uint64` bigger than `int32(inf)` saturate to `int32(inf)`.

MATLAB classifies the elements of the `str` input according to the Unicode definition of the specified category. If the numeric value of an element in the input array falls within the range that defines a Unicode character category, then this element is classified as being of that category. The set of Unicode character codes includes the set of ASCII character codes, but also covers a large number of languages beyond the scope of the ASCII set. The classification of characters is dependent on the global location of the platform on which MATLAB is installed.

Whitespace characters for which the `wspace` option returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which the `wspace` option returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isstrprop(char(1):char(intmax('uint16')), 'wspace'))
```

## Examples

Test for alphabetic characters in a string:

```
A = isstrprop('abc123def', 'alpha')
```

# isstrprop

---

```
A =  
  1 1 1 0 0 0 1 1 1
```

Test for numeric digits in a string:

```
A = isstrprop('abc123def', 'digit')  
A =  
  0 0 0 1 1 1 0 0 0
```

Test for hexadecimal digits in a string:

```
A = isstrprop('abcd1234efgh', 'xdigit')  
A =  
  1 1 1 1 1 1 1 1 1 0 0
```

Test for numeric digits in a character array:

```
A = isstrprop(char([97 98 99 49 50 51 101 102 103]), ...  
              'digit')  
A =  
  0 0 0 1 1 1 0 0 0
```

Test for alphabetic characters in a two-dimensional cell array:

```
A = isstrprop({'abc123def'; '456ghi789'}, 'alpha')  
A =  
  [1x9 logical]  
  [1x9 logical]
```

```
A{:, :}  
ans =  
  1 1 1 0 0 0 1 1 1  
  0 0 0 1 1 1 0 0 0
```

Test for white-space characters in a string:

```
A = isstrprop(sprintf('a bc\n'), 'wspace')  
A =  
  0 1 0 0 1
```

# isstruct

---

**Purpose** Determine whether input is structure array

**Syntax** `tf = isstruct(A)`

**Description** `tf = isstruct(A)` returns logical 1 (true) if A is a MATLAB structure and logical 0 (false) otherwise.

**Examples**

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];

isstruct(patient)

ans =

     1
```

**See Also** `struct` | `isfield` | `iscell` | `ischar` | `isobject` | `isnumeric` | `islogical` | `isa` | `is*`

**How To**

- dynamic field names

**Purpose** Determine if version is Student Version

**Syntax** `tf = isstudent`

**Description** `tf = isstudent` returns logical 1 (true) if the version of MATLAB software is the Student Version, and returns logical 0 (false) for commercial versions.

**See Also** `ver` | `version` | `license` | `ispc` | `isunix` | `is*`

# Tiff.isTiled

---

**Purpose** Determine if tiled image

**Syntax** `bool = tiffobj.isTiled()`

**Description** `bool = tiffobj.isTiled()` returns true if the image has a tiled organization and false if the image has a stripped organization.

## **Examples** **Determine if Image Has Tiled Organization**

Open a Tiff object and check if the image in the TIFF file has a tiled or stripped organization.

```
t = Tiff('example.tif', 'r');
tf = t.isTiled()
```

```
tf =
```

```
1
```

The image has a tiled organization.

Close the Tiff object.

```
t.close();
```

**References** This method corresponds to the `TIFFIsTiled` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Determine whether input is table

**Syntax** `tf = istable(T)`

**Description** `tf = istable(T)` returns logical 1 (true) if T is a table. Otherwise, it returns logical 0 (false) otherwise.

**Input Arguments** **T - Input variable**  
workspace variable

Input variable, specified as a workspace variable. T can be any data type.

**Examples** **Determine if Workspace Variable Is Table**

Create a workspace variable, T.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
        {'NY';'CA';'MA'},[true;false;false])
```

T =

| Var1 | Var2 | Var3 | Var4 |       |
|------|------|------|------|-------|
| M    | 45   | 45   | 'NY' | true  |
| F    | 41   | 32   | 'CA' | false |
| M    | 40   | 34   | 'MA' | false |

Verify that the workspace variable, T, is a table.

```
istable(T)
```

```
ans =
```

```
1
```

T is a table.

## Determine if Subset of Table Is Table

Create a table, T.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
         {'NY';'CA';'MA'},[true;false;false])
```

T =

| Var1 | Var2 | Var3 | Var4 |       |
|------|------|------|------|-------|
| M    | 45   | 45   | 'NY' | true  |
| F    | 41   | 32   | 'CA' | false |
| M    | 40   | 34   | 'MA' | false |

Determine if the subset of table T that contains only the second and fourth variables is a table.

```
istable(T{:[2 4]})
```

ans =

0

Conversely, accessing data with curly braces, T{:[2 4]}, returns a matrix and not a table.

table | iscell | isstruct | isnumeric | isobject |  
islogical

**Purpose** Find undefined elements in categorical array

**Syntax** `TF = isundefined(A)`

**Description** `TF = isundefined(A)` returns a logical array, `TF`, that indicates which elements in the categorical array, `A`, contain undefined values. `isundefined` returns logical 1 (`true`) for undefined elements; otherwise it returns logical 0 (`false`). The size of `TF` is the same as the size of `A`.

Any elements in `A` without a corresponding category are undefined. Undefined values are similar to NaN in numeric arrays.

**Input Arguments**

**A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**Examples**

**Categorical Array with Undefined Values**

Create a categorical array, `A`, from numeric values where 1, 2, and 3 represent red, green, and blue respectively.

```
A = categorical([4 1; 2 3; 2 1; 3 4; 1 1],1:3,{'red','green','blue'})
```

```
A =
```

```

<undefined>    red
green          blue
green          red
blue          <undefined>
red           red

```

`A` is a 5-by-2 categorical array with three categories: red, green, and blue. Array elements corresponding to the numeric value 4 in the input array to the `categorical` function do not have a corresponding category. Therefore, they are undefined in the output categorical array, `A`.

# isundefined

---

Find undefined elements in A.

```
TF = isundefined(A)
```

```
TF =
```

```
     1     0
     0     0
     0     0
     0     1
     0     0
```

A(1,1) and A(4,2) are undefined.

**See Also** `ismember`

**Purpose** Determine if version is for UNIX platform

**Syntax** `tf = isunix`

**Description** `tf = isunix` returns logical 1 (true) if the version of MATLAB software is for the UNIX platform or the Apple Mac OS X platform. Otherwise, it returns logical 0 (false).

**See Also** `ispc` | `ismac` | `computer` | `isstudent` | `is*`

# isvalid (handle)

---

**Purpose** Is object valid handle class object

**Syntax** H1 = isvalid(Hobj)

**Description** H1 = isvalid(Hobj) returns a logical array (or scalar if Hobj is scalar) in which each element is true if the corresponding element in Hobj is a valid handle. This method is Sealed, so you cannot override it in a handle subclass.

---

**Note** This method does not work with Handle Graphics objects. To determine the validity of a Handle Graphics object handle, use the ishghandle function.

---

**See Also** delete (handle) | handle

**How To** • “Testing Handle Validity”

|                    |                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Determine whether serial port objects are valid                                                                                                                                                                                                                                                                                                                                            |
| <b>Syntax</b>      | <code>out = isvalid(obj)</code>                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <code>out = isvalid(obj)</code> returns the logical array <code>out</code> , which contains a 0 where the elements of the serial port object, <code>obj</code> are invalid serial port objects and a 1 where the elements of <code>obj</code> are valid serial port objects.                                                                                                               |
| <b>Tips</b>        | <code>obj</code> becomes invalid after it is removed from memory with the <code>delete</code> function. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the <code>clear</code> command.                                                                                                                               |
| <b>Examples</b>    | <p>Suppose you create the following two serial port objects.</p> <pre>s1 = serial('COM1');<br/>s2 = serial('COM1');</pre> <p><code>s2</code> becomes invalid after it is deleted.</p> <pre>delete(s2)</pre> <p><code>isvalid</code> verifies that <code>s1</code> is valid and <code>s2</code> is invalid.</p> <pre>sarray = [s1 s2];<br/>isvalid(sarray)<br/>ans =<br/>     1     0</pre> |
| <b>See Also</b>    | <code>clear</code>   <code>delete</code>                                                                                                                                                                                                                                                                                                                                                   |

# isvarname

---

**Purpose** Determine whether input is valid variable name

**Syntax** `tf = isvarname('str')`  
`isvarname str`

**Description** `tf = isvarname('str')` returns logical 1 (true) if the string `str` is a valid MATLAB variable name and logical 0 (false) otherwise. A valid variable name is a character string of letters, digits, and underscores, totaling not more than `namelengthmax` characters and beginning with a letter.

MATLAB keywords are not valid variable names. Type the command `iskeyword` with no input arguments to see a list of MATLAB keywords.

`isvarname str` uses the MATLAB command format.

**Examples** This variable name is valid:

```
isvarname foo
ans =
     1
```

This one is not because it starts with a number:

```
isvarname 8th_column
ans =
     0
```

If you are building strings from various pieces, place the construction in parentheses.

```
d = date;
isvarname(['Monday_', d(1:2)])
ans =
     1
```

**See Also** `genvarname` | `isglobal` | `iskeyword` | `namelengthmax` | `is*`

**Purpose** Determine whether input is vector

**Syntax** `isvector(A)`

**Description** `isvector(A)` returns logical 1 (true) if `size(A)` returns `[1 n]` or `[n 1]` with a nonnegative integer value `n`, and logical 0 (false) otherwise.

**Examples** Test matrix A and its row and column vectors:

```
A = rand(5);
```

```
isvector(A)
ans =
     0
```

```
isvector(A(3, :))
ans =
     1
```

```
isvector(A(:, 2))
ans =
     1
```

**See Also** `iscolumn` | `ismatrix` | `isrow` | `isscalar` | `isempty` | `isnumeric` | `islogical` | `ischar` | `isa` | `is*`

**Purpose**            Imaginary unit

**Syntax**            j  
                      x+yj  
                      x+j\*y

**Description**        As the basic imaginary unit  $\sqrt{-1}$ , j is used to enter complex numbers. You can also use the character i as the imaginary unit. If you want to create a complex number without using i and j, you can use the `complex` function.

Since j is a function, it can be overridden and used as a variable. However, it is best to avoid using i and j for variable names if you intend to use them in complex arithmetic.

If desired, you can use the character j without a multiplication sign as a suffix in forming a complex numerical constant.

For speed and improved robustness, you can replace complex i and j by 1i. For example, instead of using

```
a = j;
```

use

```
a = 1i;
```

**Examples**            Z = 2+3j  
                      Z = x+j\*y  
                      Z = r\*exp(j\*theta)

**See Also**            conj | i | imag | real

**Purpose** Add entries to dynamic Java class path

**Syntax** `javaaddpath(dpath)`  
`javaaddpath(dpath, '-end')`

**Description** `javaaddpath(dpath)` adds one or more folders or Java Archive (JAR) files to the beginning of the current dynamic class path.

`javaaddpath(dpath, '-end')` adds files or folders to the end of the path.

- Tips**
- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.
  - To add folders to the static path, which MATLAB loads at startup, create a `javaclasspath.txt` file, as described in “The Static Path”.
  - MATLAB does not support JAR files generated by the MATLAB Builder for Java<sup>®</sup> product.

**Input Arguments**

**dpath - Folder or JAR file**

`string` | cell array of strings

Folder or JAR file, specified as a string or cell array of strings, to add to the dynamic path. When you add a folder to the path, MATLAB includes all files in that folder as part of the path.

**Data Types**

`char` | `cell`

**Examples** **Add Folder to Dynamic Class Path**

Display the current dynamic path.

```
javaclasspath('-dynamic')
```

# javaaddpath

---

DYNAMIC JAVA PATH

```
<empty>
```

The output reflects your configuration.

Add the current folder.

```
javaaddpath(pwd)
```

Display the dynamic path.

```
p = javaclasspath
```

```
p =  
    'c:\work\Java'
```

The output reflects your current folder.

## Append URL to Dynamic Class Path

```
javaaddpath('http://www.example.com', '-end')  
p = javaclasspath
```

```
p =  
    'c:\work\Java'  
    'http://www.example.com'
```

## Concepts

- “Bringing Java Classes into MATLAB Workspace”

<b>Purpose</b>	Construct Java array object
<b>Syntax</b>	<code>ObjArr = javaArray(PackageName.ClassName,x1,...,xN)</code>
<b>Description</b>	<code>ObjArr = javaArray(PackageName.ClassName,x1,...,xN)</code> constructs an empty Java array object for objects of the specified <code>PackageName.ClassName</code> class.
<b>Input Arguments</b>	<p><b>PackageName.ClassName - Name of Java class</b> string Name of Java class, including package name, specified as a string.</p> <p><b>Data Types</b> char</p> <p><b>x1,...,xN - Dimensions of the array</b> integer Dimensions of the array, specified as integer.</p> <p><b>Data Types</b> double</p>
<b>Output Arguments</b>	<p><b>ObjArr - Java array</b> Java array Java array with dimensions <code>x1, ..., xN</code>.</p>
<b>Definitions</b>	<p><b>Java Array Object</b> A Java array object is an object with Java dimensionality.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• The array created by <code>javaArray</code> is equivalent to the array created by the following Java code: <pre>A = new PackageName.ClassName[x1]...[xN];</pre></li></ul>

- To create an array of primitive Java types, create an array of the equivalent MATLAB type, shown in the Conversion of MATLAB Types to Java Types table. See “Conversion of MATLAB Argument Data”.

## Examples

### Create 4-By-5 Array

Create 4-by-5 array of `java.lang.Double` type.

```
x1 = 4; x2 = 5;  
dblArray = javaArray ('java.lang.Double',x1,x2);
```

Fill in values.

```
for m = 1:x1  
    for n = 1:x2  
        dblArray(m,n) = java.lang.Double((m*10) + n);  
    end  
end
```

Display results.

```
dblArray
```

```
dblArray =  
java.lang.Double[][]:  
    [11]    [12]    [13]    [14]    [15]  
    [21]    [22]    [23]    [24]    [25]  
    [31]    [32]    [33]    [34]    [35]  
    [41]    [42]    [43]    [44]    [45]
```

## Concepts

- “Working with Java Arrays”

<b>Purpose</b>	Error message based on Java feature support								
<b>Syntax</b>	<pre>MSG = javachk(feature) javachk(feature,component)</pre>								
<b>Description</b>	<p>MSG = javachk(feature) returns a generic error message if the specified Java feature is not available in the current MATLAB session.</p> <p>javachk(feature,component) also names the specified component in the error message.</p>								
<b>Input Arguments</b>	<p><b>feature - Java feature</b> 'awt'   'desktop'   'jvm'   'swing'</p> <p>Java feature, specified as one of these values:</p> <table><tr><td>'awt'</td><td>Java GUI components in the Abstract Window Toolkit (AWT) components are available.</td></tr><tr><td>'desktop'</td><td>MATLAB interactive desktop is running.</td></tr><tr><td>'jvm'</td><td>Java Virtual Machine software (JVM™) is running.</td></tr><tr><td>'swing'</td><td>Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.</td></tr></table> <p><b>component - Identifier</b> string</p> <p>Identifier, specified as a string, to display in the error message.</p> <p><b>Data Types</b> char</p>	'awt'	Java GUI components in the Abstract Window Toolkit (AWT) components are available.	'desktop'	MATLAB interactive desktop is running.	'jvm'	Java Virtual Machine software (JVM™) is running.	'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.
'awt'	Java GUI components in the Abstract Window Toolkit (AWT) components are available.								
'desktop'	MATLAB interactive desktop is running.								
'jvm'	Java Virtual Machine software (JVM™) is running.								
'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.								

## Output Arguments

### **MSG - Error message**

structure

Error message, returned as a structure with these fields:

If it is available, `javachk` returns an error structure with empty `message` and `identifier` fields.

### **message - Message**

string | empty

Message, specified as a string.

### **identifier - Identifier**

string | empty

Identifier, specified as a string.

## Examples

### **Generate Error**

```
if isempty(javachk('jvm'))
    scalar = java.lang.Double(5);
end
% Check that JVM is available & JavaFigures are supported
error(javachk('jvm'))
error(javachk('awt'))
```

### **Generate Error in User-Defined Script**

If you write a script, `myFile`, that displays a Java Frame and want it to error gracefully if a frame cannot be displayed, do the following:

```
error(javachk('awt','myFile'));
myFrame = java.awt.Frame;
myFrame.setVisible(1);
```

If the script cannot display a frame, it displays this error:

```
myFile is not supported on this platform.
```

**See Also**      usejava | error

# javaclasspath

---

**Purpose** Return Java class path or specify dynamic path

**Syntax**

```
javaclasspath
javaclasspath('-dynamic')
javaclasspath('-static')

dpath = javaclasspath
spath = javaclasspath('-static')
jpath = javaclasspath('-all')

javaclasspath(dpath)
javaclasspath(dpath1,dpath2)

javaclasspath(statusmsg)
```

**Description** javaclasspath displays the static and dynamic segments of the Java class path.

javaclasspath('-dynamic') displays the dynamic path.

javaclasspath('-static') displays the static path.

dpath = javaclasspath returns the dynamic path, dpath.

spath = javaclasspath('-static') returns the static path, spath.

jpath = javaclasspath('-all') returns the entire path, jpath. The returned cell array contains first the static segment of the path, and then the dynamic segment.

javaclasspath(dpath) changes the dynamic path to dpath. Use this syntax to reload Java classes.

`javaclasspath(dpath1,dpath2)` changes the dynamic path to the concatenation of paths `dpath1`, `dpath2`.

`javaclasspath(statusmsg)` enables or disables the display of status messages.

## Input Arguments

### **dpath - Path entries**

string | cell array of strings

Path entries, specified as a string or cell array of strings, to specify for the dynamic path. Converts relative paths to absolute paths.

**Example:** `javaclasspath('http://domain.com')`

### **Data Types**

char | cell

### **dpath1,dpath2 - Path entries**

string | cell array of strings

Path entries, specified as a string or cell array of strings, concatenated, to specify for the dynamic path.

### **Data Types**

char | cell

### **statusmsg - Message flag**

'-v0' (default) | '-v1'

Message flag, specified as one of these values:

- '-v0' Does not display status messages while loading the Java path from the file system.
- '-v1' Displays status messages.

Controls status message display from the `javaclasspath`, `javaaddpath`, and `javarmppath` functions.

# javaclasspath

---

## Output Arguments

### **dpath - Dynamic path entries**

cell array of strings

Dynamic path entries for the current path, returned as a cell array of strings. If no path entries are defined, `dpath` is an empty cell array.

### **spath - Static path entries**

cell array of strings

Static path entries for the current path, returned as a cell array of strings. If no path entries are defined, `spath` is an empty cell array.

### **jpath - All path entries**

cell array of strings

All path entries, returned as a cell array of strings. If no path entries are defined, `jpath` is an empty cell array.

## Tips

- MATLAB searches the static path before the dynamic path.
- Java classes on the static path should not have dependencies on classes on the dynamic path. Such dependencies produce run-time errors.
- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.
- MATLAB displays a warning if you add an entry to the dynamic path that is already specified on the static path.

## Definitions

### **Static Path**

The static path is a segment of the Java path which is loaded at the start of each MATLAB session from the MATLAB built-in Java path and the file `javaclasspath.txt`.

The static Java path offers better Java class-loading performance than the dynamic Java path. However, to modify the static Java path you

need to edit the file `javaclasspath.txt` and restart MATLAB. For more information, see “The Static Path”.

## Dynamic Path

The dynamic path is a segment of the Java path which is loaded any time during a MATLAB session using the `javaclasspath` function.

You can define the dynamic path (using `javaclasspath`), modify the path (using `javaaddpath` and `javarmppath`), and refresh the Java class definitions for all classes on the dynamic path (using `clear java`) without restarting MATLAB. For more information, see “The Dynamic Path”.

## Examples

### Modify Path Using Cell Array

Create a cell array with two path values.

```
dpath = {'http://domain.com','http://some.domain.com/jarfile.jar'};
```

Set message flag to display class-loading messages.

```
javaclasspath('-v1')
```

Modify path.

```
javaclasspath(dpath)
```

```
Loading following class path(s) from local file system:
```

```
* http://domain.com
```

```
* http://some.domain.com/jarfile.jar
```

Display updated dynamic path.

```
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
http://domain.com
```

# javaclasspath

---

```
http://some.domain.com/jarfile.jar
```

MATLAB adds folders from `dpath` to the existing path.

## Capture Contents of Dynamic Path

Create a cell array, `p`, with the entries of the dynamic path.

```
javaclasspath('-v0') %Suppress display of class-loading messages  
p = javaclasspath
```

```
p =
```

```
{}  
[]
```

If there are no entries on the dynamic path, MATLAB creates an empty cell array.

## Concepts

- “The Java Class Path”

<b>Purpose</b>	Capture error information for Java exception
<b>Description</b>	Process information from a <code>matlab.exception.JavaException</code> object to handle Java errors thrown from Java methods called from MATLAB. This class is derived from <code>MException</code> .
<b>Construction</b>	<code>e = matlab.exception.JavaException(msgID,errMsg,excObj)</code> constructs instance <code>e</code> of <code>matlab.exception.JavaException</code> class.
	<b>Input Arguments</b>
	<b>msgID</b> message identifier
	<b>errMsg</b> error message string
	<b>excObj</b> <code>java.lang.Throwable</code> object that caused the exception
	<b>Output Arguments</b>
	<b>e</b> Instance of <code>matlab.exception.JavaException</code> class
<b>Properties</b>	<b>ExceptionObject</b> Java exception object that caused the error.
<b>Tips</b>	<ul style="list-style-type: none"><li>You do not typically construct a <code>matlab.exception.JavaException</code> object explicitly. MATLAB automatically constructs a <code>JavaException</code> object whenever Java throws an exception. The <code>JavaException</code> object wraps the original Java exception.</li></ul>
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

# matlab.exception.JavaException

---

## Examples

```
try
    java.lang.Class.forName('foo');
catch e
    e.message
    if(isa(e, 'matlab.exception.JavaException'))
        ex = e.ExceptionObject;
        assert(isJava(ex));
        ex.printStackTrace;
    end
end
```

## Concepts

- “Capture Information About Exceptions”
- “Throw an Exception”

**Purpose**

Call Java method

**Syntax**

```
javaMethod(MethodName,JavaObj,x1,...,xN)  
javaMethod(StaticMethodName,ClassName,x1,...,xN)
```

**Description**

javaMethod(MethodName,JavaObj,x1,...,xN) calls the method in the class of the Java object array with the signature matching the arguments x1,...,xN.

javaMethod(StaticMethodName,ClassName,x1,...,xN) calls the static method in class ClassName.

**Input Arguments****MethodName - Name of nonstatic Java method**

string

Name of nonstatic Java method, specified as a string.

**Data Types**

char

**JavaObj - Array**

Java object

Array, specified as a Java object of the class containing the method.

**x1,...,xN - Java method input arguments**

any type

Java method input arguments, 1 through N (if any), required by MethodName or StaticMethodName, specified by any type. The argument type is specified by the method argument list.

**StaticMethodName - Name of static Java method**

string

Name of static Java method, specified as a string.

**Data Types**

char

## **ClassName - Name of Java class**

string

Name of Java class, specified as a string, containing `StaticMethodName`.

## **Data Types**

char

## **Tips**

- In most cases, use either MATLAB or Java syntax to call methods on Java objects:

```
%MATLAB syntax  
method(object,arg1,...,argn)
```

```
% Java syntax  
object.method(arg1,...,argn)
```

- Use `javaMethod` to call methods having names that exceed the maximum length of a MATLAB identifier. (Call the `namelengthmax` function to obtain the maximum identifier length.)

This is the only way you can call such a method in MATLAB. For example:

```
javaMethod('DataDefinitionAndDataManipulationTransactions',T);
```

- Use `javaMethod` when you want to specify the method name as a variable, to be invoked at runtime. When calling a static method, you also can use a variable in place of the class name argument. For example, see “Call Method Specified at Runtime” on page 1-3357.

## **Examples**

### **Call Method on Java Object**

Create a `java.util.Date` object, `myDate`, and change the month to 3.

```
myDate = java.util.Date;  
javaMethod('setMonth',myDate,3);
```

## Call Static Method

Call `java.lang.Double` static method, `isNaN`, to test variable `num`.

```
num = 2.2;
if javaMethod('isNaN', 'java.lang.Double', num)
    disp('This is not a number')
end
```

Since `num` contains a number, no message is displayed.

## Call Method Specified at Runtime

This example, searching for a text pattern in a string, uses variables for the pattern and for the search method. These variables could be set at runtime from user input.

Chose method, `startsWith`, and identify pattern, `str`.

```
fnc = 'startsWith';
str = java.lang.String('Four score');
```

Identify text to search.

```
gAddress = java.lang.String('Four score and seven years ago');
```

Search `gAddress`.

```
javaMethod(fnc, gAddress, str)
```

```
ans =
     1
```

`gAddress` starts with the words `Four score`.

## Concepts

- “Calling Syntax”

# javaMethodEDT

---

## Purpose

Call Java method from Event Dispatch Thread (EDT)

## Syntax

```
javaMethodEDT(MethodName,JavaObj,x1,...,xN)  
javaMethodEDT(StaticMethodName,ClassName,x1,...,xN)
```

## Description

javaMethodEDT(MethodName,JavaObj,x1,...,xN) calls the method in the class of the Java object array with the signature matching the arguments x1,...,xN from the Event Dispatch Thread (EDT)

javaMethodEDT(StaticMethodName,ClassName,x1,...,xN) calls the static method in class ClassName.

## Input Arguments

### **MethodName - Name of nonstatic Java method**

string

Name of nonstatic Java method, specified as a string.

### **Data Types**

char

### **JavaObj - Array**

Java object

Array, specified as a Java object of the class containing the method.

### **x1,...,xN - Java method input arguments**

any type

Java method input arguments, 1 through N (if any), required by MethodName or StaticMethodName, specified by any type. The argument type is specified by the method argument list.

### **StaticMethodName - Name of static Java method**

string

Name of static Java method, specified as a string.

### **Data Types**

char

**ClassName - Name of Java class**

string

Name of Java class, specified as a string, containing StaticMethodName.

**Data Types**

char

**Definitions****EDT**

The EDT is the Event Dispatch Thread, used in Java.

**Examples****Call Method from EDT**

Create a `java.util.Vector` object, `v`, and add a string element.

```
v = java.util.Vector;  
javaMethodEDT('add',v,'string');
```

<b>Purpose</b>	Remove entries from dynamic Java class path
<b>Syntax</b>	<code>javarmpath(dpath1,...,dpathN)</code>
<b>Description</b>	<code>javarmpath(dpath1,...,dpathN)</code> removes one or more files or folders from the current dynamic class path.
<b>Input Arguments</b>	<b>dpath1,...,dpathN - Folders or JAR files</b> <i>string</i> Folders or JAR files, specified as strings, to remove from path. <b>Data Types</b> <i>char</i>
<b>Tips</b>	<ul style="list-style-type: none"><li>MATLAB calls the <code>clear java</code> command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.</li></ul>
<b>Examples</b>	<b>Remove Folder from Dynamic Path</b> In order to preserve the state of the dynamic path on your system, this example first adds folders to the path, then removes one of these folders. Create a variable that points to the MATLAB examples folder. <pre>expath = fullfile(matlabroot,'extern','examples')  expath =  C:\Program Files\MATLAB\R2012b\extern\examples</pre> The path reflects the folder to your MATLAB installation. Add two folders to the path. <pre>javaclasspath({...</pre>

# javarmpath

---

```
    expath,...  
    'http://www.example.com'})  
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
C:\Program Files\MATLAB\R2012b\extern\examples  
http://www.example.com
```

The output displays these new folders on your existing path.

Remove one folder.

```
javarmpath(expath)  
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
http://www.example.com
```

The path no longer contains the examples folder.

**See Also** `javaclasspath` `javaaddpath` `clear`

**Concepts**

- “Bringing Java Classes into MATLAB Workspace”

**Purpose**

Merge two tables by matching up rows using key variables

**Syntax**

```
C = join(A,B)
C = join(A,B,Name,Value)
[C,ib] = join( ___ )
```

**Description**

`C = join(A,B)` merges tables `A` and `B` by matching up rows using all the variables with the same name as key variables. The key values must be common to both `A` and `B`, except for order.

`join` retains all the variables from `A` and appends the corresponding contents from the nonkey variables of `B`.

`C = join(A,B,Name,Value)` joins the tables with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the variables to use as key variables.

`[C,ib] = join( ___ )` also returns an index vector, `ib`, such that each element of `ib` identifies the row in `B` that corresponds to that row in the output table, `C`. You can use this syntax with any of the input arguments of the previous syntaxes.

**Input Arguments****A,B - Input tables**

tables

Input tables, specified as tables. For all key variables, each row of `A` must match exactly one row in `B`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' ' ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** 'Keys',2 uses the second variable in A and the second variable in B as key variables.

## **'Keys' - Variables to use as keys**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | 'RowNames'

Variables to use as keys, specified as the comma-separated pair consisting of 'Keys' and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or 'RowNames'.

If you specify the string 'RowNames', then `join` uses the row names of A and row names of B as keys. In this case, there must be a row in B for every row in A.

You cannot use the 'Keys' name-value pair argument with the 'LeftKeys' and 'RightKeys' name-value pair arguments.

**Example:** 'Keys',[1 3] uses the first and third variables from A and B as a key variables.

## **'LeftKeys' - Variables to use as keys in A**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `join` pairs key values based on their order.

**Example:** 'LeftKeys',1 uses only the first variable in A as a key variable.

## **'RightKeys' - Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in **B**, specified as the comma-separated pair consisting of `'RightKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'RightKeys'` name-value pair argument in conjunction with the `'LeftKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must specify the same number of key variables. `join` pairs values in **A** and **B** based on their order.

**Example:** `'RightKeys',3` uses only the third variable in **B** as a key variable.

#### **'LeftVariables' - Variables from A to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **A** to include in **C**, specified as the comma-separated pair consisting of `'LeftVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'LeftVariables'` to include or exclude key variables, as well as nonkey variables from the output, **C**.

By default, `join` includes all variables from **A**.

#### **'RightVariables' - Variables from B to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **B** to include in **C**, specified as the comma-separated pair consisting of `'RightVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'RightVariables'` to include or exclude key variables, as well as nonkey variables from the output, **C**.

By default, `join` includes all the variables from **B** except the key variables.

## **'KeepOneCopy' - Variables for which join retains only the copy from A**

variable name | cell array containing one or more variable names

Variables for which `join` retains only the copy from A, specified as the comma-separated pair consisting of `'KeepOneCopy'` and a variable name or a cell array containing one or more variable names.

Key variables appear once in C, but if nonkey variables with identical names occur in A and B, then `join` retains both copies in C by default. You must use the `'KeepOneCopy'` name-value pair to retain only the copy from A.

**Example:** `'KeepOneCopy',Var2` keeps only the copy from A of the nonkey variable `Var2`.

## **Output Arguments**

### **C - Merged data from A and B**

table

Merged data from A and B, returned as a table. The table, C, contains one row for each row in A, appearing in the same order. If A and B contain nonkey variables with the same name, `join` adds a unique suffix to the corresponding variable names in C, unless you specify the `'KeepOneCopy'` name-value pair argument.

`join` creates C by horizontally concatenating `A(:,LeftVars)` and `B(ib,RightVars)`. By default, `LeftVars` is all the variables of A, and `RightVars` is all the nonkey variables from B. Otherwise, `LeftVars` consists of the variables specified by the `'LeftVariables'` name-value pair argument, and `RightVars` consists of the variables specified by the `'RightVariables'` name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the output table, C. For more information, see [Table Properties](#).

### **ib - Index to B**

column vector

Index to B, returned as a column vector. Each element of `ib` identifies the row in B that corresponds to that row in the output table, C.

## Definitions

### Key Variable

Variable used to match and combine data between the input tables, A and B.

### Key Value

Entry in a key variable of A.

## Algorithms

The `join` function first finds one or more key variables. Then, `join` uses the key variables to find the row in input table B that matches each row in input table A, and combines those rows to create a row in output table C.

- If there is a one-to-one mapping between key values in A and B, then `join` sorts the data in B and appends it to table A.
- If there is a many-to-one mapping between key values in A and B, then `join` sorts and repeats the data in B before appending it to table A.
- If there is data in a key variable of B that does not map to a key value in A, then `join` does not include that data in the output table, C.

## Examples

### Append Values from One Table to Another

Create a table, A.

```
A = table({'John','Jane','Jim','Jerry','Jill'},[1;2;1;2;1],...
        'VariableNames',{'Employee' 'Department'})
```

A =

Employee	Department
'John'	1
'Jane'	2

# join

---

```
'Jim'      1
'Jerry'    2
'Jill'     1
```

Create a table, B, with a variable in common with A.

```
B = table([1 2], {'Mary' 'Mike'}', ...
          'VariableNames', {'Department' 'Manager'})
```

B =

Department	Manager
1	'Mary'
2	'Mike'

Create a new table, C, containing data from tables A and B. Use the `join` function to repeat and append Manager data from table B to the data from table A based on the key variable, Department.

```
C = join(A,B)
```

C =

Employee	Department	Manager
'John'	1	'Mary'
'Jane'	2	'Mike'
'Jim'	1	'Mary'
'Jerry'	2	'Mike'
'Jill'	1	'Mary'

## Merge Tables with One Variable in Common

Create a table, A.

```
A = table([5;12;23;2;6], ...
```

```
{'cereal';'pizza';'salmon';'cookies';'pizza'},...
'VariableNames',{ 'Age', 'FavoriteFood'},...
'RowNames',{ 'Amy', 'Bobby', 'Holly', 'Harry', 'Sally'})
```

A =

	Age	FavoriteFood
	-----	-----
Amy	5	'cereal'
Bobby	12	'pizza'
Holly	23	'salmon'
Harry	2	'cookies'
Sally	6	'pizza'

Create a table, B, with one variable in common with A.

```
B = table({'cereal';'cookies';'pizza';'salmon';'cake'},...
[110;160;140;367;243],...
{'B';'D';'B-';'A';'C-'},...
'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

B =

FavoriteFood	Calories	NutritionGrade
-----	-----	-----
'cereal'	110	'B'
'cookies'	160	'D'
'pizza'	140	'B-'
'salmon'	367	'A'
'cake'	243	'C-'

Create a new table, C, with data from tables A and B. Use FavoriteFood as a key variable to the join function.

```
C = join(A,B)
```

C =

	Age	FavoriteFood	Calories	NutritionGrade
Amy	5	'cereal'	110	'B'
Bobby	12	'pizza'	140	'B-'
Holly	23	'salmon'	367	'A'
Harry	2	'cookies'	160	'D'
Sally	6	'pizza'	140	'B-'

Table C does not include information from the last row of table B about 'cake' since there is no corresponding entry in table A.

## Merge Tables by Specifying One Key Variable

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

A =

Var1	Var2	Var3
10	5	10
4	4	3
2	9	8
3	6	8
7	1	4

Create a table, B, giving Var2 the same contents as Var2 from table A.

```
B = table([6;1;1;6;8],[5;4;9;6;1])
```

B =

Var1	Var2
------	------

6	5
1	4
1	9
6	6
8	1

Create a new table, C, containing data from tables A and B. Use Var1 in table A and Var2 in table B as key variables to the join function.

```
C = join(A,B, 'Keys', 'Var2')
```

C =

Var1_A	Var2	Var3	Var1_B
10	5	10	6
4	4	3	1
2	9	8	1
3	6	8	6
7	1	4	8

join adds a unique suffix to the nonkey variable Var1 to distinguish the data from tables A and B.

### Keep One Copy of Nonkey Variables

Create a new table with data from tables A and B. If any nonkey variables have the same name in both tables, keep only the copy from table A.

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1])
```

A =

# join

---

Var1	Var2
10	5
4	4
2	9
3	6
7	1

Create a table, B, giving Var2 the same contents as Var2 from table A.

```
B = table([6;1;1;6;8],[5;4;9;6;1],[10;3;8;8;4])
```

B =

Var1	Var2	Var3
6	5	10
1	4	3
1	9	8
6	6	8
8	1	4

Create a new table, C, with data from tables A and B. Use Var2 as a key variable to the join function and keep only the copy of Var1 from table A.

```
C = join(A,B,'Keys','Var2','KeepOneCopy','Var1')
```

C =

Var1	Var2	Var3
10	5	10
4	4	3
2	9	8

```

      3      6      8
     7      1      4

```

C does not contain the Var1 data from table B.

### Merge Tables Using Row Names as Keys

Create a table, A.

```

A = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
  'VariableNames',{'Gender' 'Age'},...
  'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})

```

A =

	Gender	Age
	-----	-----
Smith	M	38
Johnson	M	43
Williams	F	38
Jones	F	40
Brown	F	49

Create a table, B, such that there is a one-to-one correspondence between the rows of A and the rows of B.

```

B = table([64;69;67;71;64],...
  [119;163;133;176;131],...
  [122 80; 109 77; 117 75; 124 93; 125 83],...
  'VariableNames',{'Height' 'Weight' 'BloodPressure'},...
  'RowNames',{'Brown' 'Johnson' 'Jones' 'Smith' 'Williams'})

```

B =

Height	Weight	BloodPressure
-----	-----	-----

# join

---

Brown	64	119	122	80
Johnson	69	163	109	77
Jones	67	133	117	75
Smith	71	176	124	93
Williams	64	131	125	83

Create a new table, C, with data from tables A and B. Use the row names as keys to the join function.

```
C = join(A,B, 'Keys', 'RowNames')
```

```
C =
```

	Gender	Age	Height	Weight	BloodPressure	
Smith	M	38	71	176	124	93
Johnson	M	43	69	163	109	77
Williams	F	38	64	131	125	83
Jones	F	40	67	133	117	75
Brown	F	49	64	119	122	80

The rows of C are in the same order as A.

## Merge Tables Using Left and Right Keys

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

```
A =
```

Var1	Var2	Var3
10	5	10
4	4	3
2	9	8
3	6	8

7      1      4

Create a table, B, giving Var2 the same contents as Var1 from table A, except for order.

```
B = table([6;1;1;6;8],[2;3;4;7;10])
```

B =

Var1	Var2
-----	-----
6	2
1	3
1	4
6	7
8	10

Create a new table, C, containing data from tables A and B. Use Var1 from table A with Var2 from table B as key variables to the join function.

```
[C,ib] = join(A,B,'LeftKeys',1,'RightKeys',2)
```

C =

Var1_A	Var2	Var3	Var1_B
-----	-----	-----	-----
10	5	10	8
4	4	3	1
2	9	8	6
3	6	8	1
7	1	4	6

ib =

5

# join

---

```
3  
1  
2  
4
```

C is the horizontal concatenation of A and B (ib, 2).

**Purpose** Input from keyboard

**Syntax** keyboard

**Description** keyboard , when placed in a program .m file, stops execution of the file and gives control to the keyboard. The special status is indicated by a K appearing before the prompt. You can examine or change variables; all MATLAB commands are valid. This keyboard mode is useful for debugging your functions.

To terminate the keyboard mode, type return, and then press **Enter**. To terminate keyboard mode and exit the function, type dbquit, and press **Enter**.

**See Also** dbstop | input | quit | pause | return

# containers.Map.keys

---

**Purpose** Identify keys of containers.Map object

**Syntax** `keySet = keys(mapObj)`

**Description** `keySet = keys(mapObj)` returns cell array `keySet`, which contains all of the keys in `mapObj`.

**Input Arguments** **mapObj**  
Object of class `containers.Map`.

**Output Arguments** **keySet**  
1-by-n cell array, where n is the number of keys in `mapObj`.

## Examples **Get the Keys in a Map**

Create a map, and view the keys in the map:

```
myKeys = {'a','b','c'};  
myValues = [1,2,3];  
mapObj = containers.Map(myKeys,myValues);
```

```
keySet = keys(mapObj)
```

This code returns 1-by-3 cell array `keySet`:

```
keySet =  
    'a'    'b'    'c'
```

**See Also** `containers.Map` | `isKey` | `values` | `remove`

<b>Purpose</b>	Kronecker tensor product																
<b>Syntax</b>	<code>K = kron(A,B)</code>																
<b>Description</b>	<code>K = kron(A,B)</code> returns the Kronecker tensor product of matrices A and B. If A is an m-by-n matrix and B is a p-by-q matrix, then <code>kron(A,B)</code> is an m*p-by-n*q matrix formed by taking all possible products between the elements of A and the matrix B.																
<b>Input Arguments</b>	<p><b>A,B - Input matrices</b> scalars   vectors   matrices</p> <p>Input matrices, specified as scalars, vectors, or matrices. If either A or B is sparse, then <code>kron</code> multiplies only nonzero elements and the result is also sparse.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical</p> <p><b>Complex Number Support:</b> Yes</p>																
<b>Examples</b>	<p><b>Block Diagonal Matrix</b></p> <p>Create a block diagonal matrix.</p> <p>Create a 4-by-4 identity matrix and a 2-by-2 matrix that you want to be repeated along the diagonal.</p> <pre>A = eye(4); B = [1 -1;-1 1];</pre> <p>Use <code>kron</code> to find the Kronecker tensor product.</p> <pre>K = kron(A,B)</pre> <pre>K =</pre> <table style="margin-left: 40px;"> <tr> <td>1</td><td>-1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td> </tr> <tr> <td>-1</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td> </tr> </table>	1	-1	0	0	0	0	0	0	-1	1	0	0	0	0	0	0
1	-1	0	0	0	0	0	0										
-1	1	0	0	0	0	0	0										

```
0 0 1 -1 0 0 0 0
0 0 -1 1 0 0 0 0
0 0 0 0 1 -1 0 0
0 0 0 0 -1 1 0 0
0 0 0 0 0 0 1 -1
0 0 0 0 0 0 -1 1
```

The result is an 8-by-8 block diagonal matrix.

## Repeat Matrix Elements

Expand the size of a matrix by repeating elements.

Create a 2-by-2 matrix of ones and a 2-by-3 matrix whose elements you want to repeat.

```
A = [1 2 3; 4 5 6];
B = ones(2);
```

Calculate the Kronecker tensor product using `kron`.

```
K = kron(A,B)
```

```
K =
```

```
1 1 2 2 3 3
1 1 2 2 3 3
4 4 5 5 6 6
4 4 5 5 6 6
```

The result is a 4-by-6 block matrix.

## Sparse Laplacian Operator Matrix

Visualize a sparse Laplacian operator matrix.

The matrix representation of the discrete Laplacian operator on a two-dimensional,  $n$ -by- $n$  grid is a  $n^2$ -by- $n^2$  sparse matrix. There are at most five nonzero elements in each row or column. You can generate

the matrix as the Kronecker product of one-dimensional difference operators. In this example  $n = 5$ .

```
n = 5;  
I = speye(n,n);  
E = sparse(2:n,1:n-1,1,n,n);  
D = E+E'-2*I;  
A = kron(D,I)+kron(I,D);
```

Visualize the sparsity pattern with spy.

```
spy(A, 'k')
```

## Definitions **Kronecker Tensor Product**

If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is a  $p$ -by- $q$  matrix, then the Kronecker tensor product of  $A$  and  $B$  is a large matrix formed by multiplying  $B$  by each element of  $A$

$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1n}B \\ a_{21}B & a_{22}B & \cdots & a_{2n}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}B & a_{m2}B & \cdots & a_{mn}B \end{bmatrix}.$$

For example, two simple 2-by-2 matrices produce

$$A = \begin{bmatrix} 1 & -2 \\ -1 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 4 & -3 \\ 2 & 3 \end{bmatrix}$$

$$A \otimes B = \begin{bmatrix} 1 \cdot 4 & 1 \cdot (-3) & -2 \cdot 4 & -2 \cdot (-3) \\ 1 \cdot 2 & 1 \cdot 3 & -2 \cdot 2 & -2 \cdot 3 \\ -1 \cdot 4 & -1 \cdot (-3) & 0 \cdot 4 & 0 \cdot (-3) \\ -1 \cdot 2 & -1 \cdot 3 & 0 \cdot 2 & 0 \cdot 3 \end{bmatrix} = \begin{bmatrix} 4 & -3 & -8 & 6 \\ 2 & 3 & -4 & -6 \\ -4 & 3 & 0 & 0 \\ -2 & -3 & 0 & 0 \end{bmatrix}.$$

**Purpose** Last uncaught exception

**Syntax** `exception = MException.last`  
`MException.last('reset')`

**Description** `exception = MException.last` displays the contents of the `MException` object representing your most recent uncaught error. This is a static method of the `MException` class; it is not a method of an `MException` instance.

---

**Note** Use this method from the MATLAB command line only, and not within a function.

---

`MException.last('reset')` sets the `identifier` and `message` properties of the exception retrieved by `MException.last` to the empty string, the `stack` property to a 0-by-1 structure, and `cause` property to an empty cell array.

`MException.last` is not set if an exception is caught by a try-catch statement.

**Examples** This example displays the last error that was caught during this MATLAB session:

```
A = 25;  
A(2)  
??? Index exceeds matrix dimensions.
```

```
MException.last  
ans =
```

MException object with properties:

```
    identifier: 'MATLAB:badsubscript'  
    message: 'Index exceeds matrix dimensions.'
```

# last (MException)

---

```
stack: [0x1 struct]  
cause: {}
```

```

**Purpose** Determine if current IFD is last in file

**Syntax** `bool = tiffobj.lastDirectory()`

**Description** `bool = tiffobj.lastDirectory()` returns true if the current image file directory (IFD) is the last IFD in the TIFF file; otherwise, false. If the file contains only one image, the current IFD is the last.

**Examples** **Determine if Current Directory is the Last Directory**

Open a Tiff object and determine if the current directory is the last directory in the file.

```
t = Tiff('example.tif', 'r');
tf = t.lastDirectory()
```

```
tf =
    0
```

The current directory is not the last directory in the file.

Close the Tiff object.

```
t.close();
```

**References** This method corresponds to the `TIFFLastDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# lasterr

---

## Purpose

Last error message

---

**Note** `lasterr` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

## Syntax

```
msgstr = lasterr
[msgstr, msgid] = lasterr
lasterr('new_msgstr')
lasterr('new_msgstr', 'new_msgid')
[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')
```

## Description

`msgstr = lasterr` returns the last error message generated by the MATLAB software.

`[msgstr, msgid] = lasterr` returns the last error in `msgstr` and its message identifier in `msgid`. If the error was not defined with an identifier, `lasterr` returns an empty string for `msgid`. See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the `msgid` argument and how to use it.

`lasterr('new_msgstr')` sets the last error message to a new string, `new_msgstr`, so that subsequent invocations of `lasterr` return the new error message string. You can also set the last error to an empty string with `lasterr('')`.

`lasterr('new_msgstr', 'new_msgid')` sets the last error message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lasterr` return the new error message and message identifier.

`[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')` returns the last error message and its identifier, also changing these values so that subsequent invocations of `lasterr` return the message and identifier strings specified by `new_msgstr` and `new_msgid` respectively.

## Examples

### Example 1

Here is a function that examines the `lasterr` string and displays its own message based on the error that last occurred. This example deals with two cases, each of which is an error that can result from a matrix multiply:

```
function matrix_multiply(A, B)
try
    A * B
catch
    errmsg = lasterr;
    if(strfind(errmsg, 'Inner matrix dimensions'))
        disp('** Wrong dimensions for matrix multiply')
    else
        if(strfind(errmsg, 'not defined for variables of class'))
            disp('** Both arguments must be double matrices')
        end
    end
end
end
```

If you call this function with matrices that are incompatible for matrix multiplication (e.g., the column dimension of A is not equal to the row dimension of B), MATLAB catches the error and uses `lasterr` to determine its source:

```
A = [1 2 3; 6 7 2; 0 -1 5];
B = [9 5 6; 0 4 9];
```

```
matrix_multiply(A, B)
** Wrong dimensions for matrix multiply
```

### Example 2

Specify a message identifier and error message string with error:

```
error('MyToolbox:angleTooLarge', ...
    'The angle specified must be less than 90 degrees.');
```

# lasterr

---

In your error handling code, use `lasterr` to determine the message identifier and error message string for the failing operation:

```
[errmsg, msgid] = lasterr
errmsg =
    The angle specified must be less than 90 degrees.
msgid =
    MyToolbox:angleTooLarge
```

## See Also

[error](#) | [lasterror](#) | [rethrow](#) | [warning](#) | [lastwarn](#)

**Purpose** Last error message and related information

---

**Note** `lasterror` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

**Syntax**

```
s = lasterror
s = lasterror(err)
s = lasterror('reset')
```

**Description** `s = lasterror` returns a structure `s` containing information about the most recent error issued by the MATLAB software. The return structure contains the following fields:

Fieldname	Description
<code>message</code>	Character array containing the text of the error message.
<code>identifier</code>	Character array containing the message identifier of the error message. If the last error issued by MATLAB had no message identifier, then the <code>identifier</code> field is an empty character array.
<code>stack</code>	Structure providing information on the location of the error. The structure has fields <code>file</code> , <code>name</code> , and <code>line</code> , and is the same as the structure returned by the <code>dbstack</code> function. If <code>lasterror</code> returns no stack information, <code>stack</code> is a 0-by-1 structure having the same three fields.

---

**Note** The `lasterror` return structure might contain additional fields in future versions of MATLAB.

---

# lasterror

---

The fields of the structure returned in `stack` are

Fieldname	Description
<code>file</code>	Name of the file in which the function generating the error appears. This field is the empty string if there is no file.
<code>name</code>	Name of the function in which the error occurred. If this is the primary function in the file, and the function name differs from the file name, <code>name</code> is set to the file name.
<code>line</code>	Line number of the file at which the error occurred.

See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the syntax and usage of message identifiers.

`s = lasterror(err)` sets the last error information to the error message and identifier specified in the structure `err`. Subsequent invocations of `lasterror` return this new error information. The optional return structure `s` contains information on the previous error.

`s = lasterror('reset')` sets the last error information to the default state. In this state, the `message` and `identifier` fields of the return structure are empty strings, and the `stack` field is a 0-by-1 structure.

## Tips

MathWorks is gradually transitioning MATLAB error handling to an object-oriented scheme that is based on the `MException` class. Although support for `lasterror` is expected to continue, using the static `last` method of `MException` is preferable.

## Warning

**`lasterror` and `MException.last` are not guaranteed to always return identical results. For example, `MException.last` updates its error status only on uncaught errors, where `lasterror` can update its error status on any error, whether it is caught or not.**

## Examples

### Example 1

Save the following MATLAB code in a file called `average.m`:

```
function y = average(x)
% AVERAGE Mean of vector elements.
% AVERAGE(X), where X is a vector, is the mean of vector elements.
% Nonvector input results in an error.
check_inputs(x)
y = sum(x)/length(x); % The actual computation

function check_inputs(x)
[m,n] = size(x);
if (~((m == 1) || (n == 1)) || (m == 1 && n == 1))
    error('AVG:NotAVector', 'Input must be a vector.')
end
```

Now run the function. Because this function requires vector input, passing a scalar value to it forces an error. The error occurs in subroutine `check_inputs`:

```
average(200)
Error using average>check_inputs (line 11)
Input must be a vector.

Error in average (line 5)
check_inputs(x)
```

Get the three fields from `lasterror`:

```
err = lasterror
err =
    message: [1x61 char]
  identifier: 'AVG:NotAVector'
         stack: [2x1 struct]
```

Display the text of the error message:

```
msg = err.message
```

# lasterror

---

```
msg =  
    Error using average>check_inputs (line 11)  
    Input must be a vector.
```

Display the fields containing the stack information. `err.stack` is a 2-by-1 structure because it provides information on the failing subroutine `check_inputs` and also the outer, primary function `average`:

```
st1 = err.stack(1,1)  
st1 =  
    file: 'd:\matlab_test\average.m'  
    name: 'check_inputs'  
    line: 11  
  
st2 = err.stack(2,1)  
st2 =  
    file: 'd:\matlab_test\average.m'  
    name: 'average'  
    line: 5
```

---

**Note** As a rule, the name of your primary function should be the same as the name of the file that contains that function. If these names differ, MATLAB uses the file name in the `name` field of the `stack` structure.

---

## Example 2

`lasterror` is often used in conjunction with the `rethrow` function in try-catch statements. For example,

```
try  
    do_something  
catch  
    do_cleanup  
    rethrow(lasterror)  
end
```

**See Also**

last(MException) | MException | try | catch | error | assert |  
rethrow | lastwarn | dbstack

# lastwarn

---

## Purpose

Last warning message

## Syntax

```
msgstr = lastwarn
[msgstr, msgid] = lastwarn
lastwarn('new_msgstr')
lastwarn('new_msgstr', 'new_msgid')
[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')
```

## Description

`msgstr = lastwarn` returns the last warning message generated by the MATLAB software.

`[msgstr, msgid] = lastwarn` returns the last warning in `msgstr` and its message identifier in `msgid`. If the warning was not defined with an identifier, `lastwarn` returns an empty string for `msgid`.

`lastwarn('new_msgstr')` sets the last warning message to a new string, `new_msgstr`, so that subsequent invocations of `lastwarn` return the new warning message string. You can also set the last warning to an empty string with `lastwarn('')`.

`lastwarn('new_msgstr', 'new_msgid')` sets the last warning message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lastwarn` return the new warning message and message identifier.

`[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')` returns the last warning message and its identifier, also changing these values so that subsequent invocations of `lastwarn` return the message and identifier strings specified by `new_msgstr` and `new_msgid`, respectively.

## Tips

`lastwarn` does not return warnings that are reported during the parsing of MATLAB commands. (Warning messages that include the failing file name and line number are parse-time warnings.)

## Examples

Write a short function that generates a warning message. At the start of the function, enable any warnings that have a message identifier called `TestEnv:InvalidInput`:

```
function myfun(p1)
warning on TestEnv:InvalidInput;

exceedMax = find(p1 > 5000);
if any(exceedMax)
    warning('TestEnv:InvalidInput', ...
           '%d values in the "%s" array exceed the maximum.', ...
           length(exceedMax), inputname(1))
end
```

Pass an invalid value to the function:

```
dataIn = magic(10) - 2;
```

```
myfun(dataIn)
```

```
Warning: 2 values in the "dataIn" array exceed the maximum.
> In myfun at 4
```

Use lastwarn to determine the message identifier and error message string for the operation:

```
[warnmsg, msgid] = lastwarn
warnmsg =
    2 values in the "dataIn" array exceed the maximum.
msgid =
    TestEnv:InvalidInput
```

**Purpose** Least common multiple

**Syntax** `L = lcm(A,B)`

**Description** `L = lcm(A,B)` returns the least common multiples of the elements of A and B.

**Input Arguments**

**A,B - Input values**

scalars, vectors, or arrays of real, positive integer values

Input values, specified as scalars, vectors, or arrays of real, positive integer values. A and B can be any numeric type, and they can be of different types within certain limitations:

- If A or B is of type `single`, then the other can be of type `single` or `double`.
- If A or B belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

A and B must be the same size or one must be a scalar.

**Example:** `[20 3 13],[10 6 7]`

**Example:** `int16([100 30 200]),int16([20 15 9])`

**Example:** `int16([100 30 200]),20`

**Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Output Arguments**

**L - Least common multiple**

real, positive integer values

Least common multiple, returned as an array of real positive integer values. L is the same size as A and B, and it has the same type as A and B. If A and B are of different types, then L is returned as the `nondouble` type.

**Examples****Least Common Multiples of Double Array and a Scalar**

```
A = [5 17; 10 60];  
B = 45;  
L = lcm(A,B)
```

```
L =
```

```
    45    765  
    90    180
```

**Least Common Multiples of Unsigned Integers**

```
A = uint16([255 511 15]);  
B = uint16([15 127 1023]);  
L = lcm(A,B)
```

```
L =
```

```
    255   64897   5115
```

**See Also** `gcd`

**Purpose** Block LDL' factorization for Hermitian indefinite matrices

**Syntax**

```
L = ldl(A)
[L,D] = ldl(A)
[L,D,P] = ldl(A)
[L,D,p] = ldl(A, 'vector')
[U,D,P] = ldl(A, 'upper')
[U,D,p] = ldl(A, 'upper', 'vector')
[L,D,P,S] = ldl(A)
[L,D,P,S] = LDL(A, THRESH)
[U,D,p,S] = LDL(A, THRESH, 'upper', 'vector')
```

**Description** `L = ldl(A)` returns only the "psychologically lower triangular matrix" L as in the two-output form. The permutation information is lost, as is the block diagonal factor D. By default, `ldl` references only the diagonal and lower triangle of A, and assumes that the upper triangle is the complex conjugate transpose of the lower triangle. Therefore `[L,D,P] = ldl(TRIL(A))` and `[L,D,P] = ldl(A)` both return the exact same factors. Note, this syntax is not valid for sparse A.

`[L,D] = ldl(A)` stores a block diagonal matrix D and a "psychologically lower triangular matrix" (i.e a product of unit lower triangular and permutation matrices) in L such that  $A = L*D*L'$ . The block diagonal matrix D has 1-by-1 and 2-by-2 blocks on its diagonal. Note, this syntax is not valid for sparse A.

`[L,D,P] = ldl(A)` returns unit lower triangular matrix L, block diagonal D, and permutation matrix P such that  $P'*A*P = L*D*L'$ . This is equivalent to `[L,D,P] = ldl(A, 'matrix')`.

`[L,D,p] = ldl(A, 'vector')` returns the permutation information as a vector, p, instead of a matrix. The p output is a row vector such that  $A(p,p) = L*D*L'$ .

`[U,D,P] = ldl(A, 'upper')` references only the diagonal and upper triangle of A and assumes that the lower triangle is the complex conjugate transpose of the upper triangle. This syntax returns a unit upper triangular matrix U such that  $P'*A*P = U'*D*U$  (assuming that

A is Hermitian, and not just upper triangular). Similarly,  $[L,D,P] = \text{ldl}(A, 'lower')$  gives the default behavior.

$[U,D,p] = \text{ldl}(A, 'upper', 'vector')$  returns the permutation information as a vector,  $p$ , as does  $[L,D,p] = \text{ldl}(A, 'lower', 'vector')$ . A must be a full matrix.

$[L,D,P,S] = \text{ldl}(A)$  returns unit lower triangular matrix  $L$ , block diagonal  $D$ , permutation matrix  $P$ , and scaling matrix  $S$  such that  $P' * S * A * S * P = L * D * L'$ . This syntax is only available for real sparse matrices, and only the lower triangle of  $A$  is referenced. `ldl` uses MA57 for sparse real symmetric  $A$ .

$[L,D,P,S] = \text{LDL}(A, \text{THRESH})$  uses `THRESH` as the pivot tolerance in MA57. `THRESH` must be a double scalar lying in the interval  $[0, 0.5]$ . The default value for `THRESH` is 0.01. Using smaller values of `THRESH` may give faster factorization times and fewer entries, but may also result in a less stable factorization. This syntax is available only for real sparse matrices.

$[U,D,p,S] = \text{LDL}(A, \text{THRESH}, 'upper', 'vector')$  sets the pivot tolerance and returns upper triangular  $U$  and permutation vector  $p$  as described above.

## Examples

These examples illustrate the use of the various forms of the `ldl` function, including the one-, two-, and three-output form, and the use of the `vector` and `upper` options. The topics covered are:

- “Example 1 — Two-Output Form of `ldl`” on page 1-3402
- “Example 2 — Three Output Form of `ldl`” on page 1-3402
- “Example 3 — The Structure of  $D$ ” on page 1-3403
- “Example 4 — Using the `'vector'` Option” on page 1-3403
- “Example 5 — Using the `'upper'` Option” on page 1-3404
- “Example 6 — `linsolve` and the Hermitian indefinite solver” on page 1-3404

Before running any of these examples, you will need to generate the following positive definite and indefinite Hermitian matrices:

```
A = full(delsq(numgrid('L', 10)));
B = gallery('uniformdata',10,0);
M = [eye(10) B; B' zeros(10)];
```

The structure of  $M$  here is very common in optimization and fluid-flow problems, and  $M$  is in fact indefinite. Note that the positive definite matrix  $A$  must be full, as `ldl` does not accept sparse arguments.

### Example 1 – Two-Output Form of `ldl`

The two-output form of `ldl` returns  $L$  and  $D$  such that  $A - (L^*D^*L')$  is small,  $L$  is "psychologically unit lower triangular" (i.e., a permuted unit lower triangular matrix), and  $D$  is a block 2-by-2 diagonal. Note also that, because  $A$  is positive definite, the diagonal of  $D$  is all positive:

```
[LA,DA] = ldl(A);
fprintf(1, ...
'The factorization error ||A - LA*DA*LA' || is %g\n', ...
norm(A - LA*DA*LA'));
neginds = find(diag(DA) < 0)
```

Given a  $b$ , solve  $Ax=b$  using  $LA$ ,  $DA$ :

```
bA = sum(A,2);
x = LA' \ (DA \ (LA \ bA));
fprintf(...
'The absolute error norm ||x - ones(size(bA)) || is %g\n', ...
norm(x - ones(size(bA))));
```

### Example 2 – Three Output Form of `ldl`

The three output form returns the permutation matrix as well, so that  $L$  is in fact unit lower triangular:

```
[Lm, Dm, Pm] = ldl(M);
fprintf(1, ...
'The error norm ||Pm'*M*Pm - Lm*Dm*Lm' || is %g\n', ...
```

```
norm(Pm'*M*Pm - Lm*Dm*Lm');
fprintf(1, ...
'The difference between Lm and tril(Lm) is %g\n', ...
norm(Lm - tril(Lm)));
```

Given  $b$ , solve  $Mx=b$  using  $Lm$ ,  $Dm$ , and  $Pm$ :

```
bM = sum(M,2);
x = Pm*(Lm'\(Dm\((Lm\((Pm'*bM)))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

### Example 3 – The Structure of D

$D$  is a block diagonal matrix with 1-by-1 blocks and 2-by-2 blocks. That makes it a special case of a tridiagonal matrix. When the input matrix is positive definite,  $D$  is almost always diagonal (depending on how definite the matrix is). When the matrix is indefinite however,  $D$  may be diagonal or it may express the block structure. For example, with  $A$  as above,  $DA$  is diagonal. But if you shift  $A$  just a bit, you end up with an indefinite matrix, and then you can compute a  $D$  that has the block structure.

```
figure; spy(DA); title('Structure of D from ldl(A)');
[Las, Das] = ldl(A - 4*eye(size(A)));
figure; spy(Das);
title('Structure of D from ldl(A - 4*eye(size(A)))');
```

### Example 4 – Using the 'vector' Option

Like the `lu` function, `ldl` accepts an argument that determines whether the function returns a permutation vector or permutation matrix. `ldl` returns the latter by default. When you select 'vector', the function executes faster and uses less memory. For this reason, specifying the 'vector' option is recommended. Another thing to note is that indexing is typically faster than multiplying for this kind of operation:

```
[Lm, Dm, pm] = ldl(M, 'vector');
```

```

fprintf(1, 'The error norm ||M(pm,pm) - Lm*Dm*Lm'|| is %g\n', ...
        norm(M(pm,pm) - Lm*Dm*Lm'));

% Solve a system with this kind of factorization.
clear x;
x(pm,:) = Lm'\(Dm\(Lm\(bM(pm,:)));
fprintf('The absolute error norm ||x - ones(size(b))|| is %g\n', ...
        norm(x - ones(size(bM))));

```

### Example 5 – Using the 'upper' Option

Like the `chol` function, `ldl` accepts an argument that determines which triangle of the input matrix is referenced, and also whether `ldl` returns a lower (L) or upper (L') triangular factor. For dense matrices, there are no real savings with using the upper triangular version instead of the lower triangular version:

```

M1 = tril(M);
[Lm1, Dm1, Pm1] = ldl(M1, 'lower'); % 'lower' is default behavior.
fprintf(1, ...
        'The difference between Lm1 and Lm is %g\n', norm(Lm1 - Lm));
[Umu, Dmu, pmu] = ldl(triu(M), 'upper', 'vector');
fprintf(1, ...
        'The difference between Umu and Lm'' is %g\n', norm(Umu - Lm'));

% Solve a system using this factorization.
clear x;
x(pm,:) = Umu\(Dmu\(Umu\'(bM(pmu,:)));
fprintf(...
        'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
        norm(x - ones(size(bM))));

```

When specifying both the 'upper' and 'vector' options, 'upper' must precede 'vector' in the argument list.

### Example 6 – linsolve and the Hermitian indefinite solver

When using the `linsolve` function, you may experience better performance by exploiting the knowledge that a system has a symmetric

matrix. The matrices used in the examples above are a bit small to see this so, for this example, generate a larger matrix. The matrix here is symmetric positive definite, and below we will see that with each bit of knowledge about the matrix, there is a corresponding speedup. That is, the symmetric solver is faster than the general solver while the symmetric positive definite solver is faster than the symmetric solver:

```
Abig = full(delsq(numgrid('L', 30)));  
bbig = sum(Abig, 2);  
LSopts.POSDEF = false;  
LSopts.SYM = false;  
tic; linsolve(Abig, bbig, LSopts); toc;  
LSopts.SYM = true;  
tic; linsolve(Abig, bbig, LSopts); toc;  
LSopts.POSDEF = true;  
tic; linsolve(Abig, bbig, LSopts); toc;
```

## Algorithms

ldl uses the MA57 routines in the Harwell Subroutine Library (HSL) for real sparse matrices.

chol | lu | qr

# ldivide, .\

---

**Purpose** Left array division

**Syntax**  
`x = B.\A`  
`x = ldivide(B,A)`

**Description** `x = B.\A` divides each element of `A` by the corresponding element of `B`.

- If `A` and `B` are arrays, then they must be the same size.
- If either `A` or `B` is a scalar, then MATLAB expands the scalar value into an appropriately sized array.

`x = ldivide(B,A)` is an alternative way to divide `A` by `B`, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Numerator

numeric array | sparse numeric array

Numerator, specified as a full or sparse numeric array. If `B` is an integer data type, then `A` must be the same integer type or a scalar double.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Complex Number Support:** Yes

### B - Denominator

numeric array | sparse numeric array

Denominator, specified as a full or sparse numeric array. If `A` is an integer data type, then `B` must be the same integer type or a scalar double.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Complex Number Support:** Yes

**Output Arguments****x - Solution**

numeric array | sparse numeric array

Solution, returned as a sparse or full numeric array. If either A or B are integer data types, then x is that same integer data type.

**Examples****Divide Two Numeric Arrays**

```
A = ones(2, 3);  
B = [1 2 3; 4 5 6];  
x = B.\A
```

```
x =
```

```
    1.0000    0.5000    0.3333  
    0.2500    0.2000    0.1667
```

**Divide a Scalar by a Numeric Array**

```
C = 2;  
D = [1 2 3; 4 5 6];  
x = D.\C
```

```
x =
```

```
    2.0000    1.0000    0.6667  
    0.5000    0.4000    0.3333
```

**Tips**

- MATLAB does not support complex integer division.

**See Also**

rdivide | mldivide | mrdivide

# le, <=

---

**Purpose** Determine less than or equal to

**Syntax** A <= B  
le(A,B)

**Description** A <= B returns a logical array with elements set to logical 1 (true) where A is less than or equal to B; otherwise, it returns logical 0 (false). The test compares only the real part of numeric arrays. le returns logical 0 (false) where A or B have NaN or undefined categorical elements.

le(A,B) is an alternate way to execute A <= B, but is rarely used. It enables operator overloading for classes.

## **Input Arguments**

### **A - Left array**

numeric array | logical array | character array | ordinal categorical array

Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

### **B - Right array**

numeric array | logical array | character array | ordinal categorical array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one

is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

## Examples

### Test Vector Elements

Find which vector elements are less than or equal to a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than or equal to 12.

```
A <= 12
```

```
ans =
```

```
     1     1     0     1     1     1     1     0
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than or equal to 12.

```
A(A <= 12)
```

```
ans =
```

```
     1    12     7     9    11     2
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values less than or equal to 9 with the value 10.

```
A(A <= 9) = 10
```

```
A =
```

```
    16    10    10    13
    10    11    10    10
    10    10    10    12
    10    14    15    10
```

The result is a new matrix whose smallest element is 10.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
 'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
    large    medium    small
    medium    small    large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values less than or equal to the category 'medium'.

```
A <= 'medium'
```

```
ans =
```

```
    0    1    1
    1    1    0
```

A value of logical 1 (true) indicates a value less than or equal to the category 'medium'.

Compare the rows of A.

```
A(1,:) <= A(2,:)
```

```
ans =
```

```
    0    0    1
```

The function returns logical 1 (true) where the first row has a category value less than or equal to the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than or equal to 3.

```
A(A <= 3)
```

```
ans =
```

```
1.0000 + 1.0000i  2.0000 - 2.0000i  1.0000 + 3.0000i  1.0000 - 2.0000i
```

le compares only the real part of the elements in A.

Use abs to find which elements are within a radius of 3 from the origin.

## le, <=

---

```
A(abs(A) <= 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 - 2.0000i
```

The result has one less element. The element  $1.0000 + 3.0000i$  is not within a radius of 3 from the origin.

### Tips

- Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `<=` operator reflects. For more information, see “Avoiding Common Problems with Floating-Point Arithmetic”.

### Concepts

- “Ordinal Categorical Arrays”

## Purpose

Graph legend for lines and patches

## Syntax

```

legend('string1','string2',...)
legend(h,'string1','string2',...)
legend(M)
legend(h,M)
legend(M,'parameter_name','parameter_value',...)
legend(h,M,'parameter_name','parameter_value',...)
legend(axes_handle,...)
legend('off'),legend(axes_handle,'off')
legend('toggle'),legend(axes_handle,'toggle')
legend('hide'),legend(axes_handle,'hide')
legend('show'),legend(axes_handle,'show')
legend('boxoff'),legend(axes_handle,'boxoff')
legend('boxon'),legend(axes_handle,'boxon')
legend_handle = legend(...)
legend(...,'Location','location')
legend(...,'Orientation','orientation')
[legend_h,object_h,plot_h,text_strings] = legend(...)

```

## Description

The legend function places a legend on various types of graphs (line plots, bar graphs, pie charts, etc.). For each line plotted, the legend shows a sample of the line type, marker symbol, and color beside the text label you specify. When plotting filled areas (patch or surface objects), the legend contains a sample of the face color next to the text label.

The font size and font name for the legend strings match the axes `FontSize` and `FontName` properties.

`legend('string1','string2',...)` displays a legend in the current axes using the specified strings to label each set of data.

`legend(h,'string1','string2',...)` displays a legend on the plot containing the objects identified by the handles in the vector `h` and uses the specified strings to label the corresponding graphics object (line, barseries, etc.).

# legend

---

`legend(M)` adds a legend containing the rows of the matrix or cell array of strings `M` as labels. For matrices, this is the same as `legend(M(1,:),M(2,:),...)`.

`legend(h,M)` associates each row of the matrix or cell array of strings `M` with the corresponding graphics object (patch or line) in the vector of handles `h`.

`legend(M,'parameter_name','parameter_value',...)` and `legend(h,M,'parameter_name','parameter_value',...)` allow parameter/value pairs to be set when creating a legend (you can also assign them with `set` or with the Property Editor or Property Inspector). `M` must be a cell array of names. Legends inherit the properties of axes, although not all of them are relevant to legend objects.

`legend(axes_handle,...)` displays the legend for the axes specified by `axes_handle`.

`legend('off')`, `legend(axes_handle,'off')` removes the legend in the current axes or the axes specified by `axes_handle`.

`legend('toggle')`, `legend(axes_handle,'toggle')` toggles the legend visibility. If a legend does not exist, then one is created using default strings. If a legend exists, then toggling its state to invisible does not remove the legend.

The *default string* for an object is the value of the object's `DisplayName` property, if you have defined a value for `DisplayName` (which you can do using the Property Editor or calling `set`). Otherwise, `legend` constructs a string of the form `data1, data2, etc.` Setting display names is useful when you are experimenting with legends and might forget how objects in a lineseries, for example, are ordered.

When you specify legend strings in a `legend` command, their respective `DisplayNames` are set to these strings. If you delete a legend and then create a new legend without specifying labels for it, the values of `DisplayName` are (re)used as label names. Naturally, the associated plot objects must have a `DisplayName` property for this to happen: all `_series` and `_group` plot objects have a `DisplayName` property; Handle Graphics primitives, such as `line` and `patch`, do not.

Legends for graphs that contain groups of objects such as lineseries, barseries, contourgroups, etc. created by high-level plotting commands such as `plot`, `bar`, `contour`, etc., by default display a single legend entry for the entire group, regardless of how many member objects it contains. However, you can customize such legends to show individual entries for all or selected member objects and assign a unique `DisplayName` to any of them. You control how groups appear in the legend by setting values for their `Annotation` and `DisplayName` properties with code. For information and examples about customizing legends in this manner, see “Controlling Legends” in the MATLAB Graphics documentation.

You can specify `EdgeColor` and `TextColor` as RGB triplets or as `ColorSpecs`. You cannot set these colors to `'none'`. To hide the box surrounding a legend, set the `Box` property to `'off'`. To allow the background to show through the legend box, set the legend’s `Color` property to `'none'`, for example,

```
set(legend_handle, 'Box', 'off')
set(legend_handle, 'Color', 'none')
```

This is similar to the effect of the command `legend boxoff`, except that `boxoff` also hides the legend’s border.

You can use a legend’s handle to set text properties for all the strings in a legend at once with a cell array of strings, rather than looping through each of them. See the last line of the example below, which demonstrates setting a legend’s `Interpreter` property. In that example, you could reset the `String` property of the legend as follows:

```
set(h, 'String', {'cos(x)', 'sin(x)'})
```

See the documentation for `Text Properties` for additional details.

`legend('hide')`, `legend(axes_handle, 'hide')` makes the legend in the current axes or the axes specified by `axes_handle` invisible.

`legend('show')`, `legend(axes_handle, 'show')` makes the legend in the current axes or the axes specified by `axes_handle` visible. A legend is created if one did not exist previously. Legends created automatically are limited to depict only the first 20 lines in the plot; if you need more

# legend

---

legend entries, you can manually create a legend for them all with `legend('string1', 'string2', ...)` syntax.

`legend('boxoff')`, `legend(axes_handle, 'boxoff')` removes the box from the legend in the current axes or the axes specified by `axes_handle`, and makes its background transparent.

`legend('boxon')`, `legend(axes_handle, 'boxon')` adds a box with an opaque background to the legend in the current axes or the axes specified by `axes_handle`.

You can also type the above six commands using the syntax

`legend keyword`

If the keyword is not recognized, it is used as legend text, creating a legend or replacing the current legend.

`legend_handle = legend(...)` returns the handle to the legend on the current axes, or `[]` if no legend exists.

`legend(..., 'Location', 'location')` uses `location` to determine where to place the legend. `location` can be either be a 1-by-4 position vector (`[left, bottom, width, height]`) or one of the following strings.

Specifier	Location in Axes
North	Inside plot box near top
South	Inside bottom
East	Inside right
West	Inside left
NorthEast	Inside top right (default for 2-D plots)
NorthWest	Inside top left
SouthEast	Inside bottom right
SouthWest	Inside bottom left
NorthOutside	Outside plot box near top

Specifier	Location in Axes
SouthOutside	Outside bottom
EastOutside	Outside right
WestOutside	Outside left
NorthEastOutside	Outside top right (default for 3-D plots)
NorthWestOutside	Outside top left
SouthEastOutside	Outside bottom right
SouthWestOutside	Outside bottom left
Best	Least conflict with data in plot
BestOutside	Least unused space outside plot

Using one of the ...Outside values for 'Location' ensures that the legend does not overlap the plot, whereas overlaps can occur when you specify any of the other cardinal values. The *location* property applies to colorbars and legends, but not to axes.

---

**Note** You can set the legend location by passing the 4-element position vector to the `legend` function using the 'Location' option. To define the position of an existing legend, use the `set` function to assign the 4-element position vector to the 'Position' property. You cannot use the `Location` option with the `set` function.

---

## Obsolete Location Values

The first column of the following table shows the now-obsolete specifiers for legend locations that were in use prior to Version 7, along with a description of the locations and their current equivalent syntaxes.

---

**Note** Support for these numeric specifiers will be removed in a future release. Use the supported string specifiers instead.

---

# legend

---

Obsolete Specifier	Location in Axes	Current Specifier
-1	Outside axes on right side	NorthEastOutside
0	Inside axes	Best
1	Upper right corner of axes	NorthEast
2	Upper left corner of axes	NorthWest
3	Lower left corner of axes	SouthWest
4	Lower right corner of axes	SouthEast

`legend(..., 'Orientation', 'orientation')` creates a legend with the legend items arranged in the specified orientation. *orientation* can be vertical (the default) or horizontal.

`[legend_h, object_h, plot_h, text_strings] = legend(...)` returns

- `legend_h` — Handle of the legend axes
- `object_h` — Handles of the line, patch, and text graphics objects used in the legend
- `plot_h` — Handles of the lines and other objects used in the plot
- `text_strings` — Cell array of the text strings used in the legend

## Relationship to Axes

`legend` associates strings with the objects in the axes in the same order that they are listed in the axes `Children` property. By default, the legend annotates the current axes.

You can only display one legend per axes. `legend` positions the legend based on a variety of factors, such as what objects the legend obscures.

The properties that legends do not share with axes are

- `Location`
- `Orientation`
- `EdgeColor`

- TextColor
- Interpreter
- String

## Tips

### Using Keywords as Legend Labels

To use legend keywords like 'Location', 'Orientation', 'Off', 'Hide', or property names as legend labels, pass the string in a cell array to the legend function as,

```
l = legend({'Location'});
```

## Examples

Add a legend to a graph showing a sine and cosine function. The default location is upper right, within the axes:

```
figure
x = -pi:pi/20:pi;
plot(x,cos(x),'-ro',x,sin(x),'-.b')
hleg1 = legend('cos_x','sin_x');
```

# legend

The legend reflects that `plot` specified a solid, red line ('-ro') for the cosine function and a dash-dot, blue line ('-.b') for the sine function.

Update the legend. Use the returned legend handle, `hleg1`, to move the legend to the upper left. Also turn off the TeX interpreter to render underscores in legend text literally rather than as subscripts:

```
set(hleg1,'Location','NorthWest')
set(hleg1,'Interpreter','none')
```

Setting the position of the legend at a particular position.

```
set(hleg1, 'Position', [.1,.2,.1,.2]);
```

# legend

Use `besselj` to plot Bessel functions for orders 1, 2, and 3. Add a legend for the lines at the upper right, outside the axes.

```
figure
x = 0:.2:12;
plot(x,besselj(1,x),x,besselj(2,x),x,besselj(3,x));
hleg = legend('First','Second','Third',...
             'Location','NorthEastOutside')
% Make the text of the legend italic and color it brown
```

```
set(hleg,'FontAngle','italic','TextColor',[.3,.2,.1])
```

Create a bar graph and overlay a line plot on it by setting `hold on`. Create a legend that reflects both graphs and locate it to the lower right, outside the axes:

```
figure  
stream = RandStream('mrg32k3a','Seed',4);  
y1 = rand(stream,10,5);
```

# legend

```
hb = bar(y1,'stacked'); colormap(summer); hold on
y2 = rand(stream,10,1);
hp = plot(1:10,y2,'marker','square','markersize',12,...
         'markeredgecolor','y','markerfacecolor',[.6,0,.6],...
         'linestyle','-','color','r','linewidth',2); hold off
legend([hb,hp],'Carrots','Peas','Peppers','Green Beans',...
       'Cucumbers','Eggplant','Location','SouthEastOutside')
```

## Alternatives

Add a legend to a selected axes on a graph with the **Insert Legend** tool

on the figure toolbar, or use **Insert > Legend** from the figure menu. Use the Property Editor to modify the position, font, and other properties of a legend. For details, see Using Plot Edit Mode.

## Moving the Legend

Move the legend by pressing the left mouse button while the cursor is over the legend and dragging the legend to a new location. Double-clicking a label allows you to edit the label.

## How To

- “Adding a Legend to a Graph”

# legendre

---

**Purpose** Associated Legendre functions

**Syntax**  
P = legendre(n,X)  
S = legendre(n,X,'sch')  
N = legendre(n,X,'norm')

**Description** P = legendre(n,X) computes the associated Legendre functions of degree n and order m = 0,1,...,n, evaluated for each element of X. Argument n must be a scalar integer, and X must contain real values in the domain  $-1 \leq x \leq 1$ .

If X is a vector, then P is an (n+1)-by-q matrix, where q = length(X). Each element P(m+1,i) corresponds to the associated Legendre function of degree n and order m evaluated at X(i).

In general, the returned array P has one more dimension than X, and each element P(m+1,i,j,k,...) contains the associated Legendre function of degree n and order m evaluated at X(i,j,k,...). Note that the first row of P is the Legendre polynomial evaluated at X, i.e., the case where m = 0.

S = legendre(n,X,'sch') computes the “Schmidt Seminormalized Associated Legendre Functions” on page 1-3427.

N = legendre(n,X,'norm') computes the “Fully Normalized Associated Legendre Functions” on page 1-3427.

## Definitions Associated Legendre Functions

The Legendre functions are defined by

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

where

$$P_n(x)$$

is the Legendre polynomial of degree n:

$$P_n(x) = \frac{1}{2^n n!} \left[ \frac{d^n}{dx^n} (x^2 - 1)^n \right]$$

## Schmidt Seminormalized Associated Legendre Functions

The Schmidt seminormalized associated Legendre functions are related to the nonnormalized associated Legendre functions  $P_n^m(x)$  by

$$P_n(x) \text{ for } m = 0,$$

$$S_n^m(x) = (-1)^m \sqrt{\frac{2(n-m)!}{(n+m)!}} P_n^m(x) \text{ for } m > 0.$$

## Fully Normalized Associated Legendre Functions

The fully normalized associated Legendre functions are normalized such that

$$\int_{-1}^1 (N_n^m(x))^2 dx = 1$$

and are related to the unnormalized associated Legendre functions  $P_n^m(x)$  by

$$N_n^m = (-1)^m \sqrt{\frac{(n + \frac{1}{2})(n - m)!}{(n + m)!}} P_n^m(x)$$

## Examples

### Example 1

The statement `legendre(2,0:0.1:0.2)` returns the matrix

# legendre

---

	<b>x = 0</b>	<b>x = 0.1</b>	<b>x = 0.2</b>
m = 0	-0.5000	-0.4850	-0.4400
m = 1	0	-0.2985	-0.5879
m = 2	3.0000	2.9700	2.8800

## Example 2

Given,

```
X = rand(2,4,5);  
n = 2;  
P = legendre(n,X)
```

then

```
size(P)  
ans =  
     3     2     4     5
```

and

```
P(:,1,2,3)  
ans =  
    -0.2475  
    -1.1225  
     2.4950
```

is the same as

```
legendre(n,X(1,2,3))  
ans =  
    -0.2475  
    -1.1225  
     2.49501
```

## Algorithms

legendre uses a three-term backward recursion relationship in  $m$ . This recursion is on a version of the Schmidt seminormalized

associated Legendre functions  $P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x)$ , which are complex spherical harmonics. These functions are related to the standard Abramowitz and Stegun [1] functions

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x), \text{ by}$$

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

They are related to the Schmidt form given previously by

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

## References

- [1] Abramowitz, M. and I. A. Stegun, *Handbook of Mathematical Functions*, Dover Publications, 1965, Ch.8.

# length

---

**Purpose** Length of vector or largest array dimension

**Syntax** `numberOfElements = length(array)`

**Description** `numberOfElements = length(array)` finds the number of elements along the largest dimension of an array. `array` is an array of any MATLAB data type and any valid dimensions. `numberOfElements` is a whole number of the MATLAB double class.

For nonempty arrays, `numberOfElements` is equivalent to `max(size(array))`. For empty arrays, `numberOfElements` is zero.

**Examples** Create a 1-by-8 array `X` and use `length` to find the number of elements in the second (largest) dimension:

```
X = [5, 3.4, 72, 28/4, 3.61, 17 94 89];
```

```
length(X)
ans =
     8
```

---

Create a 4-dimensional array `Y` in which the third dimension is the largest. Use `length` to find the number of elements in that dimension:

```
Y = rand(2, 5, 17, 13);
```

```
length(Y)
ans =
    17
```

---

Create a struct array `S` with character and numeric fields of different lengths. Use the `structfun` function to apply `length` to each field of `S`:

```
S = struct('f1', 'Name:', 'f2', 'Charlie', ...
          'f3', 'DOB:', 'f4', 1917)
```

```
S =  
    f1: 'Name:'  
    f2: 'Charlie'  
    f3: 'DOB:'  
    f4: 1917  
  
structfun(@(field)length(field), S)  
ans =  
     5  
     7  
     4  
     1
```

## See Also

[numel](#)  |  [size](#)  |  [ndims](#)

# containers.Map.length

---

**Purpose** Length of containers.Map object

**Syntax** `mapLength = length(mapObj)`

**Description** `mapLength = length(mapObj)` returns the number of key-value pairs in `mapObj`.

**Input Arguments** **mapObj**  
Object of class `containers.Map`.

**Output Arguments** **mapLength**  
Scalar numeric value that indicates the number of key-value pairs in `mapObj`. This number is equivalent to `size(mapObj,1)` and to `mapObj.Count`.

## Examples **Determine the Length of a Map**

Create a map, and determine the number of key-value pairs:

```
myKeys = {'a','b','c'};  
myValues = [1,2,3];  
mapObj = containers.Map(myKeys,myValues);
```

```
mapLength = length(mapObj)
```

This code returns

```
mapLength =  
3
```

**See Also** `containers.Map` | `isKey` | `keys` | `size` | `values`

**Purpose** Length of serial port object array

**Syntax** length(obj)

**Description** length(obj) returns the length of the serial port object, obj. It is equivalent to the command max(size(obj)).

**See Also** size

# length (tscollection)

---

**Purpose** Length of time vector

**Syntax** `length(tsc)`

**Description** `length(tsc)` returns an integer that represents the length of the time vector for the `tscollection` object `tsc`.

**See Also** `tscollection` | `isempty (tscollection)` | `size (tscollection)`

**Purpose** Return information on functions in shared library

**Syntax**

```
libfunctions libname

m = libfunctions(libname)
___ = libfunctions(___ , '-full')
```

**Description** `libfunctions libname` displays names of functions defined in library, `libname`. If you called `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

`m = libfunctions(libname)` returns names of functions in cell array `m`.

`___ = libfunctions(___ , '-full')` returns function signatures.

## Input Arguments

### **libname - Name of shared library**

string

Name of shared library, specified as a string. If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

### **Data Types**

char

## Output Arguments

### **m - Function names**

cell array

Functions names, returned as a cell array.

## Examples

### **Display Function Signatures**

Load the example library, `shrlibsample`, and list the functions.

```
if not(libisloaded('shrlibsample'))
    addpath(fullfile(matlabroot,'extern','examples','shrlib'))
    loadlibrary('shrlibsample')
```

# libfunctions

---

```
end
m = libfunctions('shrlibsample','-full')

m =

    '[double, doublePtr] addDoubleRef(double, doublePtr, double)'
    'double addMixedTypes(int16, int32, double)'
    '[double, c_structPtr] addStructByRef(c_structPtr)'
    'double addStructFields(c_struct)'
    'c_structPtrPtr allocateStruct(c_structPtrPtr)'
    'voidPtr deallocateStruct(voidPtr)'
    'lib.pointer exportedDoubleValue'
    'lib.pointer getListOfStrings'
    'doublePtr multDoubleArray(doublePtr, int32)'
    '[lib.pointer, doublePtr] multDoubleRef(doublePtr)'
    'int16Ptr multiplyShort(int16Ptr, int32)'
    'doublePtr print2darray(doublePtr, int32)'
    'printExportedDoubleValue'
    'cstring readEnum(Enum1)'
    '[cstring, cstring] stringToUpper(cstring)'
```

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## See Also

`loadlibrary` | `libfunctionsview` | `calllib`

**Purpose** Display shared library function signatures in window

**Syntax** `libfunctionsview libname`

**Description** `libfunctionsview libname` displays information about functions in library, `libname`, in a new window.

**Input Arguments** **libname - Name of shared library**  
*string*

Name of shared library, specified as a string. If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

**Data Types**  
*char*

**Limitations** • Use with libraries that are loaded using the `loadlibrary` function.

**Examples** **Display Function Signatures for Library `libmx`**

```
if not(libisloaded('libmx'))
    hfile = fullfile(matlabroot,'extern','include','matrix.h');
    loadlibrary('libmx',hfile)
end
libfunctionsview libmx
```

MATLAB creates a new window displaying function signatures.

**See Also** `libfunctions` | `calllib`

# libisloaded

---

**Purpose** Determine if shared library is loaded

**Syntax** `tf = libisloaded(libname)`

**Description** `tf = libisloaded(libname)` returns logical 1 (true) if the shared library, `libname`, is loaded. Otherwise, it returns logical 0 (false).

**Input Arguments** **libname - Name of shared library**  
*string*

Name of shared library, specified as a string. If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

**Data Types**  
*char*

**Examples** **Load Functions in Library**

Load example library, `shrlibsample`, if it is not already loaded.

```
if ~libisloaded('shrlibsample')
    loadlibrary('shrlibsample')
end
```

**See Also** `loadlibrary` | `unloadlibrary`

**Purpose** Pointer object for use with shared library

**Syntax**

```
p = libpointer
p = libpointer(DataType)
p = libpointer(DataType,Value)
```

**Description**

`p = libpointer` creates NULL pointer `p` of type `voidPtr`.

`p = libpointer(DataType)` creates NULL pointer of specified `DataType`.

`p = libpointer(DataType,Value)` creates pointer initialized to a copy of `Value`.

**Limitations**

- Use with libraries that are loaded using the `loadlibrary` function.

**Input Arguments**

**DataType - Type of pointer**

string

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, refer to these tables in “C and MATLAB Equivalent Types”.

- MATLAB Primitive Types
- MATLAB Extended Types

**Example:** 'int16Ptr'

**Data Types**

char

**Value - Value for pointer object**

Any valid value

Value, specified as any valid value for given type.

# libpointer

---

## Tips

- This is an advanced feature for experienced C programmers. MATLAB automatically converts data passed to and from external library functions to the data type expected by the external function. Use a `lib.pointer` object instead of automatic conversion in the following situations.
  - You want to modify the data in the input arguments.
  - You are passing large amounts of data, and you want to control when MATLAB makes copies of the data.
  - The library stores and uses the pointer for a period of time so you want the MATLAB function to control the lifetime of the `lib.pointer` object.

plus	+ (plus) operator for pointer arithmetic
reshape	Reshape lib.pointer array
setdatatype	Initialize type and size of lib.pointer object

## Definitions

A passed-by-reference argument in the function signature has type names ending with Ptr or PtrPtr.

## Examples

### Create Pointer

Create a pointer, pv, of type int16, initialized to 485.

```
pv = libpointer('int16Ptr',485);
```

Display the properties of pv.

```
get(pv)
```

```
Value: 485
DataType: 'int16Ptr'
```

**See Also** libpointer

**Concepts**

- “Working with Pointer Arguments”

<b>Purpose</b>	Display lib.pointer type
<b>Syntax</b>	disp(h)
<b>Description</b>	disp(h) displays type for lib.pointer object, h.
<b>Input Arguments</b>	<b>h - lib.pointer object.</b> handle lib.pointer object, specified as a handle.
<b>Examples</b>	<b>Display lib.pointer Type</b> Create a double pointer set to 15. <pre>xp = libpointer('doublePtr',15);</pre> Display pointer data type. <pre>disp(xp)</pre> <pre>libpointer</pre>

# lib.pointer.isNull

---

<b>Purpose</b>	Points to NULL pointer
<b>Syntax</b>	<code>tf = isNull(h)</code>
<b>Description</b>	<code>tf = isNull(h)</code> returns true if <code>h</code> is a <code>lib.pointer</code> object.
<b>Input Arguments</b>	<b><code>h</code> - lib.pointer object.</b> <code>handle</code> lib.pointer object, specified as a handle.
<b>Examples</b>	<b>Create Null lib.pointer Object</b> <pre>nullp = libpointer('doublePtr', []); isNull(nullp)</pre>

<b>Purpose</b>	+ (plus) operator for pointer arithmetic
<b>Syntax</b>	<pre>hout = plus(h,offset) hout = h + offset</pre>
<b>Description</b>	<p><code>hout = plus(h,offset)</code> returns pointer <code>hout</code>. Pointer <code>hout</code> is valid only as long as the original pointer, <code>h</code>, exists.</p> <p><code>hout = h + offset</code> is an alternative syntax.</p>
<b>Input Arguments</b>	<p><b>h - lib.pointer object.</b> <code>handle</code> lib.pointer object, specified as a handle.</p> <p><b>offset - Scalar increment</b> <code>uint64</code> Scalar increment, specified as <code>uint64</code>, from <code>h</code>.</p>
<b>Related Examples</b>	<ul style="list-style-type: none"><li>• “Iterate Through an Array”</li></ul>

# lib.pointer.reshape

---

<b>Purpose</b>	Reshape lib.pointer array
<b>Syntax</b>	reshape(h,xdim,ydim)
<b>Description</b>	reshape(h,xdim,ydim) creates an xdim-by-ydim matrix from lib.pointer object h.
<b>Input Arguments</b>	<b>h - lib.pointer object.</b> handle lib.pointer object, specified as a handle. <b>xdim - Size of x dimension</b> double Size of x dimension, specified as double. <b>ydim - Size of y dimension</b> double Size of y dimension, specified as double.

<b>Purpose</b>	Initialize type and size of lib.pointer object
<b>Syntax</b>	setdatatype(h,type,size)
<b>Description</b>	setdatatype(h,type,size) sets data type, type, of size, to lib.pointer, h.
<b>Input Arguments</b>	<p><b>h - lib.pointer object.</b> handle lib.pointer object, specified as a handle.</p> <p><b>type - Data type</b> string Data type, specified as a string.</p> <p><b>size - Size</b> double Size, specified as double.</p>

## Examples **Set Size and Type of lib.pointer Output Variable**

Load the shrlibsample library.

```
if ~libisloaded('shrlibsample')
    addpath(fullfile(matlabroot,'extern','examples','shrlib'))
    loadlibrary('shrlibsample')
end
```

The multDoubleRef function takes a scalar value specified as doubleptr. Create variable xp as a lib.pointer object, and call the function.

```
xp = libpointer('doublePtr',99);
[xobj,xval] = calllib('shrlibsample','multDoubleRef',xp);
```

To use the variable xobj, set its size and data type.

# lib.pointer.setdatatype

---

```
setdatatype(xobj, 'doublePtr', 1, 1)  
xobj.Value
```

```
ans =
```

```
495
```

**Purpose** Convert MATLAB structure to C-style structure for use with shared library

**Syntax**  
`S = libstruct(structtype)`  
`S = libstruct(structtype,mlstruct)`

**Description** `S = libstruct(structtype)` creates NULL pointer to MATLAB libstruct object S.

`S = libstruct(structtype,mlstruct)` creates pointer initialized to mlstruct.

- Limitations**
- Use with libraries that are loaded using the `loadlibrary` function.
  - You can only use the `libstruct` function on scalar structures.
  - When converting a MATLAB structure to a libstruct object, the structure must adhere to the requirements listed in “Structure Argument Requirements”.

**Input Arguments**

**structtype - C structure**  
structure  
C structure defined in shared library.

**mlstruct - MATLAB structure**  
structure  
MATLAB structure used to initialize the fields in S.

**Data Types**  
struct

**Output Arguments**

**S - Pointer**  
MATLAB libstruct object  
Pointer, returned as MATLAB libstruct object.

## Examples

### Call Function with `c_struct` Input Argument

Call the `addStructFields` function by creating a variable of type `c_struct`.

Load the `shrlibsample` library, which contains the `c_struct` type.

```
if ~libisloaded('shrlibsample')
    addpath(fullfile(matlabroot,'extern','examples','shrlib'))
    loadlibrary('shrlibsample')
end
```

Display function signatures for `shrlibsample` and search the list for the `addStructFields` entry.

```
libfunctionsview shrlibsample

double addStructFields(c_struct)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `sm`.

```
sm.p1 = 476;    sm.p2 = -299;    sm.p3 = 1000;
```

Construct a `libstruct` object `sc` from the `c_struct` type.

```
sc = libstruct('c_struct',sm)
```

The fields of `sc` contain the values of the MATLAB structure, `sm`.

Call the `addStructFields` function.

```
calllib('shrlibsample','addStructFields',sc)
```

```
ans =
    1177
```

To clean up, first clear the `libstruct` object, and then unload the library.

```
clear sc
unloadlibrary shrlibsample
```

## Tips

- If a function in the shared library has a structure argument, use `libstruct` to create the argument. The `libstruct` function creates a C-style structure that you pass to functions in the library. You handle this structure in MATLAB as you would a true MATLAB structure.

## Concepts

- “Working with Structure Arguments”

# license

---

**Purpose** Return license number or perform licensing task

**Syntax**

```
license
license('inuse')
S = license('inuse')
S = license('inuse', feature)
license('test', feature)
license('test', feature, toggle)
[TF errmsg] = license('checkout', feature)
```

**Description** `license` returns the license number for this MATLAB product. The return value is always a string but is not guaranteed to be a number. The following table lists text strings that `license` can return.

String	Description
'demo'	MATLAB is a demonstration version
'student'	MATLAB is the student version
'unknown'	License number cannot be determined

`license('inuse')` returns a list of licenses checked out in the current MATLAB session. In the list, products are listed alphabetically by their license feature names, i.e., the text string used to identify products in the INCREMENT lines in a License File (`license.dat`). Note that the feature names returned in the list contain only lower-case characters.

`S = license('inuse')` returns an array of structures, where each structure represents a checked-out license. The structures contains two fields: `feature` and `user`. The `feature` field contains the license feature name. The `user` field contains the username of the person who has the license checked out.

`S = license('inuse', feature)` checks if the product specified by the text string `feature` is checked out in the current MATLAB session. If the product is checked out, the `license` function returns the product name and the username of the person who has it checked out in the

structure `S`. If the product is not currently checked out, the fields in the structure are empty.

The `feature` string must be a license feature name, spelled exactly as it appears in the `INCREMENT` lines in a License File. For example, the string `'Identification_Toolbox'` is the feature name for the System Identification Toolbox™. The `feature` string is not case-sensitive and must not exceed 27 characters.

`license('test', feature)` tests if a license exists for the product specified by the text string `feature`. The `license` command returns 1 if the license exists and 0 if the license does not exist. The `feature` string identifies a product, as described in the previous syntax.

---

**Note** Testing for a license only confirms that the license exists. It does not confirm that the license can be checked out. For example, `license` will return 1 if a license exists, even if the license has expired or if a system administrator has excluded you from using the product in an options file. The existence of a license does not indicate that the product is installed.

---

`license('test', feature, toggle)` enables or disables testing of the product specified by the text string `feature`, depending on the value of `toggle`. The parameter `toggle` can have either of two values:

'enable' The syntax `license('test', feature)` returns 1 if the product license exists and 0 if the product license does not exist.

'disable' The syntax `license('test', feature)` always returns 0 (product license does not exist) for the specified product.

---

**Note** Disabling a test for a particular product can impact other tests for the existence of the license, not just tests performed using the `license` command.

---

`[TF errmsg] = license('checkout',feature)` checks out a license for the product specified by the text string `feature`, returning 1 if it could check out a license or 0 if it could not check out a license. If you specify the optional second output argument, `errmsg`, the `license` function returns the text of any error message encountered, or an empty string if the checkout succeeded.

## Examples

Get the license number for this MATLAB.

```
license
```

Get a list of licenses currently being used. Note that the products appear in alphabetical order by their license feature name in the list returned.

```
license('inuse')
```

```
image_toolbox  
map_toolbox  
matlab
```

Get a list of licenses in use with information about who is using the license.

```
S = license('inuse');
```

```
S(1)
```

```
ans =
```

```
    feature: 'image_toolbox'  
        user: 'juser'
```

Determine if the license for MATLAB is currently in use.

```
S = license('inuse','MATLAB')
```

```
S =
```

```
    feature: 'matlab'  
    user: 'jsmith'
```

Determine if a license exists for the Mapping Toolbox™.

```
license('test','map_toolbox')
```

```
ans =
```

```
    1
```

Check out a license for the Control System Toolbox™.

```
license('checkout','control_toolbox')
```

```
ans =
```

```
    1
```

Determine if the license for the Control System Toolbox is checked out.

```
license('inuse')
```

```
control_toolbox  
image_toolbox  
map_toolbox  
matlab
```

# light

---

<b>Purpose</b>	Create light object
<b>Syntax</b>	<pre>light('PropertyName',propertyvalue,...) handle = light(...)</pre>
<b>Properties</b>	For a list of properties, see Light Properties.
<b>Description</b>	<p>light creates a light object in the current axes. Lights affect only patch and surface objects.</p> <p>light('PropertyName',propertyvalue,...) creates a light object using the specified values for the named properties. For a description of the properties, see Light Properties. The MATLAB software parents the light to the current axes unless you specify another axes with the Parent property.</p> <p>handle = light(...) returns the handle of the light object created.</p>
<b>Tips</b>	<p>You cannot see a light object <i>per se</i>, but you can see the effects of the light source on patch and surface objects. You can also specify an axes-wide ambient light color that illuminates these objects. However, ambient light is visible only when at least one light object is present and visible in the axes.</p> <p>You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see set and get for examples of how to specify these data types).</p> <p>See also the patch and surface AmbientStrength, DiffuseStrength, SpecularStrength, SpecularExponent, SpecularColorReflectance, and VertexNormals properties. Also see the lighting and material commands.</p>
<b>Examples</b>	<p>Light the peaks surface plot with a light source located at infinity and oriented along the direction defined by the vector [1 0 0], that is, along the <i>x</i>-axis.</p> <pre>h = surf(peaks);</pre>

```
set(h,'FaceLighting','phong','FaceColor','interp',...  
    'AmbientStrength',0.5)  
light('Position',[1 0 0],'Style','infinite');
```

## Setting Default Properties

You can set default light properties on the axes, figure, and root object levels:

```
set(0,'DefaultLightProperty',PropertyValue...)  
set(gcf,'DefaultLightProperty',PropertyValue...)  
set(gca,'DefaultLightProperty',PropertyValue...)
```

where *Property* is the name of the light property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access light properties.

## Tutorials

For more information about lighting, see “Lighting Overview”.

## See Also

[lighting](#) | [material](#) | [patch](#) | [surface](#) | [Light Properties](#)

# Light Properties

---

## Purpose

Light properties

## Creating Light Objects

Use `light` to create light objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Light Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`BeingDeleted`  
`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

`BusyAction`  
`cancel` | `{queue}`

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
function handle

This property is not used on lights.

`Children`  
handles

The empty matrix; light objects have no children.

`Clipping`  
on | off

*Clipping mode.* This property has no effect on light objects.

`Color`  
`ColorSpec`

# Light Properties

---

*Light color.* Defines the color of the light emanating from the light object. Use a three-element RGB vector or one of the MATLAB predefined names. Default value is [1 1 1] (white). See the `ColorSpec` reference page for more information on specifying color.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a light object. You must define this property as a default value for lights or in a call to the `light` function to create a new light object. For example, the following statement:

```
set(0,'DefaultLightCreateFcn',@light_create)
```

defines a default value for the line `CreateFcn` property on the root level that sets the current figure colormap to `gray` and uses a reddish light color whenever you create a light object.

```
function light_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    set(src,'Color',[.9 .2 .2])
    set(gcf,'Colormap',gray)
end
```

MATLAB executes this function after setting all light properties. Setting this property on an existing light object has no effect. The function must define at least two input arguments (handle of light object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete light callback function.* Executes when you delete the light object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    obj_tp = get(src,'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

HandleVisibility  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

This property is not used by light objects.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

# Light Properties

---

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## Parent

handle of parent axes

*Parent of light object.* This property contains the handle of the light object’s parent. The parent of a light object is the axes object that contains it.

Note that light objects cannot be parented to `hggroup` or `hgtransform` objects.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Position

$[x,y,z]$  in axes data units

*Location of light object.* Vector defining the location of the light object. The vector is defined from the origin to the specified  $x$ -,

$y$ -, and  $z$ -coordinates. The placement of the light depends on the setting of the `Style` property:

- If the `Style` property is `local`, `Position` specifies the actual location of the light (which is then a point source that radiates from the location in all directions).
- If the `Style` property is `infinite`, `Position` specifies the direction from which the light shines in parallel rays.

`Selected`

`on` | `off`

This property is not used by light objects.

`SelectionHighlight`

`{on}` | `off`

This property is not used by light objects.

`Style`

`{infinite}` | `local`

*Parallel or divergent light source.*

- `infinite` — MATLAB places the light object at infinity (light rays are parallel).
- `local` — MATLAB places the light object at the location specified by the `Position` property (light rays diverge in all directions).

`Tag`

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

# Light Properties

---

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For light objects, Type is always 'light'.

## UIContextMenu

handle of uicontextmenu object

This property is not used by light objects.

## UserData

matrix

*User-specified data.* Data you want to associate with the light object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Light visibility.* While light objects themselves are not visible, you can see the light on patch and surface objects. When you set Visible to off, the light emanating from the source is not visible. There must be at least one light object in the axes whose Visible property is on for any lighting features to be enabled (including the axes AmbientLightColor and patch and surface AmbientStrength).

## See Also

light

<b>Purpose</b>	Create or position light object in spherical coordinates
<b>Syntax</b>	<pre>lightangle(az,e1) light_handle = lightangle(az,e1) lightangle(light_handle,az,e1) [az,e1] = lightangle(light_handle)</pre>
<b>Description</b>	<p><code>lightangle(az,e1)</code> creates a light at the position specified by azimuth and elevation. <code>az</code> is the azimuthal (horizontal) rotation and <code>e1</code> is the vertical elevation (both in degrees). The interpretation of azimuth and elevation is the same as that of the <code>view</code> command.</p> <p><code>light_handle = lightangle(az,e1)</code> creates a light and returns the handle of the light in <code>light_handle</code>.</p> <p><code>lightangle(light_handle,az,e1)</code> sets the position of the light specified by <code>light_handle</code>.</p> <p><code>[az,e1] = lightangle(light_handle)</code> returns the azimuth and elevation of the light specified by <code>light_handle</code>.</p>
<b>Tips</b>	By default, when a light is created, its style is <code>infinite</code> . If the light handle passed in to <code>lightangle</code> refers to a local light, the distance between the light and the camera target is preserved as the position is changed.
<b>Examples</b>	<pre>surf(peaks) axis vis3d h = light; for az = -50:10:50     lightangle(h,az,30) end drawnow end</pre>

# lighting

---

<b>Purpose</b>	Specify lighting algorithm
<b>Syntax</b>	<code>lighting flat</code> <code>lighting gouraud</code> <code>lighting phong</code> <code>lighting none</code>
<b>Description</b>	<p><code>lighting</code> selects the algorithm used to calculate the effects of light objects on all surface and patch objects in the current axes. In order for the <code>lighting</code> command to have any effects, however, you must create a lighting object by using the <code>light</code> function.</p> <p><code>lighting flat</code> produces uniform lighting across each of the faces of the object. Select this method to view faceted objects.</p> <p><code>lighting gouraud</code> calculates the vertex normals and interpolates linearly across the faces. Select this method to view curved surfaces.</p> <p><code>lighting phong</code> interpolates the vertex normals across each face and calculates the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but it takes longer to render.</p> <p><code>lighting none</code> turns off lighting.</p>
<b>Tips</b>	The <code>surf</code> , <code>mesh</code> , <code>pcolor</code> , <code>fill</code> , <code>fill3</code> , <code>surface</code> , and <code>patch</code> functions create graphics objects that are affected by light sources. The <code>lighting</code> command sets the <code>FaceLighting</code> and <code>EdgeLighting</code> properties of surfaces and patches appropriately for the graphics object.
<b>See Also</b>	<code>fill</code>   <code>fill3</code>   <code>light</code>   <code>material</code>   <code>mesh</code>   <code>patch</code>   <code>pcolor</code>   <code>shading</code>   <code>surface</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Lighting Overview”</li></ul>

**Purpose** Convert linear audio signal to mu-law

**Syntax** `mu = lin2mu(y)`

**Description** `mu = lin2mu(y)` converts linear audio signal amplitudes in the range  $-1 \leq Y \leq 1$  to mu-law encoded “flints” in the range  $0 \leq u \leq 255$ .

**See Also** `auwrite` | `mu2lin`

# line

---

**Purpose** Create line object

**Syntax**

```
line
line(X,Y)
line(X,Y,Z)
line(X,Y,Z,'PropertyName',propertyvalue,...)
line('XData',x,'YData',y,'ZData',z,...)
h = line(...)
```

**Properties** For a list of properties, see Line Properties.

**Description** `line` creates a line object in the current axes with default values `x = [0 1]` and `y = [0 1]`. You can specify the color, width, line style, and marker type, as well as other characteristics.

The `line` function has two forms:

- Automatic color and line style cycling. When you specify multiple line coordinate data as a column array using the informal syntax (i.e., the first three arguments are interpreted as the coordinates),

```
line(X,Y,Z)
```

MATLAB cycles through the axes `ColorOrder` and `LineStyleOrder` property values the way the `plot` function does. However, unlike `plot`, `line` does not call the `newplot` function.

- Purely low-level behavior. When you call `line` with only property name/property value pairs,

```
line('XData',x,'YData',y,'ZData',z)
```

MATLAB draws a line object in the current axes using the default line color (see the `colordef` function for information on color defaults). Note that you cannot specify matrix coordinate data with the low-level form of the `line` function.

`line(X,Y)` adds the line defined in vectors `X` and `Y` to the current axes. If `X` and `Y` are matrices of the same size, `line` draws one line per column.

`line(X,Y,Z)` creates lines in three-dimensional coordinates.

`line(X,Y,Z,'PropertyName',propertyvalue,...)` creates a line using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see [Line Properties](#).

See the `LineStyle` and `Marker` properties for a list of supported values.

`line('XData',x,'YData',y,'ZData',z,...)` creates a line in the current axes using the property values defined as arguments. This is the low-level form of the `line` function, which does not accept matrix coordinate data as the other informal forms described above.

`h = line(...)` returns a column vector of handles corresponding to each line object the function creates.

## Tips

In its informal form, the `line` function interprets the first three arguments (two for 2-D) as the X, Y, and Z coordinate data, allowing you to omit the property names. You must specify all other properties as name/value pairs. For example,

```
line(X,Y,Z,'Color','r','LineWidth',4)
```

The low-level form of the `line` function can have arguments that are only property name/property value pairs. For example,

```
line('XData',x,'YData',y,'ZData',z,'Color','r','LineWidth',4)
```

Line properties control various aspects of the line object and are described in [Line Properties](#). You can also set and query property values after creating the line using `set` and `get`.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

Unlike high-level functions such as `plot`, `line` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds line objects to the current axes. However, axes properties that are under

automatic control, such as the axis limits, can change to accommodate the line within the current axes.

## Connecting the dots

The coordinate data is interpreted as vectors of corresponding x, y, and z values:

```
X = [x(1) x(2) x(3)...x(n)]
Y = [y(1) y(2) y(3)...y(n)]
Z = [z(1) z(2) z(3)...z(n)]
```

where a point is determined by the corresponding vector elements:

```
p1(x(i),y(i),z(i))
```

For example, to draw a line from the point located at  $x = .3$  and  $y = .4$  and  $z = 1$  to the point located at  $x = .7$  and  $y = .9$  and  $z = 1$ , use the following data:

```
axis([0 1 0 1])
line([.3 .7],[.4 .9],[1 1],'Marker','.', 'LineStyle','-')
```

## Examples

This example uses the line function to add a shadow to plotted data. First, plot some data and save the line's handle:

```
t = 0:pi/20:2*pi;
hline1 = plot(t,sin(t),'k');
```

Next, add a shadow by offsetting the  $x$ -coordinates. Make the shadow line light gray and wider than the default LineWidth:

```
hline2 = line(t+.06,sin(t),'LineWidth',4,'Color',[.8 .8 .8]);
```

Finally, pull the first line to the front:

```
set(gca,'Children',[hline1 hline2])
```

### Drawing Lines Interactively

You can use the `ginput` function to select points from a figure. For example:

```
[x,y] = ginput(5);  
line(x,y)
```

### Drawing with mouse motion

You can use the axes `CurrentPoint` property and the figure `WindowButtonDownFcn` and `WindowButtonMotionFcn` properties to select a point with a mouse click and draw a line to another point by dragging the mouse, like a simple drawing program. The following

example illustrates a few useful techniques for doing this type of interactive drawing.

Click to view in editor — This example enables you to click and drag the cursor to draw lines.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

## Input Argument Dimensions — Informal Form

This statement reuses the one-column matrix specified for ZData to produce two lines, each having four points.

```
line(rand(4,2),rand(4,2),rand(4,1))
```

If all the data has the same number of columns and one row each, MATLAB transposes the matrices to produce data for plotting. For example,

```
line(rand(1,4),rand(1,4),rand(1,4))
```

is changed to

```
line(rand(4,1),rand(4,1),rand(4,1))
```

This also applies to the case when just one or two matrices have one row. For example, the statement

```
line(rand(2,4),rand(2,4),rand(1,4))
```

is equivalent to

```
line(rand(4,2),rand(4,2),rand(4,1))
```

You can set default line properties on the axes, figure, and root object levels:

```
set(0,'DefaultLinePropertyName',PropertyValue,...)  
set(gcf,'DefaultLinePropertyName',PropertyValue,...)
```

## Setting Default Properties

```
set(gca, 'DefaultLinePropertyName', PropertyValue, ...)
```

Where *PropertyName* is the name of the line property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access line properties.

# Line Properties

---

## Purpose

Line properties

## Creating Line Objects

Use `line` to create line objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See *Core Graphics Objects* for general information about this type of object.

## Line Property Descriptions

Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this line object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the line object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
on	Represent this line object in a legend (default)
off	Do not include this line object in a legend
children	Same as on because line objects do not have children

## Setting the IconDisplayStyle property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

# Line Properties

---

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## ButtonDownFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the line object. The default is an empty array.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle

of line associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    sel_typ = get(gcf,'SelectionType')
    switch sel_typ
        case 'normal'
            disp('User clicked left-mouse button')
            set(src,'Selected','on')
        case 'extend'
            disp('User did a shift-click')
            set(src,'Selected','on')
        case 'alt'
            disp('User did a control-click')
            set(src,'Selected','on')
            set(src,'SelectionHighlight','off')
    end
end
```

Suppose `h` is the handle of a line object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

vector of handles

The empty matrix; line objects have no children.

# Line Properties

---

Clipping  
{on} | off

*Clipping mode.* MATLAB clips lines to the axes plot box by default. If you set `Clipping` to `off`, lines are displayed outside the axes plot box. This occurs if you create a line, set `hold` to `on`, freeze axis scaling (set `axis` to `manual`), and then create a longer line.

Color  
ColorSpec

*Line color.* A three-element RGB vector, or one of the MATLAB predefined names, specifying the line color. See the `ColorSpec` reference page for more information on specifying color.

CreateFcn  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a line object. The default is an empty array.

You must specify the callback during the creation of the line or in a call to the `line` function to create a new line object.

For example, the statement:

```
set(0, 'DefaultLineCreateFcn', @line_create)
```

defines a default value for the line `CreateFcn` property on the root level that sets the axes `LineStyleOrder` whenever you create a line object. The following callback function must be on your MATLAB path when you execute the above statement.

```
function line_create(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
axh = get(src, 'Parent');
set(axh, 'LineStyleOrder', '-.|-')
```

end

MATLAB executes this function after setting all line properties. Setting this property on an existing line object has no effect.

The function must define at least two input arguments (handle of line object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is MATLAB as the first argument to the callback function and is also accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete line callback function.* Executes when you delete the line object. This happens when you call the `delete` command on the object, its parent axes, or the figure containing it. The default is an empty array.

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    obj_tp = get(src,'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src,'UserData'))
end
```

# Line Properties

---

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of line object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the line object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

The following code shows how to use the `DisplayName` property from the command line or in a file.

```
t = 0:.1:2*pi;
a(:,1)=sin(t); a(:,2)=cos(t);
h = plot(a);
set(h,{'DisplayName'},{'Sine','Cosine'})
legend show
```

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase line objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the line when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it, because MATLAB stores no information about its former location.
- **xor** — Draw and erase the line by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath the line. However, the line’s color depends on the color of whatever is beneath it on the display.
- **background** — Erase the line by drawing it in the axes `background Color`, or the figure `background Color` if the axes

Color is none. This damages objects that are behind the erased line, but lines are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### HandleVisibility

{on} | callback | off

*Control access to object handle.* Determine when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

For more information, see “`HandleVisibility` Property”, “`Functions Affected by Handle Visibility`”, and “`Properties Affected by Handle Visibility`”.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the line can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line. If `HitTest` is `off`, clicking the line selects the object below it (which might be the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

# Line Properties

---

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`

{-} | -- | : | -. | none

*Line style.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`

scalar

*Width of the line* . Specify this value in points. The default value is 0.5 points.

# Line Properties

---

## Marker

character (see table)

*Marker symbol.* Specifies marks displayed at data points. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Use same color as the line `Color` property.

`MarkerFaceColor`

`ColorSpec` | `{none}` | `auto`

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`

handle of axes, `hggroup`, or `hgtransform`

# Line Properties

---

*Parent of line object.* Handle of the line object's parent. The parent of a line object is the axes that contains it. You can reparent line objects to other axes, hggroup, or hgtransform objects.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

**Selected**  
on | off

*Selection status* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

**SelectionHighlight**  
{on} | off

*Object highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing handles at each vertex. When SelectionHighlight is off, MATLAB does not draw the handles.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use this property when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks. You can define Tag as any string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

**Type**  
string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For line objects, Type is always 'line'.

## UIContextMenu

handle of uicontextmenu object

*Associate context menu with line.* Assign this property the handle of a uicontextmenu object created in the same figure as the line. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the line.

## UserData

matrix

*User-specified data.* Data you want to associate with the line object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

---

**Note** Setting the UserData property more than once erases previous entries.

---

## Visible

{on} | off

*Line visibility.*

- on — All lines are visible.
- off — Line is not visible, but still exists, and you can `get` and `set` its properties.

## XData

vector

# Line Properties

---

*x-coordinates of line.* Vector of *x*-coordinates defining the line. The default is [0 1].

YData and ZData, if set, must be the same length and have the same number of rows.

Create a line using the `line` function, then change its XData property:

```
mylin = line(rand(1,10),rand(1,10));
set(mylin,'XData',rand(1,15));
% A warning because you did not set YData
set(mylin,'XData',rand(1,15),...
    'YData',rand(1,15));
% No warning appears and the plot draws as expected.
```

## YData

vector

*y-coordinates of line.* Vector of *y*-coordinates defining the line. The default is [0 1]. XData and ZData, if set, must be the same length and have the same number of rows.

Create a line using the `line` function, then change its YData property:

```
mylin = line(rand(1,10),rand(1,10));
set(mylin,'YData',rand(1,15));
% A warning because you did not set YData
set(mylin,'YData',rand(1,15),'XData',rand(1,15));
% No warning appears and the plot draws as expected.
```

## ZData

vector

*z-coordinates of line.* Vector of *z*-coordinates defining the line. The default is [] (empty). XData and YData must have the same number of rows.

Create a line using the `line` function, then change its ZData property:

```
mylin = line(rand(1,10),rand(1,10),rand(1,10));
view(3)
set(mylin,'ZData',rand(1,15));
% A warning because you did not set YData.
set(mylin,'XData',rand(1,15),...
    'YData',rand(1,15),...
    'ZData',rand(1,15));
% No warning appears and the plot draws as expected.
```

**See Also**      `line`

# Lineseries Properties

---

## Purpose

Description of lineseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

See “Plot Objects” for more information on lineseries objects.

Note that you cannot define default properties for lineseries objects.

## Lineseries Property Descriptions

This section lists property names along with the type of values each accepts. Curly braces `{ }` enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of lineseries objects in legends.* Specifies whether this lineseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the lineseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the lineseries object in a legend as one entry, but not its children objects
off	Do not include the lineseries or its children in a legend (default)
children	Include only the children of the lineseries as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

# Lineseries Properties

---

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See `Function Handle Callbacks` for information on how to use function handles to define the callback function.

`Children`  
vector of handles

The empty matrix; line objects have no children.

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

# Lineseries Properties

---

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## `DisplayName`

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the lineseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where  $n$  is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

# Lineseries Properties

---

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is none. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

# Lineseries Properties

---

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the *gca* or *gcf* command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of lineseries object.*

# Lineseries Properties

---

**Line Style Specifiers Table**

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
'.'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`  
size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

`Marker`  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

**Marker Specifiers Table**

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk

Specifier	Marker Type
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

# Lineseries Properties

---

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`

handle of parent axes, `hgggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgggroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

`Selected`

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

SelectionHighlight

{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the Tag property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose Tag is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

Type

string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For lineseries objects, Type is always the string `line`.

UIContextMenu

handle of `uicontextmenu` object

# Lineseries Properties

---

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

`UserData`  
array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`Visible`  
{on} | off

*Visibility of object and its children.*

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

`XData`  
vector | matrix

*x-axis values for graph.* The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped.

`XDataMode`  
{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the x-axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the x-axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatablvariable')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

vector | matrix

# Lineseries Properties

---

*Y-coordinates.* A vector of  $y$ -coordinates defining the values along the  $y$ -axis for the graph. `XData` and `ZData` must be the same length and have the same number of rows.

`YDataSource`

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`ZData`

vector

*Z-coordinates.* A vector defining the  $z$ -coordinates for the graph. `XData` and `YData` must be the same length and have the same number of rows.

`ZDataSource`

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the ZData. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# LineStyle (Line Specification)

---

**Purpose** Line specification string syntax

**Description** Plotting functions accept *string specifiers* as arguments and modify the graph generated accordingly. Three components can be specified in the *string specifiers* along with the plotting command. They are:

- Line style
- Marker symbol
- Color

For example:

```
plot(x,y, '-or')
```

plots y versus x using a dash-dot line (-.), places circular markers (o) at the data points, and colors both line and marker red (r). Specify the components (in any order) as a quoted string after the data arguments. Note that linespecs are single strings, not property-value pairs.

## Plotting Data Points with No Line

If you specify a marker, but not a line style, only the markers are plotted. For example:

```
plot(x,y, 'd')
```

## Line Style Specifiers

You indicate the line styles, marker types, and colors you want to display using *string specifiers*, detailed in the following tables:

Specifier	LineStyle
'_'	Solid line (default)
'--'	Dashed line

# LineStyle (Line Specification)

---

Specifier	LineStyle
'.'	Dotted line
'-.'	Dash-dot line

## Marker Specifiers

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h ' '	Six-pointed star (hexagram)

---

**Note** The point (.) marker type does not change size when the specified value is less than 5.

---

# LineStyle (Line Specification)

---

## Color Specifiers

Specifier	Color
r	Red
g	Green
b	Blue
c	Cyan
m	Magenta
y	Yellow
k	Black
w	White

## Related Properties

This page also describes how to specify the properties of lines used for plotting. MATLAB graphics give you control over these visual characteristics:

- **LineWidth** — Specifies the width (in points) of the line.
- **MarkerEdgeColor** — Specifies the color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).
- **MarkerFaceColor** — Specifies the color of the face of filled markers.
- **MarkerSize** — Specifies the size of the marker in points (must be greater than 0).

In addition, you can specify the **LineStyle**, **Color**, and **Marker** properties instead of using the symbol string. This is useful if you want to specify a color that is not in the list by using RGB values. See **Lineseries Properties** for details on these properties and **ColorSpec** for more information on color.

## Examples

Plot the sine function over three different ranges using different line styles, colors, and markers.

# LineSpec (Line Specification)

```
figure
t = 0:pi/20:2*pi;
plot(t,sin(t),'-.r*')
hold on
plot(t,sin(t-pi/2),'--mo')
plot(t,sin(t-pi),':bs')
hold off
```

Create a plot illustrating how to set line properties:

# LineStyle (Line Specification)

```
figure
plot(t,sin(2*t),'-mo',...
     'LineWidth',2,...
     'MarkerEdgeColor','k',...
     'MarkerFaceColor',[.49 1 .63],...
     'MarkerSize',10)
```

[axes](#) | [line](#) | [plot](#) | [patch](#) | [set](#) | [surface](#) | [ColorSpec](#) | [Lineseries Properties](#)

**Purpose** Synchronize limits of specified 2-D axes

**Syntax** `linkaxes(axes_handles)`  
`linkaxes(axes_handles, 'option')`

**Description** Use `linkaxes` to synchronize the individual axis limits across several figures or subplots within a figure. Calling `linkaxes` makes all input axes have identical limits. Linking axes is best when you want to zoom or pan in one subplot and display the same range of data in another subplot.

`linkaxes(axes_handles)` links the *x*- and *y*-axis limits of the axes specified in the vector `axes_handles`. You can link any number of existing plots or subplots. The `axes_handles` input should be a vector of the handles for each plot or subplot. Entering an array of values results in an error message.

`linkaxes(axes_handles, 'option')` links the axes' `axes_handles` according to the specified option. The *option* argument can be one of the following strings:

<code>x</code>	Link <i>x</i> -axis only.
<code>y</code>	Link <i>y</i> -axis only.
<code>xy</code>	Link <i>x</i> -axis and <i>y</i> -axis.
<code>off</code>	Remove linking.

See the `linkprop` function for more advanced capabilities that allow you to link object properties on any graphics object.

**Tips** The first axes you supply to `linkaxes` determines the *x*- and *y*-limits for all linked axes. This can cause plots to partly or entirely disappear if their limits or scaling are very different. To override this behavior, after calling `linkaxes`, specify the limits of the axes that you want to control with the `set` command, as the third example illustrates.

---

**Note** `linkaxes` is not designed to be transitive across multiple invocations. If you have three axes, `ax1`, `ax2`, and `ax3` and want to link them together, call `linkaxes` with `[ax1, ax2, ax3]` as the first argument. Linking `ax1` to `ax2`, then `ax2` to `ax3`, "unbinds" the `ax1-ax2` linkage.

---

## Examples

You can use interactive zooming or panning (selected from the figure toolbar) to see the effect of axes linking. For example, pan in one graph and notice how the  $x$ -axis also changes in the other. The axes responds in the same way to `zoom` and `pan` directives you type in the Command Window.

This example loads three vectors of data and creates a subplot for each vector. After a three-second pause, it then calls `linkaxes` with the argument `'xy'` to synchronize both the  $x$  and  $y$  axes limits. By specifying the third subplot first to `linkaxes`, you establish its  $y$ -limit for all the subplots:

```
load count.dat % Contains a 3-column vector named count
figure
ax(1) = subplot(3,1,1);
bar(ax(1),count(:,1),'g');
ax(2) = subplot(3,1,2);
bar(ax(2),count(:,2),'b');
ax(3) = subplot(3,1,3);
bar(ax(3),count(:,3),'m');
```

Base the y-axis limits on the bottom subplot.

```
% Wait three seconds and then link the axes  
pause(3)  
linkaxes([ax(3) ax(2) ax(1)], 'xy');
```

# linkaxes

---

Click the **Zoom in** icon  to enter Zoom mode, and click the mouse near the middle of the top axes. You observe all three axes respond the same. If you pan in any of the axes, all of them also respond the same.

Create two subplots containing related bar graphs. Call `linkaxes` to link only the  $x$ -axis limits of the two axes. Unlike in the previous example, the  $y$ -limits of the graphs remain unchanged. The example shows the effect of restricting the  $x$ -values to a range of 5 units and then manually panning either subplot:

```
load count.dat
figure
ax(1) = subplot(2,1,1);
```

# linkaxes

---

```
bar(ax(1),count(:,1),'g');  
ax(2) = subplot(2,1,2);  
bar(ax(2),count(:,2),'b');  
linkaxes(ax,'x');  
% Restrict either axis to show 5 values  
set(ax(1),'XLim',[4.5 9.5])
```

Choose the Pan tool (**Tools > Pan**) (or type `pan on`). Drag the top axes. Both axes pan uniformly in  $x$ , but only the one you pan moves in the  $y$  direction.

---

Create two subplots containing data having different ranges. The first axes handle passed to `linkaxes` determines the data range for all other linked axes. In this example, calling `set` for the lower axes overrides the  $x$ -limits established by the call to `linkaxes`:

```
a1 = subplot(2,1,1);

% Plot 10 numbers on top
plot(randn(10,1));
a2 = subplot(2,1,2);

% Plot 100 numbers below
plot(a2,randn(100,1))

% Link the axes; subplot 2 now out of range
linkaxes([a1 a2], 'x');
```

# linkaxes

---

In order to display the full range of  $x$ -values, override the axes limits that linkaxes established.

```
set(a2, 'xlimmode', 'auto');
```

Now both  $x$ -axes run from 1 to 100. You could also use `set(a2, 'xlim', [1 100])`.

## See Also

[linkdata](#) | [linkprop](#) | [pan](#) | [zoom](#)

# linkdata

---

**Purpose** Automatically update graphs when variables change

**Syntax**

```
linkdata on
linkdata off
linkdata
linkdata(figure_handle,...)
linkobj = linkdata(figure_handle)
```

**Description** `linkdata on` turns on data linking for the current figure.

`linkdata off` turns data linking off.

`linkdata` by itself toggles the state of data linking.

`linkdata(figure_handle,...)` applies the function to the specified figure handle.

`linkobj = linkdata(figure_handle)` returns a *linkdata object* for the specified figure. The object has one read-only property, `Enable`, the string 'on' or 'off', depending on the linked state of the figure.

Data linking connects graphs in figure windows to variables in the base or a function's workspace via their `XDataSource`, `YDataSource`, and `ZDataSource` properties. When you turn on data linking for a figure, MATLAB compares variables in the current (base or function caller) workspace with the `XData`, `YData`, and `ZData` properties of graphs in the affected figure to try to match them. When a match is found, the appropriate `XDataSource`, `YDataSource` and/or `ZDataSource` for the graph are set to strings that name the matching variables.

Any subsequent changes to linked variables are reflected in graphs that use them as data sources and in the Variables editor, if the linked variables are displayed there. Conversely, any changes to plotted data values made at the command line, in the Variables editor, or with the Brush tool (such as deleting or replacing data points), are immediately reflected in the workspace variables linked to the data points.

When a figure containing graphs is linked and any variable identified as `XDataSource`, `YDataSource`, and/or `ZDataSource` changes its values in the workspace, all graphs displaying it in that and other linked figures

automatically update. This operation is equivalent to automatically calling the `refreshdata` function on the corresponding figure when a variable changes.

Linked figure windows identify themselves by the appearance of the Linked Plot information bar at the top of the window. When `linkdata` is off for a figure, the Linked Plot information bar is removed. If `linkdata` cannot unambiguously identify data sources for a graph in a linked figure, it reports this via the Linked Plot information bar, which gives the user an opportunity to identify data sources. The information bar displays a warning icon and a message, **No graphics have data sources** and also prompts **fix it**. Clicking **fix it** opens the Specify Data Source Properties dialog box for identifying variable names and ranges of data sources used in the graph.

## Tips

- “Types of Variables You Can Link” on page 1-3527
- “Restoring Links that Break” on page 1-3527
- “Linking Rapidly Changing Data” on page 1-3528
- “Linking Brushed Graphs” on page 1-3528

## Types of Variables You Can Link

You can use `linkdata` to connect a graph with scalar, vector and matrix numeric variables of any class (including `complex`, if the graphing function can plot it) — essentially any data for which `isnumeric` equals `true`. See “Example 3” on page 1-3530 for instructions on linking complex variables. You can also link plots to numeric fields within structures. You can specify MATLAB expressions as data sources, for example, `sqrt(y)+1`.

## Restoring Links that Break

Refreshing data on a linked plot fails if the strings in the `XDataSource`, `YDataSource`, or `ZDataSource` properties, when evaluated, are incompatible with what is in the current workspace, such that the corresponding `XData`, `YData`, or `ZData` are unable to respond. The visual appearance of the object in the graph is not affected by such failures, so graphic objects show no indication of broken links. Instead,

a warning icon and the message **Failing links** appear on the Linked Plot information bar along with an **Edit** button that opens the Specify Data Sources dialog box.

## Linking Rapidly Changing Data

linkdata buffers updates to data and dispatches them to plots at roughly half-second intervals. This makes data linking not suitable for smoothly animating changes in data values unless they are updated in loops that are forced to execute two times per second or less.

One consequence of buffering link updates is that linkdata might not detect changes in data streams it monitors. If you are running a function that uses `assignin` or `evalin` to update workspace variables, linkdata can sometimes fail to process updates that change values but not the size and class of workspace variables. Such failures only happen when the function itself updates the plot.

## Linking Brushed Graphs

If you link data sources to graphs that have been brushed, their brushing marks can change or vanish. This is because the workspace variables in those graphs now dictate which, if any, observations are brushed, superseding any brushing annotations that were applied to their graphical data (YData, etc.). For more details, see “How Data Linking Affects Data Brushing” on page 1-570 in the brush reference page.

## Examples

### Example 1

Create two variables, graph them as areaseries, and link the plot to them:

```
x = [1:20];  
y = rand(20,3);  
area(x,y)  
linkdata on
```

Change values for linked variable  $y$  in the workspace:

```
y(10,:) = 0;
```

The area graph immediately updates.

## Example 2

Delete a figure if it is not linked, based on a returned linkdata object:

```
ld = linkdata(fig)

ld =
    graphics.linkdata

if strcmp(ld.Enable,'off')
    delete(fig)
end
```

## Example 3

If a graphing function can display a complex variable, you can link such plots. To do so, you need to describe the data sources as expressions to separate the real and imaginary parts of the variable. For example,

```
x = eig(randn(20,20))
```

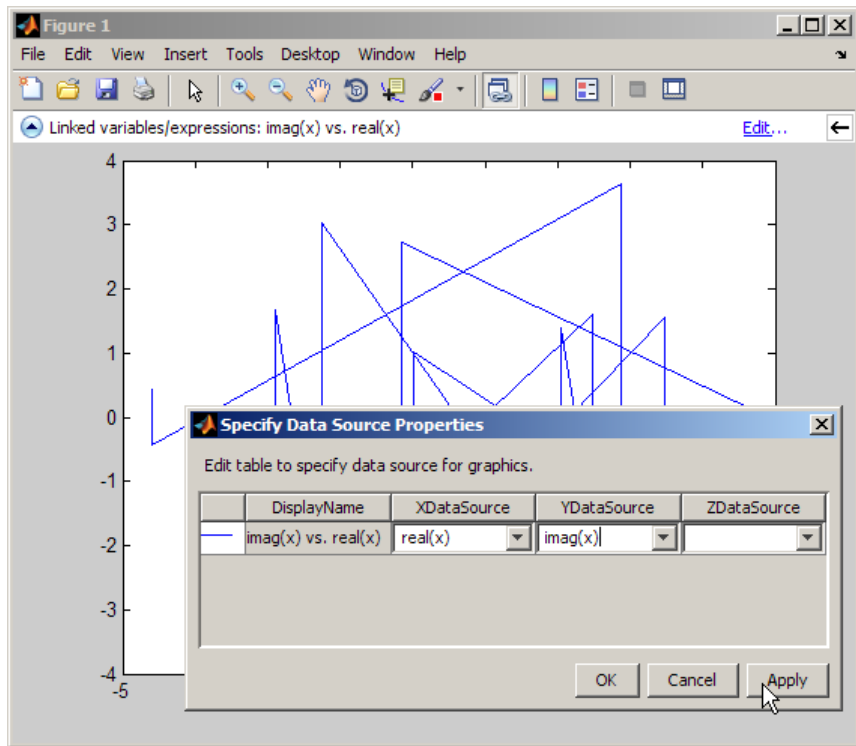

```
whos
```

Name	Size	Bytes	Class	Attributes
x	20x1	320	double	complex

yields a complex vector. You can use `plot` to display the real portion as  $x$  and the imaginary portion as  $y$ , then link the graph to the variable:

```
plot(x)  
linkdata
```

However, `linkdata` cannot unambiguously identify the graph's data sources, and you must tell it by typing `real(x)` and `imag(x)` into the Specify Data Source Properties dialog box that displays when you click **fix it** in the Linked Plot information bar.

To avoid having to type the data source names in the dialog box, you can specify them when you plot:

```
plot(x, 'XDataSource', 'real(x)', 'YDataSource', 'imag(x)')
```

If you subsequently change values of  $x$  programmatically or manually, the plot updates accordingly.

---

**Note** Although you can use data brushing on linked plots of complex data, your brush marks only appear in the plot you are brushing, not in other plots or in the Variables editor. This is because function calls, such as `real(x)` and `imag(x)`, that you specify as data sources are not interpreted when brushing graphed data.

**How To**

- “Making Graphs Responsive with Data Linking”

# linkprop

---

<b>Purpose</b>	Keep same value for corresponding properties of graphics objects
<b>Syntax</b>	<pre>hlink = linkprop(obj_handles, 'PropertyName') hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})</pre>
<b>Description</b>	Use linkprop to maintain the same values for the corresponding properties of different graphics objects.

---

**Note** Use linkprop only with Handle Graphics objects.

---

`hlink = linkprop(obj_handles, 'PropertyName')` maintains the same value for the property *PropertyName* on all objects whose handles appear in `obj_handles`. `linkprop` returns the link object in `hlink`. See “About Link Objects” on page 1-3535 for more information.

`hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})` maintains the same respective values for all properties passed as a cell array on all objects whose handles appear in `obj_handles`.

MATLAB updates the linked properties of all linked objects immediately when `linkprop` is called. The first object in the list `obj_handles` determines the property values for the other objects.

A set of graphics objects can have only one link object connecting their properties at any given time. Calling `linkprop` creates a new link object. This new link object replaces any existing link object that is associated with the objects specified in `obj_handles`. However, you can manage which properties and which objects are linked by calling methods on that object:

- To add an object to the list of linked objects, use the `addtarget` method.
- To link new properties of currently-linked objects, use the `addprop` method.
- To stop linking an object, use the `removetarget` method.

## About Link Objects

- To stop properties from linking, use the `removeprop` method.

The link object that `linkprop` returns stores the mechanism that links the properties of different graphics objects. Therefore, the link object must exist within the context where you want property linking to occur (such as in the base workspace if users are to interact with the objects from the command line or figure tools).

The following list describes ways to maintain a reference to the link object.

- Return the link object as an output argument from a function and keep it in the base workspace while interacting with the linked objects.
- Make the `hlink` variable global.
- Store the `hlink` variable in an object's `UserData` property or in application data. See the “Examples” on page 1-3536 section for an example that uses application data.

## Updating a Link Object

If you want to change either the graphics objects or the properties that are linked, you need to use the link object methods designed for that purpose. These methods are functions that operate only on link objects. To use them, you must first create a link object using `linkprop`.

Method	Purpose
<code>addtarget</code>	Add specified graphics object to the link object's targets.
<code>removetarget</code>	Remove specified graphics object from the link object's targets.
<code>addprop</code>	Add specified property to the linked properties.
<code>removeprop</code>	Remove specified property from the linked properties.

### Method Syntax

```
addtarget(hlink,obj_handles)
```

```
removetarget(hlink,obj_handles)
addprop(hlink,'PropertyName')
removeprop(hlink,'PropertyName')
```

## Method Arguments

- `hlink` — Link object returned by `linkprop`
- `obj_handles` — One or more graphic object handles
- `PropertyName` — Name of a property common to all target objects

## Examples

This example creates four isosurface graphs of fluid flow data, each displaying a different isovalue. The `CameraPosition` and `CameraUpVector` properties of each subplot axes are linked so that the user can rotate all subplots in unison.

After running the example, select **Rotate 3D** from the figure **Tools** menu and observe how all subplots rotate together.

---

**Note** You can run this example or open it in the MATLAB editor.

---

The property linking code is in step 3.

- 1 Define the data using `flow` and specify property values for the isosurface (which is a patch object).

```
[x,y,z,v] = flow;
isoval = [-3,-1,0,1];
props.FaceColor = [0,0,0.5];
props.EdgeColor = 'none';
props.AmbientStrength = 1;
props.FaceLighting = ' gouraud';
```

- 2 Create four subplot axes and add an isosurface graph to each one. Add a title and set viewing and lighting parameters. MATLAB functions used are `subplot`, `patch`, `isosurface`, `title`, and `num2str`.

Also set the viewing and lighting parameters for each axes to be the same by calling `view`, `axis`, and `camlight`.

```
figure
% Preallocate h
h = zeros(1,4);
for k = 1:4
    h(k) = subplot(2,2,k);
    patch(isosurface(x,y,z,v,isoval(k)),props)
    title(h(k),['Isovalue = ',num2str(k)])
    % Set the view and add lighting
    view(h(k),3); axis(h(k),'tight','equal')
    camlight left; camlight right
    % Make axes invisible and title visible
    axis(h(k),'off')
    set(get(h(k),'title'),'Visible','on')
end
```

- 3 Link the `CameraPosition` and `CameraTarget` properties of all subplot axes. Since this code already is completed executing when you rotate the subplots, the link object is stored in the first subplot axes application data. See `setappdata` for more information on using application data.

```
if ishghandle(h)
    hlink = linkprop(h,{'CameraPosition','CameraUpVector'});
    key = 'graphics_linkprop';
    % Store link object on first subplot axes
    setappdata(h(1),key,hlink);
end
```

**4** Turn on the **Rotate 3D** tool. Click any object in the figure and rotate it. As you turn it, all three other subplots turn in the same manner.

```
rotate3d on
```

### Linking an Additional Property

Suppose you want to add the axes `PlotBoxAspectRatio` to the linked properties in the previous example. You can do this by modifying the link object that is stored in the first subplot axes' application data.

- 1 First click the first subplot axes to make it the current axes (since its handle was saved only within the creating function). Then get the link object's handle from application data (`getappdata`).

```
hlink = getappdata(gca, 'graphics_linkprop');
```

- 2 Use the `addprop` method to add a new property to the link object.

```
addprop(hlink, 'PlotBoxAspectRatio')
```

Since `hlink` is a reference to the link object (i.e., not a copy), `addprop` can change the object that is stored in application data.

# linsolve

---

**Purpose** Solve linear system of equations

**Syntax**  
`X = linsolve(A,B)`  
`X = linsolve(A,B,opts)`

**Description** `X = linsolve(A,B)` solves the linear system  $A*X = B$  using LU factorization with partial pivoting when A is square and QR factorization with column pivoting otherwise. The number of rows of A must equal the number of rows of B. If A is m-by-n and B is m-by-k, then X is n-by-k. `linsolve` returns a warning if A is square and ill conditioned or if it is not square and rank deficient.

`[X, R] = linsolve(A,B)` suppresses these warnings and returns R, which is the reciprocal of the condition number of A if A is square, or the rank of A if A is not square.

`X = linsolve(A,B,opts)` solves the linear system  $A*X = B$  or  $A'*X = B$ , using the solver that is most appropriate given the properties of the matrix A, which you specify in `opts`. For example, if A is upper triangular, you can set `opts.UT = true` to make `linsolve` use a solver designed for upper triangular matrices. If A has the properties in `opts`, `linsolve` is faster than `mldivide`, because `linsolve` does not perform any tests to verify that A has the specified properties.

---

**Notes** If A does not have the properties that you specify in `opts`, `linsolve` returns incorrect results and does not return an error message. If you are not sure whether A has the specified properties, use `mldivide` instead.

For small problems, there is no speed benefit in using `linsolve` on triangular matrices as opposed to using the `mldivide` function.

---

The `TRANSA` field of the `opts` structure specifies the form of the linear system you want to solve:

- If you set `opts.TRANSA = false`, `linsolve(A,B,opts)` solves  $A \cdot X = B$ .
- If you set `opts.TRANSA = true`, `linsolve(A,B,opts)` solves  $A' \cdot X = B$ .

The following table lists all the field of `opts` and their corresponding matrix properties. The values of the fields of `opts` must be logical and the default value for all fields is `false`.

Field Name	Matrix Property
LT	Lower triangular
UT	Upper triangular
UHESS	Upper Hessenberg
SYM	Real symmetric or complex Hermitian
POSDEF	Positive definite
RECT	General rectangular
TRANSA	Conjugate transpose — specifies whether the function solves $A \cdot X = B$ or $A' \cdot X = B$

The following table lists all combinations of field values in `opts` that are valid for `linsolve`. A true/false entry indicates that `linsolve` accepts either true or false.

LT	UT	UHESS	SYM	POSDEF	RECT	TRANSA
true	false	false	false	false	true/false	true/false
false	true	false	false	false	true/false	true/false
false	false	true	false	false	false	true/false
false	false	false	true	true/false	false	true/false
false	false	false	false	false	true/false	true/false

# linsolve

---

## Examples

The following code solves the system  $A'x = b$  for an upper triangular matrix  $A$  using both `mldivide` and `linsolve`.

```
A = triu(rand(5,3)); x = [1 1 1 0 0]'; b = A'*x;  
y1 = (A')\b  
opts.UT = true; opts.TRANS_A = true;  
y2 = linsolve(A,b,opts)
```

y1 =

```
1.0000  
1.0000  
1.0000  
0  
0
```

y2 =

```
1.0000  
1.0000  
1.0000  
0  
0
```

---

**Note** If you are working with matrices having different properties, it is useful to create an options structure for each type of matrix, such as `opts_sym`. This way you do not need to change the fields whenever you solve a system with a different type of matrix  $A$ .

---

## See Also

`mldivide`

**Purpose** Generate linearly spaced vectors

**Syntax**  
`y = linspace(a,b)`  
`y = linspace(a,b,n)`

**Description** The `linspace` function generates linearly spaced vectors. It is similar to the colon operator `:`, but gives direct control over the number of points.

`y = linspace(a,b)` generates a row vector `y` of 100 points linearly spaced between and including `a` and `b`.

`y = linspace(a,b,n)` generates a row vector `y` of `n` points linearly spaced between and including `a` and `b`. For `n = 1`, `linspace` returns `b`.

**Examples** Create a vector of 100 linearly spaced numbers from 1 to 500:

```
A = linspace(1,500);
```

Create a vector of 12 linearly spaced numbers from 1 to 36:

```
A = linspace(1,36,12);
```

**See Also** `logspace` | `colon operator`

# RandStream.list

---

**Purpose** Random number generator algorithms

**Class** RandStream

**Syntax** RandStream.list

**Description** RandStream.list lists all the generator algorithms that may be used when creating a random number stream with RandStream or RandStream.create. The available generator algorithms and their properties are given in the following table.

<b>Keyword</b>	<b>Generator</b>	<b>Multiple Stream and Substream Support</b>	<b>Approximate Period In Full Precision</b>
mt19937ar	Mersenne twister (used by default stream at MATLAB startup)	No	$2^{19937} - 1$
mcg16807	Multiplicative congruential generator	No	$2^{31} - 2$
mlfg6331_64	Multiplicative lagged Fibonacci generator	Yes	$2^{124}$
mrg32k3a	Combined multiple recursive generator	Yes	$2^{127}$

<b>Keyword</b>	<b>Generator</b>	<b>Multiple Stream and Substream Support</b>	<b>Approximate Period In Full Precision</b>
shr3cong	Shift-register generator summed with linear congruential generator	No	$2^{64}$
swb2712	Modified subtract with borrow generator	No	$2^{1492}$

See “Choosing a Random Number Generator” for details about these generator algorithms. See <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html> for a full description of the Mersenne twister algorithm.

# listdlg

---

**Purpose** Create and open list-selection dialog box

**Syntax** [Selection,ok] = listdlg('ListString',S)

**Description** [Selection,ok] = listdlg('ListString',S) creates a modal dialog box that enables you to select one or more items from a list. **Selection** is a vector of indices of the selected strings (in single selection mode, its length is 1). **Selection** is [] when **ok** is 0. **ok** is 1 if you click the **OK** button, or 0 if you click the **Cancel** button or close the dialog box. Double-clicking on an item or pressing **Return** when multiple items are selected has the same effect as clicking the **OK** button. The dialog box has a **Select all** button (when in multiple selection mode) that enables you to select all list items.

Inputs are in parameter/value pairs:

Parameter	Description
'ListString'	Cell array of strings that specify the list box items.
'SelectionMode'	String indicating whether one or many items can be selected: 'single' or 'multiple' (the default).
'ListSize'	List box size in pixels, specified as a two-element vector [width height]. Default is [160 300].
'InitialValue'	Vector of indices of the list box items that are initially selected. Default is 1, the first item.
'Name'	String for the dialog box's title. Default is ''.
'PromptString'	String matrix or cell array of strings that appears as text above the list box. Default is {}.
'OKString'	String for the OK button. Default is 'OK'.
'CancelString'	String for the Cancel button. Default is 'Cancel'.
'uh'	Uicontrol button height, in pixels. Default is 18.

---

Parameter	Description
'fus'	Frame/uicontrol spacing, in pixels. Default is 8.
'ffs'	Frame/figure spacing, in pixels. Default is 8.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

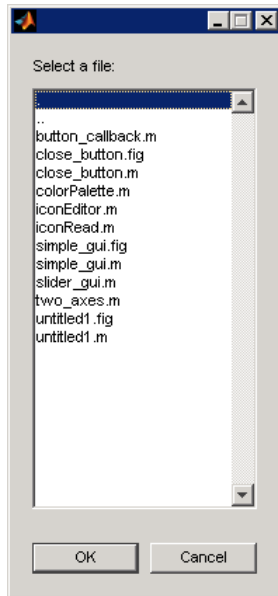

## Examples

This example displays a dialog box that enables the user to select a file from the current directory. The function returns a vector. Its first element is the index to the selected file; its second element is 0 if no selection is made, or 1 if a selection is made.

```
d = dir;
str = {d.name};
[s,v] = listdlg('PromptString','Select a file:',...
               'SelectionMode','single',...
               'ListString',str)
```

# listdlg

---

## See Also

`dialog` | `errordlg` | `helpdlg` | `inputdlg` | `msgbox` | `questdlg` | `warndlg` | `dir` | `figure` | `uiwait` | `uiresume`

**Purpose** List available system fonts

**Syntax** `c = listfonts`  
`c = listfonts(h)`

**Description** `c = listfonts` returns sorted list of available system fonts.  
`c = listfonts(h)` returns sorted list of available system fonts and includes the `FontName` property of the object with handle `h`.

**Tips** Calling `listfonts` returns a list of all fonts residing on your system, possibly including fonts that cannot be used because they are bitmapped. You can instead use the `uifont` utility (a GUI) to preview fonts you might want to use; it only displays fonts that can be rendered in MATLAB figures and GUIs. Like `uifont`, the **Custom Fonts** pane of MATLAB Preferences also previews available fonts and only shows those that can be rendered.

## Examples **Example 1**

This example returns a list of available system fonts similar in format to the one shown.

```
list = listfonts

list =
    'Agency FB'
    'Algerian'
    'Arial'
    ...
    'ZapfChancery'
    'ZapfDingbats'
    'ZWAdobeF'
```

## **Example 2**

This example returns a list of available system fonts with the value of the `FontName` property, for the object with handle `h`, sorted into the list.

# listfonts

---

```
h = uicontrol('Style','text','String',...
             'My Font','FontName','MyFont');
list = listfonts(h)

list =
    'Agency FB'
    'Algerian'
    'Arial'
    ...
    'MyFont'
    ...
    'ZapfChancery'
    'ZapfDingbats'
    'ZWAdobeF'
```

## See Also

uisetfont

**Purpose**

Load variables from file into workspace

**Syntax**

```
load(filename)
load(filename,variables)
load(filename,'-ascii')
load(filename,'-mat')
load(filename,'-mat',variables)
```

```
S = load( ___ )
```

```
load filename
```

**Description**

`load(filename)` loads data from `filename`.

- If `filename` is a MAT-file, then `load(filename)` loads variables in the MAT-File into the MATLAB workspace.
- If `filename` is an ASCII file, then `load(filename)` creates a double-precision array containing data from the file.

`load(filename,variables)` loads the specified variables from the MAT-file, `filename`.

`load(filename,'-ascii')` treats `filename` as an ASCII file, regardless of the file extension.

`load(filename,'-mat')` treats `filename` as a MAT-file, regardless of the file extension.

`load(filename,'-mat',variables)` loads the specified variables from `filename`.

`S = load( ___ )` loads data into `S`, using any of the input arguments in the previous syntax group.

- If `filename` is a MAT-file, then `S` is a structure array.

# load

---

- If `filename` is an ASCII file, then `S` is a double-precision array containing data from the file.

`load filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to load a file named `durer.mat`, these statements are equivalent:

```
load durer.mat      % command form
load('durer.mat')  % function form
```

You can include any of the inputs described in previous syntaxes. For example, to load the variable named `X`:

```
load durer.mat X    % command form
load('durer.mat','X') % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

## Input Arguments

### **filename** - Name of file

`matlab.mat` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `load` function searches for a file named `matlab.mat`.

`filename` can include a file extension and a full or partial path. If `filename` has no extension (that is, no text after a period), `load` looks for a file named `filename.mat`. If `filename` has an extension other than `.mat`, the `load` function treats the file as ASCII data.

When using the command form of `load`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, `load 'filename withspace.mat'`.

ASCII files must contain a rectangular table of numbers, with an equal number of elements in each row. The file delimiter (the character between elements in each row) can be a blank, comma, semicolon, or tab character. The file can contain MATLAB comments (lines that begin with a percent sign, %).

**Example:** 'myFile.mat'

### Data Types

char

### variables - Names of variables to load

string

Names of variables to load, specified as one or more strings. When using the command form of `load`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of variables Input	Variables to Load
<i>var1, ..., varN</i>	Load the listed variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>load('filename.mat', 'A*')</code> or <code>load filename.mat A*</code> loads all variables in the file whose names start with A.
'-regex', <i>expr1, ..., exprN</i>	Load only the variables or fields whose names match the regular expressions, specified as strings. For example, <code>load('filename.mat', '-regex', '^Mon', '^Tue</code> or <code>load filename.mat -regex ^Mon ^Tues</code> loads only the variables in the file whose names begin with Mon or Tues.

# load

---

## Data Types

char

## Output Arguments

### S - Loaded variables or data

structure array | m-by-n array

Loaded variables, returned as a structure array, if `filename` is a MAT-File.

Loaded data, returned as an m-by-n array of type `double`, if `filename` is an ASCII file. `m` is equal to the number of lines in the file, and `n` is equal to the number of values on a line.

## Examples

### Load All Variables from MAT-File

Load all variables from the example MAT-file, `gong.mat`. Check the contents of the workspace before and after the load operation.

```
disp('Contents of workspace before loading file:')  
whos
```

```
disp('Contents of gong.mat:')  
whos('-file','gong.mat')
```

```
load('gong.mat')  
disp('Contents of workspace after loading file:')  
whos
```

You also can use command syntax to load the variables. Clear the previously loaded variables and repeat the `load` operation.

```
clear y Fs
```

```
load gong.mat
```

## Load Specific Variable From MAT-File

Load only variable `y` from example file `handel.mat`. If the workspace already contains variable `y`, the load operation overwrites it with data from the file.

```
load('handel.mat','y')
```

You also can use command syntax to load the variable, `y`.

```
load handel.mat y
```

## Use Regular Expressions to Load Specific Variables

View the contents of the example file, `accidents.mat`.

```
whos -file accidents.mat
```

Name	Size	Bytes	Class	Attributes
<code>datasources</code>	3x1	2724	cell	
<code>hwycols</code>	1x1	8	double	
<code>hwydata</code>	51x17	6936	double	
<code>hwyheaders</code>	1x17	2758	cell	
<code>hwyidx</code>	51x1	408	double	
<code>hwyrows</code>	1x1	8	double	
<code>statelabel</code>	51x1	6596	cell	
<code>ushwydata</code>	1x17	136	double	
<code>uslabel</code>	1x1	138	cell	

Use function syntax to load all variables with names not beginning with `'hwy'`, from the file.

```
load('accidents.mat', '-regexp', '^(!hwy)...')
```

Alternatively, use command syntax to load the same variables.

```
load accidents.mat -regexp '^(!hwy)...'
```

## Load List of Variables into Structure Array

The file, `durer.mat`, contains variables `X`, `caption`, and `map`. Create a cell array of variable names to load.

```
filename = 'durer.mat';  
myVars = {'X','caption'};  
S = load(filename,myVars{:})
```

```
S =  
  
          X: [648x509 double]  
    caption: [2x28 char]
```

Only the variables `X` and `caption` are loaded into the structure array, `S`.

## Load ASCII File

Create an ASCII file from several 4-column matrices, and load the data back into a double-precision array.

```
a = magic(4);  
b = ones(2, 4) * -5.7;  
c = [8 6 4 2];  
save -ascii mydata.dat a b c  
clear a b c
```

```
load mydata.dat -ascii
```

`load` creates an array of type `double` named `mydata`.

View information about `mydata`.

```
whos mydata
```

Name	Size	Bytes	Class	Attributes
mydata	7x4	224	double	

**Algorithms**

If you do not specify an output for the `load` function, MATLAB creates a variable named after the loaded file (minus any file extension). For example, the command

```
load mydata.dat
```

reads data into a variable called `mydata`.

To create the variable name, `load` precedes any leading underscores or digits in `filename` with an `X` and replaces any other nonalphanumeric characters with underscores. For example, the command

```
load 10-May-data.dat
```

creates a variable called `X10_May_data`.

# load (COM)

---

**Purpose** Initialize control object from file

**Syntax** `h.load('filename')`  
`load(h, 'filename')`

**Description** `h.load('filename')` initializes the COM object associated with the interface represented by the MATLAB COM object `h` from file specified in the string `filename`. The file must have been created previously by serializing an instance of the same control.

`load(h, 'filename')` is an alternate syntax for the same operation.

---

**Note** The COM load function is only supported for controls at this time.

---

**Tips** COM functions are available on Microsoft Windows systems only.

**Examples** Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl1.2', [0 0 200 200], f);  
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';  
h.Radius = 50;  
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');  
h.get
```

MATLAB displays the original values:

```
ans =
```

```
Label: 'Label'  
Radius: 20
```

## See Also

save (COM) | actxcontrol | actxserver | release | delete (COM)

# load (serial)

---

**Purpose** Load serial port objects and variables into MATLAB workspace

**Syntax** `load filename`  
`load filename obj1 obj2...`

**Description** `load filename` returns all variables from the file specified by `filename` into the MATLAB workspace.

`load filename obj1 obj2...` returns the serial port objects specified by `obj1 obj2 ...` from the file `filename` into the MATLAB workspace.

`out = load('filename','obj1','obj2',...)` returns the specified serial port objects from the file `filename` as a structure to `out` instead of directly loading them into the workspace. The field names in `out` match the names of the loaded serial port objects.

**Tips** Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

## Examples

---

**Note** This example is based on a Windows platform.

---

Suppose you create the serial port objects `s1` and `s2`, configure a few properties for `s1`, and connect both objects to their instruments:

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s1,'Parity','mark','DataBits',7);
fopen(s1);
fopen(s2);
```

Save `s1` and `s2` to the file `MyObject.mat`, and then load the objects back into the workspace:

```
save MyObject s1 s2;
load MyObject s1;
```

```
load MyObject s2;

get(s1, {'Parity', 'DataBits'})
ans =
    'mark'    [7]
get(s2, {'Parity', 'DataBits'})
ans =
    'none'    [8]
```

# loadlibrary

---

**Purpose** Load shared library into MATLAB

**Syntax** `loadlibrary(libname,hfile)`  
`loadlibrary(libname,hfile,Name,Value)`

`loadlibrary(libname,@protofile)`

`[notfound,warnings] = loadlibrary( __ )`

**Description** `loadlibrary(libname,hfile)` loads functions from shared library, `libname`, defined in header file, `hfile`, into MATLAB.

`loadlibrary(libname,hfile,Name,Value)` loads the library with one or more `Name,Value` arguments.

`loadlibrary(libname,@protofile)` uses a prototype file, `protofile`, in place of a header file.

`[notfound,warnings] = loadlibrary( __ )` returns warning information, and can include any of the input arguments in previous syntaxes.

## Limitations

- You must select a supported C compiler and Perl must be available. To select a compiler, use the `mex -setup` command, described in “Selecting a Compiler on Windows Platforms” or “Selecting a Compiler on UNIX Platforms”. For an up-to-date list of supported compilers, see the Supported and Compatible Compilers Web page.
- Do not call `loadlibrary` if the library is already in memory. To test this condition, call `libisloaded`.
- `loadlibrary` does not support libraries generated by the MATLAB Compiler™ product.
- The MATLAB Shared Library interface does not support library functions with function pointer inputs.

## Input Arguments

### **libname - Name of shared library**

string

Name of shared library, specified as a string. The name is case sensitive and must match the file on your system.

On Microsoft Windows systems, `libname` refers to the name of a shared library (.dll) file. On Linux systems, it refers to the name of a shared object (.so) file. On Apple Macintosh systems, it refers to a dynamic shared library (.dylib).

If you do not include a file extension with the `libname` argument, `loadlibrary` attempts to find the library with either the appropriate platform MEX-file extension or the appropriate platform library extension (usually .dll, .so, or .dylib). For a list of MEX-file extensions, use `mexext`.

### **Data Types**

char

### **hfile - Name of C header file**

string

Name of C header file, specified as a string. The name is case sensitive and must match the file on your system. If you do not include a file extension in the file name, `loadlibrary` uses .h for the extension.

### **Data Types**

char

### **protofile - Name of prototype file**

string

Name of prototype file, specified as a string. The name is case sensitive and must match the file on your system. The string `@protofile` specifies a function handle to the prototype file. When using a prototype file, the only valid Name, Value pair argument is **alias**.

### **Data Types**

char

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **Example:**

#### **'addheader' - Header file**

string

Header file, specified as the comma-separated pair consisting of `'addheader'` and a string. Specify the file name without a file extension.

Each file specified by `addheader` must have a corresponding `#include` statement in the base header file. Use `addheader` to load only the functions defined in the header file that you want to use in MATLAB.

MATLAB does not verify the existence of header files and ignores any that are not needed.

#### **'alias' - Alternative name for library**

string

Alternative name for library, specified as the comma-separated pair consisting of `'alias'` and a string. Associates the specified name with the library. All subsequent calls to MATLAB functions that reference this library must use this alias until the library is unloaded.

#### **'includepath' - Additional search path for header files**

string

Additional search path for header files, specified as the comma-separated pair consisting of `'includepath'` and a string.

#### **'mfilename' - Prototype file**

string

Prototype file, specified as the comma-separated pair consisting of 'mfilename' and a string. Generates a prototype file in the current folder. The prototype file name must be different from the library name. Use this file in place of a header file when loading the library.

### **'thunkfilename' - Thunk file**

string

Thunk file, specified as the comma-separated pair consisting of 'thunkfilename' and a string. Overrides the default thunk file name.

## **Output Arguments**

### **notfound - Names of functions**

cell array

Names of functions found in header files but missing from the library, returned as cell array.

### **Data Types**

cell

### **warnings - Warnings**

character array

Warnings produced while processing the header file, returned as character array.

## **Examples**

### **Load Functions in shrlibsample Library**

Add path to examples folder.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

Load shrlibsample.

```
loadlibrary('shrlibsample')
```

Clean up.

```
unloadlibrary shrlibsample
```

## Load Library Using Header File

The header file for the libmx library is matrix.h.

```
hfile = fullfile(matlabroot,'extern','include','matrix.h');  
loadlibrary('libmx',hfile)
```

Clean up.

```
unloadlibrary libmx
```

## Load Library Using Multiple Header Files

Suppose you have a library, mylib, with the header file, mylib.h. The header file contains the statement, #include header2.h. To use functions defined in header2.h, call loadlibrary with the addheader option.

```
loadlibrary('mylib','mylib.h','addheader','header2')
```

## Load Library Using an Alias Name

Create an alias, lib, for library, shrlibsamle.

```
loadlibrary('shrlibsamle','alias','lib')
```

Use the alias name, lib, to call a function in the library.

```
str = 'This was a Mixed Case string';  
calllib('lib','stringToUpper',str)
```

```
ans =  
    THIS WAS A MIXED CASE STRING
```

Clean up.

```
unloadlibrary lib
```

## Search Alternative Paths for Header Files

Create an alternative path, apath, containing header files.

```
apath = fullfile(matlabroot,'extern','include');
```

Load shrlibsample.

```
loadlibrary('shrlibsample','includepath',apath);
```

Clean up.

```
unloadlibrary shrlibsample
```

## Tips

- If you have more than one library file of the same name, load the first using the library file name, and load the additional libraries using the **alias** option.

## Definitions

### Prototype File

A prototype file is a file of MATLAB commands which you can modify and use in place of a header file.

### Thunk File

A thunk file is a compatibility layer to a 64-bit library generated by MATLAB. The name of the thunk file is `BASENAME_thunk_COMPUTER.c` where *BASENAME* is either the name of the shared library or the `mfilename` prototype name, if specified. *COMPUTER* is the string returned by the `computer` function.

MATLAB compiles this file and creates the file `BASENAME_thunk_COMPUTER.LIBEXT`, where *LIBEXT* is the platform-dependent default shared library extension, for example, `dll` on Windows.

# loadobj

---

<b>Purpose</b>	Modify load process for object
<b>Syntax</b>	<code>b = loadobj(a)</code>
<b>Description</b>	<p><code>b = loadobj(a)</code> is called by the <code>load</code> function if the class of <code>a</code> defines a <code>loadobj</code> method. <code>load</code> returns <code>b</code> as the value loaded from a MAT-file.</p> <p>Define a <code>loadobj</code> method when objects of the class require special processing when loaded from MAT-files. If you define a <code>saveobj</code> method, then define a <code>loadobj</code> method to restore the object to the desired state. Define <code>loadobj</code> as a static method so it can accept as an argument whatever object or structure that you saved in the MAT-file. See “Implement <code>loadobj</code> as a Static Method”.</p> <p>When loading a subclass object, <code>load</code> calls only the subclass <code>loadobj</code> method. If a superclass defines a <code>loadobj</code> method, the subclass inherits this method. However, it is possible that the inherited method does not perform the necessary operations to load the subclass object. Consider overriding superclass <code>loadobj</code> methods.</p> <p>If any superclass in a class hierarchy defines a <code>loadobj</code> method, then the subclass <code>loadobj</code> method must ensure that the subclass and superclass objects load properly. Ensure proper loading by calling the superclass <code>loadobj</code> (or other methods) from the subclass <code>loadobj</code> method. See “Saving and Loading Objects from Class Hierarchies”.</p>
<b>Input Arguments</b>	<p><b>a</b></p> <p>The input argument, <code>a</code>, can be:</p> <ul style="list-style-type: none"><li>• The object as loaded from the MAT-file.</li><li>• A structure created by <code>load</code> (if <code>load</code> cannot resolve the object).</li><li>• A struct returned by the <code>saveobj</code> method.</li></ul>
<b>See Also</b>	<code>load</code>   <code>save</code>   <code>saveobj</code>
<b>Tutorials</b>	<ul style="list-style-type: none"><li>• “Control Save and Load”</li></ul>

**Purpose** Function handles to all local functions in MATLAB file

**Syntax** `fcns = localfunctions`

**Description** `fcns = localfunctions` returns a cell array of function handles, `fcns`, to all local functions in the current file.

You cannot define local functions in the context of the command line, scripts, or anonymous functions, so when you call `localfunctions` from these contexts, you get an empty cell array. Within the cell array, `localfunctions` returns the function handles in an undefined order.

## Examples **Display Handles to Local Functions in File**

Create a new file, `fileWithLocalFunctions.m`, in your MATLAB path. In the main function, call and display the results of `localfunctions`. In the same file, create two local functions.

```
function fileWithLocalFunctions
```

```
    fcns = localfunctions;  
    display(fcns);
```

```
function alocalfunction
```

```
function anotherlocalfunction
```

From the command line, call your function.

```
fileWithLocalFunctions
```

```
fcns =
```

```
    @alocalfunction  
    @anotherlocalfunction
```

## Concepts

- “Local Functions”

---

<b>Purpose</b>	Natural logarithm
<b>Syntax</b>	$Y = \log(X)$
<b>Description</b>	<p>The <code>log</code> function operates element-wise on arrays. Its domain includes complex and negative numbers, which can lead to unexpected results if used unintentionally.</p> <p><math>Y = \log(X)</math> returns the natural logarithm of the elements of <math>X</math>. For complex or negative input, <math>z</math>, where <math>z = a + bi</math>, the <code>log</code> function returns:</p> $\log(z) = \log(\text{abs}(z)) + 1i \cdot \text{atan2}(b, a)$ <p>where <math>\text{atan}(b, a)</math> is on the half-closed interval, <math>(-\pi, \pi]</math>.</p>
<b>Examples</b>	<p>The statement <code>abs(log(-1))</code> is a clever way to generate <math>\pi</math>.</p> <pre>ans =      3.1416</pre>
<b>See Also</b>	<code>exp</code>   <code>log10</code>   <code>log2</code>   <code>logm</code>   <code>reallog</code>

# log10

---

**Purpose** Common (base 10) logarithm

**Syntax**  $Y = \log_{10}(X)$

**Description** The `log10` function operates element-by-element on arrays. Its domain includes complex numbers, which may lead to unexpected results if used unintentionally.

$Y = \log_{10}(X)$  returns the base 10 logarithm of the elements of  $X$ .

**Examples** `log10(realmax)` is 308.2547

and

`log10(eps)` is -15.6536

**See Also** `exp` | `log` | `log2` | `logm`

**Purpose** Compute  $\log(1+x)$  accurately for small values of  $x$

**Syntax**  $y = \log1p(x)$

**Description**  $y = \log1p(x)$  computes  $\log(1+x)$ , compensating for the roundoff in  $1+x$ .  $\log1p(x)$  is more accurate than  $\log(1+x)$  for small values of  $x$ . For small  $x$ ,  $\log1p(x)$  is approximately  $x$ , whereas  $\log(1+x)$  can be zero.

**See Also** `log` | `expm1`

# log2

---

**Purpose** Base 2 logarithm and dissect floating-point numbers into exponent and mantissa

**Syntax**  $Y = \log_2(X)$   
 $[F, E] = \log_2(X)$

**Description**  $Y = \log_2(X)$  computes the base 2 logarithm of the elements of  $X$ .  
 $[F, E] = \log_2(X)$  returns arrays  $F$  and  $E$ . Argument  $F$  is an array of real values, usually in the range  $0.5 \leq \text{abs}(F) < 1$ . For real  $X$ ,  $F$  satisfies the equation:  $X = F \cdot 2.^E$ . Argument  $E$  is an array of integers that, for real  $X$ , satisfy the equation:  $X = F \cdot 2.^E$ .

**Tips** This function corresponds to the ANSI C function `frexp()` and the IEEE floating-point standard function `logb()`. Any zeros in  $X$  produce  $F = 0$  and  $E = 0$ .

**Examples** For IEEE arithmetic, the statement  $[F, E] = \log_2(X)$  yields the values:

<b>X</b>	<b>F</b>	<b>E</b>
1	1/2	1
pi	pi/4	2
-3	-3/4	2
eps	1/2	-51
realmax	1 - eps/2	1024
realmin	1/2	-1021

**See Also** `log` | `pow2`

**Purpose** Convert numeric values to logicals

**Syntax** `L = logical(A)`

**Description** `L = logical(A)` converts numeric input `A` into an array of logical values. Any nonzero element of input `A` is converted to logical 1 (true) and zeros are converted to logical 0 (false). Complex values and NaNs cannot be converted to logical values and result in a conversion error.

**Input Arguments**

**A - Numeric input**

scalar | vector | matrix | multidimensional array

Numeric input, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Examples**

**Pick Odd Elements from Numeric Matrix**

Pick out the odd-numbered elements of a numeric matrix.

Create a numeric matrix.

```
A = [1 -3 2;5 4 7;-8 1 3];
```

Find the modulus, `mod(A,2)`, and convert it to a logical array for indexing.

```
L = logical(mod(A,2))
```

L =

```

     1     1     0
     1     0     1
     0     1     1

```

The array has logical 1 (true) values where `A` is odd.

# logical

---

Use L as a logical index to pick out the odd elements of A.

A(L)

ans =

```
1
5
-3
1
7
3
```

The result is a vector containing all odd elements of A.

Use the logical NOT operator, ~, on L to find the even elements of A.

A(~L)

ans =

```
-8
4
2
```

## Tips

- Most arithmetic operations involving logical arrays return double values. For example, adding zero to a logical array returns a double array.
- Logical arrays also are created by the relational operators (==,<,>,<=,>=,~) and functions like any, all, isnan, isinf, and isfinite.

## See Also

[islogical](#) | [false](#) | [true](#) [Logical Operators: Elementwise](#) | [Logical Operators: Short-circuit](#) |

## Concepts

- “Using Logicals in Array Indexing”

**Purpose** Log-log scale plot

## Syntax

```
loglog(Y)
loglog(X1,Y1,...)
loglog(X1,Y1,LineStyle,...)
loglog(...,'PropertyName',PropertyValue,...)
h = loglog(...)
```

## Description

`loglog(Y)` plots the columns of `Y` versus their index if `Y` contains real numbers. If `Y` contains complex numbers, `loglog(Y)` and `loglog(real(Y),imag(Y))` are equivalent. `loglog` ignores the imaginary component in all other uses of this function.

`loglog(X1,Y1,...)` plots all  $Y_n$  versus  $X_n$  pairs. If only one of  $X_n$  or  $Y_n$  is a matrix, `loglog` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`loglog(X1,Y1,LineStyle,...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples, where `LineStyle` determines line type, marker symbol, and color of the plotted lines. You can mix  $X_n, Y_n, LineSpec$  triples with  $X_n, Y_n$  pairs, for example,

```
loglog(X1,Y1,X2,Y2,LineStyle,X3,Y3)
```

`loglog(...,'PropertyName',PropertyValue,...)` sets property values for all lineseries properties graphics objects created by `loglog`.

`h = loglog(...)` returns a column vector of handles to lineseries graphics objects, one handle per line.

If you do not specify a color when plotting more than one line, `loglog` automatically cycles through the colors and line styles in the order specified by the current axes.

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

## Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

## Examples

### Logarithmic Scale for Both Axes

Create a plot using a logarithmic scale for both the x-axis and the y-axis. Set the `LineStyle` to specify square markers with a solid line and display the grid.

```
x = logspace(-1,2);
y = exp(x);

figure
loglog(x,y,'-s');
grid on
```

**See Also**[LineSpec](#) | [plot](#) | [semilogx](#) | [semilogy](#)

# logm

---

**Purpose** Matrix logarithm

**Syntax**  $L = \text{logm}(A)$   
 $[L, \text{exitflag}] = \text{logm}(A)$

**Description**  $L = \text{logm}(A)$  is the principal matrix logarithm of  $A$ , the inverse of  $\text{expm}(A)$ .  $L$  is the unique logarithm for which every eigenvalue has imaginary part lying strictly between  $-\pi$  and  $\pi$ . If  $A$  is singular or has any eigenvalues on the negative real axis, the principal logarithm is undefined. In this case, `logm` computes a nonprincipal logarithm and returns a warning message.

$[L, \text{exitflag}] = \text{logm}(A)$  returns a scalar `exitflag` that describes the exit condition of `logm`:

- If `exitflag` = 0, the algorithm was successfully completed.
- If `exitflag` = 1, too many matrix square roots had to be computed. However, the computed value of  $L$  might still be accurate.

The input  $A$  can have class `double` or `single`.

**Tips** If  $A$  is real symmetric or complex Hermitian, then so is  $\text{logm}(A)$ .

Some matrices, like  $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ , do not have any logarithms, real or complex, so `logm` cannot be expected to produce one.

**Limitations** For most matrices:  
 $\text{logm}(\text{expm}(A)) = A = \text{expm}(\text{logm}(A))$

These identities may fail for some  $A$ . For example, if the computed eigenvalues of  $A$  include an exact zero, then  $\text{logm}(A)$  generates infinity. Or, if the elements of  $A$  are too large,  $\text{expm}(A)$  may overflow.

**Examples** Suppose  $A$  is the 3-by-3 matrix

$$\begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix}$$

$$\begin{matrix} 0 & 0 & -1 \end{matrix}$$

and  $Y = \text{expm}(A)$  is

$Y =$

$$\begin{matrix} 2.7183 & 1.7183 & 1.0862 \\ 0 & 1.0000 & 1.2642 \\ 0 & 0 & 0.3679 \end{matrix}$$

Then  $A = \text{logm}(Y)$  produces the original matrix  $A$ .

$Y =$

$$\begin{matrix} 1.0000 & 1.0000 & 0.0000 \\ 0 & 0 & 2.0000 \\ 0 & 0 & -1.0000 \end{matrix}$$

But  $\text{log}(A)$  involves taking the logarithm of zero, and so produces

ans =

$$\begin{matrix} 0.0000 & 0 & -35.5119 \\ -\text{Inf} & -\text{Inf} & 0.6931 \\ -\text{Inf} & -\text{Inf} & 0.0000 + 3.1416i \end{matrix}$$

## Algorithms

The algorithm `logm` uses is described in [1].

**Purpose** Generate logarithmically spaced vectors

**Syntax**

```
y = logspace(a,b)
y = logspace(a,b,n)
y = logspace(a,pi)
```

**Description**

The `logspace` function generates logarithmically spaced vectors. Especially useful for creating frequency vectors, it is a logarithmic equivalent of `linspace` and the “:” or colon operator.

`y = logspace(a,b)` generates a row vector `y` of 50 logarithmically spaced points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,b,n)` generates `n` points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,pi)` generates the points between  $10^a$  and  $\pi$ , which is useful for digital signal processing where frequencies over this interval go around the unit circle.

**Tips** All the arguments to `logspace` must be scalars.

**See Also** `linspace` | colon operator

# lookfor

---

<b>Purpose</b>	Search for keyword in all help entries
<b>Alternatives</b>	As an alternative to the <code>lookfor</code> function, use the Function Browser.
<b>Syntax</b>	<code>lookfor topic</code> <code>lookfor topic -all</code>
<b>Description</b>	<p><code>lookfor topic</code> searches for the string <code>topic</code> in the first comment line (the H1 line) of the help text in all MATLAB program files found on the search path. For all files in which a match occurs, <code>lookfor</code> displays the H1 line.</p> <p><code>lookfor topic -all</code> searches the entire first comment block of a MATLAB program file looking for <code>topic</code>.</p>
<b>Examples</b>	<p>For example:</p> <pre>lookfor inverse</pre> <p>finds at least a dozen matches, including H1 lines containing "inverse hyperbolic cosine," "two-dimensional inverse FFT," and "pseudoinverse." Contrast this with</p> <pre>which inverse</pre> <p>or</p> <pre>what inverse</pre> <p>These functions run more quickly, but probably fail to find anything because MATLAB does not have a function <code>inverse</code>.</p> <p>In summary, <code>what</code> lists the functions in a given folder, <code>which</code> finds the folder containing a given function or file, and <code>lookfor</code> finds all functions in all folders that might have something to do with a given keyword.</p> <p>Even more extensive than the <code>lookfor</code> function are the find features in the Current Folder browser. For example, you can look for all occurrences of a specified word in all the MATLAB program files in the</p>

current folder and its subfolders. For more information, see “Finding Files and Folders”.

## **How To**

- “Find Functions to Use”
- “Search Syntax and Tips”

# lower

---

**Purpose** Convert string to lowercase

**Syntax**  
`t = lower('str')`  
`B = lower(A)`

**Description** `t = lower('str')` returns the string formed by converting any uppercase characters in `str` to the corresponding lowercase characters and leaving all other characters unchanged.

`B = lower(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `lower` to each string within `A`.

**Examples** `lower('MathWorks')` is `mathworks`.

**Tips** Character sets supported:

- PC: Latin-1 for the Microsoft Windows operating system
- Other: ISO Latin-1 (ISO 8859-1)

**See Also** `upper`

## How To

- “Working with Files and Folders”

**Purpose**

Least-squares solution in presence of known covariance

**Syntax**

```
x = lscov(A,b)
x = lscov(A,b,w)
x = lscov(A,b,V)
x = lscov(A,b,V,alg)
[x,stdx] = lscov(...)
[x,stdx,mse] = lscov(...)
[x,stdx,mse,S] = lscov(...)
```

**Description**

`x = lscov(A,b)` returns the ordinary least squares solution to the linear system of equations  $A*x = b$ , i.e.,  $x$  is the  $n$ -by-1 vector that minimizes the sum of squared errors  $(b - A*x)'*(b - A*x)$ , where  $A$  is  $m$ -by- $n$ , and  $b$  is  $m$ -by-1.  $b$  can also be an  $m$ -by- $k$  matrix, and `lscov` returns one solution for each column of  $b$ . When  $\text{rank}(A) < n$ , `lscov` sets the maximum possible number of elements of  $x$  to zero to obtain a "basic solution".

`x = lscov(A,b,w)`, where  $w$  is a vector length  $m$  of real positive weights, returns the weighted least squares solution to the linear system  $A*x = b$ , that is,  $x$  minimizes  $(b - A*x)'*diag(w)*(b - A*x)$ .  $w$  typically contains either counts or inverse variances.

`x = lscov(A,b,V)`, where  $V$  is an  $m$ -by- $m$  real symmetric positive definite matrix, returns the generalized least squares solution to the linear system  $A*x = b$  with covariance matrix proportional to  $V$ , that is,  $x$  minimizes  $(b - A*x)'*inv(V)*(b - A*x)$ .

More generally,  $V$  can be positive semidefinite, and `lscov` returns  $x$  that minimizes  $e'*e$ , subject to  $A*x + T*e = b$ , where the minimization is over  $x$  and  $e$ , and  $T*T' = V$ . When  $V$  is semidefinite, this problem has a solution only if  $b$  is consistent with  $A$  and  $V$  (that is,  $b$  is in the column space of  $[A \ T]$ ), otherwise `lscov` returns an error.

By default, `lscov` computes the Cholesky decomposition of  $V$  and, in effect, inverts that factor to transform the problem into ordinary least squares. However, if `lscov` determines that  $V$  is semidefinite, it uses an orthogonal decomposition algorithm that avoids inverting  $V$ .

`x = lscov(A,b,V,alg)` specifies the algorithm used to compute `x` when `V` is a matrix. `alg` can have the following values:

- `'chol'` uses the Cholesky decomposition of `V`.
- `'orth'` uses orthogonal decompositions, and is more appropriate when `V` is ill-conditioned or singular, but is computationally more expensive.

`[x,stdx] = lscov(...)` returns the estimated standard errors of `x`. When `A` is rank deficient, `stdx` contains zeros in the elements corresponding to the necessarily zero elements of `x`.

`[x,stdx,mse] = lscov(...)` returns the mean squared error. If `b` is assumed to have covariance matrix  $\sigma^2V$  (or  $(\sigma^2)\times\text{diag}(1/M)$ ), then `mse` is an estimate of  $\sigma^2$ .

`[x,stdx,mse,S] = lscov(...)` returns the estimated covariance matrix of `x`. When `A` is rank deficient, `S` contains zeros in the rows and columns corresponding to the necessarily zero elements of `x`. `lscov` cannot return `S` if it is called with multiple right-hand sides, that is, if `size(B,2) > 1`.

The standard formulas for these quantities, when `A` and `V` are full rank, are

- $x = \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot A' \cdot \text{inv}(V) \cdot B$
- $\text{mse} = B' \cdot (\text{inv}(V) - \text{inv}(V) \cdot A \cdot \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot A' \cdot \text{inv}(V)) \cdot B ./ (m-n)$
- $S = \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot \text{mse}$
- $\text{stdx} = \text{sqrt}(\text{diag}(S))$

However, `lscov` uses methods that are faster and more stable, and are applicable to rank deficient cases.

`lscov` assumes that the covariance matrix of `B` is known only up to a scale factor. `mse` is an estimate of that unknown scale factor, and `lscov` scales the outputs `S` and `stdx` appropriately. However, if `V` is known to be exactly the covariance matrix of `B`, then that scaling is unnecessary.

To get the appropriate estimates in this case, you should rescale  $S$  and  $stdx$  by  $1/mse$  and  $\sqrt{1/mse}$ , respectively.

## Algorithms

The vector  $x$  minimizes the quantity  $(A*x-b)'*inv(V)*(A*x-b)$ . The classical linear algebra solution to this problem is

$$x = inv(A'*inv(V)*A)*A'*inv(V)*b$$

but the `lscov` function instead computes the QR decomposition of  $A$  and then modifies  $Q$  by  $V$ .

## Examples

### Example 1 – Computing Ordinary Least Squares

The MATLAB backslash operator (`\`) enables you to perform linear regression by computing ordinary least-squares (OLS) estimates of the regression coefficients. You can also use `lscov` to compute the same OLS estimates. By using `lscov`, you can also compute estimates of the standard errors for those coefficients, and an estimate of the standard deviation of the regression error term:

```
x1 = [.2 .5 .6 .8 1.0 1.1]';
x2 = [.1 .3 .4 .9 1.1 1.4]';
X = [ones(size(x1)) x1 x2];
y = [.17 .26 .28 .23 .27 .34]';
```

```
a = X\y
a =
    0.1203
    0.3284
   -0.1312
```

```
[b,se_b,mse] = lscov(X,y)
b =
    0.1203
    0.3284
   -0.1312
se_b =
    0.0643
```

```
    0.2267
    0.1488
mse =
    0.0015
```

## Example 2 – Computing Weighted Least Squares

Use `lscov` to compute a weighted least-squares (WLS) fit by providing a vector of relative observation weights. For example, you might want to downweight the influence of an unreliable observation on the fit:

```
w = [1 1 1 1 1 .1]';

[bw,sew_b,msew] = lscov(X,y,w)
bw =
    0.1046
    0.4614
   -0.2621
sew_b =
    0.0309
    0.1152
    0.0814
msew =
    3.4741e-004
```

## Example 3 – Computing General Least Squares

Use `lscov` to compute a general least-squares (GLS) fit by providing an observation covariance matrix. For example, your data may not be independent:

```
V = .2*ones(length(x1)) + .8*diag(ones(size(x1)));

[bg,sew_b,mseg] = lscov(X,y,V)
bg =
    0.1203
    0.3284
   -0.1312
sew_b =
```

```

0.0672
0.2267
0.1488
mse =
0.0019

```

#### Example 4 – Estimating the Coefficient Covariance Matrix

Compute an estimate of the coefficient covariance matrix for either OLS, WLS, or GLS fits. The coefficient standard errors are equal to the square roots of the values on the diagonal of this covariance matrix:

```
[b,se_b,mse,S] = lscov(X,y);
```

```

S
S =
    0.0041    -0.0130     0.0075
   -0.0130     0.0514    -0.0328
    0.0075    -0.0328     0.0221

```

```

[se_b sqrt(diag(S))]
ans =
    0.0643     0.0643
    0.2267     0.2267
    0.1488     0.1488

```

lsqnonneg | qr

# lsqnonneg

---

**Purpose** Solve nonnegative least-squares constraints problem

**Equation** Solves nonnegative least-squares curve fitting problems of the form

$$\min_x \|C \cdot x - d\|_2^2, \text{ where } x \geq 0.$$

**Syntax**

```
x = lsqnonneg(C,d)
x = lsqnonneg(C,d,options)
[x,resnorm] = lsqnonneg(...)
[x,resnorm,residual] = lsqnonneg(...)
[x,resnorm,residual,exitflag] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)
```

**Description**

`x = lsqnonneg(C,d)` returns the vector `x` that minimizes `norm(C*x-d)` subject to `x >= 0`. `C` and `d` must be real.

`x = lsqnonneg(C,d,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `lsqnonneg` uses these `options` structure fields:

`Display` Level of display. 'off' displays no output; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge.

`TolX` Termination tolerance on `x`.

`[x,resnorm] = lsqnonneg(...)` returns the value of the squared 2-norm of the residual: `norm(C*x-d)^2`.

`[x,resnorm,residual] = lsqnonneg(...)` returns the residual, `d-C*x`.

`[x,resnorm,residual,exitflag] = lsqnonneg(...)` returns a value `exitflag` that describes the exit condition of `lsqnonneg`:

>0            Indicates that the function converged to a solution  $x$ .

0             Indicates that the iteration count was exceeded.  
 Increasing the tolerance (TolX parameter in options)  
 may lead to a solution.

`[x,resnorm,residual,exitflag,output] = lsqnonneg(...)` returns a structure output that contains information about the operation in the following fields:

<code>algorithm</code>	<code>'active-set'</code>
<code>iterations</code>	The number of iterations taken
<code>message</code>	Exit message

`[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)` returns the dual vector (Lagrange multipliers) `lambda`, where `lambda(i) <= 0` when `x(i)` is (approximately) 0, and `lambda(i)` is (approximately) 0 when `x(i) > 0`.

## Examples

Compare the unconstrained least squares solution to the `lsqnonneg` solution for a 4-by-2 problem:

```
C = [
    0.0372    0.2869
    0.6861    0.7071
    0.6233    0.6245
    0.6344    0.6170];
d = [
    0.8587
    0.1781
    0.0747
    0.8405];
[C\d lsqnonneg(C,d)] =
   -2.5627         0
    3.1108    0.6929
[norm(C*(C\d)-d) norm(C*lsqnonneg(C,d)-d)] =
    0.6674    0.9118
```

# lsqnonneg

---

The solution from `lsqnonneg` does not fit as well (has a larger residual), as the least squares solution. However, the nonnegative least squares solution has no negative components.

## Algorithms

`lsqnonneg` uses the algorithm described in [1]. The algorithm starts with a set of possible basis vectors and computes the associated dual vector `lambda`. It then selects the basis vector corresponding to the maximum value in `lambda` in order to swap out of the basis in exchange for another possible candidate. This continues until `lambda <= 0`.

## See Also

`optimset`

**Purpose**

LSQR method

**Syntax**

```

x = lsqr(A,b)
lsqr(A,b,tol)
lsqr(A,b,tol,maxit)
lsqr(A,b,tol,maxit,M)
lsqr(A,b,tol,maxit,M1,M2)
lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,
x0)

```

**Description**

`x = lsqr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$  if  $A$  is consistent, otherwise it attempts to solve the least squares solution  $x$  that minimizes  $\text{norm}(b-A*x)$ . The  $m$ -by- $n$  coefficient matrix  $A$  need not be square but it should be large and sparse. The column vector  $b$  must have length  $m$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A'*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `lsqr` converges, a message to that effect is displayed. If `lsqr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$  and the iteration number at which the method stopped or failed.

`lsqr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `lsqr` uses the default,  $1e-6$ .

`lsqr(A,b,tol,maxit)` specifies the maximum number of iterations.

`lsqr(A,b,tol,maxit,M)` and `lsqr(A,b,tol,maxit,M1,M2)` use  $n$ -by- $n$  preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $A*inv(M)*y = b$  for  $y$ , where  $y = M*x$ . If  $M$  is `[]` then `lsqr` applies no preconditioner.  $M$  can be a function `mfun` such that `mfun(x, 'notransp')` returns  $M \setminus x$  and `mfun(x, 'transp')` returns  $M' \setminus x$ .

`lsqr(A,b,tol,maxit,M1,M2,x0)` specifies the  $n$ -by-1 initial guess. If `x0` is `[]`, then `lsqr` uses the default, an all zero vector.

`[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a convergence flag.

Flag	Convergence
0	<code>lsqr</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>lsqr</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	<code>lsqr</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>lsqr</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if you specify the `flag` output.

`[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns an estimate of the relative residual norm  $(b-A*x)/norm(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns the iteration number at which `x` was computed, where  $0 \leq iter \leq maxit$ .

`[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of the residual norm estimates at each iteration, including  $norm(b-A*x0)$ .

`[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2, x0)` also returns a vector of estimates of the scaled normal equations residual at each iteration:  $\text{norm}((A \cdot \text{inv}(M))' * (B - A * X)) / \text{norm}(A \cdot \text{inv}(M), 'fro')$ . Note that the estimate of  $\text{norm}(A \cdot \text{inv}(M), 'fro')$  changes, and hopefully improves, at each iteration.

## Examples

### Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
```

```
x = lsqr(A,b,tol,maxit,M1,M2);
```

displays the following message:

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

### Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in a function `run_lsqr` that

- Calls `lsqr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_lsqr` are available to `afun`.

The following shows the code for `run_lsqr`:

```
function x1 = run_lsqr
n = 100;
```

```
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = lsqr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
    if strcmp(transp_flag,'transp') % y = A'*x
        y = 4 * x;
        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
        y(2:n) = y(2:n) - x(1:n-1);
    elseif strcmp(transp_flag,'notransp') % y = A*x
        y = 4 * x;
        y(2:n) = y(2:n) - 2 * x(1:n-1);
        y(1:n-1) = y(1:n-1) - x(2:n);
    end
end
end
```

When you enter

```
x1=run_lsqr;
```

MATLAB software displays the message

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

| function\_handle

**Purpose** Determine less than

**Syntax** A < B  
lt(A,B)

**Description** A < B returns an array with elements set to logical 1 (true) where A is less than B; otherwise, it returns logical 0 (false). The test compares only the real part of numeric arrays. lt returns logical 0 (false) where A or B have NaN or undefined categorical elements.

lt(A,B) is an alternate way to execute A < B, but is rarely used. It enables operator overloading for classes.

## **Input Arguments**

### **A - Left array**

numeric array | logical array | character array | ordinal categorical array

Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

### **B - Right array**

numeric array | logical array | character array | ordinal categorical array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

## Examples

### Test Vector Elements

Determine if vector elements are less than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than 12.

```
A < 12
```

```
ans =
```

```
     1     0     0     1     1     1     1     0
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than 12.

```
A(A < 12)
```

```
ans =
```

```
     1     7     9    11     2
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values less than 9 with the value 10.

```
A(A < 9) = 10
```

```
A =
```

```
    16    10    10    13
    10    11    10    10
     9    10    10    12
    10    14    15    10
```

The result is a new matrix whose smallest element is 9.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
 'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
    large    medium    small
    medium    small    large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values less than the category 'medium'.

```
A < 'medium'
```

```
ans =
```

```
    0    0    1
    0    1    0
```

A value of logical 1 (true) indicates a value less than the category 'medium'.

Compare the rows of A.

```
A(1,:) < A(2,:)
```

```
ans =
```

```
    0    0    1
```

The function returns logical 1 (true) where the first row has a category value less than the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than 3.

```
A(A < 3)
```

```
ans =
```

```
1.0000 + 1.0000i  2.0000 - 2.0000i  1.0000 + 3.0000i  1.0000 - 2.0000i
```

It compares only the real part of the elements in A.

Use `abs` to find which elements are within a radius of 3 from the origin.

```
A(abs(A) < 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 - 2.0000i
```

The result has one less element. The element  $1.0000 + 3.0000i$  is not within a radius of 3 from the origin.

**See Also**

**Concepts**

- “Ordinal Categorical Arrays”

**Purpose**

LU matrix factorization

**Syntax**

```

Y = lu(A)
[L,U] = lu(A)
[L,U,P] = lu(A)
[L,U,P,Q] = lu(A)
[L,U,P,Q,R] = lu(A)
[...] = lu(A,'vector')
[...] = lu(A,thresh)
[...] = lu(A,thresh,'vector')

```

**Description**

The `lu` function expresses a matrix  $A$  as the product of two essentially triangular matrices, one of them a permutation of a lower triangular matrix and the other an upper triangular matrix. The factorization is often called the  $LU$ , or sometimes the  $LR$ , factorization.  $A$  can be rectangular.

`Y = lu(A)` returns matrix  $Y$  that, for sparse  $A$ , contains the strictly lower triangular  $L$ , i.e., without its unit diagonal, and the upper triangular  $U$  as submatrices. That is, if `[L,U,P] = lu(A)`, then  $Y = U+L - \text{eye}(\text{size}(A))$ . For nonsparse  $A$ ,  $Y$  is the output from the LAPACK `dgetrf` or `zgetrf` routine. The permutation matrix  $P$  is not returned.

`[L,U] = lu(A)` returns an upper triangular matrix in  $U$  and a permuted lower triangular matrix in  $L$  such that  $A = L*U$ . Return value  $L$  is a product of lower triangular and permutation matrices.

`[L,U,P] = lu(A)` returns an upper triangular matrix in  $U$ , a lower triangular matrix  $L$  with a unit diagonal, and a permutation matrix  $P$ , such that  $L*U = P*A$ . The statement `lu(A,'matrix')` returns identical output values.

`[L,U,P,Q] = lu(A)` for sparse nonempty  $A$ , returns a unit lower triangular matrix  $L$ , an upper triangular matrix  $U$ , a row permutation matrix  $P$ , and a column reordering matrix  $Q$ , so that  $P*A*Q = L*U$ . If  $A$  is empty or not sparse, `lu` displays an error message. The statement `lu(A,'matrix')` returns identical output values.

`[L,U,P,Q,R] = lu(A)` returns unit lower triangular matrix L, upper triangular matrix U, permutation matrices P and Q, and a diagonal scaling matrix R so that  $P*(R\backslash A)*Q = L*U$  for sparse non-empty A. Typically, but not always, the row-scaling leads to a sparser and more stable factorization. The statement `lu(A, 'matrix')` returns identical output values.

`[...] = lu(A, 'vector')` returns the permutation information in two row vectors p and q. You can specify from 1 to 5 outputs. Output p is defined as  $A(p,:) = L*U$ , output q is defined as  $A(p,q) = L*U$ , and output R is defined as  $R(:,p)\backslash A(:,q) = L*U$ .

`[...] = lu(A,thresh)` controls pivoting. This syntax applies to sparse matrices only. The `thresh` input is a one- or two-element vector of type `single` or `double` that defaults to `[0.1, 0.001]`. If A is a square matrix with a mostly symmetric structure and mostly nonzero diagonal, MATLAB uses a symmetric pivoting strategy. For this strategy, the diagonal where

$$A(i,j) \geq \text{thresh}(2) * \max(\text{abs}(A(j:m,j)))$$

is selected. If the diagonal entry fails this test, a pivot entry below the diagonal is selected, using `thresh(1)`. In this case, L has entries with absolute value  $1/\min(\text{thresh})$  or less.

If A is not as described above, MATLAB uses an asymmetric strategy. In this case, the sparsest row i where

$$A(i,j) \geq \text{thresh}(1) * \max(\text{abs}(A(j:m,j)))$$

is selected. A value of 1.0 results in conventional partial pivoting. Entries in L have an absolute value of  $1/\text{thresh}(1)$  or less. The second element of the `thresh` input vector is not used when MATLAB uses an asymmetric strategy.

Smaller values of `thresh(1)` and `thresh(2)` tend to lead to sparser LU factors, but the solution can become inaccurate. Larger values can lead to a more accurate solution (but not always), and usually an increase in the total work and memory usage. The statement `lu(A,thresh, 'matrix')` returns identical output values.

[...] = lu(A,thresh,'vector') controls the pivoting strategy and also returns the permutation information in row vectors, as described above. The thresh input must precede 'vector' in the input argument list.

---

**Note** In rare instances, incorrect factorization results in  $P*A*Q \neq L*U$ . Increase thresh, to a maximum of 1.0 (regular partial pivoting), and try again.

---

## Tips

Most of the algorithms for computing LU factorization are variants of Gaussian elimination. The factorization is a key step in obtaining the inverse with inv and the determinant with det. It is also the basis for the linear equation solution or matrix division obtained with \ and /.

## Arguments

A	Rectangular matrix to be factored.
thresh	Pivot threshold for sparse matrices. Valid values are in the interval [0, 1]. If you specify the fourth output Q, the default is 0.1. Otherwise, the default is 1.0.
L	Factor of A. Depending on the form of the function, L is either a unit lower triangular matrix, or else the product of a unit lower triangular matrix with P'.
U	Upper triangular matrix that is a factor of A.
P	Row permutation matrix satisfying the equation $L*U = P*A$ , or $L*U = P*A*Q$ . Used for numerical stability.
Q	Column permutation matrix satisfying the equation $P*A*Q = L*U$ . Used to reduce fill-in in the sparse case.
R	Row-scaling matrix

**Examples****Example 1**

Start with

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 0 \end{bmatrix};$$

To see the LU factorization, call `lu` with two output arguments.

$$[L1,U] = \text{lu}(A)$$

L1 =

$$\begin{bmatrix} 0.1429 & 1.0000 & 0 \\ 0.5714 & 0.5000 & 1.0000 \\ 1.0000 & 0 & 0 \end{bmatrix}$$

U =

$$\begin{bmatrix} 7.0000 & 8.0000 & 0 \\ 0 & 0.8571 & 3.0000 \\ 0 & 0 & 4.5000 \end{bmatrix}$$

Notice that L1 is a permutation of a lower triangular matrix: if you switch rows 2 and 3, and then switch rows 1 and 2, the resulting matrix is lower triangular and has 1s on the diagonal. Notice also that U is upper triangular. To check that the factorization does its job, compute the product

`L1*U`

which returns the original A. The inverse of the example matrix,  $X = \text{inv}(A)$ , is actually computed from the inverses of the triangular factors

$$X = \text{inv}(U) * \text{inv}(L1)$$

Using three arguments on the left side to get the permutation matrix as well,

$$[L2,U,P] = \text{lu}(A)$$

returns a truly lower triangular L2, the same value of U, and the permutation matrix P.

L2 =

1.0000	0	0
0.1429	1.0000	0
0.5714	0.5000	1.0000

U =

7.0000	8.0000	0
0	0.8571	3.0000
0	0	4.5000

P =

0	0	1
1	0	0
0	1	0

Note that  $L2 = P*L1$ .

P\*L1

ans =

1.0000	0	0
0.1429	1.0000	0
0.5714	0.5000	1.0000

To verify that  $L2*U$  is a permuted version of A, compute  $L2*U$  and subtract it from  $P*A$ :

$P*A - L2*U$

ans =

0	0	0
0	0	0
0	0	0

In this case,  $\text{inv}(U) * \text{inv}(L)$  results in the permutation of  $\text{inv}(A)$  given by  $\text{inv}(P) * \text{inv}(A)$ .

The determinant of the example matrix is

$$d = \det(A)$$

$$d = 27$$

It is computed from the determinants of the triangular factors

$$d = \det(L) * \det(U)$$

The solution to  $Ax = b$  is obtained with matrix division

$$x = A \backslash b$$

The solution is actually computed by solving two triangular systems

$$y = L \backslash b$$

$$x = U \backslash y$$

### **Example 2**

The 1-norm of their difference is within roundoff error, indicating that  $L*U = P*B*Q$ .

Generate a 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster-Fuller geodesic dome.

$$B = \text{bucky};$$

Use the sparse matrix syntax with four outputs to get the row and column permutation matrices.

$$[L,U,P,Q] = \text{lu}(B);$$

Apply the permutation matrices to B, and subtract the product of the lower and upper triangular matrices.

$$Z = P*B*Q - L*U;$$

```
norm(Z,1)

ans =
    7.9936e-015
```

### Example 3

This example illustrates the benefits of using the 'vector' option. Note how much memory is saved by using the `lu(F, 'vector')` syntax.

```
F = gallery('uniformdata',[1000 1000],0);
g = sum(F,2);
[L,U,P] = lu(F);
[L,U,p] = lu(F,'vector');
whos P p
```

Name	Size	Bytes	Class	Attributes
P	1000x1000	8000000	double	
p	1x1000	8000	double	

The following two statements are equivalent. The first typically requires less time:

```
x = U \ (L \ (g(p, :)));
y = U \ (L \ (P * g));
```

# luinc

---

**Purpose** Sparse incomplete LU factorization

---

**Note** `luinc` has been removed. Use `ilu` instead.

---

**Syntax**

```
luinc(A, '0')
luinc(A, droptol)
luinc(A, options)
[L,U] = luinc(A, '0')
[L,U] = luinc(A, options)
[L,U,P] = luinc(...)
```

**Description** `luinc` produces a unit lower triangular matrix, an upper triangular matrix, and a permutation matrix.

`luinc(A, '0')` computes the incomplete LU factorization of level 0 of a square sparse matrix. The triangular factors have the same sparsity pattern as the permutation of the original sparse matrix `A`, and their product agrees with the permuted `A` over its sparsity pattern. `luinc(A, '0')` returns the strict lower triangular part of the factor and the upper triangular factor embedded within the same matrix. The permutation information is lost, but `nnz(luinc(A, '0')) = nnz(A)`, with the possible exception of some zeros due to cancellation.

`luinc(A, droptol)` computes the incomplete LU factorization of any sparse matrix using the drop tolerance specified by the non-negative scalar `droptol`. The result is an approximation of the complete LU factors returned by `lu(A)`. For increasingly smaller values of the drop tolerance, this approximation improves until the drop tolerance is 0, at which time the complete LU factorization is produced, as in `lu(A)`.

As each column `j` of the triangular incomplete factors is being computed, the entries smaller in magnitude than the local drop tolerance (the product of the drop tolerance and the norm of the corresponding column of `A`)

```
droptol*norm(A(:,j))
```

are dropped from the appropriate factor.

The only exceptions to this dropping rule are the diagonal entries of the upper triangular factor, which are preserved to avoid a singular factor.

`luinc(A,options)` computes the factorization with up to four options. These options are specified by fields of the input structure `options`. The fields must be named exactly as shown in the table below. You can include any number of these fields in the structure and define them in any order. Any additional fields are ignored.

Field Name	Description
<code>droptol</code>	Drop tolerance of the incomplete factorization.
<code>milu</code>	If <code>milu</code> is 1, <code>luinc</code> produces the modified incomplete LU factorization that subtracts the dropped elements in any column from the diagonal element of the upper triangular factor. The default value is 0.
<code>udiag</code>	If <code>udiag</code> is 1, any zeros on the diagonal of the upper triangular factor are replaced by the local drop tolerance. The default is 0.
<code>thresh</code>	Pivot threshold between 0 (forces diagonal pivoting) and 1, the default, which always chooses the maximum magnitude entry in the column to be the pivot. <code>thresh</code> is described in greater detail in the <code>lu</code> reference page.

`luinc(A,options)` is the same as `luinc(A,droptol)` if `options` has `droptol` as its only field.

`[L,U] = luinc(A,'0')` returns the product of permutation matrices and a unit lower triangular matrix in `L` and an upper triangular matrix in `U`. The exact sparsity patterns of `L`, `U`, and `A` are not comparable but the number of nonzeros is maintained with the possible exception of some zeros in `L` and `U` due to cancellation:

$$\text{nnz}(L) + \text{nnz}(U) = \text{nnz}(A) + n, \text{ where } A \text{ is } n\text{-by-}n.$$

The product  $L*U$  agrees with  $A$  over its sparsity pattern.  
 $(L*U) .* \text{spones}(A) - A$  has entries of the order of  $\text{eps}$ .

$[L,U] = \text{luinc}(A,\text{options})$  returns a permutation of a unit lower triangular matrix in  $L$  and an upper triangular matrix in  $U$ . The product  $L*U$  is an approximation to  $A$ .  $\text{luinc}(A,\text{options})$  returns the strict lower triangular part of the factor and the upper triangular factor embedded within the same matrix. The permutation information is lost.

$[L,U,P] = \text{luinc}(\dots)$  returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$ , and a permutation matrix in  $P$ .

$[L,U,P] = \text{luinc}(A, '0')$  returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$  and a permutation matrix in  $P$ .  $L$  has the same sparsity pattern as the lower triangle of permuted  $A$

```
spones(L) = spones(tril(P*A))
```

with the possible exceptions of 1s on the diagonal of  $L$  where  $P*A$  may be zero, and zeros in  $L$  due to cancellation where  $P*A$  may be nonzero.  $U$  has the same sparsity pattern as the upper triangle of  $P*A$

```
spones(U) = spones(triu(P*A))
```

with the possible exceptions of zeros in  $U$  due to cancellation where  $P*A$  may be nonzero. The product  $L*U$  agrees within rounding error with the permuted matrix  $P*A$  over its sparsity pattern.  
 $(L*U) .* \text{spones}(P*A) - P*A$  has entries of the order of  $\text{eps}$ .

$[L,U,P] = \text{luinc}(A,\text{options})$  returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$ , and a permutation matrix in  $P$ . The nonzero entries of  $U$  satisfy

```
abs(U(i,j)) >= droptol*norm((A:,j)),
```

with the possible exception of the diagonal entries, which were retained despite not satisfying the criterion. The entries of  $L$  were tested against the local drop tolerance before being scaled by the pivot, so for nonzeros in  $L$

```
abs(L(i,j)) >= droptol*norm(A(:,j))/U(j,j).
```

The product  $L*U$  is an approximation to the permuted  $P*A$ .

## Tips

These incomplete factorizations may be useful as preconditioners for solving large sparse systems of linear equations. The lower triangular factors all have 1s along the main diagonal but a single 0 on the diagonal of the upper triangular factor makes it singular. The incomplete factorization with a drop tolerance prints a warning message if the upper triangular factor has zeros on the diagonal. Similarly, using the `udiag` option to replace a zero diagonal only gets rid of the symptoms of the problem but does not solve it. The preconditioner may not be singular, but it probably is not useful and a warning message is printed.

## Limitations

`luinc(X, '0')` works on square matrices only.

## Examples

Start with a sparse matrix and compute its LU factorization.

```
load west0479;
S = west0479;
[L,U] = lu(S);
```

Compute the incomplete LU factorization of level 0.

```
[L,U,P] = luinc(S, '0');
```

```
D = (L*U).*spones(P*S) - P*S;
```

`spones(U)` and `spones(triu(P*S))` are identical.

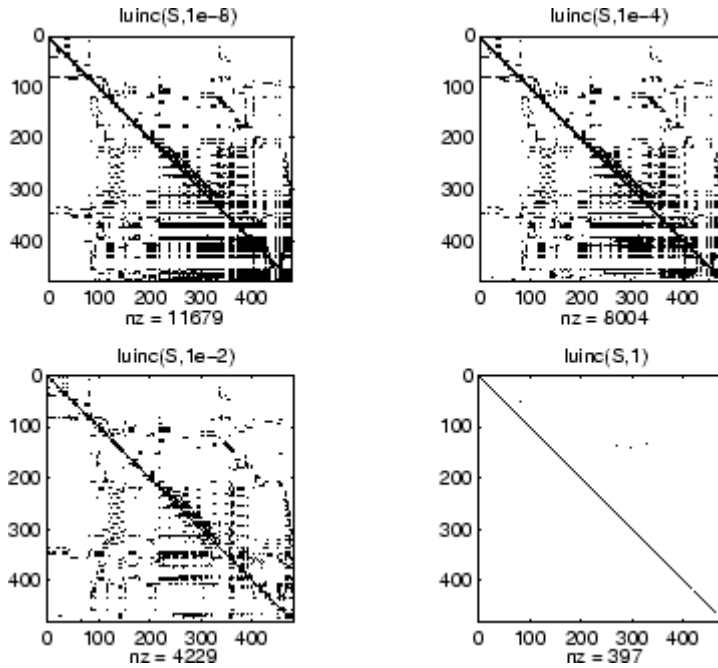

`spones(L)` and `spones(tril(P*S))` disagree at 73 places on the diagonal, where L is 1 and P\*S is 0, and also at position (206,113), where L is 0 due to cancellation, and P\*S is -1. D has entries of the order of `eps`.

```
[ILO,IU0,IP0] = luinc(S,0);  
[IL1,IU1,IP1] = luinc(S,1e-10);
```

```
·  
·  
·
```

A drop tolerance of 0 produces the complete LU factorization. Increasing the drop tolerance increases the sparsity of the factors (decreases the number of nonzeros) but also increases the error in the factors, as seen in the plot of drop tolerance versus  $\text{norm}(L*U-P*S, 1) / \text{norm}(S, 1)$  in the second figure below.

## Algorithms

`luinc(A, '0')` is based on the “KJJ” variant of the LU factorization with partial pivoting. Updates are made only to positions which are nonzero in A.

`luinc(A,droptol)` and `luinc(A,options)` are based on the column-oriented lu for sparse matrices.

## See Also

`bicg` | `cholinc` | `ilu` | `lu`

**Purpose** Magic square

**Syntax** `M = magic(n)`

**Description** `M = magic(n)` returns an  $n$ -by- $n$  matrix constructed from the integers 1 through  $n^2$  with equal row and column sums. The order  $n$  must be a scalar greater than or equal to 3.

**Tips** A magic square, scaled by its magic sum, is doubly stochastic.

**Examples** The magic square of order 3 is

```
M = magic(3)
```

```
M =
```

```

     8     1     6
     3     5     7
     4     9     2

```

This is called a magic square because the sum of the elements in each column is the same.

```
sum(M) =
```

```

    15    15    15

```

And the sum of the elements in each row, obtained by transposing twice, is the same.

```
sum(M')' =
```

```

    15
    15
    15

```

This is also a special magic square because the diagonal elements have the same sum.

```
sum(diag(M)) =
```

```
15
```

The value of the characteristic sum for a magic square of order  $n$  is

```
sum(1:n^2)/n
```

which, when  $n = 3$ , is 15.

## Algorithms

There are three different algorithms:

- $n$  odd
- $n$  even but not divisible by four
- $n$  divisible by four

To make this apparent, type

```
for n = 3:20
    A = magic(n);
    r(n) = rank(A);
end
```

For  $n$  odd, the rank of the magic square is  $n$ . For  $n$  divisible by 4, the rank is 3. For  $n$  even but not divisible by 4, the rank is  $n/2 + 2$ .

```
[(3:20)', r(3:20)']
```

```
ans =
     3     3
     4     3
     5     5
     6     5
     7     7
     8     3
     9     9
    10     7
    11    11
    12     3
```

13	13
14	9
15	15
16	3
17	17
18	11
19	19
20	3

Plotting A for  $n = 18, 19, 20$  shows the characteristic plot for each category.

**Limitations**

If you supply  $n$  less than 3, `magic` returns either a nonmagic square, or else the degenerate magic squares 1 and [].

`ones` | `rand`

# makehgtform

---

**Purpose** Create 4-by-4 transform matrix

**Syntax**

```
M = makehgtform
M = makehgtform('translate',[tx ty tz])
M = makehgtform('scale',s)
M = makehgtform('scale',[sx,sy,sz])
M = makehgtform('xrotate',t)
M = makehgtform('yrotate',t)
M = makehgtform('zrotate',t)
M = makehgtform('axisrotate',[ax,ay,az],t)
```

**Description** Use `makehgtform` to create transform matrices for translation, scaling, and rotation of graphics objects. Apply the transform to graphics objects by assigning the transform to the `Matrix` property of a parent `hgtransform` object. See [Examples](#) for more information.

`M = makehgtform` returns an identity transform.

`M = makehgtform('translate',[tx ty tz])` or `M = makehgtform('translate',tx,ty,tz)` returns a transform that translates along the *x*-axis by `tx`, along the *y*-axis by `ty`, and along the *z*-axis by `tz`.

`M = makehgtform('scale',s)` returns a transform that scales uniformly along the *x*-, *y*-, and *z*-axes.

`M = makehgtform('scale',[sx,sy,sz])` returns a transform that scales along the *x*-axis by `sx`, along the *y*-axis by `sy`, and along the *z*-axis by `sz`.

`M = makehgtform('xrotate',t)` returns a transform that rotates around the *x*-axis by `t` radians.

`M = makehgtform('yrotate',t)` returns a transform that rotates around the *y*-axis by `t` radians.

`M = makehgtform('zrotate',t)` returns a transform that rotates around the *z*-axis by `t` radians.

`M = makehgtform('axisrotate',[ax,ay,az],t)` Rotate around axis [`ax ay az`] by `t` radians.

Note that you can specify multiple operations in one call to `makehgtform` and the MATLAB software returns a transform matrix that is the result of concatenating all specified operations. For example,

```
m = makehgtform('xrotate',pi/2,'yrotate',pi/2);
```

is the same as

```
m = makehgtform('xrotate',pi/2)*makehgtform('yrotate',pi/2);
```

## How To

- “Group Objects”

# containers.Map

---

**Purpose** Map values to unique keys

**Description** A Map object is a data structure that allows you to retrieve values using a corresponding key. Keys can be real numbers or text strings and provide more flexibility for data access than array indices, which must be positive integers. Values can be scalar or nonscalar arrays.

**Construction** `mapObj = containers.Map` constructs an empty Map container `mapObj`.  
`mapObj = containers.Map(keySet,valueSet)` constructs a Map that contains one or more values and a unique key for each value.  
`mapObj = containers.Map(keySet,valueSet,'UniformValues',isUniform)` specifies whether all values must be uniform (either all scalars of the same data type, or all strings). Possible values for `isUniform` are logical true (1) or false (0).  
`mapObj = containers.Map('KeyType',kType,'ValueType',vType)` constructs an empty Map object and sets the `KeyType` and `ValueType` properties. The order of the key type and value type argument pairs is not important, but both pairs are required.

## Input Arguments

### **keySet**

1-by-n array that specifies n unique keys for the map.

All keys in a Map object are real numeric values or all keys are strings. If  $n > 1$  and the keys are strings, `keySet` must be a cell array. The number of keys in `keySet` must equal the number of values in `valueSet`.

### **valueSet**

1-by-n array of any class that specifies n values for the map. The number of values in `valueSet` must equal the number of keys in `keySet`.

### **'UniformValues'**

Parameter string to use with the `isUniform` argument.

## **isUniform**

Logical value that specifies whether all values are uniform. If `isUniform` is `true` (1), all values must be scalars of the same data type, or all values must be strings. If `isUniform` is `false` (0), then `containers.Map` sets the `ValueType` to `'any'`.

**Default:** `true` for empty `Map` objects, otherwise determined by the data types of values in `valueSet`.

## **'KeyType'**

Parameter string to use with the `kType` argument.

## **kType**

String that specifies the data type for the keys. Possible values are `'char'`, `'double'`, `'single'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'char'` for empty `Map` objects, otherwise determined by the data types of keys in `keySet`. If you specify keys of different numeric types, `kType` is `'double'`.

## **'ValueType'**

Literal string parameter to use with the `vType` argument.

## **vType**

String that specifies the data type for the values. Possible values are `'any'`, `'char'`, `'logical'`, `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'any'` when you create an empty `Map` object or when you specify values of different sizes or types, otherwise determined by the data type of `valueSet`.

# containers.Map

---

## Properties

### Count

Unsigned 64-bit integer that represents the total number of key-value pairs contained in the `Map` object. Read only.

### KeyType

Character array that indicates the data type of all keys in the `Map` object. The default `KeyType` for empty `Map` objects is `'char'`. Otherwise, `KeyType` is determined from the data type of the `keySet` inputs. Read only.

### ValueType

Character array that indicates the data type of all values in the `Map` object. If you construct an empty `Map` object or specify values with different data types, then the value of `ValueType` is `'any'`. Otherwise, `ValueType` is determined from the data type of the `valueSet` inputs. Read only.

## Methods

<code>isKey</code>	Determine if <code>containers.Map</code> object contains key
<code>keys</code>	Identify keys of <code>containers.Map</code> object
<code>length</code>	Length of <code>containers.Map</code> object
<code>remove</code>	Remove key-value pairs from <code>containers.Map</code> object
<code>size</code>	Size of <code>containers.Map</code> object
<code>values</code>	Identify values in <code>containers.Map</code> object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Construct a Map and View Properties

Construct a Map object that contains rainfall data for several months:

```
keySet =    {'Jan', 'Feb', 'Mar', 'Apr'};  
valueSet = [327.2, 368.2, 197.6, 178.4];  
mapObj = containers.Map(keySet,valueSet)
```

This code returns a description of the map, including the property values:

```
mapObj =  
  
    containers.Map handle  
    Package: containers  
  
    Properties:  
        Count: 4  
        KeyType: 'char'  
        ValueType: 'double'  
  
    Methods, Events, Superclasses
```

Get a specific property using dot notation, such as

```
mapObj.Count
```

which returns

```
ans =  
  
         4
```

### Look Up Values in a Map

Use the map created in the previous example to find the rainfall data for February:

```
rainFeb = mapObj('Feb')
```

This code returns

# containers.Map

---

```
rainFeb =  
    368.2000
```

## Add a Single Value and Key to a Map

Add data for the month of May to the map created in the first example:

```
mapObj('May') = 100.0;
```

## Add Multiple Values and Keys by Concatenating Maps

Create a map that contains rainfall data for June, July, and August, and add the data to `mapObj` (from previous examples):

```
keySet = {'Jun', 'Jul', 'Aug'};  
valueSet = [ 69.9, 32.3, 37.3];  
newMap = containers.Map(keySet, valueSet);  
  
mapObj = [mapObj; newMap];
```

Map objects only support vertical concatenation (that is, adding columns with a semicolon, `;`). When concatenating maps, the data type of all values must be consistent with the `ValueType` of the leftmost map. In this example, both maps have the a `ValueType` of `double`.

## Get the Keys or Values in a Map

Determine all the keys of `mapObj` (from previous examples) by calling the `keys` method:

```
allKeys = keys(mapObj)
```

This method returns the keys in alphabetical order:

```
allKeys =  
    'Apr'    'Aug'    'Feb'    'Jan'    'Jul'    'Jun'    'Mar'    'May'
```

Get multiple values from the map by calling the `values` method. Like the `keys` method, you can request all values with the syntax `values(mapObj)`. Alternatively, request values for specific keys. For example, view the values for March, April, and May in `mapObj`:

```
springValues = values(mapObj,{'Mar','Apr','May'})
```

This method returns the values in a cell array, in the order corresponding to the specified keys:

```
springValues =  
    [197.6000]    [178.4000]    [100]
```

## Remove Keys and Values

Remove the data for March and April from `mapObj` (from previous examples) by calling the `remove` method, and view the remaining keys:

```
remove(mapObj,{'Mar','Apr'});  
keys(mapObj)
```

This code returns

```
ans =  
    'Aug'    'Feb'    'Jan'    'Jul'    'Jun'    'May'
```

## Create a Map with Nonscalar Values

Map integer keys to nonscalar arrays, and view the value for one of the keys:

```
keySet = [5,10,15];  
valueSet = {magic(5),magic(10),magic(15)};  
mapObj = containers.Map(keySet,valueSet);  
mapObj(5)
```

This code returns

```
ans =  
    17    24     1     8    15  
    23     5     7    14    16  
     4     6    13    20    22  
    10    12    19    21     3  
    11    18    25     2     9
```

# containers.Map

---

## Construct an Empty Map

Construct a map with no values, but set the KeyType and ValueType properties:

```
mapObj = containers.Map('KeyType','char','ValueType','int32')
```

This code returns

```
mapObj =  
  
containers.Map handle  
Package: containers  
  
Properties:  
    Count: 0  
    KeyType: 'char'  
    ValueType: 'int32'
```

Methods, Events, Superclasses

## Specify Whether Values Are Uniform

Construct a map with numeric values, and specify that the values do not have to be uniform:

```
keySet = {'a','b','c'};  
valueSet = {1,2,3};  
mapObj = containers.Map(keySet,valueSet,'UniformValues',false);
```

This map allows nonnumeric values, so

```
mapObj('d') = 'OK';  
values(mapObj)  
  
returns  
  
ans =  
    [1]    [2]    [3]    'OK'
```

**See Also**    keys | isKey | values

# mat2cell

---

**Purpose** Convert array to cell array with potentially different sized cells

**Syntax**  
`C = mat2cell(A,dim1Dist,...,dimNDist)`  
`C = mat2cell(A,rowDist)`

**Description** `C = mat2cell(A,dim1Dist,...,dimNDist)` divides array `A` into smaller arrays within cell array `C`. Vectors `dim1Dist,...,dimNDist` specify how to divide the rows, columns, and (when applicable) higher dimensions of `A`.

`C = mat2cell(A,rowDist)` divides array `A` into an `n`-by-1 cell array `C`, where `n == numel(rowDist)`.

## Input Arguments

**A**  
Any type of array.

### **dim1Dist,...,dimNDist**

Numeric vectors that describe how to divide each dimension of `A`. For example, this command

```
c = mat2cell(x, [10, 20, 30], [25, 25])
```

divides a 60-by-50 array into six arrays contained in a cell array.

For the  $k$ th dimension, `sum(dimkDist) == size(A, k)`.

If the  $k$ th dimension of `A` is zero, set the corresponding `dimkDist` to the empty array, `[]`. For example,

```
a = rand(3, 0, 4);
c = mat2cell(a, [1, 2], [], [2, 1, 1]);
```

### rowDist

Numeric vector that describes how to divide the rows of `A`. When you do not specify distributions for any other dimension, the `mat2cell` function creates an  $n$ -by-1 cell array `C`, where  $n == \text{numel}(\text{rowDist})$ .

## Output Arguments

### C

Cell array. The  $k$ th dimension of array `C` is given by `size(C, k) == numel(dimkDist)`. The  $k$ th dimension of the  $i$ th cell of `C` is given by `size(C{i}, k) == dimkDist(i)`.

## Examples

Divide the 5-by-4 matrix `X` into 2-by-3 and 2-by-2 matrices contained in a cell array.

```
X = reshape(1:20,5,4)';
C = mat2cell(X, [2 2], [3 2])
celldisp(C)
```

This code returns

```
X =
     1     2     3     4     5
     6     7     8     9    10
    11    12    13    14    15
    16    17    18    19    20
```

```
C =
 [2x3 double]    [2x2 double]
 [2x3 double]    [2x2 double]
```

# mat2cell

---

```
C{1,1} =  
     1     2     3  
     6     7     8  
  
C{2,1} =  
    11    12    13  
    16    17    18  
  
C{1,2} =  
     4     5  
     9    10  
  
C{2,2} =  
    14    15  
    19    20
```

---

Divide X (created in the previous example) into a 2-by-1 cell array.

```
C = mat2cell(X, [1 3])  
celldisp(C)
```

This code returns

```
C =  
    [1x5 double]  
    [3x5 double]  
  
C{1} =  
     1     2     3     4     5  
  
C{2} =  
     6     7     8     9    10  
    11    12    13    14    15  
    16    17    18    19    20
```

## See Also

[cell2mat](#) | [num2cell](#)

**Purpose** Convert matrix to string

**Syntax**

```
str = mat2str(A)
str = mat2str(A,n)
str = mat2str(A, 'class')
str = mat2str(A, n, 'class')
```

**Description**

`str = mat2str(A)` converts matrix `A` into a string. This string is suitable for input to the `eval` function such that `eval(str)` produces the original matrix to within 15 digits of precision.

`str = mat2str(A,n)` converts matrix `A` using `n` digits of precision.

`str = mat2str(A, 'class')` creates a string with the name of the class of `A` included. This option ensures that the result of evaluating `str` will also contain the class information.

`str = mat2str(A, n, 'class')` uses `n` digits of precision and includes the class information.

**Limitations** The `mat2str` function is intended to operate on scalar, vector, or rectangular array inputs only. An error will result if `A` is a multidimensional array.

## Examples

### Example 1

Consider the matrix

```
x = [3.85 2.91; 7.74 8.99]
x =
    3.8500    2.9100
    7.7400    8.9900
```

The statement

```
A = mat2str(x)
```

produces

```
A =  
    [3.85 2.91;7.74 8.99]
```

where A is a string of 21 characters, including the square brackets, spaces, and a semicolon.

`eval(mat2str(x))` reproduces x.

## Example 2

Create a 1-by-6 matrix of signed 16-bit integers, and then use `mat2str` to convert the matrix to a 1-by-33 character array, A. Note that output string A includes the class name, `int16`:

```
x1 = int16([-300 407 213 418 32 -125]);
```

```
A = mat2str(x1, 'class')  
A =  
    int16([-300 407 213 418 32 -125])
```

```
class(A)  
ans =  
    char
```

Evaluating the string A gives you an output x2 that is the same as the original `int16` matrix:

```
x2 = eval(A);  
  
if isnumeric(x2) && isa(x2, 'int16') && all(x2 == x1)  
    disp 'Conversion back to int16 worked'  
end
```

Conversion back to int16 worked

## See Also

`num2str` | `int2str` | `str2num` | `sprintf` | `fprintf`

**Purpose** Control reflectance properties of surfaces and patches

**Syntax**

```
material shiny
material dull
material metal
material([ka kd ks])
material([ka kd ks n])
material([ka kd ks n sc])
material default
```

**Description** `material` sets the lighting characteristics of surface and patch objects.

`material shiny` sets the reflectance properties so that the object has a high specular reflectance relative to the diffuse and ambient light, and the color of the specular light depends only on the color of the light source.

`material dull` sets the reflectance properties so that the object reflects more diffuse light and has no specular highlights, but the color of the reflected light depends only on the light source.

`material metal` sets the reflectance properties so that the object has a very high specular reflectance, very low ambient and diffuse reflectance, and the color of the reflected light depends on both the color of the light source and the color of the object.

`material([ka kd ks])` sets the ambient/diffuse/specular strength of the objects.

`material([ka kd ks n])` sets the ambient/diffuse/specular strength and specular exponent of the objects.

`material([ka kd ks n sc])` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects.

`material default` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects to their defaults.

# material

---

## Tips

The `material` command sets the `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, and `SpecularColorReflectance` properties of all surface and patch objects in the axes. There must be visible light objects in the axes for lighting to be enabled. Look at the `material.m` file to see the actual values set (enter the command type `material`).

## See Also

`light` | `lighting` | `patch` | `surface`

## How To

- “Lighting Overview”

**Purpose** Access and change variables directly in MAT-files, without loading into memory

**Syntax**

```
m = matfile(filename)
m = matfile(filename, 'Writable', isWritable)
```

**Description** `m = matfile(filename)` creates a MAT-file object, `m`, connected to the MAT-file named `filename`. The object allows you to access and change variables directly in a MAT-file, without having to load the variables into memory.

The partial loading and saving that the `matfile` function provides requires less memory than the `load` and `save` commands, which always operate on entire variables.

`m = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file.

## Input Arguments

### **filename** - Name of MAT-file

string

Name of a MAT-file, specified as a string. If the file is not in the current folder, `filename` must include a full or a relative path. If `filename` does not include an extension, then `matfile` appends `.mat`.

If the file does not exist, then `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports efficient partial loading and saving for MAT-files in Version 7.3 format. If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

**Example:** `'myFile.mat'`

### **Data Types**

char

### **isWritable** - Write access to MAT-file

true | false

Write access to the MAT-file, specified as either `true` or `false`.

- `true` enables saving to the MAT-file. If the file is read only, MATLAB changes the system permissions with the `fileattrib` function.
- `false` disables saving to the MAT-file. MATLAB does not change the system permissions.

The default value is `true` for new files, and `false` for existing files.

## Data Types

logical

## Output Arguments

### **m** - MAT-file object

`matlab.io.MatFile` object

MAT-file object connected to a MAT-file.

Access variables in the MAT-file with dot notation similar to accessing fields of structure arrays:

- To load part of variable `varName` from the MAT-file corresponding to `m`, call:

```
loadedData = m.varName(indices);
```

- To save part of variable `varName` to the MAT-file corresponding to `m`, call:

```
m.varName(indices) = dataToSave;
```

When accessing variables, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (`:`); for example:

```
m.varName(100:500,200:600)
m.varName(:,501:1000)
m.varName(1:2:1000,80)
```

## Examples

### Add Variable to a MAT-File

Generate a 20-by-20 example array, `x`.

```
x = magic(20);
```

Create a MAT-file object connected to an existing MAT-file named `myFile.mat`.

```
m = matfile('myFile.mat');
```

Save `x` to the MAT-file. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.x = x;
```

MATLAB adds a variable named `x` to the file.

### Save to and Load Data from Part of Variable

Access specific elements of a MAT-file variable.

Open the MAT-file, `myFile2.mat`.

```
m = matfile('myFile2.mat');
```

Save a 20-by-20 example array to part of a variable, `y`, in `myFile2.mat`. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y(81:100,81:100) = magic(20);
```

MATLAB inserts the 20-by-20 array into the elements of `y` specified by the indices `(81:100,81:100)`.

Read a subset of array `y` into a new workspace variable, `z`.

```
z = m.y(85:94,85:94);
```

MATLAB reads the 10-by-10 subarray specified by the indices (85:94,85:94) from the MAT-file into workspace variable `z`.

## Load Entire Variable

Load variable `topo` from the example file, `topography.mat`.

Open the example MAT-file, `topography.mat`.

```
filename = 'topography.mat';  
m = matfile(filename);
```

Read the variable `topo` from the MAT-file.

```
topo = m.topo;
```

## Operate on a Variable of Any Dimensions

Determine the dimensions of a variable, and then calculate the average of each column.

Open the example MAT-file, `stocks.mat`.

```
filename = 'stocks.mat';  
m = matfile(filename);
```

Determine the size of the variable, `stocks`, in `stocks.mat`.

```
[nrows,ncols] = size(m,'stocks');
```

Compute the average of each column of the variable `stocks`.

```
avgs = zeros(1,ncols);  
for idx = 1:ncols  
    avgs(idx) = mean(m.stocks(:,idx));  
end
```

## Enable Write Access to MAT-file

Enable write access to the MAT-file, `myFile.mat`, by setting `Writable` to `true` when you open the MAT-file. By default, `matfile` only supports loading data from existing files.

```
filename = 'myFile.mat';  
m = matfile(filename, 'Writable', true);
```

Alternatively, set `Properties.Writable` in a separate step after you open the MAT-file.

```
m.Properties.Writable = true;
```

## Tips

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in `Out of Memory` errors. Rather than using `end`, determine the extent of a variable, `myVar`, with the `size` method, such as:

```
sizeMyVar = size(m, 'myVar')
```

## Limitations

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Cells of cell arrays
  - Fields of structure arrays
  - User-defined classes
  - Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using the `m` output. For example, if your MAT-file contains function handle `myfunc`, the

syntax `m.myfunc()` attempts to index into the function handle, and does not invoke the function.

- Efficient partial loading and saving requires Version 7.3 MAT-files. To create a Version 7.3 MAT-file, call the `save` function with the `'-v7.3'` option. For example, to convert an existing MAT-file named `durer.mat` to Version 7.3, call:

```
load('durer.mat');  
save('mycopy_durer.mat', '-v7.3');
```

## Concepts

- “Load Parts of Variables from MAT-Files”
- “Save Parts of Variables to MAT-Files”
- MAT-File Versions

**Purpose**

Load and save parts of variables in MAT-files

**Description**

The `matfile` function constructs a `matlab.io.MatFile` object that corresponds to a MAT-File, such as

```
matObj = matfile('myFile.mat')
```

Access variables in the MAT-file as properties of `matObj`, with dot notation similar to accessing fields of structs. The syntax for loading and saving part of variable `varName` in the MAT-file corresponding to `matObj` is:

```
loadedData = matObj.varName(indices);    % Load into workspace  
matObj.varName(indices) = dataToSave;    % Save to file
```

When indexing, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (:), such as

```
matObj.varName(100:500, 200:600)  
matObj.varName(:, 501:1000)  
matObj.varName(1:2:1000, 80)
```

**Limitations**

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in Out of Memory errors. Rather than using `end`, determine the extent of a variable with the `size` method, such as:

```
sizeMyVar = size(matObj, 'myVar')
```

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Cells of cell arrays
  - Fields of structs

- User-defined classes
- Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using a `MatFile` object. For example, if your MAT-file contains function handle `myfunc`, the syntax `matObj.myfunc()` attempts to index into the function handle, and does not invoke the function.

## Construction

`matObj = matfile(filename)` constructs a `matlab.io.MatFile` object that can load or save parts of variables in MAT-file `filename`. MATLAB does not load any data from the file into memory when creating the object.

`matObj = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file for object `matObj`. Possible values for `isWritable` are logical `true` (1) or `false` (0).

## Input Arguments

### `filename`

String enclosed in single quotation marks that specifies the name of a MAT-file.

`filename` can include a full or partial path, otherwise `matfile` searches for the file along the MATLAB search path. If `filename` does not include an extension, `matfile` appends `.mat`.

If the file does not exist, `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports partial loading and saving for MAT-files in Version 7.3 format (described in *MAT-File Versions*). If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

### 'Writable'

Parameter to use with the `isWritable` argument.

### **isWritable**

Logical value that specifies whether to allow saving to the file.

Possible values:

<code>true</code> (1)	Enable saving. If the file is read only, change the system permissions with <code>fileattrib</code> .
<code>false</code> (0)	Disable saving with <code>matfile</code> . MATLAB does not change the system permissions.

**Default:** `true` for new files, `false` for existing files

## **Properties**

### **Properties.Source**

String that contains the fully qualified path to the file. Read only.

### **Properties.Writable**

Logical value that specifies whether to allow saving to the file.

Possible values:

<code>true</code> (1)	Enable saving. If the file is read only, change the system permissions with <code>fileattrib</code> .
<code>false</code> (0)	Disable saving with <code>matfile</code> . MATLAB does not change the system permissions.

**Default:** `true` for new files, `false` for existing files

## **Methods**

<code>size</code>	Array dimensions
<code>who</code>	Names of variables in MAT-file
<code>whos</code>	Names, sizes, and types of variables in MAT-file

You cannot access help for these methods using the `help` command. Find help on the methods from the command line using the `doc` command, such as `doc matlab.io.MatFile/size`.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Create `myFile.mat` in a temporary folder and save data to part of variable `savedVar`:

```
filename = fullfile(tempdir,'myFile.mat');
matObj = matfile(filename);
matObj.savedVar(81:100,81:100) = magic(20);
```

Load part of the data into variable `loadVar`:

```
loadVar = matObj.savedVar(85:94,85:94);
```

---

Load or save an entire variable by omitting the indices. For example, load variable `topo` from `topography.mat`:

```
filename = 'topography.mat';
matObj = matfile(filename);
topo = matObj.topo;
```

---

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
```

```
        avgs(idx) = mean(matObj.stocks(:,idx));  
end
```

---

By default, `matfile` only supports loading data from existing files. To enable saving, set `Writable` to `true` either during construction of the object,

```
filename = 'myFile.mat';  
matObj = matfile(filename, 'Writable', true);
```

or in a separate step, by setting `Properties.Writable`:

```
filename = 'myFile.mat';  
matObj = matfile(filename);  
matObj.Properties.Writable = true;
```

## See Also

[load](#) | [save](#) | [size](#) | [whos](#)

# matlab.io.fits.closeFile

---

**Purpose** Close FITS file

**Syntax** `closeFile(fptr)`

**Description** `closeFile(fptr)` closes an open FITS file.

This function corresponds to the `fits_close_file` (`ffclos`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits','READONLY');
fits.closeFile(fptr);
```

**See Also** `createFile` | `openFile`

**Purpose** Create FITS file

**Syntax** `fptr = createFile(filename)`

**Description** `fptr = createFile(filename)` creates a FITS file. An error will be returned if the specified file already exists, unless the filename is prefixed with an exclamation point (!). In that case CFITSIO will overwrite (delete) any existing file with the same name.

This function corresponds to the `fits_create_file` (`ffinit`) function in the CFITSIO library C API.

**Examples** Create a new FITS file, overwriting any existing file by the same name.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[256 512]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

**See Also** `openFile` | `closeFile` | `createImg` | `createTbl`

# matlab.io.fits.deleteFile

---

**Purpose** Delete FITS file

**Syntax** deleteFile(fptr)

**Description** deleteFile(fptr) closes and deletes an open FITS file. This can be useful if a FITS file cannot be properly closed.

This function corresponds to the fits\_delete\_file (ffdel) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.deleteFile(fptr);
fptrs = fits.getOpenFiles()
```

**See Also** createFile | closeFile

**Purpose** Name of FITS file

**Syntax** name = fileName(fptr)

**Description** name = fileName(fptr) returns the name of the FITS file associated with the file handle.

This function corresponds to the fits\_file\_name (ffflnm) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits','READONLY');
name = fits.fileName(fptr);
fits.closeFile(fptr);
```

**See Also** createFile | openFile

# matlab.io.fits.fileMode

---

**Purpose** I/O mode of FITS file

**Syntax** `mode = fileMode(fpPtr)`

**Description** `mode = fileMode(fpPtr)` returns the I/O mode of the opened FITS file. Possible values returned for mode are 'READONLY' or 'READWRITE'.  
This function corresponds to the `fits_file_mode (ffflmd)` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
mode = fits.fileMode(fpPtr);
fits.closeFile(fpPtr);
```

**See Also** [createFile](#) | [openFile](#)

**Purpose** Open FITS file

**Syntax**  
`fptr = openFile(filename)`  
`fptr = openFile(filename,mode)`

**Description** `fptr = openFile(filename)` opens an existing FITS file in read-only mode and returns a file pointer, `fptr`, which references the primary array (first header data unit, or "HDU").

`fptr = openFile(filename,mode)` opens an existing FITS file according to the `mode`, which describes the type of access. `mode` may be either 'READONLY' or 'READWRITE'.

This function corresponds to the `fits_open_file` (`ffopen`) function in the CFITSIO library C API.

**Examples** Open a file in read-only mode and read image data from the primary array.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
imagedata = fits.readImg(fptr);
fits.closeFile(fptr);
```

---

Open a file in read-write mode and add a comment to the primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.writeComment(fptr,'This is just a comment.');
```

**See Also** `createFile` | `closeFile`

# matlab.io.fits.createImg

---

**Purpose** Create FITS image

**Syntax** `createImg(fptr,bitpix,naxes)`

**Description** `createImg(fptr,bitpix,naxes)` creates a new primary image or image extension with a specified datatype `bitpix` and size `naxes`. If the FITS file is currently empty then a primary array is created, otherwise a new image extension is appended to the file.

The first two elements of `naxes` correspond to the NAXIS2 and NAXIS1 keywords, while any additional elements correspond to the NAXIS3, NAXIS4 ... NAXISn keywords.

The datatype `bitpix` may be given as either a CFITSIO name or as the corresponding MATLAB datatype.

'byte_img'	'uint8'
'short_img'	'int16'
'long_img'	'int32'
'longlong_img'	'int64'
'float_img'	'single'
'double_img'	'double'

This function corresponds to the `fits_create_img11` (`ffcrim11`) function in the CFITSIO library C API.

## Examples

Create two images in a new FITS file. There are 100 rows (NAXIS2 keyword) and 200 columns (NAXIS1 keyword) in the first image, and 256 rows (NAXIS2 keyword), 512 columns (NAXIS1 keyword), and 3 planes (NAXIS3 keyword) in the second image.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'int16',[100 200]);
fits.createImg(fptr,'byte_img',[256 512 3]);
fits.closeFile(fptr);
```

```
fitsdisp('myfile.fits');
```

## See Also

```
insertImg | createTbl | readImg | writeImg |  
setCompressionType
```

# matlab.io.fits.getImgSize

---

**Purpose** Size of image

**Syntax** `imagesize = getImgSize(fptr)`

**Description** `imagesize = getImgSize(fptr)` returns the number of rows and columns of an image. This function corresponds to the `fits_get_img_size (ffgisz)` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*;
fptr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
    htype = fits.movAbsHDU(fptr,j);
    sz = fits.getImgSize(fptr);
    fprintf('HDU %d: "%s", [' , j, htype);
    for k = 1:numel(sz)
        fprintf(' %d ', sz(k));
    end
    fprintf(']\n');
end
fits.closeFile(fptr);
```

**See Also** `createImg` | `getImgType`

**Purpose** Data type of image

**Syntax** `datatype = getImgType(fptr)`

**Description** `datatype = getImgType(fptr)` gets the data type of an image. `datatype` can be one of the following strings:

```
'BYTE_IMG'  
'SHORT_IMG'  
'LONG_IMG'  
'LONGLONG_IMG'  
'FLOAT_IMG'  
'DOUBLE_IMG'
```

This function corresponds to the `fits_get_img_type` (`ffgidt`) function in the CFITSIO library C API.

## Examples

```
fptr = fits.openFile('tst0012.fits');  
hdus = [1 3 4];  
for j = hdus;  
    htype = fits.movAbsHDU(fptr,j);  
    dtype = fits.getImgType(fptr);  
    fprintf('HDU %d: "%s", "%s"\n', j, htype, dtype);  
end  
fits.closeFile(fptr);
```

**See Also** `getImgSize`

# matlab.io.fits.insertImg

---

**Purpose** Insert FITS image after current image

**Syntax** `insertImage(fptr,bitpix,naxes)`

**Description** `insertImage(fptr,bitpix,naxes)` inserts a new image extension immediately following the current HDU. If the file has just been created, a new primary array is inserted at the beginning of the file. Any following extensions in the file will be shifted down to make room for the new extension. If the current HDU is the last HDU in the file, then the new image extension will be appended to the end of the file.

This function corresponds to the `fits_insert_img11` (`ffiimg11`) function in the CFITSIO library C API.

**Examples** Create a 150x300 image between the 1st and 2nd images in a FITS file.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.createImg(fptr,'byte_img',[200 400]);
fits.movAbsHDU(fptr,1);
fits.insertImg(fptr,'byte_img',[150 300]);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

**See Also** `createImg`

**Purpose** Read image data

**Syntax**

```
imgdata = readImg(fptr)
imgdata = readImg(fptr,fpixel,lpixel)
imgdata = readImg(fptr,fpixel,lpixel,inc)
```

**Description** `imgdata = readImg(fptr)` reads the entire current image. The number of rows in `imgdata` will correspond to the value of the NAXIS2 keyword, while the number of columns will correspond to the value of the NAXIS1 keyword. Any further dimensions of `imgdata` will correspond to NAXIS3, NAXIS4, and so on.

`imgdata = readImg(fptr,fpixel,lpixel)` reads the subimage defined by pixel coordinates `fpixel` and `lpixel`. The `fpixel` argument is the coordinate of the first pixel and `lpixel` is the coordinate of the last pixel. `fpixel` and `lpixel` are one-based.

`imgdata = readImg(fptr,fpixel,lpixel,inc)` reads the subimage defined by `fpixel`, `lpixel`, and `inc`. The `inc` argument denotes the inter- element spacing along each extent.

This function corresponds to the `fits_read_subset (ffgsv)` function in the CFITSIO library C API.

**Examples** Read an entire image.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

---

Read a 70x80 image subset.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
img = fits.readImg(fptr,[11 11],[80 90]);
fits.closeFile(fptr);
```

# matlab.io.fits.readImg

---

## See Also

`createImg` | `writeImg`

**Purpose** Reset image scaling

**Syntax** `setBscale(fptr,BSCALE,BZERO)`

**Description** `setBscale(fptr,BSCALE,BZERO)` resets the scaling factors in the primary array or image extension according to the equation

$$\text{output} = (\text{FITS array}) * \text{BSCALE} + \text{BZERO}$$

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the BSCALE and BZERO keyword values.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.setBscale(fptr,2.0,0.5);
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

**See Also** `readImg`

# matlab.io.fits.writeImg

---

**Purpose** Write to FITS image

**Syntax** `writeImg(fptr,data)`  
`writeImg(fptr,data,fpixel)`

**Description** `writeImg(fptr,data)` writes an entire image to the FITS data array. The number of rows and columns in `data` must equal the values of the `NAXIS2` and `NAXIS1` keywords, respectively. Any further extents must correspond to the `NAXIS3`, `NAXIS4` ... `NAXISn` keywords respectively.

`writeImg(fptr,data,fpixel)` writes a subset of an image to the FITS data array. `fpixel` gives the coordinate of the first pixel in the image region.

This function corresponds to the `fits_write_subset` (`ffpss`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

---

Create an 80x40 `uint8` image and set all but the outermost pixels to 1.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[80 40]);
data = ones(78,38);
fits.writeImg(fptr,data,[1 1]);
fits.closeFile(fptr);
```

**See Also** `readImg` | `createImg`

**Purpose** Delete key by name

**Syntax** deleteKey(fptr, keyname)

**Description** deleteKey(fptr, keyname) deletes a keyword by name.

This function corresponds to the fits\_delete\_key (ffdrec) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fprintf('Before key deletion...\n');
fitsdisp('myfile.fits', 'index', 1);
fptr = fits.openFile('myfile.fits', 'readwrite');
fits.deleteKey(fptr, 'DATE');
fits.closeFile(fptr);
fprintf('\n\n\nAfter key deletion...\n');
fitsdisp('myfile.fits', 'index', 1);
```

**See Also** deleteRecord | writeKey

# matlab.io.fits.deleteRecord

---

**Purpose** Delete key by record number

**Syntax** `deleteRecord(fptr,keynum)`

**Description** `deleteRecord(fptr,keynum)` deletes a keyword by record number. This function corresponds to the `fits_delete_record` (`ffdrec`) function in the CFITSIO library C API.

**Examples** Delete the 18th keyword ("ORIGIN") in a primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
card = fits.readRecord(fptr,18);
fits.deleteRecord(fptr,18);
fits.closeFile(fptr);
```

**See Also** `readRecord` | `deleteKey`

**Purpose** Number of keywords in header

**Syntax** [nkeys,morekeys] = fits.getHdrSpace(fptr)

**Description** [nkeys,morekeys] = fits.getHdrSpace(fptr) returns the number of existing keywords (not counting the END keyword) and the amount of space currently available for more keywords. It returns morekeys = -1 if the header has not yet been closed. Note that the CFITSIO library will dynamically add space if required when writing new keywords to a header so in practice there is no limit to the number of keywords that can be added to a header.

This function corresponds to the fits\_get\_hdrspace (ffghsp) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
[nkeys,morekeys] = fits.getHdrSpace(fptr);
fits.closeFile(fptr);
```

# matlab.io.fits.readCard

---

**Purpose** Header record of keyword

**Syntax** `card = readCard(fpPtr,keyname)`

**Description** `card = readCard(fpPtr,keyname)` returns the entire 80-character header record of the keyword, with any trailing blank characters stripped off.

This function corresponds to the `fits_read_card` (`ffgcrd`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
    fits.movAbsHDU(fpPtr,j);
    card = fits.readCard(fpPtr,'NAXIS');
    fprintf('HDU %d:  '%s'\n', j, card);
end
fits.closeFile(fpPtr);
```

**See Also** `readRecord` | `readKey`

**Purpose** Keyword

**Syntax** [value,comment] = readKey(fpPtr,keyname)

**Description** [value,comment] = readKey(fpPtr,keyname) returns the specified key and comment. value is returned as a string.

This function corresponds to the fits\_read\_key\_str (ffgkys) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
    fits.movAbsHDU(fpPtr,j);
    [key,comment] = fits.readKey(fpPtr,'NAXIS');
    fprintf('HDU %d: NAXIS %s, "%s"\n', j, key, comment);
end
fits.closeFile(fpPtr);
```

**See Also** readKeyCmplx | readKeyDb1 | readKeyLongLong

# matlab.io.fits.readKeyCmplx

---

**Purpose** Keyword as complex scalar value

**Syntax** `[value,comment] = readKeyCmplx(fptr,keyname)`

**Description** `[value,comment] = readKeyCmplx(fptr,keyname)` returns the specified key and comment. `value` is returned as a double precision complex scalar value.

This function corresponds to the `fits_read_key_dblcmp` (ffgkym) function in the CFITSIO library C API.

**See Also** `readKey` | `readKeyDb1` | `readKeyLongLong`

<b>Purpose</b>	Keyword as double precision value
<b>Syntax</b>	<code>[value,comment] = readKeyDbl(fpPtr,keyname)</code>
<b>Description</b>	<p><code>[value,comment] = readKeyDbl(fpPtr,keyname)</code> returns the specified key and comment.</p> <p>This function corresponds to the <code>fits_read_key_dbl</code> (ffgkyd) function in the CFITSIO library C API.</p>
<b>Examples</b>	<pre>import matlab.io.* fpPtr = fits.openFile('tst0012.fits'); n = fits.getNumHDUs(fpPtr); for j = 1:n     fits.movAbsHDU(fpPtr,j);     [key,comment] = fits.readKeyDbl(fpPtr,'NAXIS');     fprintf('HDU %d: NAXIS %s, "%s"\n', j, key, comment); end fits.closeFile(fpPtr);</pre>
<b>See Also</b>	<code>readKey</code>   <code>readKeyCmplx</code>   <code>readKeyLongLong</code>

# matlab.io.fits.readKeyLongLong

---

**Purpose** Keyword as int64

**Syntax** [value,comment] = readKeyLongLong(fpPtr,keyname)

**Description** [value,comment] = readKeyLongLong(fpPtr,keyname) returns the specified key and comment. value is returned an int64 scalar value. This function corresponds to the fits\_read\_key\_lnglng (ffgkyjj) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
    fits.movAbsHDU(fpPtr,j);
    [key,comment] = fits.readKeyLongLong(fpPtr,'NAXIS');
    fprintf('HDU %d: NAXIS %d, "%s"\n', j, key, comment);
end
fits.closeFile(fpPtr);
```

**See Also** readKey | readKeyCmplx | readKeyDb1

**Purpose** Long string value

**Syntax** [value,comment] = readKeyLongStr(fptr,keyname)

**Description** [value,comment] = readKeyLongStr(fptr,keyname) returns the specified long string value and comment.

This function corresponds to the `fits_read_key_longstr` (ffgk1s) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
idata = repmat(char(97:106),1,10);
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeKey(fptr,'mykey',idata);
odata1 = fits.readKey(fptr,'mykey');
odata2 = fits.readKeyLongStr(fptr,'mykey');
fits.closeFile(fptr);
```

**See Also** readKey

# matlab.io.fits.readKeyUnit

---

**Purpose** Physical units string from keyword

**Syntax** `units = readKeyUnit(fpPtr,keyname)`

**Description** `units = readKeyUnit(fpPtr,keyname)` returns the physical units string from an existing keyword. If no units are defined, `units` is returned as an empty string.

This function corresponds to the `fits_read_key_unit` (ffgunt) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'long_img',[10 20]);
fits.writeKey(fpPtr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fpPtr,'VELOCITY','km/s');
units = fits.readKeyUnit(fpPtr,'VELOCITY');
fits.closeFile(fpPtr);
```

**See Also** [readKey](#) | [writeKeyUnit](#)

**Purpose** Header record specified by number

**Syntax** `card = readRecord(fptr,keynum)`

**Description** `card = readRecord(fptr,keynum)` returns the entire 80-character header record identified by the numeric `keynum`. Trailing blanks are truncated.

This function corresponds to the `fits_read_record` (`ffgrec`) function in the CFITSIO library C API.

**Examples** Read the second record in each HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHdrSpace(fptr);
for j = 1:n
    card = fits.readRecord(fptr,j);
    fprintf('record %d: "%s"\n', j, card);
end
fits.closeFile(fptr);
```

**See Also** `deleteRecord` | `readKey` | `readCard`

# matlab.io.fits.writeComment

---

**Purpose** Write or append COMMENT keyword to CHU

**Syntax** writeComment(fpPtr,comment)

**Description** writeComment(fpPtr,comment) writes (appends) a COMMENT keyword to the CHU. The comment string will be continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the fits\_write\_comment (ffpcom) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'byte_img',[100 200]);
fits.writeComment(fpPtr,'this is a comment');
fits.writeComment(fpPtr,'this is another comment');
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** writeHistory | writeDate

**Purpose** Write DATE keyword to CHU

**Syntax** writeDate(FPTR)

**Description** writeDate(FPTR) writes the DATE keyword to the CHU.  
This function corresponds to the fits\_write\_date (ffpdat) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeDate(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** writeComment | writeHistory

# matlab.io.fits.writeKey

---

**Purpose** Update or add new keyword into current HDU

**Syntax** `writeKey(fpPtr, keyname, value, comment)`  
`writeKey(fpPtr, keyname, value, comment, decimals)`

**Description** `writeKey(fpPtr, keyname, value, comment)` adds a new record in the current HDU, or updates it if it already exists. `comment` is optional.

`writeKey(fpPtr, keyname, value, comment, decimals)` adds a new floating point keyword in the current HDU, or updates it if it already exists. You must use this syntax to write a keyword with imaginary components. `decimals` is ignored otherwise.

If a character `value` exceeds 68 characters in length, the LONGWARN convention is automatically employed.

This function corresponds to the `fits_write_key` (`ffpky`) and `fits_update_key` (`ffuky`) family of functions in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr, 'byte_img', [100 200]);
fits.writeKey(fpPtr, 'mykey1', 'a char value', 'with a comment');
fits.writeKey(fpPtr, 'mykey2', int32(1));
fits.writeKey(fpPtr, 'mykey3', 5+7*j, 'with another comment');
fits.writeKey(fpPtr, 'mykey4', 4/3, 'with yet another comment', 2);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'mode', 'full');
```

**See Also** `readKey` | `deleteKey` | `readRecord`

**Purpose** Write physical units string

**Syntax** writeKeyUnit(fpPtr,keyname,unit)

**Description** writeKeyUnit(fpPtr,keyname,unit) writes a physical units string into an existing keyword.

This function corresponds to the fits\_write\_key\_unit (ffpunit) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myFitsFile.fits');
fits.createImg(fpPtr,'long_img',[10 20]);
fits.writeKey(fpPtr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fpPtr,'VELOCITY','km/s');
fits.closeFile(fpPtr);
```

**See Also** readKeyUnit

# matlab.io.fits.writeHistory

---

**Purpose** Write or append HISTORY keyword to CHU

**Syntax** writeHistory(fpPtr,history)

**Description** writeHistory(fpPtr,history) writes (appends) a HISTORY keyword to the CHU. The history string is continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the fits\_write\_history (ffphis) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'byte_img',[100 200]);
fits.writeHistory(fpPtr,'this is a history keyword');
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** writeComment | writeDate

**Purpose** Copy current HDU from one file to another

**Syntax** `copyHDU(infptr,outfptr)`

**Description** `copyHDU(infptr,outfptr)` copies the current HDU from the FITS file associated with `infptr` and appends it to the end of the FITS file associated with `outfptr`.

This function corresponds to the `fits_copy_hdu` (`ffcopy`) function in the CFITSIO library C API.

**Examples** Copy the first, third, and fifth HDUs from one file to another.

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,3);
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,5);
fits.copyHDU(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
fitsdisp('tst0012.fits','mode','min','index',[1 3 5]);
fitsdisp('myfile.fits','mode','min');
```

**See Also** `deleteHDU`

# matlab.io.fits.deleteHDU

---

**Purpose** Delete current HDU in FITS file

**Syntax** HDU\_TYPE = deleteHDU(fptr)

**Description** HDU\_TYPE = deleteHDU(fptr) deletes the current HDU in the FITS file. Any following HDUs will be shifted forward in the file, filling the gap created by the deleted HDU. In the case of deleting the primary array (the first HDU in the file) then the current primary array will be replaced by a null primary array containing the minimum set of required keywords and no data. If there are more HDUs in the file following the HDU being deleted, then the current HDU will be redefined to point to the following HDU. If there are no following HDUs then the current HDU will be redefined to point to the previous HDU. HDU\_TYPE returns the type of the new current HDU.

This function corresponds to the fits\_delete\_hdu (ffdhdu) function in the CFITSIO library C API.

**Examples** Delete the second HDU in a FITS file.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fitsdisp('myfile.fits','mode','min');
fptr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fptr,2);
new_current_hdu = fits.deleteHDU(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

**See Also** copyHDU

**Purpose** Number of current HDU in FITS file

**Syntax** N = getHDUnum(fptr)

**Description** N = getHDUnum(fptr) returns the number of the current HDU in the FITS file. The primary array has HDU number 1.

This function corresponds to the `fits_get_hdu_num` (`ffghdn`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHDUnum(fptr);
fits.closeFile(fptr);
```

**See Also** [getNumHDUs](#) | [getHDUtype](#)

# matlab.io.fits.getHDUtype

---

**Purpose** Type of current HDU

**Syntax** `htype = getHDUtype(fp_ptr)`

**Description** `htype = getHDUtype(fp_ptr)` returns the type of the current HDU in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'  
'ASCII_TBL'  
'BINARY_TBL'
```

This function corresponds to the `fits_get_hdu_type` (`ffghdt`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*  
fp_ptr = fits.openFile('tst0012.fits');  
n = fits.getNumHDUs(fp_ptr);  
for j = 1:n  
    fits.getHDUtype(fp_ptr);  
end  
fits.closeFile(fp_ptr);
```

**See Also** `getHDUenum`

**Purpose** Total number of HDUs in FITS file

**Syntax** N = getNumHDUs(fpnr)

**Description** N = getNumHDUs(fpnr) returns the number of completely defined HDUs in a FITS file. If a new HDU has just been added to the FITS file, then that last HDU will only be counted if it has been closed, or if data has been written to the HDU. The current HDU remains unchanged by this routine.

This function corresponds to the fits\_get\_num\_hdus (ffthdu) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpnr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpnr);
fits.closeFile(fpnr);
```

**See Also** getHDUnum

# matlab.io.fits.movAbsHDU

---

**Purpose** Move to absolute HDU number

**Syntax** `hType = fits.movAbsHDU(fpPtr,HDUNUM)`

**Description** `hType = fits.movAbsHDU(fpPtr,HDUNUM)` moves to a specified absolute HDU number (starting with 1 for the primary array) in the FITS file. The possible values for `hType` are:

```
'IMAGE_HDU'  
'ASCII_TBL'  
'BINARY_TBL'
```

This function corresponds to the `fits_move_abs_hdu` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*  
fpPtr = fits.openFile('tst0012.fits');  
n = fits.getNumHDUs(fpPtr);  
for j = 1:n  
    hType = fits.movAbsHDU(fpPtr,j);  
    fprintf('HDU %d: "%s"\n',j,hType);  
end  
fits.closeFile(fpPtr);
```

**See Also** `getNumHDUs` | `movRelHDU` | `movNamHDU`

**Purpose** Move to first HDU having specific type and keyword values

**Syntax** `movNamHDU(fptr,hdutype,EXTNAME,EXTVER)`

**Description** `movNamHDU(fptr,hdutype,EXTNAME,EXTVER)` moves to the first HDU which has the specified extension type and `EXTNAME` and `EXTVER` keyword values (or `HDUNAME` and `HDUVER` keywords).

The `hdutype` parameter may have a value of:

```
'IMAGE_HDU'  
'ASCII_TBL'  
'BINARY_TBL'  
'ANY_HDU'
```

If `hdutype` is `'ANY_HDU'`, only the `EXTNAME` and `EXTVER` values are used to locate the correct extension. If the input value of `EXTVER` is 0, then the `EXTVER` keyword is ignored and the first HDU with a matching `EXTNAME` (or `HDUNAME`) keyword will be found.

This function corresponds to the `fits_movnam_hdu` (`ffmnhd`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*  
fptr = fits.openFile('tst0012.fits');  
fits.movNamHDU(fptr,'IMAGE_HDU','quality',1);  
fits.closeFile(fptr);
```

**See Also** `movAbsHDU` | `movRelHDU`

**Purpose** Move relative number of HDUs from current HDU

**Syntax** `htype = moveRelHDU(fpPtr,nmove)`

**Description** `htype = moveRelHDU(fpPtr,nmove)` moves a relative number of HDUs forward or backward from the current HDU and returns the HDU type, `htype`, of the resulting HDU. The possible values for `htype` are:

```
'IMAGE_HDU'  
'ASCII_TBL'  
'BINARY_TBL'
```

This function corresponds to the `fits_movrel_hdu` (`ffmrhd`) function in the CFITSIO library C API.

**Examples** Move through each HDU in succession, then move backwards twice by two HDUs.

```
import matlab.io.*  
fpPtr = fits.openFile('tst0012.fits');  
n = fits.getNumHDUs(fpPtr);  
for j = 1:n  
    htype = fits.movAbsHDU(fpPtr,j);  
    fprintf('HDU %d: "%s"\n',j,htype);  
end  
htype = fits.movRelHDU(fpPtr,-2);  
n = fits.getHDUum(fpPtr);  
fprintf('HDU %d: "%s"\n',n,htype);  
htype = fits.movRelHDU(fpPtr,-2);  
n = fits.getHDUum(fpPtr);  
fprintf('HDU %d: "%s"\n',n,htype);  
fits.closeFile(fpPtr);
```

**See Also** `movAbsHDU` | `movNamHDU`

**Purpose** Compute and write checksum for current HDU

**Syntax** `writeChecksum(fptr)`

**Description** `writeChecksum(fptr)` computes and writes the DATASUM and CHECKSUM keyword values for the current HDU into the current header. If the keywords already exist, their values are updated only if necessary (for example, if the file has been modified since the original keyword values were computed).

This function corresponds to the `fits_write_chksum (ffpcks)` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'long_img', [10 20]);
fits.writeChecksum(fptr)
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

**See Also** `fitsdisp`

# matlab.io.fits.imgCompress

---

**Purpose** Compress HDU from one file into another

**Syntax** `imgCompress(infptr,outfptr)`

**Description** `imgCompress(infptr,outfptr)` initializes the output HDU, copies all the keywords, and loops through the input image, compressing the data and writing the compressed data to the output HDU.

This function corresponds to the `fits_img_compress` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.setCompressionType(outfptr,'rice');
fits.imgCompress(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
```

**See Also** `setCompressionType`

**Purpose** Determine if current image is compressed

**Syntax** TF = isCompressedImg(fptr)

**Description** TF = isCompressedImg(fptr) returns true if the image in the current HDU is compressed.

This function corresponds to the fits\_is\_compressed\_image function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
bool = fits.isCompressedImg(fptr);
fits.closeFile(fptr);
```

**See Also** setCompressionType

# matlab.io.fits.setCompressionType

---

**Purpose** Set image compression type

**Syntax** `setCompressionType(fpPtr,comptype)`

**Description** `setCompressionType(fpPtr,comptype)` specifies the image compression algorithm that should be used when writing a FITS image.

Supported values for `comptype` include:

```
'GZIP'  
'GZIP2'  
'RICE'  
'PLIO'  
'HCOMPRESS'  
'NOCOMPRESS'
```

This function corresponds to the `fits_set_compression_type` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*  
fpPtr = fits.createFile('myfile.fits');  
fits.setCompressionType(fpPtr,'GZIP2');  
fits.createImg(fpPtr,'long_img',[256 512]);  
data = reshape(1:256*512,[256 512]);  
data = int32(data);  
fits.writeImg(fpPtr,data);  
fits.closeFile(fpPtr);  
fitsdisp('myfile.fits','mode','full');
```

## See Also

`setTileDim` | `createImg`

**Purpose** Set scale parameter for HCOMPRESS algorithm

**Syntax** `setHCompScale(fptr, scale)`

**Description** `setHCompScale(fptr, scale)` sets the scale parameter to be used with the HCOMPRESS compression algorithm. Setting the scale parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_scale` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
data = 50*ones(256,512,'double') + 10 * rand([256 512]);
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr, 'HCOMPRESS_1');
fits.setHCompScale(fptr, 2.5);
fits.createImg(fptr, 'double_img', [256 512]);
fits.writeImg(fptr, data);
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

**See Also** `setHCompSmooth` | `setCompressionType`

# matlab.io.fits.setHCompSmooth

---

**Purpose** Set smoothing for images compressed with HCOMPRESS

**Syntax** `setHCompSmooth(fptr,smooth)`

**Description** `setHCompSmooth(fptr,smooth)` sets the smoothing to be used when compressing an image with the HCOMPRESS algorithm. Setting either the scale or smoothing parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_smooth` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
data = int32(50*ones(256,512,'double') + 10 * rand([256 512]));
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'HCOMPRESS');
fits.setHCompSmooth(fptr,1);
fits.createImg(fptr,'long_img',[256 512]);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** `setHCompScale` | `setCompressionType`

**Purpose** Set tile dimensions

**Syntax** `fits.setTileDim(fpPtr,tiledims)`

**Description** `fits.setTileDim(fpPtr,tiledims)` specifies the size of the image compression tiles to be used when creating a compressed image. This function corresponds to the `fits_set_tile_dim` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.setCompressionType(fpPtr,'RICE_1');
fits.setTileDim(fpPtr,[64 128]);
fits.createImg(fpPtr,'byte_img',[256 512]);
data = ones(256,512,'uint8');
fits.writeImg(fpPtr,data);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** `setCompressionType`

# matlab.io.fits.createTbl

---

**Purpose** Create new ASCII or binary table extension

**Syntax** `fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)`

**Description** `fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)` creates a new ASCII or bintable table extension. `ttype` must be either 'binary' or 'ascii'. The `nrows` argument gives the initial number of rows to be created in the table and should normally be zero. `tunit` specifies the units for each column, but can be an empty cell array if no units are desired. `extname` specifies the extension name, but can be omitted.

`tform` specifies the format of the column. For binary tables, the values should be in the form of 'rt', where 'r' is the repeat count and 't' is one of the following letters.

'A'	ASCII character
'B'	Byte or uint8
'C'	Complex (single precision)
'D'	Double precision
'E'	Single precision
'I'	int16
'J'	int32
'K'	int64
'L'	Logical
'M'	Complex (double precision)
'X'	Bit (int8 zeros and ones)

A column can also be specified as having variable-width if the `tform` value has the form '1Pt' or '1Qt', where 't' specifies the data type as above.

For ASCII tables, the `tform` values take the form:

<code>Iw</code>	int16 column with width 'w'
<code>Aw</code>	ASCII column with width 'w'
<code>Fww.dd</code>	Fixed point
<code>Eww.dd</code>	Single precision with width 'ww' and precision 'dd'
<code>Dww.dd</code>	Double precision with width 'ww' and precision 'dd'

This function corresponds to the `fits_create_tbl` (`ffcrtb`) function in the CFITSIO library C API.

## Examples

Create a binary table. The first column contains strings of nine characters each. The second column contains four-element sequences of bits. The third column contains three-element sequences of `uint8` values. The fourth column contains double-precision scalars.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1', 'Col2', 'Col3', 'Col4'};
tform = {'9A', '4X', '3B', '1D'};
tunit = {'m/s', 'kg', 'kg/m^3', 'candela'};
fits.createTbl(fptr, 'binary', 10, ttype, tform, tunit, 'my-table');
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

---

Create a two-column table where the first column has a single double-precision value, but the second column has a variable-length double-precision value.

```
import matlab.io.*
fptr = fits.createFile('myfile2.fits');
ttype = {'Col1', 'Col2'};
```

# matlab.io.fits.createTbl

---

```
tform = {'1D','1PD'};
fits.createTbl(fptr,'binary',0,ttype,tform);
fits.closeFile(fptr);
fitsdisp('myfile2.fits');
```

## See Also

[insertATbl](#) | [insertBTbl](#) | [readCol](#) | [writeCol](#) | [createImg](#)

**Purpose** Delete column from table

**Syntax** deleteCol(fpnr,colnum)

**Description** deleteCol(fpnr,colnum) deletes the column from an ASCII or binary table.

This function corresponds to the fits\_delete\_col (ffdcoll) function in the CFITSIO library C API.

**Examples** Delete the second column in a binary table.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fpnr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fpnr,2);
fits.deleteCol(fpnr,2);
fits.closeFile(fpnr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

**See Also** deleteRows

# matlab.io.fits.deleteRows

---

**Purpose** Delete rows from table

**Syntax** deleteRows(fpPtr,firstrow,nrows)

**Description** deleteRows(fpPtr,firstrow,nrows) deletes rows from an ASCII or binary table.

This function corresponds to the fits\_delete\_rows (ffdraw) function in the CFITSIO library C API.

**Examples** Delete the second, third, and fourth rows in a binary table (second HDU).

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fpPtr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fpPtr,2);
fits.deleteRows(fpPtr,2,2);
fits.closeFile(fpPtr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

**See Also** deleteCol | insertRows

**Purpose** Insert rows into table

**Syntax** `insertRows(fptr,firstrow,nrows)`

**Description** `insertRows(fptr,firstrow,nrows)` inserts rows into an ASCII or binary table. `firstrow` is a one-based number.

This function corresponds to the `fits_insert_rows` (`fffirow`) function in the CFITSIO library C API.

**Examples** Insert five rows into an empty table.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertRows(fptr,1,5);
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2);
```

**See Also** `insertCol` | `deleteRows`

# matlab.io.fits.getAColParms

---

**Purpose** ASCII table information

**Syntax** [ttype,tbcol,tunit,tform,scale,zero,nulstr,  
tdisp] = getAColParms(fptr,colnum)

**Description** [ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = getAColParms(fptr,colnum) gets information about an existing ASCII table column.

This function corresponds to the fits\_get\_acolparms (fffacl) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = fits.getAColParms(fptr,colnum);
fits.closeFile(fptr);
```

**See Also** getBColParms

**Purpose** Binary table information

**Syntax** [ttype,tunit,typechar,repeat,scale,zero,nulval,  
tdisp] = getBColParms(fptr,colnum)

**Description** [ttype,tunit,typechar,repeat,scale,zero,nulval, tdisp] =  
getBColParms(fptr,colnum) gets information about an existing binary  
table column.

This function corresponds to the fits\_get\_bcolparms (ffgbcl)  
function in the CFITSIO library C API.

**Examples** Get information about the second column in a binary table.

```
import matlab.io.*  
fptr = fits.openFile('tst0012.fits');  
fits.movAbsHDU(fptr,2);  
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp]= fits.getBColPar  
fits.closeFile(fptr);
```

**See Also** getAColParms

# matlab.io.fits.getColName

---

**Purpose** Table column name

**Syntax** `[colnum,colname] = getColNum(fpPtr,templt,casesen)`

**Description** `[colnum,colname] = getColNum(fpPtr,templt,casesen)` gets the table column numbers and names of the columns whose names match an input template name. If `casesen` is true, then the column name match is case-sensitive. `casesen` defaults to false.

The input column name template may be either the exact name of the column to be searched for, or it may contain wildcard characters (\*, ?, or #), or it may contain the integer number of the desired column (with the first column = 1). The '\*' wildcard character matches any sequence of characters (including zero characters) and the '?' character matches any single character. The # wildcard matches any consecutive string of decimal digits (0-9).

**Examples** Return all the columns starting with the letter 'C'.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
[nums,names] = fits.getColName(fpPtr,'C*');
fits.closeFile(fpPtr);
```

**See Also** [getAColParms](#) | [getBColParms](#)

**Purpose** Scaled column data type, repeat value, width

**Syntax** [dtype,repeat,width] = getColType(fptr,colnum)

**Description** [dtype,repeat,width] = getColType(fptr,colnum) returns the data type, vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the fits\_get\_coltypell (ffgtclll) function in the CFITSIO library C API.

**Examples** Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getColType(fptr,5);
fits.closeFile(fptr);
```

**See Also** getEqColType

# matlab.io.fits.getEqColType

---

**Purpose** Column data type, repeat value, width

**Syntax** [dtype,repeat,width] = getColType(fptr,colnum)

**Description** [dtype,repeat,width] = getColType(fptr,colnum) returns the scaled data type needed to store the scaled column data type, the vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the `fits_get_eqcoltype11` (`ffeqty11`) function in the CFITSIO library C API.

**Examples** Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getEqColType(fptr,5);
fits.closeFile(fptr);
```

**See Also** `getColType`

**Purpose** Number of columns in table

**Syntax** `ncols = getNumCols(fpPtr)`

**Description** `ncols = getNumCols(fpPtr)` gets the number of columns in the current FITS table. This function corresponds to the `fits_get_num_cols` (`ffgncl`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
ncols = fits.getNumCols(fpPtr);
nrows = fits.getNumRows(fpPtr);
fits.closeFile(fpPtr);
```

**See Also** `getNumRows`

# matlab.io.fits.getNumRows

---

**Purpose**            Number of rows in table

**Syntax**            `nrows = getNumRows(fpPtr)`

**Description**       `nrows = getNumRows(fpPtr)` gets the number of rows in the current FITS table. This function corresponds to the `fits_get_num_rows11` (`ffgnrwl1`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
nCols = fits.getNumCols(fpPtr);
nRows = fits.getNumRows(fpPtr);
fits.closeFile(fpPtr);
```

**See Also**    `getNumCols`

**Purpose** Insert column into table

**Syntax** `insertCol(fptr,colnum,ttype,tform)`

**Description** `insertCol(fptr,colnum,ttype,tform)` inserts a column into an ASCII or binary table.

This function corresponds to the `fits_insert_col` (`fficol`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertCol(fptr,3,'Col3','3D');
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2);
```

**See Also** `insertRows`

# matlab.io.fits.insertATbl

---

**Purpose** Insert ASCII table after current HDU

**Syntax** `insertATbl(fptr, rowlen, nrows, ttype, tbc, tform, tunit, extname)`

**Description** `insertATbl(fptr, rowlen, nrows, ttype, tbc, tform, tunit, extname)` inserts a new ASCII table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions, then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the current HDU. If `rowlen` is 0, then CFITSIO calculates the default `rowlen` based on the `tbc` and `ttype` values.

`tform` can take the following forms. In each case, 'w' and 'ww' represent the widths of the ASCII columns.

Iw	int16 column
Aw	ASCII column
Fww.dd	Fixed point with 'dd' digits after the decimal point
Eww.dd	Single precision with 'dd' digits of precision
Dww.dd	Double precision with 'dd' digits of precision

Binary tables are recommended instead of ASCII tables.

This function corresponds to the `fits_insert_atbl` (`ffitab`) function in the CFITSIO library C API.

**Examples** Create an ASCII table between two images.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'uint8', [20 30]);
```

```
fits.createImg(fpPtr,'int16',[30 40]);
fits.movRelHDU(fpPtr,-1);
ttype = {'Name','Short','Fix','Double'};
tbcol = [1 17 28 43];
tform = {'A15','I10','F14.2','D12.4'};
tunit = {'','m**2','cm','km/s'};
fits.insertATbl(fpPtr,0,0,ttype,tbcol,tform,tunit,'my-table');
fits.writeCol(fpPtr,1,1,char('abracadabra','hocus-pocus'));
fits.writeCol(fpPtr,2,1,int16([0; 1]));
fits.writeCol(fpPtr,3,1,[12.4; 4/3]);
fits.writeCol(fpPtr,4,1,[12.4; 4e8/3]);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','min');
```

[createTbl](#) | [insertBTbl](#)

# matlab.io.fits.insertBTbl

---

<b>Purpose</b>	Insert binary table after current HDU
<b>Syntax</b>	<code>insertBTbl(fptr,nrows,ttype,tform,tunit,extname,pcount)</code>
<b>Description</b>	<p><code>insertBTbl(fptr,nrows,ttype,tform,tunit,extname,pcount)</code> inserts a new binary table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the CHDU. If there are following extensions in the file and if the table contains variable-length array columns then <code>pcount</code> must specify the expected final size of the data heap. Otherwise, <code>pcount</code> must be zero.</p> <p>This function corresponds to the <code>fits_insert_btbl</code> (<code>ffibin</code>) function in the CFITSIO library C API.</p>

**Examples** Create a table following the primary array. Then, insert a new table just before it.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'9A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',10,ttype,tform,tunit,'my-table');
fits.movRelHDU(fptr,-1);
fits.insertBTbl(fptr,5,ttype,tform,tunit,'my-new-table',0);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

**See Also** [createTbl](#) | [insertATbl](#)

**Purpose** Read header information from current ASCII table

**Syntax** [rowlen,nrows,ttype,tbcol,tform,tunit,extname] = readATblHdr(fptr)

**Description** [rowlen,nrows,ttype,tbcol,tform,tunit, extname] = readATblHdr(fptr) reads header information for the current ASCII table.

This function corresponds to the fits\_read\_atblhdr11 (ffghtb11) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[rowlen,nrows,ttype,tbcol,tform,tunit,extname] = fits.readATblHdr(fptr);
fits.closeFile(fptr);
```

**See Also** readBTblHdr

# matlab.io.fits.readBTblHdr

---

**Purpose** Read header information from current binary table

**Syntax** [nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr)

**Description** [nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr) reads header information for the current binary table.

This function corresponds to the fits\_read\_btblhdr11 (ffghbn11) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[nrows,ttype,tform,tunit,extname,pcount] = fits.readBTblHdr(fptr);
fits.closeFile(fptr);
```

**See Also** readATblHdr

**Purpose**

Read rows of ASCII or binary table column

**Syntax**

```
[coldata,nullval] = readCol(fpPtr,colnum)
[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows)
```

**Description**

[coldata,nullval] = readCol(fpPtr,colnum) reads an entire column from an ASCII or binary table column. nullval is a logical array specifying if a particular element of coldata should be treated as undefined. It is the same size as coldata.

[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows) reads a subsection of rows from an ASCII or binary table column.

The MATLAB data type returned by readCol corresponds to the data type returned by getEqColType.

This function corresponds to the fits\_read\_col (ffgcv) function in the CFITSIO library C API.

**Examples**

Read an entire column.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
colnum = fits.getColName(fpPtr,'flux');
fluxdata = fits.readCol(fpPtr,colnum);
fits.closeFile(fpPtr);
```

---

Read the first five rows in a column.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
colnum = fits.getColName(fpPtr,'flux');
fluxdata = fits.readCol(fpPtr,colnum,1,5);
fits.closeFile(fpPtr);
```

# matlab.io.fits.readCol

---

**See Also** [writeCol](#)

**Purpose** Reset image scaling

**Syntax** `setTscale(fptr,colnum,tscale,tzero)`

**Description** `setTscale(fptr,colnum,tscale,tzero)` resets the scaling factors for a table column according to the equation:

$$\text{output} = (\text{FITS array}) * \text{tscale} + \text{tzero}$$

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the `tscale` and `tzero` keyword values.

**Examples** Turn off automatic scaling in a table column where the `tscale` and `tzero` keywords are present.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
scaled_data = fits.readCol(fptr,3);
fits.setTscale(fptr,3,1.0,0.0);
unscaled_data = fits.readCol(fptr,3);
fits.closeFile(fptr);
```

**See Also** `readImg`

# matlab.io.fits.writeCol

---

**Purpose** Write elements into ASCII or binary table column

**Syntax** `writeCol(fpPtr,colnum,firstrow,coldata)`

**Description** `writeCol(fpPtr,colnum,firstrow,coldata)` writes elements into an ASCII or binary table extension column.

When writing rows of data to a variable length field, `coldata` must be a cell array.

This function corresponds to the `fits_write_col` (ffpcol) function in the CFITSIO library C API.

**Examples** Write to a table with ASCII, uint8, double-precision, and variable-length double-precision columns.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'3A','3B','1D','1PD'};
tunit = {'m/s','kg/m^3','candela','parsec'};
fits.createTbl(fpPtr,'binary',0,ttype,tform,tunit,'my-table');
fits.writeCol(fpPtr,1,1,['dog','cat']);
fits.writeCol(fpPtr,2,1,[0 1 2; 3 4 5; 6 7 8; 9 10 11]);
fits.writeCol(fpPtr,3,1,[1; 2; 3; 4]);
fits.writeCol(fpPtr,4,1,{1;[1 2];[1 2 3];[1 2 3 4]});
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','index',2,'mode','full');
```

---

Write to a table with logical, bit, double precision, and variable-length complex single-precision columns.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'2L','3X','1D','1PC'};
```

```
tunit = {'','kg/m^3','candela','parsec'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.writeCol(fptr,1,1,[false false; true false]);
fits.writeCol(fptr,2,1,int8([0 1 1; 1 1 1; 1 1 1; 1 0 1]));
fits.writeCol(fptr,3,1,[1; 2; 3; 4]);
data = cell(4,1);
data{1} = single(1);
data{2} = single(1+2j);
data{3} = single([1j 2 3+j]);
data{4} = single([1 2+3j 3 4]);
fits.writeCol(fptr,4,1,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2,'mode','full');
```

## See Also

[createTbl](#) | [readCol](#)

# matlab.io.fits.getConstantValue

---

**Purpose** Numeric value of named constant

**Syntax** N = getConstantValue(name)

**Description** N = getConstantValue(name) returns the numeric value corresponding to the named CFITSIO constant.

**Examples**

```
import matlab.io.*  
n = fits.getConstantValue('BYTE_IMG');
```

**Purpose** Revision number of the CFITSIO library

**Syntax** `V = getVersion()`

**Description** `V = getVersion()` returns the revision number of the CFITSIO library. This function corresponds to the `fits_get_version` (`ffvers`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*  
v = fits.getVersion();
```

# matlab.io.fits.getOpenFiles

---

**Purpose** List of open FITS files

**Syntax** `fptrs = getOpenFiles()`

**Description** `fptrs = getOpenFiles()` returns a list of file pointers of all open FITS files.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
clear fptr;
fptr = fits.getOpenFiles();
fits.closeFile(fptr);
```

**See Also** `openFile` | `closeFile`

<b>Purpose</b>	Startup file for MATLAB program
<b>Description</b>	<p>At startup time, MATLAB automatically executes the file <code>matlabrc.m</code>. This function establishes the MATLAB path, sets the default figure size, and sets some uicontrol defaults.</p> <p>On multiuser or networked systems, system administrators can put messages, definitions, or other code that applies to all users in their <code>matlabrc.m</code> file.</p> <p>The file <code>matlabrc.m</code> invokes the <code>startup.m</code> file, if it exists on the search path MATLAB uses.</p> <p>Individual users should use the <code>startup.m</code> file to customize MATLAB startup. The <code>matlabrc.m</code> file, located in the <code>matlabroot/toolbox/local</code> folder, is reserved for system administrators.</p>
<b>Algorithms</b>	<p>MATLAB invokes <code>matlabrc</code> at startup. <code>matlabrc.m</code> contains the statements</p> <pre>if exist('startup') == 2     startup end</pre> <p>that invokes <code>startup.m</code>, if it exists. Extend this process to create additional startup files, if required.</p>
<b>Tips</b>	You can also start MATLAB using options you define at the Command Window prompt or in your Microsoft Windows shortcut for MATLAB.
<b>Examples</b>	<p><b>Turning Off the Figure Window Toolbar</b></p> <p>If you do not want the toolbar to appear in the figure window, remove the comment marks from the following line in the <code>matlabrc.m</code> file, or create a similar line in your own <code>startup.m</code> file.</p> <pre>% set(0,'defaultfiguretoolbar','none')</pre>

# matlabrc

---

## See Also

matlabroot | quit | restoredefaultpath | startup

## How To

- Startup Options

**Purpose** Root folder

**Syntax** matlabroot  
mr = matlabroot

**Description** matlabroot returns the name of the folder where the MATLAB software is installed. Use matlabroot to create a path to MATLAB and toolbox folders that does not depend on a specific platform, MATLAB version, or installation location.

mr = matlabroot returns the name of the folder in which the MATLAB software is installed and assigns it to mr.

**Tips** **matlabroot as Folder Name**

The term *matlabroot* also refers to the folder where MATLAB files are installed. For example, “save to *matlabroot/toolbox/local*” means save to the *toolbox/local* folder in the MATLAB root folder.

### Using \$matlabroot as a Literal

In some files, \$matlabroot is literal. In those files, MATLAB interprets \$matlabroot as the full path to the MATLAB root folder. For example, including the line:

```
$matlabroot/toolbox/local/myfile.jar
```

in *javaclasspath.txt*, adds *myfile.jar*, which is located in the *toolbox/local* folder, to the static Java class path.

Sometimes, particularly in older code examples, the term \$matlabroot or \$MATLABROOT is not meant to be interpreted literally but is used to represent the value returned by the matlabroot function.

### matlabroot on Macintosh Platforms

In R2008b (V7,7) and more recent versions, running matlabroot on Apple Macintosh platforms returns

```
/Applications/MATLAB_R2008b.app
```

In versions prior to R2008b (V7.7), such as R2008a (V7.6), running `matlabroot` on Macintosh platforms returns, for example

```
/Applications/MATLAB_R2008a
```

When you use GUIs on Macintosh platforms, you cannot directly view the contents of the MATLAB root folder. For more information, see “Navigating Within the MATLAB Root Folder on Macintosh Platforms”.

## Examples

Get the location where MATLAB is installed:

```
matlabroot
```

MATLAB returns:

```
C:\Program Files\MATLAB\R2009a
```

Produce a full path to the `toolbox/matlab/general` folder that is correct for the platform on which it is executed:

```
fullfile(matlabroot, 'toolbox', 'matlab', 'general')
```

Change the current folder to the MATLAB root folder:

```
cd(matlabroot)
```

To add the folder `myfiles` to the MATLAB search path, run

```
addpath([matlabroot ' /toolbox/local/myfiles'])
```

## See Also

`fullfile` | `path` | `toolboxdir`

## How To

- “Understanding File Locations in MATLAB”

**Purpose** Start MATLAB program (UNIX platforms)

**Syntax**

```
matlab helpOption
matlab envDispOption
matlab archOption
matlab dispOption
matlab modeOption
matlab -c licensefile
matlab -debug
matlab -Ddebugger options
matlab -jdb portnumber
matlab -logfile filename
matlab -mwvisual visualid
matlab -noFigureWindows
matlab -nosplash
matlab -nouserjavapath
matlab -r "command"
matlab -singleCompThread
```

---

**Note** You can enter more than one of these options in the same `matlab` command. If you use `-Ddebugger` to start MATLAB in debug mode, the first option in the command must be `-Ddebugger`.

---

## Description

`matlab` is a Bourne shell script that starts the MATLAB executable on UNIX platforms. (In this document, `matlab` refers to this script; MATLAB refers to the application program). Before actually initiating the execution of MATLAB, this script configures the run-time environment by:

- Determining the MATLAB root folder
- Determining the host machine architecture
- Processing any command line options
- Reading the MATLAB startup file, `.matlab7rc.sh`

# matlab (UNIX)

---

- Setting MATLAB environment variables

There are two ways in which you can control the way the `matlab` script works:

- By specifying command line options
- By assigning values in the MATLAB startup file, `.matlab7rc.sh`

## Specifying Options at the Command Line

---

**Note** On Apple Macintosh platforms, the `matlab` script is located inside the MATLAB application package:

```
/Applications/MATLAB_R2012b.app/bin/matlab
```

To run the `matlab` script from Terminal, specify the full path as shown above, or `cd` to the `bin` directory within the application package and preface the command with `./` characters. For example:

```
./matlab -nojvm -nodisplay -nosplash -r "myfun(10,30)"
```

---

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified `helpOption` argument without starting MATLAB. `helpOption` can be any one of the keywords shown in the table below. Enter only one `helpOption` keyword in a `matlab` command.

### Values for helpOption

Option	Description
<code>-help</code>	Display <code>matlab</code> command usage.
<code>-h</code>	The same as <code>-help</code> .

`matlab envDispOption` displays the values of environment variables passed to MATLAB or their values just prior to exiting MATLAB. `envDispOption` can be either one of the options shown in the table below.

## Values for `envDispOption`

Option	Description
<b>-n</b>	Display all the final values of the environment variables and arguments passed to the MATLAB executable as well as other diagnostic information. Does not start MATLAB.
<b>-e</b>	Display <i>all</i> environment variables and their values just prior to exiting. This argument must have been parsed before exiting for anything to be displayed. The last possible exiting point is just before the MATLAB image would have been executed and a status of 0 is returned. If the exit status is not 0 on return, then the variables and values may not be correct. Does not start MATLAB.

`matlab archOption` starts MATLAB and assumes that you are running on the system architecture specified by `arch`, or using the MATLAB version specified by `variant`, or both. The values for the `archOption` argument are shown in the table below. Enter only one of these options in a `matlab` command.

# matlab (UNIX)

---

## Values for archOption

Option	Description
<code>-arch</code>	Run MATLAB assuming this architecture rather than the actual architecture of the machine you are using. Replace the term <i>arch</i> with a string representing a recognized system architecture. For example:  <code>matlab -glnx86</code>
<code>v=variant</code>	Execute the version of MATLAB found in the folder <code>bin/\$ARCH/variant</code> instead of <code>bin/\$ARCH</code> . Replace the term <i>variant</i> with a string representing a MATLAB version.
<code>v=arch/variant</code>	Execute the version of MATLAB found in the folder <code>bin/arch/variant</code> instead of <code>bin/\$ARCH</code> . Replace the terms <i>arch</i> and <i>variant</i> with strings representing a specific architecture and MATLAB version.

`matlab dispOption` starts MATLAB using one of the display options shown in the table below. Enter only one of these options in a `matlab` command.

## Values for dispOption

Option	Description
<code>-display xDisp</code>	Send X commands to X Window Server display <code>xDisp</code> . This supersedes the value of the <code>DISPLAY</code> environment variable.  On Macintosh platforms, this option is ignored.
<code>-nodisplay</code>	Start the Oracle JVM software, but do not start the MATLAB desktop. Do not display

(Continued)

Option	Description
	<p>any X commands, and ignore the DISPLAY environment variable.</p> <p>On Macintosh platforms, start the JVM in headless mode, and prevent all windows from being displayed.</p>

matlab modeOption starts MATLAB without its usual desktop component. Enter only one of the options shown below.

### Values for modeOption

Option	Description
<b>-desktop</b>	Allow the MATLAB desktop to be started by a process without a controlling terminal. This is usually a required command line argument when attempting to start MATLAB from a window manager menu or desktop icon.
<b>-nodesktop</b>	Start MATLAB without bringing up the MATLAB desktop. The JVM software <i>is</i> started. Use the current window in the operating system to enter commands. Use this option to run in batch processing mode. Note that if you pipe to MATLAB using the > constructor, the nodesktop option is used automatically. With nodesktop, MATLAB does not save statements to the Command History. With nodesktop, you can still use most development environment tools by starting them via a function. For example, use preferences to open the Preferences dialog box and doc to open the Help browser. Do not use nodesktop to provide a Command

(Continued)

Option	Description
	Window-only interface; instead, select <b>Desktop &gt; Desktop Layout &gt; Command Window Only</b> .
<b>-nojvm</b>	Start MATLAB without the JVM software. Use the current window to enter commands. The MATLAB desktop does not open. Any tools that require Java software, such as the desktop tools, cannot be used. Handle Graphics and related functionality are not supported; MATLAB produces a warning when you use them.

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host` or it can be a colon-separated list of license filenames. This option causes the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables to be ignored.

`matlab -debug` starts MATLAB and displays debugging information that can be useful, especially for X based problems. This option should be used only when working with a Technical Support Representative from The MathWorks, Inc.

`matlab -Ddebugger options` starts MATLAB in debug mode, using the named debugger (for example, `dbx`, `gdb`, `xdb`, `cvd`, `lldb`). A full path can be specified for debugger.

### Notes for -Ddebugger Argument

- The options argument can include *only* those options that follow the debugger name in the syntax of the actual debug command. For most debuggers, there is a very limited number of such options. Options that would normally be passed to the MATLAB executable should be

used as parameters of a command inside the debugger (like `run`). They should not be used when running the `matlab` script.

- If any other `matlab` command options are placed before the **-Ddebugger** argument, they will be handled as if they were part of the options after the **-Ddebugger** argument and will be treated as illegal options by most debuggers. The `MATLAB_DEBUG` environment variable is set to the filename part of the debugger argument.
- To customize your debugging session, use a startup file. See your debugger documentation for details.
- For certain debuggers like `gdb`, the `SHELL` environment variable is *always* set to `/bin/sh`.

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the command window in file `log`. This includes all crash reports.

`matlab -mwvisual visualid` starts MATLAB and uses `visualid` as the default X visual for figure windows. `visualid` is a hexadecimal number that can be found using `xdpyinfo`.

`matlab -noFigureWindows` starts MATLAB, but disables the display of any figure windows in MATLAB.

`matlab -nosplash` starts MATLAB but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

`matlab -r "command"` starts MATLAB and executes the specified MATLAB command. Include the command in double quotation marks

("command"). If `command` is the name of a MATLAB function or script, do not specify the file extension. Use semicolons or commas to separate multiple statements.

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

## Specifying Options in the MATLAB Startup File

The `.matlab7rc.sh` shell script contains definitions for a number of variables that the `matlab` script uses. These variables are defined within the `matlab` script, but can be redefined in `.matlab7rc.sh`. When invoked, `matlab` looks for the first occurrence of `.matlab7rc.sh` in the current folder, in the home folder (`$HOME`), and in the `matlabroot/bin` folder, where the template version of `.matlab7rc.sh` is located.

You can edit the template file to redefine information used by the `matlab` script. If you do not want your changes applied systemwide, copy the edited version of the script to your current or home folder. Ensure that you edit the section that applies to your machine architecture.

The following table lists the variables defined in the `.matlab7rc.sh` file. See the comments in the `.matlab7rc.sh` file for more information about these variables.

## Variable Options for Startup File

Variable	Definition and Standard Assignment Behavior
ARCH	The machine architecture.  The value ARCH passed with the <code>-arch</code> or <code>-arch/ext</code> argument to the script is tried first, then the value of the environment variable <code>MATLAB_ARCH</code> is tried next, and finally it is

Variable	Definition and Standard Assignment Behavior
	computed. The first one that gives a valid architecture is used.
DISPLAY	<p>Linux platforms only. The hostname of the X Window display MATLAB uses for output.</p> <p>The value of <code>Xdisplay</code> passed with the <code>-display</code> argument to the script is used; otherwise, the value in the environment is used. DISPLAY is ignored by MATLAB if the <code>-nodisplay</code> argument is passed.</p>
<p>LD_LIBRARY_PATH on Linux platforms.</p> <p>DYLD_LIBRARY_PATH on Macintosh platforms.</p>	<p>Final Load library path. The name LD_LIBRARY_PATH is platform dependent.</p> <p>The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_PREFIX</code>. The second sublist is computed in the script and includes folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of LD_LIBRARY_PATH from the environment possibly augmented in <code>.matlab7rc.sh</code>. The final sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_SUFFIX</code>.</p>

# matlab (UNIX)

---

Variable	Definition and Standard Assignment Behavior
LM_LICENSE_FILE	<p>The FLEX lm license variable.</p> <p>The license file value passed with the <code>-c</code> argument to the script is used; otherwise it is the value set in <code>.matlab7rc.sh</code>. In general, the final value is a colon-separated list of license files and/or <code>port@host</code> entries. The shipping <code>.matlab7rc.sh</code> file starts out the value by prepending <code>LM_LICENSE_FILE</code> in the environment to a default <code>license.file</code>.</p> <p>Later in the <code>matlab</code> script, if the <code>-c</code> option is not used, the <code>matlabroot/etc</code> folder is searched for the files that start with <code>license.dat.DEMO</code>. These files are assumed to contain demo licenses and are added automatically to the end of the current list.</p>
MATLAB	<p>The MATLAB root folder.</p> <p>The default computed by the script is used unless <code>MATLABdefault</code> is reset in <code>.matlab7rc.sh</code>.</p> <p>Currently <code>MATLABdefault</code> is not reset in the shipping <code>.matlab7rc.sh</code>.</p>
MATLAB_DEBUG	<p>Normally set to the name of the debugger.</p> <p>The <code>-Ddebugger</code> argument passed to the script sets this variable. Otherwise, a nonempty value in the environment is used.</p>

<b>Variable</b>	<b>Definition and Standard Assignment Behavior</b>
MATLAB_JAVA	<p>The path to the root of the Java Runtime Environment.</p> <p>The default set in the script is used unless MATLAB_JAVA is already set. Any nonempty value from <code>.matlab7rc.sh</code> is used first, then any nonempty value from the environment. Currently there is no value set in the shipping <code>.matlab67rc.sh</code>, so that environment alone is used.</p>
MATLABPATH	<p>The MATLAB search path.</p> <p>The final value is a colon-separated list with the MATLABPATH from the environment prepended to a list of computed defaults. You can add subfolders of <code>userpath</code> to the MATLAB search path upon startup. See <code>userpath</code> for details.</p>
SHELL	<p>The shell to use when the “!” or <code>unix</code> command is issued in MATLAB. This is taken from the environment unless SHELL is reset in <code>.matlab7rc.sh</code>.</p> <p>Note that an additional environment variable called <code>MATLAB_SHELL</code> takes precedence over SHELL. MATLAB checks internally for <code>MATLAB_SHELL</code> first and, if empty or not defined, then checks SHELL. If SHELL is also empty or not defined, MATLAB uses <code>/bin/sh</code>. The value of <code>MATLAB_SHELL</code> should be an absolute path, i.e. <code>/bin/sh</code>, not simply <code>sh</code>.</p> <p>Currently, the shipping <code>.matlab7rc.sh</code> file does not reset SHELL and also does not reference or set <code>MATLAB_SHELL</code>.</p>

# matlab (UNIX)

---

Variable	Definition and Standard Assignment Behavior
TOOLBOX	Path of the toolbox folder.  A nonempty value in the environment is used first. Otherwise, <i>matlabroot</i> /toolbox, computed by the script, is used unless TOOLBOX is reset in <i>.matlab7rc.sh</i> . Currently TOOLBOX is not reset in the shipping <i>.matlab7rc.sh</i> .
XAPPLRESDIR	The X application resource folder (Linux systems only).  A nonempty value in the environment is used first unless XAPPLRESDIR is reset in <i>.matlab7rc.sh</i> .
XKEYSYMDB	The X keysym database file (Linux systems only).  A nonempty value in the environment is used first unless XKEYSYMDB is reset in <i>.matlab7rc.sh</i> .

The `matlab` script determines the path of the MATLAB root folder by looking up the folder tree from the *matlabroot/bin* folder (where the `matlab` script is located). The MATLAB variable is then used to locate all files within the MATLAB folder tree.

You can change the definition of MATLAB if, for example, you want to run a different version of MATLAB or if, for some reason, the path determined by the `matlab` script is not correct. (This can happen when certain types of automounting schemes are used by your system.)

## See Also

`matlab` (Windows) | `mex`

## How To

- “Start MATLAB on Linux Platforms”
- “Start MATLAB on Macintosh Platforms”

- “Startup Options”

# matlab (Windows)

---

**Purpose** Start MATLAB program (Windows platforms)

**Syntax**

```
matlab helpOption
matlab -automation
matlab -c licensefile
matlab -jdb portnumber
matlab -logfile filename
matlab -noFigureWindows
matlab -nosplash
matlab -nouserjavapath
matlab -r "statement"
matlab -regserver
matlab -sd "startdir"
matlab shieldOption
matlab -singleCompThread
matlab -unregserver
matlab -wait
```

---

**Note** You can enter more than one of these options in the same `matlab` command.

---

**Description** `matlab` is a script that runs the main MATLAB executable on Microsoft Windows platforms. (In this document, the term `matlab` refers to the script, and MATLAB refers to the main executable). Before actually initiating the execution of MATLAB, it configures the run-time environment by:

- Determining the MATLAB root folder.
- Determining the host machine architecture.
- Selectively processing command line options with the rest passed to MATLAB.
- Setting certain MATLAB environment variables.

There are two ways in which you can control the way `matlab` works:

- By specifying command line options.
- By setting environment variables before calling the program.

## Specifying Options at the Command Line

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified *helpOption* argument without starting MATLAB. *helpOption* can be any one of the keywords shown in the table below. Enter only one *helpOption* keyword in a `matlab` statement.

### Values for helpOption

Option	Description
<b>-help</b>	Display <code>matlab</code> command usage.
<b>-h</b>	The same as <b>-help</b> .
<b>-?</b>	The same as <b>-help</b> .

`matlab -automation` starts MATLAB as an automation server. The server window is minimized, and the MATLAB splash screen does not display on startup.

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host`. This option causes MATLAB to ignore the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables.

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

# matlab (Windows)

---

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the Command Window in `filename`. This includes all crash reports.

`matlab -noFigureWindows` starts MATLAB, but disables the display of any figure windows in MATLAB.

`matlab -nosplash` starts MATLAB, but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

`matlab -r "statement"` starts MATLAB and executes the specified MATLAB statement. If `statement` is the name of a MATLAB function or script, do not specify the file extension. Any required file must be on the MATLAB search path or in the startup folder.

`matlab -regserver` registers MATLAB as a Component Object Model (COM) server.

`matlab -sd "startdir"` specifies the startup folder for MATLAB (the current folder in MATLAB after startup). The `-sd` option has been deprecated. For information about alternatives, see “Startup Folder on Windows Platforms”.

`matlab shieldOption` provides the specified level of protection of the address space used by MATLAB during startup on Windows 32-bit platforms. It attempts to help ensure the largest contiguous block of memory available after startup, which is useful for processing large data sets. The *shieldOption* does this by ensuring resources such as DLLs, are loaded into locations that will not fragment the address space. With *shieldOption* set to a value other than none, address space is protected up to or after the processing of `matlabrc`. Use higher levels of protection to secure larger initial blocks of contiguous memory, however a higher level might not always provide a larger size block and might cause startup problems. Therefore, start with a lower level of protection, and if successful, try the next higher level. You can use the `memory` function after startup to see the size of the largest contiguous block of memory; this helps you determine the actual effect of the *shieldOption* setting

you used. If your `matlabrc` (or `startup.m`) requires significant memory, a higher level of protection for `shieldOption` might cause startup to fail; in that event try a lower level. Values for `shieldOption` can be any one of the keywords shown in the table below.

Option	Description
<p><b>-shield minimum</b></p>	<p>This is the default setting. It protects the range 0x50000000 to 0x70000000 during MATLAB startup until just before startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>Start with this, the default value. To use the default, do not specify a shield option upon startup.</p> <p>If MATLAB fails to start successfully using the default option, <b>-shield minimum</b>, instead use <b>-shield none</b>.</p> <p>If MATLAB starts successfully with the default value for <code>shieldOption</code> and you want to try to ensure an even larger contiguous block after startup, try using the <b>-shield medium</b> option.</p>
<p><b>-shield medium</b></p>	<p>This protects the same range as for minimum, 0x50000000 to 0x70000000, but protects the range until just after startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>If MATLAB fails to start successfully with the <b>-shield medium</b> option, instead use the default option (<b>-shield minimum</b>).</p>

# matlab (Windows)

---

Option	Description
	If MATLAB starts successfully with the <b>-shield medium</b> option and you want to try to ensure an even larger contiguous block after startup, try using the <b>-shield maximum</b> option.
<b>-shield maximum</b>	This protects the maximum possible range, which can be up to approximately 1.5 GB, until just after startup processes <code>matlabrc</code> .  If MATLAB fails to start successfully with the <b>-shield maximum</b> option, instead use the <b>-shield medium</b> option.
<b>-shield none</b>	This completely disables address shielding. Use this if MATLAB fails to start successfully with the default ( <b>-shield minimum</b> ) option.

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

`matlab -unregserver` removes all MATLAB COM server entries from the registry.

`matlab -wait` MATLAB is started by a separate starter program which normally launches MATLAB and then immediately quits. Using this option tells the starter program not to quit until MATLAB has terminated. This option is useful when you need to process the results from MATLAB in a script. Calling MATLAB with this option blocks the script from continuing until the results are generated.

## Setting Environment Variables

You can set the following environment variables before starting MATLAB.

Variable Name	Description
LM_LICENSE_FILE	This variable specifies the License File to use. If you use the <b>-c</b> argument to specify the License File it overrides this variable. The value of this variable can be a list of License Files, separated by semi-colons, or <code>port@host</code> entries.

## How To

- “Start MATLAB on Windows Platforms”
- “Startup Options”

**Purpose**

Largest elements in array

**Syntax**

```
C = max(A)
C = max(A, [], dim)
[C, I] = max(...)
```

```
C = max(A, B)
```

**Description**

`C = max(A)` returns the largest elements along different dimensions of an array.

If `A` is a vector, `max(A)` returns the largest element in `A`.

If `A` is a matrix, `max(A)` treats the columns of `A` as vectors, returning a row vector containing the maximum element from each column.

If `A` is a multidimensional array, `max(A)` treats the values along the first non-singleton dimension as vectors, returning the maximum value of each vector.

`C = max(A, [], dim)` returns the largest elements along the dimension of `A` specified by scalar `dim`. For example, `max(A, [], 1)` produces the maximum values along the first dimension of `A`.

`[C, I] = max(...)` finds the indices of the maximum values of `A`, and returns them in output vector `I`. If there are several identical maximum values, the index of the first one found is returned.

`C = max(A, B)` returns an array the same size as `A` and `B` with the largest elements taken from `A` or `B`. The dimensions of `A` and `B` must match, or they may be scalar.

**Examples**

Return the maximum of a 2-by-3 matrix from each column:

```
X = [2 8 4; 7 3 9];
max(X, [], 1)
ans =
```

```
7 8 9
```

Return the maximum from each row:

```
max(X,[],2)
ans =
```

```
8
9
```

Compare each element of X to a scalar:

```
max(X,5)
ans =
```

```
5 8 5
7 5 9
```

## Tips

For complex input A, `max` returns the complex number with the largest complex modulus (magnitude), computed with `max(abs(A))`. Then computes the largest phase angle with `max(angle(x))`, if necessary.

The `max` function ignores NaNs.

# MaximizeCommandWindow

---

**Purpose** Open Automation server window

**Syntax** **MATLAB Client**  
h.MaximizeCommandWindow  
MaximizeCommandWindow(h)

**IDL Method Signature**

HRESULT MaximizeCommandWindow(void)

**Microsoft Visual Basic Client**

MaximizeCommandWindow

**Description** h.MaximizeCommandWindow displays the window for the server attached to handle h, and makes it the currently active window on the desktop.

MaximizeCommandWindow(h) is an alternate syntax.

MaximizeCommandWindow restores the window to the size it had at the time it was minimized, not to the maximum size on the desktop. If the server window was not previously in a minimized state, MaximizeCommandWindow does nothing.

**Examples** From a MATLAB client, modify the size of the command window in a MATLAB Automation server:

```
h = actxserver('matlab.application');  
h.MinimizeCommandWindow;  
% Now return the server window to its former state on  
% the desktop and make it the currently active window.  
h.MaximizeCommandWindow;
```

---

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server:

```
Dim Matlab As Object
```

```
Matlab = CreateObject("matlab.application")  
Matlab.MinimizeCommandWindow
```

```
'Now return the server window to its former state on  
'the desktop and make it the currently active window.
```

```
Matlab.MaximizeCommandWindow
```

# maxNumCompThreads

---

## Purpose

Control maximum number of computational threads

---

**Note** `maxNumCompThreads` will be removed in a future version. You can set the `-singleCompThread` option when starting MATLAB to limit MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

---

## Syntax

```
N = maxNumCompThreads
LASTN = maxNumCompThreads(N)
LASTN = maxNumCompThreads('automatic')
```

## Description

`N = maxNumCompThreads` returns the current maximum number of computational threads `N`.

`LASTN = maxNumCompThreads(N)` sets the maximum number of computational threads to `N`, and returns the previous maximum number of computational threads, `LASTN`.

`LASTN = maxNumCompThreads('automatic')` sets the maximum number of computational threads using what the MATLAB software determines to be the most desirable. It additionally returns the previous maximum number of computational threads, `LASTN`.

Currently, the maximum number of computational threads is equal to the number of computational cores on your machine.

---

**Note** Setting the maximum number of computational threads using `maxNumCompThreads` does not propagate to your next MATLAB session.

---

**Purpose** Average or mean value of array

**Syntax**  
`M = mean(A)`  
`M = mean(A,dim)`

**Description** `M = mean(A)` returns the mean values of the elements along different dimensions of an array.

If `A` is a vector, `mean(A)` returns the mean value of `A`.

If `A` is a matrix, `mean(A)` treats the columns of `A` as vectors, returning a row vector of mean values.

If `A` is a multidimensional array, `mean(A)` treats the values along the first non-singleton dimension as vectors, returning an array of mean values.

`M = mean(A,dim)` returns the mean values for elements along the dimension of `A` specified by scalar `dim`. For matrices, `mean(A,2)` is a column vector containing the mean value of each row.

**Examples**

```
A = [1 2 3; 3 3 6; 4 6 8; 4 7 7];
mean(A)
ans =
    3.0000    4.5000    6.0000

mean(A,2)
ans =
    2.0000
    4.0000
    6.0000
    6.0000
```

**See Also** `corrcoef` | `cov` | `max` | `median` | `min` | `mode` | `std` | `var`

# median

---

**Purpose** Median value of array

**Syntax**  
`M = median(A)`  
`M = median(A,dim)`

**Description** `M = median(A)` returns the median value of A.

- If A is a vector, then `median(A)` returns the median value of A.
- If A is a nonempty matrix, then `median(A)` treats the columns of A as vectors and returns a row vector of median values.
- If A is an empty 0-by-0 matrix, `median(A)` returns NaN.
- If A is a multidimensional array, then `median(A)` acts along the first nonsingleton dimension and returns an array of median values. The size of this dimension reduces to 1 while the sizes of all other dimensions remain the same.

`median` computes natively in the numeric class of A, such that `class(M) = class(A)`.

`M = median(A,dim)` returns the median of elements along dimension `dim`. For example, if A is a matrix, then `median(A,2)` is a column vector containing the median value of each row.

## Input Arguments

**A - Input array**  
vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

If A contains NaN, then M returns NaN.

**Data Types**  
double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**dim - Dimension to operate along**  
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The size(`M`,`dim`) is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `median(A,1)` returns a row vector containing the median of the elements in each column.
- If `dim = 2`, then `median(A,2)` returns a column vector containing the median of the elements in each row.

`median` returns `A` if `dim` is greater than `ndims(A)`.

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
 uint16 | uint32 | uint64

## Definitions

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If `X` is a 1-by-`n` row vector, then the second dimension is the first nonsingleton dimension of `X`.

- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

## Examples

### Median of Matrix Columns

Define a 4-by-3 matrix.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =
```

```
    0     1     1
    2     3     2
    1     3     2
    4     2     2
```

Find the median value of each column.

```
M = median(A)
```

```
M =
```

```
    1.5000    2.5000    2.0000
```

For each column, the median value is the mean of the middle two numbers in sorted order.

### Median of Matrix Rows

Define a 2-by-3 matrix.

```
A = [0 1 1; 2 3 2]
```

```
A =
```

```
    0     1     1
```

```

     2     3     2

```

Find the median value of each row.

```
M = median(A,2)
```

```
M =
```

```

     1
     2

```

For each row, the median value is the middle number in sorted order.

### Median of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =
```

```

    10     8    10

```

```
A(:,:,2) =
```

```

     6     9     5

```

```
A(:,:,3) =
```

```

     9     6     1

```

```
A(:,:,4) =
```

```

     4     9     5

```

Find the median values of this 3-D array along the second dimension.

# median

---

```
M = median(A)
```

```
M(:,:,1) =
```

```
    10
```

```
M(:,:,2) =
```

```
     6
```

```
M(:,:,3) =
```

```
     6
```

```
M(:,:,4) =
```

```
     5
```

This operation produces a 1-by-1-by-4 array by computing the median of the three values along the second dimension. The size of the second dimension is reduced to 1.

Compute the median along the first dimension of A.

```
M = median(A,1);  
isequal(A,M)
```

```
ans =
```

```
    1
```

This returns the same array as A because the size of the first dimension is 1.

### Median of 8-bit Integer Array

Define a 1-by-4 vector of 8-bit integers.

```
A = int8(1:4)
```

```
A =
```

```
     1     2     3     4
```

Compute the median value.

```
M = median(A),  
class(M)
```

```
M =
```

```
     3
```

```
ans =
```

```
int8
```

M is the mean of the middle two numbers in sorted order returned as an 8-bit integer.

# memmapfile

---

**Purpose** Create memory map to a file

**Syntax**  
`m = memmapfile(filename)`  
`m = memmapfile(filename,Name,Value)`

**Description** `m = memmapfile(filename)` maps an existing file, `filename`, to memory and returns the memory map, `m`.

Memory-mapping is a mechanism that maps a portion of a file, or an entire file, on disk to a range of memory addresses within the MATLAB address space. Then, MATLAB can access files on disk in the same way it accesses dynamic memory, accelerating file reading and writing. Memory-mapping allows you to work with data in a file as if it were a MATLAB array.

`m = memmapfile(filename,Name,Value)` specifies the properties of `m` using one or more name-value pair arguments. For example, you can specify the format of the data in the file.

## Input Arguments

### **filename - Name of file to map**

string

Name of the file to map including the file extension, specified as a string. The `filename` argument cannot include any wildcard characters (for example, `*` or `?`).

**Example:** `'myFile.dat'`

### **Data Types**

char

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `m = memmapfile('myFile.dat', 'Format', 'int32', 'Offset', 255)`  
maps int32 data in the file, myFile.dat, to memory starting from the 256th byte.

## **'Writable' - Type of access allowed to mapped region**

false (default) | true

Type of access allowed to the mapped region, specified as the comma-separated pair consisting of 'Writable' and either true or false. If the Writable property is set to false, the mapped region is read-only. If true, then write access is allowed.

**Example:** 'Writeable', true

## **Data Types**

logical

## **'Offset' - Number of bytes from start of file to start of mapped region**

0 (default) | nonnegative integer

Number of bytes from the start of the file to the start of the mapped region, specified as the comma-separated pair consisting of 'Offset' and a nonnegative integer. This value is zero-based. That is, an Offset value of 0 represents the start of the file.

**Example:** 'Offset', 1024

## **Data Types**

double

## **'Format' - Format of mapped region**

'uint8' (default) | string | n-by-3 cell array

Format of the mapped region contents, specified as the comma-separated pair consisting of 'Format' and a single string or an n-by-3 cell array.

- If the file region you are mapping contains data of only one type, specify the Format value as a string identifying that type.

**Example:** 'int16'

# memmapfile

---

- To specify an array shape to apply to the data read or written to the mapped file, and a field name to reference this array, specify the `Format` value as a 1-by-3 cell array. The first cell contains a string identifying the data type to apply to the mapped region. The second cell contains the array dimensions to apply to the region. The third cell contains a string specifying the field name to use in the `Data` structure array of the memory map.

**Example:** {'uint64',[30 4 10],'x'}

- If the region you are mapping is composed of segments of varying data types or array shapes, you can specify an individual format for each segment using an n-by-3 cell array, where n is the number of segments.

**Example:** {'uint64',[30 4 10],'x'; 'uint32',[30 4 6],'y'}

You can use any of the following data types when you specify a `Format` value:

- 'int8'
- 'int16'
- 'int32'
- 'int64'
- 'uint8'
- 'uint16'
- 'uint32'
- 'uint64'
- 'single'
- 'double'

## Data Types

char | cell

## 'Repeat' - Number of times to apply Format parameter

Inf (default) | positive integer

Number of times to apply the Format parameter to the mapped region of the file, specified as the comma-separated pair consisting of 'Repeat' and a positive integer. If the value of Repeat is Inf, then memmapfile applies the Format parameter until the end of the file.

**Example:** 'Repeat',2000

### Data Types

double

## Output Arguments

### m - Memory map

memmapfile object

Memory map, returned as a memmapfile object with the following properties.

Property	Description
Filename	Path and name of the mapped file
Writable	Type of access allowed to the mapped region
Offset	Number of bytes from the start of the file to the start of the mapped region
Format	Format of the contents of the mapped region, including data type, array size, and field name by which to access the data
Repeat	Number of times to apply the pattern specified by the Format property to the mapped region of the file
Data	Memory-mapped data from the file. Data can be a numeric array or a structure array with field names specified in the Format property

The values for any property (except for Data) are set at the time you call memmapfile, using name-value pair arguments.

# memmapfile

---

Access any property of `m` with dot notation similar to accessing fields of a structure array. For example, to access the memory-mapped data in the `Data` property, do one of the following:

- If `Data` is a numeric array, call `m.Data`.
- If `Data` is a scalar (1-by-1) structure array, call `m.Data.fieldname`, where *fieldname* is the name of a field.
- If `Data` is a nonscalar structure array, call `m.Data(index).fieldname` where *index* is the index for the element in the structure array, and *fieldname* is the name of a field. For example, to access the file data in the `temperature` field of the first element of `Data`, call `m.Data(1).temperature`.

After you create a memory map, `m`, you can change the value of any of its properties, except for `Data`. To assign a new value, use dot notation. For example, to set a new `Offset` value for `m`, type:

```
m.Offset = 2048;
```

## Examples

### Map Entire File of uint8 Data

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 `uint8` values.

```
myData = uint8(1:10)';  
  
fileID = fopen('records.dat','w');  
fwrite(fileID, myData, 'uint8');  
fclose(fileID);
```

Create a map for `records.dat`. When using `memmapfile`, the default data format is `uint8` so the file name is the only required input argument in this case.

```
m = memmapfile('records.dat')
```

```
m =
```

```
Filename: 'd:\matlab\records.dat'  
Writable: false  
Offset: 0  
Format: 'uint8'  
Repeat: Inf  
Data: 10x1 uint8 array
```

MATLAB maps the entire `records.dat` file to memory, setting all properties of the memory map to their default values. The memory map is assigned to the variable, `m`. In this example, the command maps the entire file as a sequence of unsigned 8-bit integers and gives the caller read-only access to its contents.

View the mapped data by accessing the `Data` property of `m`.

```
m.Data
```

```
ans =
```

```
1  
2  
3  
4  
5  
6  
7  
8  
9  
10
```

## Map Entire File of Double-Precision Data

Create a memory map for double-precision data. The syntax is similar when specifying other data types.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 double values.

```
myData = (1:10)';
```

# memmapfile

---

```
fileID = fopen('records.dat','w');  
fwrite(fileID,myData,'double');  
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `'double'`.

```
m = memmapfile('records.dat','Format','double')
```

```
m =
```

```
    Filename: 'd:\matlab\records.dat'  
    Writable: false  
    Offset: 0  
    Format: 'double'  
    Repeat: Inf  
    Data: 10x1 double array
```

The `Data` property contains the 10 double-precision values in `records.dat`.

## Map and Change Part of a File

Create a memory map for a large array of `int32` data. Specify write access, and nondefault `Format` and `Offset` values.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10,000 `int32` values.

```
myData = int32([1:10000]);  
  
fileID = fopen('records.dat','w');  
fwrite(fileID,myData,'int32');  
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `int32`. Also, set the `Offset` property to disregard the first 9000 bytes in the file, and the `Writable` property to permit write access.

```
m = memmapfile('records.dat',...
              'Offset',9000,...
              'Format','int32',...
              'Writable',true);
```

An `Offset` value of 9000 indicates that the first 9000 bytes of `records.dat` are not mapped.

Type the name of the memory map to see the current settings for all properties.

```
m

m =
  Filename: 'd:\matlab\records.dat'
  Writable: true
  Offset: 9000
  Format: 'int32'
  Repeat: Inf
  Data: 7750x1 int32 array
```

The `Format` property indicates that any read or write operation made via the memory map reads and writes the file contents as a sequence of signed 32-bit integers. The `Data` property contains only 7750 elements because the first 9000 bytes of `records.dat`, representing the first 2250 values in the file, are not mapped.

View the first five elements of the mapped data by accessing the `Data` property of `m`.

```
m.Data(1:5)

ans =

    2251
    2252
    2253
    2254
```

2255

## Map Region of File to Specific Array Shape

Create a memory map for a region of a file containing 100 double-precision values.

At the command prompt, create a sample file in your current folder called `mybinary.bin`, containing 100 double-precision values.

```
randData = gallery('uniformdata',[100,1],0,'double');

fileID = fopen('mybinary.bin','w');
fwrite(fileID,randData,'double');
fclose(fileID);
```

Map the first 75 values in `mybinary.bin` to a 5-by-5-by-3 array of double-precision values that can be referenced in the structure of the memory map using the field name `x`. Specify these parameters with the `Format` name-value pair argument.

```
m = memmapfile('mybinary.bin',...
              'Format',{'double',[5 5 3],'x'})
```

```
m =
```

```
Filename: 'd:\matlab\mybinary.bin'
Writable: false
Offset: 0
Format: {'double' [5 5 3] 'x'}
Repeat: Inf
Data: 1x1 struct array with fields:
      x
```

The `Data` property is a structure array that contains the mapped values in the field, `x`.

Assign the mapped data to a variable, `A`. Because the `Data` property is a structure array, you must index into the field, `x`, to access the data.

```
A = m.Data.x;
```

View information about A.

```
whos A
```

Name	Size	Bytes	Class	Attributes
A	5x5x3	600	double	

### Map Segments of File to Multiple Arrays

Map segments of a file with different array shapes and data types to memory.

At the command prompt, create a sample file in your current folder called `mybinary.bin`. Write `uint16` data and double-precision data representing sample pressure, temperature, and volume values into the file. In this case, each of the `uint16` arrays are 50-by-1 and the double-precision arrays are 5-by-10. `k` is a sample scaling factor.

```
k = 8.21;
[pres1,temp1] = gallery('integerdata',[1,300],[50,1],0,'uint16');
vol1 = double(reshape(k*temp1./pres1,5,10));
[pres2,temp2] = gallery('integerdata',[5,500],[50,1],5,'uint16');
vol2 = double(reshape(k*temp2./pres2,5,10));

fileID = fopen('mybinary.bin','w');
fwrite(fileID,pres1,'uint16');
fwrite(fileID,temp1,'uint16');
fwrite(fileID,vol1,'double');
fwrite(fileID,pres2,'uint16');
fwrite(fileID,temp2,'uint16');
fwrite(fileID,vol2,'double');
fclose(fileID);
```

Map the file to arrays accessible by unique names. Define a field, `pressure`, containing a 50-by-1 array of `uint16` values, followed by a field, `temperature`, containing 50-by-1 `uint16` values. Define a field,

# memmapfile

---

volume, containing a 5-by-10 array of double-precision values. Use a cell array to define the format of the mapped region and repeat the pattern twice.

```
m = memmapfile('mybinary.bin',...
'Format',{'uint16',[50 1],'pressure';...
'uint16',[50,1],'temperature';...
'double',[5,10],'volume'},'Repeat',2)
```

```
m =
```

```
Filename: 'd:\matlab\mybinary.bin'
Writable: false
Offset: 0
Format: {'uint16' [50 1] 'pressure'
         'uint16' [50 1] 'temperature'
         'double' [5 10] 'volume'}
Repeat: 2
Data: 2x1 struct array with fields:
    pressure
    temperature
    volume
```

The Data property of the memory map, m, is a 2-by-1 structure array because the Format is applied twice.

Copy the Data property to a variable, A. Then, view the last block of double data, which you can access using the field name, volume.

```
A = m.Data;
myVolume = A(2).volume
```

```
myVolume =
```

```
     2     13     32     5     5     16     4     22     3     8
     2     9     53    38    13    19    23    85     2    120
    29    10     6     1     2     5     6    58    20    11
     7    15     4     1     5    18     1     4    14     8
```

9 8 4 2 0 9 8 6 3 3

## Tips

- You can map only an existing file. You cannot create a new file and map that file to memory in one operation. Use the MATLAB file I/O functions to create the file before attempting to map it to memory.
- After `memmapfile` locates the file, MATLAB stores the file's absolute pathname internally, and then uses this stored path to locate the file from that point on. As a result, you can work in other directories outside your current work directory and retain access to the mapped file.
- `memmapfile` does not expand or append to a mapped file. Use instead standard file I/O functions like `fopen` and `fwrite`.

# memory

---

**Purpose** Display memory information

**Syntax**

```
memory  
userview = memory  
[userview systemview] = memory
```

**Description** `memory` displays information showing how much memory is available and how much the MATLAB software is currently using. The information displayed at your computer screen includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-3773
- “Memory Available for All Arrays” on page 1-3774
- “Memory Used By MATLAB” on page 1-3775
- “Total Physical Memory (RAM)” on page 1-3775

`userview = memory` returns user-focused information on memory use in structure `userview`. The information returned in `userview` includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-3773
- “Memory Available for All Arrays” on page 1-3774
- “Memory Used By MATLAB” on page 1-3775

`[userview systemview] = memory` returns both user- and system-focused information on memory use in structures `userview` and `systemview`, respectively. The `userview` structure is described in the command syntax above. The information returned in `systemview` includes the following items, each of which is described in a section below:

- “Virtual Address Space” on page 1-3776
- “System Memory” on page 1-3776
- “Physical Memory” on page 1-3777

## Output Arguments

Each of the sections below describes a value that is displayed or returned by the `memory` function.

### Maximum Possible Array

Maximum Possible Array is the size of the largest contiguous free memory block. As such, it is an upper bound on the largest single array MATLAB can create at this time.

MATLAB derives this number from the smaller of the following two values:

- The largest contiguous memory block found in the MATLAB virtual address space
- The total available system memory

To see how many array elements this number represents, divide by the number of bytes in the array class. For example, for a `double` array, divide by 8. The actual number of elements MATLAB can create is always fewer than this number.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Maximum possible array:
<code>user = memory</code>	Structure field <code>user.MaxPossibleArrayBytes</code>

All values are double-precision and in units of bytes.

### Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the second footnote:

Limited by contiguous virtual address space available.

There is sufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

## Memory Available for All Arrays

Memory Available for All Arrays is the total amount of memory available to hold data. The amount of memory available is guaranteed to be at least as large as this field.

MATLAB derives this number from the smaller of the following two values:

- The total available MATLAB virtual address space
- The total available system memory

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Memory available for all arrays:
<code>user = memory</code>	Structure field <code>user.MemAvailableAllArrays</code>

## Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the latter footnote:

Limited by virtual address space available.

There is sufficient system memory to allow mapping of all available virtual addresses in the MATLAB process virtual address space to system memory. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all available virtual addresses in the MATLAB process.

### Memory Used By MATLAB

Memory Used By MATLAB is the total amount of system memory reserved for the MATLAB process. It is the sum of the physical memory and potential swap file usage.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Memory used by MATLAB:
<code>user = memory</code>	Structure field <code>user.MemUsedMATLAB</code>

### Total Physical Memory (RAM)

Physical Memory (RAM) is the total physical memory (or RAM) in the computer.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. See the table below.

Command	Returned in
<code>memory</code>	String labelled Physical Memory (RAM):

## Virtual Address Space

Virtual Address Space is the amount of available and total virtual memory for the MATLAB process. MATLAB returns the information in two fields of the return structure: Available and Total.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.VirtualAddressSpace.Available
	Total memory	sys.VirtualAddressSpace.Total

You can monitor the difference:

```
VirtualAddressSpace.Total - VirtualAddressSpace.Available
```

as the Virtual Bytes counter in the WindowsPerformance program. (e.g., Windows XP Control Panel/Administrative Tool/Performance program).

## System Memory

System Memory is the amount of available system memory on your computer system. This number includes the amount of available physical memory and the amount of available swap file space on the computer running MATLAB. MATLAB returns the information in the SystemMemory field of the return structure.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.SystemMemory

This is the same as the difference:

```
limit - total (in bytes)
```

found in the Windows Task Manager: Performance/Commit Charge.

## Physical Memory

Physical Memory is the available and total amounts of physical memory (RAM) on the computer running MATLAB. MATLAB returns the information in two fields of the return structure: Available and Total.

Command	Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.PhysicalMemory.Available
	Total memory	sys.PhysicalMemory.Total

Available physical memory is the same as:

Available (in bytes)

found in the Windows Task Manager: Performance/Physical Memory

The total physical memory is the same as

Total (in bytes)

found in the Windows Task Manager: Performance/Physical Memory

You can use the amount of available physical memory as a measure of how much data you can access quickly.

## Tips

The `memory` function is currently available on Microsoft Windows systems only. Results vary, depending on the computer running MATLAB, the load on that computer, and what MATLAB is doing at the time.

## Details on Memory Used By MATLAB

MATLAB computes the value for Memory Used By MATLAB by walking the MATLAB process memory structures and summing all the sections that have physical storage allocated in memory or in the paging file on disk.

Using the Windows Task Manager, you have for the MATLAB.exe image:

$$\text{Mem Usage} < \text{MemUsedMATLAB} < \text{Mem Usage} + \text{VM Size (in bytes)}$$

where both of the following are true:

- Mem Usage is the working set size in kilobytes.
- VM Size is the page file usage, or private bytes, in kilobytes.

The working set size is the portion of the MATLAB virtual address space that is *currently* resident in RAM and can be referenced without a memory page fault. The page file usage gives the portion of the MATLAB virtual address space that requires a backup that doesn't already exist. Another name for page file usage is *private bytes*. It includes all MATLAB variables and workspaces. Since some of the pages in the page file may also be part of the working set, this sum is an overestimate of MemUsedMATLAB. Note that there are virtual pages in the MATLAB process space that already have a backup. For example, code loaded from EXEs and DLLs and memory-mapped files. If any part of those files is in memory when the memory builtin is called, that memory will be counted as part of MemUsedMATLAB.

## Reserved Addresses

Reserved addresses are addresses sets aside in the process virtual address space for some specific future use. These reserved addresses reduce the size of MemAvailableAllArrays and can reduce the size of the current or future value of MaxPossibleArrayBytes.

### Example 1 – Java Virtual Machine (JVM)

At MATLAB startup, part of the MATLAB virtual address space is reserved by the Java Virtual Machine (JVM) and cannot be used for storing MATLAB arrays.

### Example 2 – Standard Windows Heap Manager

MATLAB, by default, uses the standard Windows heap manager except for a set of small preselected allocation sizes. One characteristic of this heap manager is that its behavior depends upon whether the requested allocation is less than or greater than the fixed number of 524,280 bytes.

For, example, if you create a sequence of MATLAB arrays, each less than 524,280 bytes, and then clear them all, the MemUsedMATLAB value before and after shows little change, and the MemAvailableAllArrays value is now smaller by the total space allocated.

The result is that, instead of globally freeing the extra memory, the memory becomes reserved. It can *only* be reused for arrays less than 524,280 bytes. You cannot reclaim this memory for a larger array except by restarting MATLAB.

## Examples

Display memory statistics on a 32-bit Windows system:

```
memory
```

```
Maximum possible array:          677 MB (7.101e+008 bytes) *
Memory available for all arrays: 1601 MB (1.679e+009 bytes) **
Memory used by MATLAB:          446 MB (4.681e+008 bytes)
Physical Memory (RAM):          3327 MB (3.489e+009 bytes)
```

\* Limited by contiguous virtual address space available.

\*\* Limited by virtual address space available.

Return in the structure `userview`, information on the largest array MATLAB can create at this time, how much memory is available to hold data, and the amount of memory currently being used by your MATLAB process:

```
userview = memory
```

```
userview =
    MaxPossibleArrayBytes: 710127616
    MemAvailableAllArrays: 1.6792e+009
    MemUsedMATLAB: 468127744
```

Assign the output to two structures, `user` and `sys`, to obtain the information shown here:

```
[user sys] = memory;
```

# memory

---

```
% --- Largest array MATLAB can create ---
user.MaxPossibleArrayBytes
ans =
    710127616

% --- Memory available for data ---
user.MemAvailableAllArrays
ans =
    1.6797e+009

% --- Memory used by MATLAB process ---
user.MemUsedMATLAB
ans =
    467603456

% --- Virtual memory for MATLAB process ---
sys.VirtualAddressSpace
ans =
    Available: 1.6797e+009
    Total: 2.1474e+009

% --- Physical memory and paging file ---
sys.SystemMemory
ans =
    Available: 4.4775e+009

% --- Computer's physical memory ---
sys.PhysicalMemory
ans =
    Available: 2.3941e+009
    Total: 3.4889e+009
```

# menu

---

**Purpose** Generate menu of choices for user input

**Syntax**

```
choice = menu('mtitle','opt1','opt2',..., 'optn')
choice = menu('mtitle',options)
```

**Description** `choice = menu('mtitle','opt1','opt2',..., 'optn')` displays the menu whose title is in the string variable 'mtitle' and whose choices are string variables 'opt1', 'opt2', and so on. The menu opens in a modal dialog box. `menu` returns the number of the selected menu item, or 0 if the user clicks the close button on the window.

`choice = menu('mtitle',options)` , where `options` is a 1-by-N cell array of strings containing the menu choices.

If the user's terminal provides a graphics capability, `menu` displays the menu items as push buttons in a figure window (Example 1). Otherwise, they will be given as a numbered list in the Command Window (Example 2).

**Tips** To call `menu` from a `uicontrol` or other `ui` object, set that object's `Interruptible` property to 'on'. For more information, see `Uicontrol Properties`.

**Examples** **Example 1**

On a system with a display, `menu` displays choices as buttons in a dialog box:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following dialog box.

The number entered by the user in response to the prompt is returned as `choice` (i.e., `choice = 2` implies that the user selected Blue).

After input is accepted, the dialog box closes, returning the output in `choice`. You can use `choice` to control the color of a graph:

```
t = 0:.1:60;  
s = sin(t);  
color = ['r','b','g']  
plot(t,s,color(choice))
```

## Example 2

On a system without a display, `menu` displays choices in the Command Window:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following text.

```
----- Choose a color -----  
1) Red  
2) Blue  
3) Green  
Select a menu number:
```

# mergecats

---

**Purpose** Merge categories in categorical array

**Syntax**  
B = mergecats(A,oldcats)  
B = mergecats(A,oldcats,newcat)

**Description** B = mergecats(A,oldcats) merges two or more categories in A into the first category, oldcats(1). Any values in A from oldcats become oldcats(1) in B.

B = mergecats(A,oldcats,newcat) merges oldcats into a single new category, newcat. Any values in A from oldcats become newcat in B.

## Input Arguments

**A - Categorical array**  
vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**oldcats - Categories to merge**  
cell array of strings

Categories to merge, specified as a cell array of strings. If A is ordinal, the categories to merge must be consecutive.

**newcat - New category**  
oldcats(1) (default) | string

New category, specified as a string.

## Examples

### Merge Two Categories into One

Create a categorical array containing various colors.

```
A = categorical({'red';'blue';'pink';'red';'blue';'red'})
```

```
A =
```

```
    red
```

```
blue
pink
red
blue
red
```

A is a 6-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'blue'
'pink'
'red'
```

The three categories are in alphabetical order.

Merge the categories red and pink into the category red. Specify red first in oldcats to use it as the merged category.

```
oldcats = {'red','pink'};
B = mergecats(A,oldcats)
```

```
B =
```

```
red
blue
red
red
blue
red
```

mergecats replaces the value pink from A(3) with red.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
    'blue'  
    'red'
```

B has two categories instead of three.

## **Merge Alphabetically Listed Categories**

Create a categorical array containing various items.

```
A = categorical({'shirt' 'pants'; 'shoes' 'shirt'; 'dress' 'belt'})
```

```
A =
```

```
    shirt    pants  
    shoes    shirt  
    dress    belt
```

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
    'belt'  
    'dress'  
    'pants'  
    'shirt'  
    'shoes'
```

The five categories are in alphabetical order.

Merge the categories `belt` and `shoes` into a new category called `other`.

```
B = mergecats(A,{'belt' 'shoes'}, 'other')
```

```
B =
```

```
shirt  pants
other  shirt
dress  other
```

The value `other` replaces all instances of `belt` and `shoes`.

Display the categories of `B`.

```
categories(B)
```

```
ans =
```

```
'other'
'dress'
'pants'
'shirt'
```

`B` has four categories and the order is no longer alphabetical. `other` appears in place of `belt`.

### **Merge Categories of Ordinal Categorical Array**

Create an ordinal categorical array.

```
A = categorical([1 2 3 2 1],1:3,{'poor','fair','good'},'Ordinal',true)
```

```
A =
```

```
poor    fair    good    fair    poor
```

Display the categories of `A`.

```
categories(A)
```

```
ans =
```

```
'poor'
'fair'
```

# mergecats

---

```
'good'
```

Since A is ordinal, the categories have the mathematical ordering `poor < fair < good`.

Consider all `fair` or `poor` values to be `bad`. Since A is ordinal, the categories to merge must be consecutive.

```
B = mergecats(A, {'fair' 'poor'}, 'bad')
```

```
B =
```

```
      bad      bad      good      bad      bad
```

The value `bad` replaces all instances of `fair` and `poor`.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
      'bad'  
      'good'
```

B has two categories with the mathematical ordering: `bad < good`.

categories | addcats | removecats | iscategory | renamecats  
| reordercats
```

**Purpose**

Mesh plot

**Syntax**

```
mesh(X,Y,Z)
mesh(Z)
mesh(...,C)
mesh(...,'PropertyName',PropertyValue,...)
mesh(axes_handles,...)
h = mesh(...)
```

**Description**

`mesh(X,Y,Z)` draws a wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`mesh(Z)` draws a wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`mesh(...,C)` draws a wireframe mesh with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`mesh(...,'PropertyName',PropertyValue,...)` sets the value of the specified surface property. Multiple property values can be set with a single statement.

`mesh(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = mesh(...)` returns a handle to a Surfaceplot graphics object.

## Tips

`mesh` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

## Examples

Evaluate  $\sin(r)/r$ , or the *sinc* function

```
figure;  
[X,Y] = meshgrid(-8:.5:8);  
R = sqrt(X.^2 + Y.^2) + eps;  
Z = sin(R)./R;  
mesh(Z);
```

Displaying the *sinc* function between -8 and 8 on a 2-D grid

```
figure;  
mesh(X,Y,Z);  
axis([-8 8 -8 8 -0.5 1]);
```

# mesh

---

---

Specifying color matrix for the data in the mesh function

```
C = gradient(Z);  
figure;  
mesh(X,Y,Z,C);
```

Specifying the property name-value pairs in the argument list.

```
C = del2(Z);  
h = axes;  
mesh(h,Z,C,'FaceLighting','gouraud','LineWidth',0.3);
```

# mesh

---

`meshc` | `meshz` | `hidden` | `griddata` | `scatteredInterpolant` | `meshgrid` | `surface` | `surf` | `waterfall` | `axis` | `colormap` | `hold` | `shading` | `view`

## How To

- “Representing Data as a Surface”

**Purpose** Plot a contour graph under mesh graph

**Syntax**

```
meshc(X,Y,Z)
meshc(Z)
meshc(...,C)
meshc(axes_handles,...)
h = meshc(...)
```

**Description** `meshc(X,Y,Z)` draws a wireframe mesh and a contour plot under it with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case,  $(X(j), Y(i), Z(i, j))$  are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices,  $(X(i, j), Y(i, j), Z(i, j))$  are the intersections of the wireframe grid lines.

`meshc(Z)` draws a contour plot under wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshc(...,C)` draws a `meshc` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshc(...)` returns a handle to a `Surfaceplot` graphics object.

**Tips** `meshc` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background

# meshc

---

color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

## Examples

Produce a combination mesh and contour plot of the peaks surface with `meshc`:

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshc(Z);
```

Specifying axes limits for the meshc function.

```
figure;  
meshc(X,Y,Z);  
axis([-3 3 -3 3 -10 5]);
```

## Algorithms

The range of  $X$ ,  $Y$ , and  $Z$ , or the current settings of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties, determine the axis limits. `axis` sets these properties.

The range of  $C$ , or the current settings of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function), determine the color scaling. Use the scaled color values are used as indices into the current colormap.

The mesh rendering functions produce color values by mapping the  $z$  data values (or an explicit color array) onto the current colormap. The

MATLAB default behavior is to compute the color limits automatically using the minimum and maximum data values (also set using `caxis auto`). The minimum data value maps to the first color value in the colormap and the maximum data value maps to the last color value in the colormap. MATLAB performs a linear transformation on the intermediate values to map them to the current colormap.

`meshc` calls `mesh`, turns `hold` on, and then calls `contour` and positions the contour on the  $x$ - $y$  plane. For additional control over the appearance of the contours, issue these commands directly. You can combine other types of graphs in this manner, for example `surf` and `pcolor` plots.

`meshc` assumes that  $X$  and  $Y$  are monotonically increasing. If  $X$  or  $Y$  is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then it transforms the data to  $X$  or  $Y$ .

# meshz

---

## Purpose

Plot a curtain around mesh plot

## Syntax

```
meshz(X,Y,Z)
meshz(Z)
meshz(...,C)
meshz(axes_handles,...)
h = meshz(...)
```

## Description

`meshz(X,Y,Z)` draws a curtain around the wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case,  $(X(j), Y(i), Z(i,j))$  are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices,  $(X(i,j), Y(i,j), Z(i,j))$  are the intersections of the wireframe grid lines.

`meshz(Z)` draws a curtain around the wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshz(...,C)` draws a `meshz` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshz(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshz(...)` returns a handle to a `Surfaceplot` graphics object.

## Tips

`meshz` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background

color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The hidden command controls the simulation of hidden-surface elimination in the mesh, and the shading command controls the shading model.

## Examples

Generate a curtain plot for the peaks function using meshz

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshz(Z);
```

# meshz

---

---

Specifying axes limits for the graph

```
figure;  
meshz(X,Y,Z);  
axis([-3 3 -3 3 -7 9]);
```

Specifying a color matrix

```
C = gradient(Z);  
figure;  
meshz(X,Y,Z,C);
```

# meshz

---

<b>Purpose</b>	Rectangular grid in 2-D and 3-D space
<b>Syntax</b>	<pre>[X,Y] = meshgrid(xgv,ygv) [X,Y,Z] = meshgrid(xgv,ygv,zgv) [X,Y] = meshgrid(gv) [X,Y,Z] = meshgrid(gv)</pre>
<b>Description</b>	<p><code>[X,Y] = meshgrid(xgv,ygv)</code> replicates the grid vectors <code>xgv</code> and <code>ygv</code> to produce a full grid. This grid is represented by the output coordinate arrays <code>X</code> and <code>Y</code>. The output coordinate arrays <code>X</code> and <code>Y</code> contain copies of the grid vectors <code>xgv</code> and <code>ygv</code> respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors <code>xgv</code> and <code>ygv</code> of length <code>M</code> and <code>N</code> respectively, <code>X</code> and <code>Y</code> will have <code>N</code> rows and <code>M</code> columns.</p> <p><code>[X,Y,Z] = meshgrid(xgv,ygv,zgv)</code> produces three-dimensional coordinate arrays. The output coordinate arrays <code>X</code>, <code>Y</code>, and <code>Z</code> contain copies of the grid vectors <code>xgv</code>, <code>ygv</code>, and <code>zgv</code> respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors <code>xgv</code>, <code>ygv</code>, and <code>zgv</code> of length <code>M</code>, <code>N</code>, and <code>P</code> respectively, <code>X</code>, <code>Y</code>, and <code>Z</code> will have <code>N</code> rows, <code>M</code> columns, and <code>P</code> pages.</p> <p><code>[X,Y] = meshgrid(gv)</code> is the same as <code>[X,Y] = meshgrid(gv,gv)</code>. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.</p> <p><code>[X,Y,Z] = meshgrid(gv)</code> is the same as <code>[X,Y,Z] = meshgrid(gv,gv,gv)</code>. Again, the dimensionality of the output arrays is determined by the number of output arguments.</p> <p>The output coordinate arrays are typically used to evaluate functions of two or three variables. They are also frequently used to create surface and volumetric plots.</p>
<b>Input Arguments</b>	<p><b>xgv,ygv,zgv</b></p> <p>Grid vectors specifying a series of grid point coordinates in the <code>x</code>, <code>y</code> and <code>z</code> directions, respectively.</p>

# meshgrid

---

## **gv**

Generic grid vector specifying a series of point coordinates.

## **Output Arguments**

### **X,Y,Z**

Output arrays that specify the full grid.

## **Tips**

The `meshgrid` function is similar to `ndgrid`, however `meshgrid` is restricted to 2-D and 3-D while `ndgrid` supports 1-D to N-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `meshgrid(x1gv, x2gv)` will output arrays of size `N-by-M` while `ndgrid(x1gv, x2gv)` outputs arrays of size `M-by-N`. Similarly, `meshgrid(x1gv, x2gv, x3gv)` will output arrays of size `N-by-M-by-P` while `ndgrid(x1gv, x2gv, x3gv)` outputs arrays of size `M-by-N-by-P`. See “Grid Representation” in the MATLAB Mathematics documentation for more information.

## **Examples**

Create a full grid from two monotonically increasing grid vectors:

```
[X,Y] = meshgrid(1:3,10:14)
```

```
X =
```

```
     1     2     3
     1     2     3
     1     2     3
     1     2     3
     1     2     3
```

```
Y =
```

```
    10    10    10
    11    11    11
    12    12    12
    13    13    13
    14    14    14
```

---

Use `meshgrid` to create a 3-D surface plot of a function:

```
[X,Y] = meshgrid(-2:.2:2, -2:.2:2);  
Z = X .* exp(-X.^2 - Y.^2);  
surf(X,Y,Z)
```

# meta.class

---

## Purpose

`meta.class` class describes MATLAB classes

## Description

Instances of the `meta.class` class contains information about MATLAB classes. The read/write properties of the `meta.class` class correspond to class attributes and are set only from within class definitions on the `classdef` line. You can query the read-only properties of the `meta.class` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class).

You cannot instantiate a `meta.class` object directly. You can construct a `meta.class` object from an instance of a class or using the class name:

- `metaclass` — returns a `meta.class` object representing the object passed as an argument.
- `?ClassName` — returns a `meta.class` object representing the named class.
- `fromName` — static method returns a `meta.class` object representing the named class.

For example, the `metaclass` function returns the `meta.class` object representing `MyClass`.

```
ob = MyClass;  
obmeta = metaclass(ob);  
obmeta.Name  
ans =  
MyClass
```

You can use the class name to obtain the `meta.class` object:

```
obmeta = ?MyClass;
```

You can also use the `fromName` static method:

```
obmeta = meta.class.fromName('MyClass');
```

**Properties**

<b>Property</b>	<b>Purpose</b>
Abstract attribute, default = false	If true, this class is an abstract class (cannot be instantiated).  See “Defining Abstract Classes” for more information.
AllowedSubclasses attribute, write only from clasdef statement	List classes that can subclass this class. Specify subclasses as meta.class objects in the form:  <ul style="list-style-type: none"> <li>• A single meta.class object</li> <li>• A cell array of meta.class objects</li> </ul> Specify meta.class objects using the ?ClassName syntax only.
ConstructOnLoad attribute, default = false	If true, MATLAB calls the class constructor automatically when loading an object from a MAT-file. Therefore, the construction must be implemented so that calling it with no arguments does not produce an error.  See “Tips for Saving and Loading”
ContainingPackage read only	A meta.package object describing the package within which this class is contained, or an empty object if this class is not in a package.  See “Packages Create Namespaces”.
Description read only	Currently not used
DetailedDescription read only	Currently not used

# meta.class

---

Property	Purpose
EventList read only	An array of <code>meta.event</code> objects describing each event defined by this class, including all inherited events.  See “Events”.
Events read only Use EventList instead	A cell array of <code>meta.event</code> objects describing each event defined by this class, including all inherited events.
EnumerationMemberList	An array of <code>meta.EnumeratedValue</code> objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
EnumeratedValues read only Use EnumeratedMemberList instead	A cell array of <code>meta.EnumeratedValue</code> objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
Hidden attribute, default = false	If set to <code>true</code> , the class does not appear in the output of MATLAB commands or tools that display class names.
InferiorClasses attribute, default = {}	A cell array of <code>meta.class</code> objects defining the precedence of classes represented by the list as inferior to this class.  See “Class Precedence”
MethodList read only	An array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods.  See “How to Use Methods”.

<b>Property</b>	<b>Purpose</b>
Methods read only Use <code>MethodList</code> instead	A cell array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods.
Name read only	Name of the class associated with this <code>meta.class</code> object (char array)
<code>PropertyList</code> read only	An array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties. See “Properties”.
<code>Properties</code> read only Use <code>PropertyList</code> instead	A cell array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties. See “Properties”.
Sealed attribute, default = false	If true, the class cannot be subclassed.
<code>SuperClassList</code> read only	An array of <code>meta.class</code> objects describing each direct superclass from which this class is derived. See “Creating Subclasses — Syntax and Techniques”.
<code>SuperClasses</code> read only Use <code>SuperClassList</code> instead	A cell array of <code>meta.class</code> objects describing each direct superclass from which this class is derived.

# meta.class

---

## Methods

Method	Purpose
<code>fromName</code>	Returns the <code>meta.class</code> object associated with the specified class name.
<code>tf = eq(Cls)</code>	Equality function ( <code>a == b</code> ). Use to test if two variables refer to equal classes (classes that contain exactly the same list of elements).
<code>tf = ne(Cls)</code>	Not equal function ( <code>a ~= b</code> ). Use to test if two variables refer to different meta-classes.
<code>tf = lt(ClsA,ClsB)</code>	Less than function ( <code>ClsA &lt; ClsB</code> ). Use to determine if <code>ClsA</code> is a strict subclass of <code>ClsB</code> (i.e., a strict subclass means <code>ClsX &lt; ClsX</code> is false).
<code>tf = le(ClsA,ClsB)</code>	Less than or equal to function ( <code>ClsA &lt;= ClsB</code> ). Use to determine if <code>ClsA</code> is a subclass of <code>ClsB</code> .
<code>tf = gt(ClsA,ClsB)</code>	Greater than function ( <code>ClsB &gt; ClsA</code> ). Use to determine if <code>ClsB</code> is a strict superclass of <code>ClsA</code> (i.e., a strict superclass means <code>ClsX &gt; ClsX</code> is false).
<code>tf = ge(ClsA,ClsB)</code>	Greater than or equal to function ( <code>ClsB &gt;= ClsA</code> ). Use to determine if <code>ClsB</code> is a superclass of <code>ClsA</code> .

## How To

- “Getting Information About Classes and Objects”

**Purpose** Return meta.class object associated with named class

**Syntax** `mcls = meta.class.fromName('ClassName')`

**Description** `mcls = meta.class.fromName('ClassName')` is a static method that returns the meta.class object associated with the class `ClassName`. Note that you can also use the `?` operator to obtain the meta.class object for a class name:

```
mcls = ?ClassName;
```

The equivalent call to `meta.class.fromName` is:

```
mcls = meta.class.fromName('ClassName');
```

Use `meta.class.fromName` when using a char variable for the class name:

```
function mcls = getMetaClass(cname)
    % Do error checking
    mcls = meta.class.fromName(cname);
    ...
end
```

**See Also** `meta.class`

# meta.DynamicProperty

---

**Purpose** `meta.DynamicProperty` class describes dynamic property of MATLAB object

**Description** The `meta.DynamicProperty` class contains descriptive information about dynamic properties that you have added to an instance of a MATLAB classes. The MATLAB class must be a subclass of `dynamicprops`. The properties of the `meta.DynamicProperty` class correspond to property attributes that you specify from within class definitions. Dynamic properties are not defined in `classdef` blocks, but you can set their attributes by setting the `meta.DynamicProperty` object properties.

You add a dynamic property to an object using the `addprop` method of the `dynamicprops` class. The `addprop` method returns a `meta.DynamicProperty` instance representing the new dynamic property. You can modify the properties of the `meta.DynamicProperty` object to set the attributes of the dynamic property or to add set and get access methods, which would be defined in the `classdef` for regular properties.

You cannot instantiate the `meta.DynamicProperty` class. You must use `addprop` to obtain a `meta.DynamicProperty` object.

To remove the dynamic property, call the `delete` handle class method on the `meta.DynamicProperty` object.

Obtain a `meta.DynamicProperty` object from the `addprops` method, which returns an array of `meta.DynamicProperty` objects, one for each dynamic property.

See “Dynamic Properties — Adding Properties to an Instance” for more information.

## Properties

Property	Purpose
Name	Name of the property.
Description	Currently not used

Property	Purpose
DetailedDescription	Currently not used
AbortSet	If true, and this property belongs to a handle class, then MATLAB does not set the property value if the new value is the same as the current value. This approach prevents the triggering of property PreSet and PostSet events.
Abstract attribute, default = false	<p>If true, the property has no implementation, but a concrete subclass must redefine this property without <code>Abstract</code> being set to true.</p> <ul style="list-style-type: none"><li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li><li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li><li>• All subclasses must specify the same values as the superclass for the property <code>SetAccess</code> and <code>GetAccess</code> attributes.</li><li>• <code>Abstract=true</code> should be used with the class attribute <code>Sealed=false</code> (the default).</li></ul>

# meta.DynamicProperty

---

Property	Purpose
Access	<p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"><li>• A single <code>meta.class</code> object</li><li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as private access.</li></ul> <p>Use <code>Access</code> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <code>Access</code>).</p>
Constant attribute, default = false	<p>Set to true if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"><li>• Subclasses inherit constant properties, but cannot change them.</li><li>• Constant properties cannot be <code>Dependent</code></li><li>• <code>SetAccess</code> is ignored.</li></ul> <p>See “Properties with Constant Values”</p>
DefaultValue	<p>Querying this property returns an error because dynamic properties cannot define default values.</p>

Property	Purpose
DefiningClass	The meta.class object representing the class that defines this property.
GetAccess attribute, default = public	public – unrestricted access protected – access from class or subclasses private – access by class members only
SetAccess attribute, default = public	public – unrestricted access protected – access from class or subclasses private – access by class members only
Dependent attribute, default = false	If false, property value is stored in object. If true, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.  See “Property Get Methods”
Transient attribute, default = false	If true, property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.
Hidden attribute, default = false	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to properties, etc.).
GetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”

# meta.DynamicProperty

---

Property	Purpose
SetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”
GetMethod	Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”
SetMethod	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
HasDefault	Always false. Dynamic properties cannot define default values.

## Events

See “Listen for Changes to Property Values” for information on using property events.

Event Name	Purpose
PreGet	Event occurs just before property is queried.
PostGet	Event occurs just after property has been queried
PreSet	Event occurs just before this property is modified
PostSet	Event occurs just after this property has been modified
ObjectBeingDestroyed	Inherited from handle

## See Also

addprop | handle

## Purpose

Describes enumeration members of MATLAB class

## Description

The `meta.EnumeratedValue` class contains information about enumeration members defined by MATLAB classes. The properties of a `meta.EnumeratedValue` object correspond to the attributes of the enumeration member being described.

All `meta.EnumeratedValue` properties are read-only. Query the `meta.EnumeratedValue` object to obtain information about the enumeration member it describes.

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object. `EnumerationMemberList` is an array of `Meta.EnumeratedValue` instances, one per enumeration member.

The `meta.EnumeratedValue` class is a subclass of the `handle` class.

## Example

To access the `meta.EnumeratedValue` objects for a class, first create a `meta.class` object for that class. For example, give the following `OnOff` class definition:

```
classdef OnOff < logical
    enumeration
        On (true)
        Off (false)
    end
end
```

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object:

```
% Obtain the meta.class instance for the OnOff class
mc = ?OnOff;
% Get the array of EnumerateValue objects
enumList = mc.EnumerationMemberList;
% Access the Name property of the first object in the array
enumList(1).Name =
```

# meta.EnumeratedValue

---

```
ans =  
On
```

## Properties

Property	Purpose
Name read only	Name of the enumeration member associated with this meta.EnumeratedValue object
Description read only	This property is not used
DetailedDescription read only	This property is not used

## Methods

See the handle superclass for inherited methods.

## Events

See the handle superclass for inherited events.

## See Also

## How To

- “Working with Enumerations”
- “Getting Information About Classes and Objects”

**Purpose**

meta.event class describes MATLAB class events

**Description**

The meta.event class provides information about MATLAB class events. The read/write properties of the meta.event class correspond to event attributes and are specified only from within class definitions.

You can query the read-only properties of the meta.event object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining the event).

You cannot instantiate a meta.event object directly. Obtain a meta.event object from the meta.class EventList property, which contains an array of meta.event objects, one for each event defined by the class. For example, replace *ClassName* with the name of the class whose events you want to query:

```
mco = ?ClassName;
elist = mco.EventList;
elist(1).Name; % name of first event in list
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

**Properties**

Property	Purpose
Name read only	Name of the event.
Description read only	Currently not used
DetailedDescription read only	Currently not used

# meta.event

---

Property	Purpose
Hidden	If true, the event does not appear in the list of events returned by the <code>events</code> function (or other event listing functions or viewers)
ListenAccess	<p>Determines where you can create listeners for the event.</p> <ul style="list-style-type: none"><li>• <code>public</code> — unrestricted access</li><li>• <code>protected</code> — access from methods in class or subclasses</li><li>• <code>private</code> — access by class methods only (not from subclasses)</li><li>• List classes that have listen access to this event. Specify classes as <code>meta.class</code> objects in the form:<ul style="list-style-type: none"><li>▪ A single <code>meta.class</code> object</li><li>▪ A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li></ul></li></ul> <p>See “Controlling Access to Class Members”</p>

<b>Property</b>	<b>Purpose</b>
NotifyAccess	<p>Determines where code can trigger the event.</p> <ul style="list-style-type: none"> <li>• <code>public</code> — any code can trigger event</li> <li>• <code>protected</code> — can trigger event from methods in class or subclasses</li> <li>• <code>private</code> — can trigger event by class methods only (not from subclasses)</li> <li>• List classes that have notify access to this event. Specify classes as <code>meta.class</code> objects in the form: <ul style="list-style-type: none"> <li>▪ A single <code>meta.class</code> object</li> <li>▪ A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> </li> </ul> <p>See “Controlling Access to Class Members”</p>
DefiningClass	<p>The <code>meta.class</code> object representing the class that defines this event.</p>

- “Getting Information About Classes and Objects”

# meta.MetaData

---

<b>Superclasses</b>	Heterogeneous
<b>Purpose</b>	Superclass for MATLAB object metadata
<b>Description</b>	<p>The <code>meta.MetaData</code> class of objects represent MATLAB class definitions and the constituent parts of those definitions, such as properties and methods. Metadata enable a program to get information about a class definition.</p> <p>The <code>meta.MetaData</code> class forms the root of the metadata class hierarchy, which enables the formation of arrays of metadata objects belonging to different specific classes.</p> <p>MATLAB uses instances of the <code>meta.MetaData</code> class as the default object to fill in missing array elements.</p> <p><code>findobj</code> and <code>findprop</code>, can search the metadata hierarchy and return an array of different metadata objects. These function require the ability to form heterogeneous arrays containing various metaclass objects.</p> <p>See the <code>matlab.mixin.Heterogeneous</code> class for more information on heterogeneous hierarchies.</p>
<b>Construction</b>	You cannot create an instance of the <code>meta.MetaData</code> class directly. MATLAB constructs instances of this class as required.
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.
<b>Examples</b>	<p>This example shows how the <code>meta.MetaData</code> class facilitates working with metaclasses.</p> <p>Create a <code>meta.class</code> instance representing the MATLAB <code>timeseries</code> class:</p> <pre>&gt;&gt; mc = ?timeseries;</pre> <p>MATLAB uses <code>meta.MetaData</code> objects to fill empty array elements:</p>

```
>> m(2) = mc
>> class(m(1))
```

```
ans =
```

```
meta.MetaData
>> class(m(2))
```

```
ans =
```

```
meta.class
```

Use `findobj` to find all properties and methods that have protected access:

```
>> protectedMembers = findobj(mc,{'Access','protected'},...
'-or',{'SetAccess','protected'},...
'-or',{'GetAccess','protected'}});
```

The `timeseries` class defines both properties and methods that have protected access. Therefore, `findobj` returns a heterogeneous array of class `meta.MetaData`. This array contains both `meta.property` and `meta.method` objects.

```
>> protectedMembers
```

```
protectedMembers =
```

```
11x1 heterogeneous meta.MetaData (meta.property, meta.method)
```

```
handle with no properties.
```

```
Package: meta
```

```
>> class(protectedMembers(1))
```

```
ans =
```

```
meta.property
```

```
>> protectedMembers(1).Name
```

```
ans =  
  
Length  
>> protectedMembers(1).SetAccess  
  
ans =  
  
protected  
>> protectedMembers(1).GetAccess  
  
ans =  
  
public
```

## See Also

## Purpose

meta.method class describes MATLAB class methods

## Description

The meta.method class provides information about the methods of MATLAB classes. The read/write properties of the meta.method class correspond to method attributes and are specified only from within class definitions.

You can query the read-only properties of the meta.method object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining a method).

You cannot instantiate a meta.method object directly. Obtain a meta.method object from the meta.class MethodList property, which contains an array of meta.method objects, one for each class method. For example, replace *ClassName* with the name of the class whose methods you want to query:

```
mco = ?ClassName;
mlist = mco.MethodList;
mlist(1).Name; % name of first method in the list
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

## Properties

Property	Purpose
Abstract	<p>If true, the method has no implementation. The method has a syntax line that can include arguments, which subclasses use when implementing the method.</p> <ul style="list-style-type: none"> <li>Subclasses are not required to define the same number of input and output arguments.</li> </ul>

# meta.method

---

Property	Purpose
	<ul style="list-style-type: none"><li>• The method can have comments after the function line</li><li>• Does not contain function or end keywords, only the function syntax (e.g., <code>[a,b] = myMethod(x,y)</code>)</li></ul>
Access attribute, default = public	Determines what code can call this method. <ul style="list-style-type: none"><li>• <code>public</code> — unrestricted access</li><li>• <code>protected</code> — access from methods in class</li></ul>
DefiningClass	The <code>meta.class</code> object representing the class that defines this method.
Description read only	Currently not used
DetailedDescription read only	Currently not used
Hidden attribute, default = false	When <code>false</code> , the method name shows in the list of methods displayed using the <code>methods</code> or <code>methodsview</code> commands. If set to <code>true</code> , the method name is not included in these listings.
Name read only	Name of the method.

Property	Purpose
Sealed attribute, default = false	If true, the method cannot be redefined in a subclass. Attempting to define a method with the same name in a subclass causes an error.
Static attribute, default = false	Set to true to define a method that does not depend on an object of the class and does not require an object argument. Call static methods using the class name in place of the object:  <code>classname.methodname()</code>  Or with an instance of the class, like any method:  <code>o.methodname()</code>  See “Static Methods”

# meta.package

---

**Purpose** meta.package class describes MATLAB packages

**Description** The meta.package class contains information about MATLAB packages. You cannot instantiate a meta.package object directly. Obtain a meta.package object from the meta.class ContainingPackage property, which contains a meta.package object, or an empty object, if the class is not in a package.

## Properties

Property	Purpose
Name read only	Name of the package associated with this meta.package object
ClassList read only	List of classes that are scoped to this package. An object array of meta.class objects.
Classes read only Use ClassList instead	List of classes that are scoped to this package. A cell array of meta.class objects.
FunctionList read only	List of functions that are scoped to this package. An object array of function handles.
Functions read only Use FunctionList instead	List of functions that are scoped to this package. A cell array of function handles.
PackageList read only	List of packages that are scoped to this package. An object array of meta.package objects.
Packages read only Use PackageList instead	List of packages that are scoped to this package. A cell array of meta.package objects.
ContainingPackage read only	A meta.package object describing the package within which this package is contained, or an empty object if this package is not nested.

## Methods

Method	Purpose
<code>fromName</code>	Static method returns a <code>meta.package</code> object for a specified package name.
<code>getAllPackages</code>	Static method returns a cell array of <code>meta.package</code> objects representing all top-level packages.

`meta.class` | `meta.property` | `meta.method` | `meta.event`

## How To

- “Getting Information About Classes and Objects”

# meta.abstractDetails

---

**Purpose** Find abstract methods and properties

**Syntax**

```
meta.abstractDetails(ClassName)
meta.abstractDetails(mc)
absMembers = meta.abstractDetails( ___ )
```

**Description** `meta.abstractDetails(ClassName)` displays a list of abstract methods and properties for the class with name `ClassName`. Use the fully specified name for classes in packages. MATLAB displays all public and protected abstract methods and properties, including those declared `Hidden`.

`meta.abstractDetails(mc)` displays a list of abstract methods and properties for the class represented by the `meta.class` object `mc`.

`absMembers = meta.abstractDetails( ___ )` returns an array of the metaclass objects corresponding to the abstract members of the class, and can include any of the input arguments in previous syntaxes. If the class has both abstract methods and abstract properties, `absMembers` is a heterogeneous array of class `meta.MetaData` containing `meta.method` and `meta.property` objects.

A class can be abstract without defining any abstract methods or properties if it declares the `Abstract` class attribute. In this case, `meta.abstractDetails` returns no abstract members for that class, but the class is abstract. See “Determine If a Class Is Abstract” for more information.

## Input Arguments

### **ClassName**

Name of the class specified as a character string (for example, 'MyClass')

### **mc**

`meta.class` object representing the class (for example, ?MyClass)

## Output Arguments

### **absMembers**

Array of metaclass objects representing abstract class members

## Examples

### **Display Abstract Member Names**

Define the class, `AbsBase`, with an abstract property:

```
classdef AbsBase
    properties (Abstract)
        Prop1
    end
    methods(AbsBase)
        result = methodOne(obj)
        output = methodTwo(obj)
    end
end
```

Pass the class name (`AbsBase`) as a string:

```
meta.abstractDetails('AbsBase')
```

`meta.abstractDetails` displays the names of the abstract properties and methods defined in the class `AbsBase`.

```
Abstract methods for class AbsBase:
    methodTwo    % defined in AbsBase
    methodOne    % defined in AbsBase
```

```
Abstract properties for class AbsBase:
    Prop1       % defined in AbsBase
```

### **Return Abstract Member Metaclass Objects**

Pass a `meta.class` object representing the `AbsBase` class and return the metaclass objects for the abstract members. Use the definition of the `AbsBase` class from the previous example.

```
mc = ?AbsBase;
```

# meta.abstractDetails

---

```
absMembers = meta.abstractDetails(mc);
```

absMembers is a heterogeneous array containing a meta.property object for the Prop1 abstract property and meta.method objects for the methodOne and methodTwo abstract methods.

List the names of the metaclass objects.

```
for k=1:length(absMembers)
    disp(absMembers(k).Name)
end
```

```
methodTwo
methodOne
Prop1
```

## Find Inherited Abstract Members

Derive the SubAbsBase class from AbsBase, which is defined in a previous example.

```
classdef SubAbsBase < AbsBase
    properties
        SubProp = 1;
    end
    methods
        function result = methodOne(obj)
            result = obj.SubProp + 1;
        end
    end
end
```

Display the names of the abstract members inherited by SubAbsBase.

```
meta.abstractDetails('SubAbsBase')
```

```
Abstract methods for class SubAbsBase:
    methodTwo    % defined in AbsBase
```

```
Abstract properties for class SubAbsBase:  
  Prop1  % defined in AbsBase
```

To make SubAbsBase a concrete class, you need to implement concrete versions of methodTwo and Prop1 in the subclass.

## See Also

`meta.class` | `meta.class.forName`

## Concepts

- “Defining Abstract Classes”
- “Getting Information About Classes and Objects”

# meta.package.fromName

---

**Purpose** Return meta.package object for specified package

**Syntax** mpkg = meta.package.fromName('pkgname')

**Description** mpkg = meta.package.fromName('pkgname') is a static method that returns the meta.package object associated with the named package. If pkgname is a nested package, then you must provide the fully qualified name (e.g., 'pkgname1.pkgname2').

**Examples** List the classes in the event package:

```
mev = meta.package.fromName('event');
for k=1:length(mev.Classes)
    disp(mev.Classes{k}.Name)
end
event.EventData
event.PropertyEvent
event.listener
event.propListener
```

**See Also** meta.package | meta.package.getAllPackages

**Purpose** Get all top-level packages

**Syntax** `P = meta.package.getAllPackages`

**Description** `P = meta.package.getAllPackages` is a static method that returns a cell array of `meta.package` objects representing all the top-level packages that are visible on the MATLAB path or defined as top-level built-in packages. You can access subpackages using the `Packages` property of each `meta.package` object.

Note that the time required to find all the packages on the path might be excessively long in some cases. You should therefore avoid using this method in any code where execution time is a consideration. `getAllPackages` is generally intended for interactive use only.

**See Also** `meta.package` | `meta.package.fromName`

# meta.property

---

**Purpose** meta.property class describes MATLAB class properties

**Description** The meta.property class provides information about the properties of MATLAB classes. The read/write properties of the meta.property class correspond to property attributes and are specified only from within your class definitions.

You can query the read-only properties of the meta.property object to obtain information that is specified syntactically by the class (for example, to obtain the function handle of a property's set access method).

You cannot instantiate a meta.property object directly. Obtain a meta.property object from the meta.class PropertyList property, which contains an array of meta.property objects, one for each class property. For example, replace *ClassName* with the name of the class whose properties you want to query:

```
mco = ?ClassName;  
plist = mco.PropertyList;  
plist(1).Name; % name of first property
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

## Properties

Property	Purpose
Name read only	Name of the property.
Description read only	Currently not used
DetailedDescription read only	Currently not used

Property	Purpose
AbortSet attribute, default = false	<p>If true, and this property belongs to a handle class, then MATLAB does not set the property value if the new value is the same as the current value. This prevents the triggering of property PreSet and PostSet events.</p> <p>See “Listen for Changes to Property Values”</p>
Abstract attribute, default = false	<p>If true, the property has no implementation, but a concrete subclass must redefine this property without Abstract being set to true.</p> <ul style="list-style-type: none"> <li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li> <li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li> <li>• All subclasses must specify the same values as the superclass for the property SetAccess and GetAccess attributes.</li> <li>• Abstract=true should be used with the class attribute Sealed=false (the default).</li> </ul>
Access	<p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as meta.class objects in the form:</p> <ul style="list-style-type: none"> <li>• A single meta.class object</li> </ul>

# meta.property

---

Property	Purpose
	<ul style="list-style-type: none"><li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as <code>private</code> access.</li></ul> <p>Use <code>Access</code> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <code>Access</code>).</p>
Constant attribute, default = false	<p>Set to true if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"><li>• Subclasses inherit constant properties, but cannot change them.</li><li>• Constant properties cannot be <code>Dependent</code></li><li>• <code>SetAccess</code> is ignored.</li></ul> <p>See “Properties with Constant Values”</p>
DefaultValue	Property default value (if specified in class definition). See also <code>HasDefault</code> property. Abstract, dependent and dynamic properties cannot specify default values.
DefiningClass	The <code>meta.class</code> object representing the class that defines this property.

<b>Property</b>	<b>Purpose</b>
<p>GetAccess attribute, default = public</p>	<p>public – unrestricted access                      protected – access from class or subclasses                      private – access by class members only</p> <p>List classes that have get access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as private access.</li> </ul> <p>See “Controlling Access to Class Members”</p>
<p>Dependent attribute, default = false</p>	<p>If false, property value is stored in object. If true, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.</p> <p>See “Property Get Methods”</p>
<p>Transient attribute, default = false</p>	<p>If true, property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.</p>
<p>GetMethod read only</p>	<p>Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”</p>

# meta.property

Property	Purpose
GetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”
HasDefault	Property contains a boolean value indicating if the property defines a default value. Test HasDefault before querying the DefaultValue property to avoid a MATLAB: class:NoDefaultDefined error.
Hidden attribute, default = false	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to properties, etc.).
SetAccess attribute, default = public	<p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only</p> <p>immutable — property can be set only in the constructor.</p> <p>See “Mutable and Immutable Properties”</p> <p>List classes that have set access to this property. Specify classes as meta.class objects in the form:</p> <ul style="list-style-type: none"><li>• A single meta.class object</li><li>• A cell array of meta.class objects. An empty cell array, {}, is the same as private access.</li></ul> <p>See “Controlling Access to Class Members”</p>

<b>Property</b>	<b>Purpose</b>
SetMethod read only	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
SetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”

**Events**

See “Listen for Changes to Property Values” for information on using property events.

<b>Event Name</b>	<b>Purpose</b>
PreGet	Event occurs just before property is queried.
PostGet	Event occurs just after property has been queried
PreSet	Event occurs just before this property is modified
PostSet	Event occurs just after this property has been modified

- “Getting Information About Classes and Objects”

# metaclass

---

**Purpose** Obtain `meta.class` object

**Syntax** `mc = metaclass(object)`  
`mc = ?ClassName`

**Description** `mc = metaclass(object)` returns the `meta.class` object for the class of `object`. The `object` input argument can be a scalar or an array of objects. However, `metaclass` always returns a scalar `meta.class` object.

`mc = ?ClassName` returns the `meta.class` object for the class with name, *ClassName*. The `?` operator works only with a class name, not an object.

If you pass a class name as a string to the `metaclass` function, it returns the `meta.class` object for the `char` class. Use the `?` operator or the `meta.class.fromName` method to obtain the `meta.class` object from a class name. Use this method if you want to pass the class name in a string variable.

**Examples** Return the `meta.class` object for an instance of the `MException` class:

```
obj = MException('Msg:ID', 'MsgTxt');  
mc = metaclass(obj);
```

Use the `?` operator to get the `meta.class` object for the `hgsetget` class:

```
mc = ?hgsetget;
```

**See Also** `meta.class` | `meta.class.fromName`

**Tutorials** • “Class Metadata”

## Purpose

Class method names

## Syntax

```
methods('classname')
methods(..., '-full')
m = methods(...)
```

## Description

`methods('classname')` displays the names of the methods for the class *classname*. If *classname* is a MATLAB or Java class, then `methods` displays only public methods, including those methods inherited from superclasses.

`methods(..., '-full')` displays a full description of the methods, including inheritance information and, for MATLAB and Java methods, method attributes and signatures. `methods` does not remove duplicate method names with different signatures. Do not use this option with classes defined before MATLAB 7.6.

`m = methods(...)` returns the method names in a cell array of strings.

`methods` is also a MATLAB class-definition keyword. See `classdef` for more information on class-definition keywords.

This function does not show generic methods from classes based on the Microsoft .NET Framework. Use your product documentation to get information on generic methods.

## Examples

Retrieve the names of the static methods in class `MException`:

```
methods('MException')
```

Methods for class `MException`:

<code>addCause</code>	<code>getReport</code>	<code>ne</code>	<code>throw</code>
<code>eq</code>	<code>isequal</code>	<code>rethrow</code>	<code>throwAsCaller</code>

Static methods:

```
last
```

# methods

---

## **See Also**

[methodsview](#) | [properties](#) | [events](#) | [what](#) | [which](#)

## **Tutorials**

- [“Methods”](#)

**Purpose**

View class methods

**Syntax**

```
methodsview packagename.classname  
methodsview classname  
methodsview(object)
```

**Description**

`methodsview packagename.classname` displays information about the methods in the class, `classname`. If the class is in a package, include `packagename`. If `classname` is a MATLAB or Java class, `methodsview` lists only public methods, including those methods inherited from superclasses.

`methodsview classname` displays information describing the class `classname`.

`methodsview(object)` displays information about the methods of the class of `object`.

`methodsview` creates a window that displays the methods defined in the specified class. `methodsview` provides additional information like arguments, returned values, and superclasses. It also includes method qualifiers (for example, `abstract` or `synchronized`) and possible exceptions thrown.

**Examples**

List information on all methods in the `java.awt.MenuItem` class:

```
methodsview java.awt.MenuItem
```

MATLAB displays this information in a new window.

**See Also**

[methods](#) | [import](#) | [class](#) | [javaArray](#)

**Purpose** Build MEX-function from C/C++ or Fortran source code

**Syntax**

```
mex -setup
mex filenames
mex option1 ... optionN filenames
```

**Description** `mex -setup` selects or changes the compiler configuration. MATLAB searches for installed compilers and allows you to choose a compiler for future invocations of `mex`.

`mex filenames` compiles and links one or more C, C++, or Fortran source files into a shared library. `filenames` specifies the source files. The shared library is a binary MEX-file, callable from MATLAB.

`mex option1 ... optionN filenames` builds the MEX-file with the specified build options. The `option1 ... optionN` arguments supplement or override the default `mex` build options.

## Input Arguments

### **filenames - One or more file names**

string

One or more file names, including name and file extension, specified as a string. If the file is not in the current folder, specify the full path to the file. File names can be any combination of:

- C, C++, or Fortran language source files
- Simulink S-function files
- object files
- library files

The first file listed in `filenames` is the name of the binary MEX-file. To override this naming convention, use the `'-outdir'` option.

### **Data Types**

char

**option1 ... optionN - One or more build options**

Strings corresponding to valid option flags

One or more build options, specified as one of these values. Options can appear in any order on any platform, except where indicated.

Option	Description
<i>@rspfile</i>	Uses Windows RSP file. An RSP file is a text file containing command-line options.
-c	Compiles an object file. Does not build a binary MEX-file.
-compatibleArrayDims (default) -largeArrayDims	<p>Links with the specified MATLAB array-handling API.</p> <ul style="list-style-type: none"> <li>• -compatibleArrayDims — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option.</li> <li>• -largeArrayDims — Uses the MATLAB large-array-handling API. This API handles arrays with more than <math>2^{31}-1</math> elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> <p>In verbose mode (-v option), if you do not specify either the -compatibleArrayDims or the -largeArrayDims option, MATLAB displays a message showing the default option.</p>

**(Continued)**

<b>Option</b>	<b>Description</b>
<p>-cxx -fortran</p>	<p>UNIX systems only. Overrides the assumption that the first source file in the list determines which linker to use.</p> <p>-cxx use the C++ linker if the first source file is C and there are one or more C++ source or object files.</p> <p>-fortran uses the Fortran linker.</p>
<p>-DsymbolName -DsymbolName=symbolValue -UsymbolName</p>	<p>The -D options create C preprocessor symbols. Equivalent to the following in the source file:</p> <ul style="list-style-type: none"> <li>• #define symbolName</li> <li>• #define symbolName symbolValue</li> </ul> <p>The -U option removes any initial definition of the C preprocessor symbol, symbolName. Inverse of the -D option.</p> <p>Do not add a space between <b>D</b> or <b>U</b> and symbolName. Do not add spaces around the = sign.</p> <p>Example: “Define Directive” on page 1-3858</p>
<p>-f optionsfile</p>	<p>Overrides the default mex “Options File” on page 1-3862. optionsfile is the name and full path of the options file, specified as a string.</p> <p>Example: “Specify Options File by Name” on page 1-3860</p>

(Continued)

Option	Description
-fortran -cxx	UNIX systems only. Overrides the assumption that the first source file in the list determines which linker to use.  -cxx use the C++ linker if the first source file is C and there are one or more C++ source or object files.  -fortran uses the Fortran linker.
-g	Adds symbolic information and disables optimizing built object code. Use for debugging. To debug with optimization, add the -O option.
-h[elp]	Displays help for mex.
-I <i>pathname</i>	Adds <i>pathname</i> to the list of folders to search for #include files.  Do not add a space between I and <i>pathname</i> .  Example: “Specify Path to Include File” on page 1-3857
-llibname -Llibfolder -llibname	Links with object library <i>libname</i> in (optional) <i>libfolder</i> .  MATLAB expands <i>libname</i> to: <ul style="list-style-type: none"> <li>• <i>libname.lib</i> or <i>liblibname.lib</i> — Windows systems</li> <li>• <i>liblibname.so</i> — Linux systems</li> <li>• <i>liblibname.dylib</i> — Macintosh systems</li> </ul> If used, the -L option must precede the -l option. When using the -L option on UNIX

**(Continued)**

Option	Description
	<p>systems, you also must set the runtime library path, as explained in “Setting Run-Time Library Path”.</p> <p>Do not add a space between <b>l</b> and <i>libname</i> or between <b>L</b> and <i>libfolder</i>.</p> <p>Specify the -l option with the lowercase letter <b>L</b>.</p> <p>Example: “Specify Path to Library File” on page 1-3858</p>
<p>-largeArrayDims -compatibleArrayDims (default)</p>	<p>Links with the specified MATLAB array-handling API.</p> <ul style="list-style-type: none"> <li>• -compatibleArrayDims — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option.</li> <li>• -largeArrayDims — Uses the MATLAB large-array-handling API. This API handles arrays with more than <math>2^{31}-1</math> elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> <p>In verbose mode (-v option), if you do not specify either the -compatibleArrayDims or the -largeArrayDims option, MATLAB displays a message showing the default option.</p>
<p>-n</p>	<p>Displays, but does not execute, commands that mex would execute.</p> <p>Example: “Preview Build Commands” on page 1-3856</p>

(Continued)

Option	Description
-O	<p>Optimizes the object code. Use this option to compile with optimization.</p> <p>Optimization is enabled by default. Optimization is disabled when the -g option appears without the -O option.</p> <p>Specify this option with the capital letter <b>O</b>.</p>
-outdir <i>dirname</i>	<p>Places all output files in folder <i>dirname</i>.</p> <p>Example: “Create and Link to Separate Object Files” on page 1-3856</p>
-output <i>mexname</i>	<p>Overrides the default MEX-file naming mechanism. Creates binary MEX-file named <i>mexname</i> with the appropriate MEX-file extension.</p>
-setup	<p>Specify the compiler options file to use when calling the mex function. When you use this option, all other command-line options are ignored.</p>
-U <i>symbolname</i>	<p>Removes any initial definition of the C preprocessor symbol <i>symbolname</i>. (Inverse of the -D option.)</p> <p>Do not add a space between <b>U</b> and <i>symbolname</i>.</p>

(Continued)

Option	Description
-v	Builds in verbose mode. Displays values for internal variables after processing the options file and all build options. Displays each compile and link step fully evaluated.  Example: “Display Detailed Build Information” on page 1-3856
<i>varname=varvalue</i>	Overrides an options file variable for variable <i>varname</i> . This option is processed after the options file is processed and all command line arguments are considered. Use the shell’s quoting syntax to protect characters such as spaces, which have a meaning in the shell syntax.

## Examples

### Select C Compiler

```
mex -setup
```

MATLAB displays the options for your version and system based on the list of Supported and Compatible Compilers.

### Build C MEX-File

Build a single C program, `yprime.c`, into a MEX-file.

You must have a supported compiler installed on your system to run any of these examples. For more information, see “Select C Compiler” on page 1-3854.

Each example is based on MEX examples in the `matlabroot/extern/examples` subfolders. To build the example code, copy the source file to a writable folder on your path, such as `c:\work`. Set the current folder to `c:\work`.

```
[s,msg,msgid] = mkdir('c:\work');  
if (isempty(msgid))  
    mkdir('c:\work')  
end  
cd c:\work
```

Copy the source code, `yprime.c`.

```
copyfile(fullfile(matlabroot,'extern','examples','mex',...  
    'yprime.c'),'.','f');
```

Build the MEX-file.

```
mex yprime.c
```

To test:

```
T=1; Y=1:4;  
yprime(T,Y)
```

```
ans =  
    2.0000    8.9685    4.0000   -1.0947
```

### **Build MEX-File from Multiple Source Files**

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`.

Select a Fortran compiler.

Copy the source files to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...  
    'loadsparse.F'),'.','f');  
copyfile(fullfile(matlabroot,'extern','examples','refbook',...  
    'fulltosparse.F'),'.','f');
```

Build the `fulltosparse` MEX-file.

```
mex fulltosparse.F loadsparse.F
```

### **Preview Build Commands**

Use the `-n` option to preview the build command details without executing the commands.

```
mex -n yprime.c
```

The output displays information specific to your platform and compiler.

### **Display Detailed Build Information**

Use verbose mode to display the compile and link commands. Use the `-g` option to include debugging information.

```
mex -v -g -compatibleArrayDims yprime.c
```

The output displays information specific to your platform and compiler.

### **Create and Link to Separate Object Files**

You can link to object files that you compile separately from your source MEX-files.

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`. The `fulltosparse` file is the gateway routine (contains the `mexFunction` subroutine) and `loadsparse` contains the computational routine.

Select a Fortran compiler.

Copy the computational subroutine to your current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', ...  
    'loadsparse.F'), '.', 'f');
```

Compile the subroutine and place the object file in a separate folder, `c:\objfiles`.

```
mkdir c:\objfiles  
mex -largeArrayDims -c -outdir c:\objfiles loadsparse.F
```

Copy the gateway subroutine to your current folder. Compile and link with the loadsparse object file.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
    'fulltosparse.F'),'.','f');
mex -largeArrayDims fulltosparse.F c:\objfiles\loadsparse.obj
```

### Specify Path to Include File

Use the `-I` option to specify the path to include the MATLAB LAPACK library subroutines for handling complex number routines. To use these subroutines, your MEX-file must access the header file, `fort.h`.

Run the “Select C Compiler” on page 1-3854 example.

Copy the `matrixDivideComplex.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
    'matrixDivideComplex.c'),'.','f');
```

Create a variable, `fortheaderdir`, containing the path to `fort.h`.

```
fortheaderdir = fullfile(matlabroot,'extern','examples','refbook');
```

Create the `-I` argument by concatenating `'-I'` with the variable, `fortheaderdir`.

```
ipath = ['-I' fortheaderdir];
```

Create variables for the names and paths to the LAPACK library file and the file, `fort.c`, containing the complex number handling routines.

```
lapacklib = fullfile(matlabroot, ...
    'extern','lib',computer('arch'),'microsoft','libmwlapack.lib');
fortfile = fullfile(matlabroot,'extern','examples',...
    'refbook','fort.c');
```

Build the MEX-file.

```
mex('-v', '-largeArrayDims', ipath, ...  
    'matrixDivideComplex.c', fortfile, lapacklib)
```

## Specify Path to Library File

Use the `-L` and `-l` options to specify the `libmwlapack.lib` library, located in the folder, `matlabroot\extern\lib\arch\microsoft`.

Copy the `matrixDivide.c` example to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', ...  
    'matrixDivide.c'), '.', 'f');
```

The variable, `lapackpath`, identifies the path to the library, `libmwlapack.lib`.

```
lapackpath = fullfile(matlabroot, ...  
    'extern', 'lib', computer('arch'), 'microsoft');
```

Build the MEX-file.

```
mex('-largeArrayDims', ['-L' lapackpath], '-llibmwlapack', 'matrixDivide.c')
```

## Define Directive

Define the character to use between strings in a matrix.

The MATLAB example, `mxcreatecharmatrixfromstr.c`, uses a `#define` symbol, `SPACE_PADDING`, to determine what character to use between strings in a matrix. To set the value, build the MEX-file with the `-D` option.

Copy the `mxcreatecharmatrixfromstr.c` example to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'mx', ...  
    'mxcreatecharmatrixfromstr.c'), '.', 'f');
```

Set the `SPACE_PADDING` directive to add a space between strings.

```
mex mxcreatecharmatrixfromstr.c -DSPACE_PADDING
```

## Override Option Containing Special Character on Windows Platform

Use the *name=value* command-line argument to override a variable specified in the options file at the command line.

Append the COMPFLAGS variable with the value -Wall.

```
$COMPFLAGS -Wall
```

Use double quotes (") to preserve the space character.

```
COMPFLAGS="$COMPFLAGS -Wall"
```

Use this notation at either the MATLAB prompt or the DOS prompt

Build the `yprime.c` MEX-file.

```
mex -v COMPFLAGS="$COMPFLAGS -Wall" LINKFLAGS="$LINKFLAGS /VERBOSE" yprime.c
```

## Override Option Containing Special Characters on UNIX Platform

Build `yprime.c` at the MATLAB command line on a UNIX platform.

Override the CFLAGS variable with the value -Wall.

```
$CFLAGS -Wall
```

Use double quotes (") to preserve the space character and the backslash (\) escape character to preserve the dollar sign (\$).

```
CFLAGS="\$CFLAGS -Wall"
```

Build the `yprime.c` MEX-file.

```
mex -v CFLAGS="\$CFLAGS -Wall" LDFLAGS="\$LDFLAGS -w" yprime.c
```

To use this command from the shell command line, use single quotes (') to preserve the space character.

```
CFLAGS=' $CFLAGS -Wall'
```

Build the `yprime.c` MEX-file.

```
mex -v CFLAGS=' $CFLAGS -Wall' LDFLAGS=' $LDFLAGS -w' yprime.c
```

## Specify Options File by Name

Use the `-f` option to specify a particular Windows options file. The options files are in the `matlabroot\bin\arch\mexopts` folder.

Copy the `convec.F` example to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', ...  
    'convec.F'), '.', 'f');
```

The name of the options file for one of the supported Intel Fortran compilers is `intelf12msvs2010opts.bat`. Build the MEX-file.

```
mex('-f', [matlabroot '\bin\win64\mexopts\intelf12msvs2010opts.bat'], ...  
    'convec.F')
```

## Build Engine Application

Copy the `engwindemo.c` engine example to the current folder.

```
copyfile(fullfile(matlabroot, ...  
    'extern', 'examples', 'eng_mat', 'engwindemo.c'), '.', 'f');
```

Using `mex -setup`, select the Microsoft Visual C++® 2010 compiler.

```
cc = mex.getCompilerConfigurations
```

```
cc =
```

```
    CompilerConfiguration with properties:
```

```
        Name: 'Microsoft Visual C++ 2010'  
    ShortName: 'MSVC100'
```

```

Manufacturer: 'Microsoft'
Language: 'C++'
Version: '10.0'
Location: 'C:\Program Files (x86)\Microsoft Visual Studio 10.0'
Details: [1x1 mex.CompilerConfigurationDetails]
LinkerName: 'Microsoft Visual C++ 2010'
LinkerVersion: '10.0'
MexOpt: 'C:\Users\ouser\AppData\Roaming\MathWorks\MATLAB\R2010a\bin\
Priority: 'A'

```

Create the path to the folder containing the options files.

```
optionsPath = fullfile(matlabroot,...
    'bin',computer('arch'),'mexopts');
```

Create the options file name, as described in “Engine Options Files on Windows”.

```
optfile = [cc.ShortName,'engmatopts.bat']
```

Build the engine example, using the '-f' option.

```
mex('-v','-f',fullfile(optionsPath,optfile),'engwindemo.c');
```

Run the example.

```
!engwindemo
```

For details about this examples, see “Call MATLAB Functions from C Applications”.

## Tips

- You can run `mex` from:
  - MATLAB Command Window
  - Windows system prompt
  - UNIX shell
- The MEX-file has a platform-dependent extension. This means you can place binary MEX-files for different platforms in the same folder.

(Continued)

Platform	Binary MEX-File Extension
Linux (64-bit)	mexa64
Apple Mac (64-bit)	mexmaci64
Microsoft Windows (32-bit)	mexw32
Windows (64-bit)	mexw64

Use the `mexext` function to identify the MEX-file extension.

- To use `mex` to build executable files for standalone MATLAB engine and MAT-file applications, you must use the `-f` option and specify an options file.

### Options Files to Build Engine and MAT-File Applications

Platform	Options File Name	File Location
Windows systems	*engmatopts.bat	<i>matlabroot</i> \bin\arch\mexopts
UNIX systems	engopts.sh matopts.sh	<i>matlabroot</i> /bin

The `*` character in the `*engmatopts.bat` file name is a string that identifies the compiler type and version.

## Definitions

### Options File

A file containing the compiler and build options that MATLAB uses when you invoke the `mex` build script.

By default, `mex` uses an options file to specify variables and values that you pass as arguments to the compiler, linker, and other tools.

Platform	Options File Name	File Location
Windows systems	mexopts.bat	<i>prefdir</i>
UNIX systems	mexopts.sh	<i>matlabroot/bin</i>

MATLAB provides template options files for the compilers that are supported by mex. These template files are used by the `-setup` option to define the selected default options file.

# mex.getCompilerConfigurations

---

**Purpose** Get compiler configuration information for building MEX-files

**Syntax**

```
cc = mex.getCompilerConfigurations
cc = mex.getCompilerConfigurations(lang)
cc = mex.getCompilerConfigurations(lang,list)
```

**Description** `cc = mex.getCompilerConfigurations` returns an object `cc` containing information about the “Selected Compiler” on page 1-3864 configuration used by the `mex` command.

`cc = mex.getCompilerConfigurations(lang)` returns an array of objects for the given language, `lang`. If the language of the selected compiler is different from `lang`, then `cc` is empty.

`cc = mex.getCompilerConfigurations(lang,list)` returns information about the set of configurations, `list`.

## Definitions **Selected Compiler**

The selected compiler is the one you choose when you run the `mex -setup` command.

## Input Arguments

### **lang - Language**

'Any' (default) | 'C' | 'C++' | 'CPP' | 'Fortran'

Language, specified as one of these values.

'Any'	All supported languages. This is the default value.
'C'	All C compiler configurations, including C++ configurations.
'C++' or 'CPP'	All C++ compiler configurations.
'Fortran'	All Fortran compiler configurations.

## list - Set of configurations

'Selected' (default) | 'Installed' | 'Supported'

Set of configurations, specified as one of these values.

'Selected'	The compiler you chose when you ran <code>mex-setup</code> . This is the default value.
'Installed'	All supported compilers <code>mex</code> finds installed on your system.
'Supported'	All compilers supported in the current release. For an up-to-date list of supported compilers, see the Supported and Compatible Compilers Web page.

## Output Arguments

### cc - Compiler information

`mex.CompilerConfiguration` object or array of objects

Compiler information, specified as a `mex.CompilerConfiguration` object or array of `mex.CompilerConfiguration` objects. The `mex.CompilerConfiguration` class contains the following read-only properties.

Property	Purpose
Name	Compiler name.
ShortName	Character string used to identify options file for the compiler.
Manufacturer	Name of the manufacturer of the compiler.
Language	Compiler language.
Version	(Windows platforms only) Version of the compiler.
Location	(Windows platforms only) Folder where compiler is installed.

# mex.getCompilerConfigurations

---

Property	Purpose
Details	Additional read-only properties about the compiler configuration. These properties might differ across compilers, platforms, and releases of MATLAB.
LinkerName	Linker name.
LinkerVersion	(Windows platforms only) Version of the linker.
MexOpt	Name and full path to options file.
Priority	The priority of this compiler.

## Examples

### Display Information for Selected Compiler

```
myCompiler = mex.getCompilerConfigurations
```

```
myCompiler =
```

```
    CompilerConfiguration with properties:
```

```
        Name: 'Microsoft Visual C++ 2010'  
        ShortName: 'MSVC100'  
        Manufacturer: 'Microsoft'  
        Language: 'C++'  
        Version: '10.0'  
        Location: 'C:\Program Files (x86)\Microsoft Visual Studio 10.0'  
        Details: [1x1 mex.CompilerConfigurationDetails]  
        LinkerName: 'Microsoft Visual C++ 2010'  
        LinkerVersion: '10.0'  
        MexOpt: 'C:\Users\ouser\AppData\Roaming\MathWorks\MATLAB\R2013  
        Priority: 'A'
```

MATLAB displays information depending on your architecture, your version of MATLAB, and what you selected when you ran `mex -setup`.

## Display Names of Supported Compilers and Linkers

Get the list of supported compilers for your version of MATLAB.

```
allCC = mex.getCompilerConfigurations('Any','Supported');
```

Display compiler names.

```
for k = 1:length(allCC)
    disp([allCC(k).Name ' Version: ' allCC(k).Version ...
        ' with linker: ' allCC(k).LinkerName])
end
```

MATLAB displays information depending on your version of MATLAB.

## Display Number of Supported C Compilers

```
cLanguageCC = mex.getCompilerConfigurations('C','Supported');
length(cLanguageCC)
```

```
ans =
     11
```

The number of compilers for your version of MATLAB might be different.

## View Build Options for Selected C Compiler

Display build options MATLAB uses with a particular C compiler.

Create an array, `CC`, of all supported C compiler configurations.

```
CC = mex.getCompilerConfigurations('C','Installed');
for i = 1:length(CC); disp(CC(i).Name); end;
```

```
Intel C++
Microsoft Visual C++ 2010
Microsoft Visual C++ 2005 SP1
```

The list is dependent on your system.

# mex.getCompilerConfigurations

---

From the list above, display the build options for the Microsoft Visual C++ compiler. The compiler is item number 2 in the list. If your list is different, enter an appropriate item number in the following command.

```
CC(2).Details
```

```
ans =  
  CompilerConfigurationDetails with properties:  
  
      CompilerExecutable: 'cl'  
      CompilerFlags: '/c /GR /W3 /EHs /D_CRT_SECURE_NO_DEPRECATED  
/D_SCL_SECURE_NO_DEPRECATED /D_SECURE_SCL=0 /DMATLAB_MEX_FILE /nologo /MD'  
      OptimizationFlags: '/O2 /Oy- /DNDEBUG'  
      DebugFlags: '/Z7'  
      LinkerExecutable: 'link'  
      LinkerFlags: [1x327 char]  
      LinkerOptimizationFlags: ''  
      LinkerDebugFlags: '/debug /PDB:"%OUTDIR%%MEX_NAME%%MEX_EXT%.po  
      SetEnv: [1x3059 char]  
      CommandLineShell: 'C:\Program Files (x86)\Microsoft Visual  
Studio 10.0\VC\vcvarsall.bat'  
      CommandLineShellArg: 'AMD64'
```

MATLAB displays information similar to that shown here.

## Concepts

- “Selecting a Compiler on Windows Platforms”
- “Selecting a Compiler on UNIX Platforms”

## Purpose

Capture error information

## Syntax

```
exception = MException(msgIdent, msgString, v1, v2, ..., vN)
```

## Description

`exception = MException(msgIdent, msgString, v1, v2, ..., vN)` captures information about a specific error and stores it in MException object, *exception*. Information stored in the object includes a message identifier *msgIdent* and an error message string *msgString*. Optional arguments *v<sub>1</sub>*, *v<sub>2</sub>*, ... represent text or numeric values that replace conversion specifiers in *msgString* at run time.

Message identifier *msgIdent* is a character string composed of at least two substrings, the *component* and the *mnemonic*, separated by a colon (e.g., *component:mnemonic*). The purpose of the identifier is to better identify the source of the error. See the documentation on “Message Identifiers” for more information.

Message string *msgString* is a character string that informs the user about the cause of the error and can also suggest how to correct the faulty condition. The *msgString* string can include escape sequences such as `\t` or `\n`, as well as any of the format specifiers supported by the `sprintf` function (such as `%s` or `%d`). Additional arguments *v<sub>1</sub>*, *v<sub>2</sub>*, ..., *v<sub>N</sub>* provide values that correspond to and replace the conversion specifiers.

For example, if *msgString* is “Error on line %d, command %s”, then *v<sub>1</sub>* is the line number at which the error was detected, and *v<sub>2</sub>* is the command that failed. See “Formatting Strings” in the MATLAB Programming Fundamentals documentation for more detailed information on using string formatting commands.

The *exception* output is an object of the MException class. MException is the constructor for this class. In addition to calling the constructor directly, you can also create an object of MException with any of the following functions: `error` and `assert`. See the documentation and figure in the section “The MException Class” for more information on this class.

# MException

---

## Properties

The MException object has four properties: `identifier`, `message`, `stack`, and `cause`. Click any of the links below to find out more about MException properties:

Property	Description
<code>identifier</code>	Identifies the error.
<code>message</code>	Formatted error message that is displayed.
<code>stack</code>	Structure containing stack trace information such as file name, function name, and line number where the MException was thrown.
<code>cause</code>	Cell array of MException that caused this exception to be created.

## Methods

The MException class has the following methods. Click any of the links below to find out more about MException methods:

Method	Description
<code>addCause</code>	Appends an MException to the <code>cause</code> field of another MException.
<code>eq</code>	Tests scalar MException objects for equality.
<code>getReport</code>	Returns a formatted message string that uses the same format as errors thrown by internal MATLAB code.
<code>isequal</code>	Tests scalar MException objects for equality.
<code>last</code>	Returns an MException object for the most recently thrown exception.
<code>ne</code>	Tests scalar MException objects for inequality.

Method	Description
rethrow	Reissues an exception that has been caught, causing the program to stop.
throw	Issues an exception from the currently running function.
throwAsCaller	Issues an exception from the currently running function, also omitting the current stack frame from the <code>stack</code> field of the <code>MException</code> .

## Tips

Valid escape sequences for the `msgString` argument are `\b`, `\f`, `\n`, `\r`, `\t`, and `\x` or `\` when followed by a valid hexadecimal or octal number, respectively. Following a backslash in the `msgString` with any other character causes MATLAB to issue a warning. Conversion specifiers are similar to those used in the C programming language and in the `sprintf` function.

All string input arguments must be enclosed in single quotation marks.

## Examples

### Example 1 – Formatted Messages

If your message string requires formatting specifications like those used with the `sprintf` function, you can use this syntax to compose the error message string:

```
exception = MException(msgIdent, msgString, v1, v2, ...)
```

For example,

```
exception = MException('AcctError:Incomplete', ...  
    'Field ''%.%.s'' is not defined.', ...  
    'Accounts', 'ClientName');
```

```
exception.message  
ans =  
    Field 'Accounts.ClientName' is not defined.
```

## Example 2

The catch block in this example checks to see if the specified file could not be found. If this is the case, the program allows for the possibility that a common variation of the filename extension (e.g., jpeg instead of jpg) was used by retrying the operation with a modified extension. This is done using a try/catch statement that is nested within the original try/catch.

```
function d_in = read_image(filename)
[path name ext] = fileparts(filename);
try
    fid = fopen(filename, 'r');
    d_in = fread(fid);
catch exception

    % Did the read fail because the file could not be found?
    if ~exist(filename, 'file')

        % Yes. Try modifying the filename extension.
        switch ext
        case '.jpg'      % Change jpg to jpeg
            altFilename = strrep(filename, '.jpg', '.jpeg')
        case '.jpeg'   % Change jpeg to jpg
            altFilename = strrep(filename, '.jpeg', '.jpg')
        case '.tif'    % Change tif to tiff
            altFilename = strrep(filename, '.tif', '.tiff')
        case '.tiff'   % Change tiff to tif
            altFilename = strrep(filename, '.tiff', '.tif')
        otherwise
            rethrow(exception);
        end

        % Try again, with modified filename.
        try
            fid = fopen(altFilename, 'r');
            d_in = fread(fid);
        catch
```

```

        rethrow(exception)
    end
end
end
end

```

### Example 3 – Nested try/catch

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested try-catch block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second:

```

function data = read_it(filename);
try
    % Attempt to open and read from a file.
    fid = fopen(filename, 'r');
    data = fread(fid);
catch exception1
    % If the error was caused by an invalid file ID, try
    % reading from another location.
    if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
        msg = sprintf( ...
            '\nCannot open file %s. Try another location? ', ...
            filename);
        reply = input(msg, 's')
        if reply(1) == 'y'
            newFolder = input('Enter folder name: ', 's');
        else
            throw(exception1);
        end
        oldpath = addpath(newFolder);
    try
        fid = fopen(filename, 'r');
        data = fread(fid);
    catch exception2
        exception3 = addCause(exception2, exception1)
        path(oldpath);
        throw(exception3);
    end
end

```

# MException

---

```
        end
        path(oldpath);
    end
end
fclose(fid);
```

If you run this function in a try-catch block at the command line, you can look at the MException object by assigning it to a variable (e) with the catch command.

| isequal(MException) | ne(MException) | last(MException) |
dbstack
```

## How To

- “The MException Class”

**Purpose** Binary MEX-file-name extension

**Syntax**  
`ext = mexext`  
`extlist = mexext('all')`

**Description** `ext = mexext` returns the file-name extension for the current platform.

`extlist = mexext('all')` returns the extensions for all platforms.

## Output Arguments

### **ext - File-name extension**

`mexa64` | `mexmaci64` | `mexw32` | `mexw64`

File-name extension for MEX-file, returned as one of these values.

Platform	Binary MEX-File Extension
Linux (64-bit)	<code>mexa64</code>
Apple Mac (64-bit)	<code>mexmaci64</code>
Microsoft Windows (32-bit)	<code>mexw32</code>
Windows (64-bit)	<code>mexw64</code>

### **extlist - All file-name extensions**

structure

All file-name extensions, returned as a structure with these fields:

#### **arch - Platform**

string

Platform, specified as a string. The name of the platform is the output of the `computer('arch')` command.

#### **ext - File extension**

string

File extension, specified as a string.

## Examples

### Display File Extension for Your Computer

Find the MEX-file extension for the system you are currently working on.

```
ext = mexext
```

```
ext =  
    mexw32
```

Your results reflect your system.

### Find File Extension for Specific Platform

Find the MEX-file extension for the Apple Macintosh systems.

Get the list for supported platforms.

```
extlist = mexext('all');
```

The mex function identifies a platform by its arch value, which is the output of the computer('arch') command. For Macintosh platforms, the value is maci64.

Search the arch field in the results, extlist, for 'maci64', and display the corresponding ext field.

```
for k=1:length(extlist)  
    if strcmp(extlist(k).arch, 'maci64')  
        disp(sprintf('Arch: %s      Ext: %s', ...  
                    extlist(k).arch, extlist(k).ext))  
    end, end
```

```
Arch: maci64      Ext: mexmaci64
```

The file extension is mexmaci64.

**Tips**

- To use the MEX-file-name extension in makefiles or scripts outside MATLAB, type one of the following from the system command prompt. The script is located in the *matlabroot*\bin folder.
  - `mexext.bat` — Windows platform.
  - `mexext.sh` — UNIX platform.

For example, the following commands are in a GNU® makefile.

```
ext = $(shell mexext)
yprime.$(ext) : yprime.c
    mex yprime.c
```

**See Also**

`mex` | `computer`

# mfilename

---

**Purpose** File name of currently running function

**Syntax**

```
mfilename  
p = mfilename('fullpath')  
c = mfilename('class')
```

**Description** mfilename returns a string containing the file name of the most recently invoked function. When called from within the file, it returns the name of that file. This allows a function to determine its name, even if the file name has been changed.

p = mfilename('fullpath') returns the full path and name of the file in which the call occurs, not including the filename extension.

c = mfilename('class') in a method, returns the class of the method, not including the leading @ sign. If called from a nonmethod, it yields the empty string.

**Tips** If mfilename is called with any argument other than the above two, it behaves as if it were called with no argument.

When called from the command line, mfilename returns an empty string.

To get the names of the callers of a MATLAB function file, use dbstack with an output argument.

**See Also** dbstack | function | nargin | nargout | inputname

<b>Purpose</b>	Download files from FTP server
<b>Syntax</b>	<code>mget(ftpobj, contents)</code> <code>mget(ftpobj, contents, target)</code>
<b>Description</b>	<p><code>mget(ftpobj, contents)</code> retrieves the file or folder specified by <code>contents</code> from an FTP server into the MATLAB current folder.</p> <p><code>mget(ftpobj, contents, target)</code> retrieves the file or folder into the local folder specified by <code>target</code>, which includes an absolute or relative path.</p>
<b>Input Arguments</b>	<p><b>ftpobj</b> FTP object created by <code>ftp</code>.</p> <p><b>contents</b> String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (*).</p> <p><b>target</b> String enclosed in single quotation marks that specifies the absolute or relative path of the local folder to contain the downloaded contents.</p>
<b>Examples</b>	<p>Connect to an FTP server and retrieve the file README into the current MATLAB folder:</p> <pre>mw = ftp('ftp.mathworks.com'); mget(mw, 'README'); close(mw);</pre>
<b>See Also</b>	<code>cd</code>   <code>ftp</code>   <code>mput</code>

# min

---

**Purpose**            Smallest elements in array

**Syntax**            `C = min(A)`  
`C = min(A, [], dim)`  
`[C,I] = min(...)`

`C = min(A,B)`

**Description**      `C = min(A)` returns the smallest elements along different dimensions of an array.

If `A` is a vector, `min(A)` returns the smallest element in `A`.

If `A` is a matrix, `min(A)` treats the columns of `A` as vectors, returning a row vector containing the minimum element from each column.

If `A` is a multidimensional array, `min` operates along the first nonsingleton dimension.

`C = min(A, [], dim)` returns the smallest elements along the dimension of `A` specified by scalar `dim`. For example, `min(A, [], 1)` produces the minimum values along the first dimension of `A`.

`[C,I] = min(...)` finds the indices of the minimum values of `A`, and returns them in output vector `I`. If there are several identical minimum values, the index of the first one found is returned.

`C = min(A,B)` returns an array the same size as `A` and `B` with the smallest elements taken from `A` or `B`. The dimensions of `A` and `B` must match, or they may be scalar.

**Examples**            Return the minimum of a 2-by-3 matrix from each column:

```
X = [2 8 4; 7 3 9];  
min(X, [], 1)  
ans =
```

```
2 3 4
```

Return the minimum from each row:

```
min(X,[],2)  
ans =
```

```
2  
3
```

Compare each element of X to a scalar:

```
min(X,5)  
ans =
```

```
2 5 4  
5 3 5
```

## Tips

For complex input A, `min` returns the complex number with the smallest complex modulus (magnitude), computed with `min(abs(A))`. Then computes the smallest phase angle with `min(angle(x))`, if necessary.

The `min` function ignores NaNs.

# MinimizeCommandWindow

---

**Purpose** Minimize size of Automation server window

**Syntax** **MATLAB Client**  
h.MinimizeCommandWindow  
MinimizeCommandWindow(h)

**IDL Method Signature**

HRESULT MinimizeCommandWindow(void)

**Microsoft Visual Basic Client**

MinimizeCommandWindow

**Description** h.MinimizeCommandWindow minimizes the window for the server attached to handle h, and makes it inactive.

MinimizeCommandWindow(h) is an alternate syntax.

If the server window was already in a minimized state, MinimizeCommandWindow does nothing.

**Examples** From a MATLAB client, modify the size of the command window in a MATLAB Automation server:

```
h = actxserver('matlab.application');  
h.MinimizeCommandWindow;  
% Now return the server window to its former state on  
% the desktop and make it the currently active window.  
h.MaximizeCommandWindow;
```

---

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server:

```
Dim Matlab As Object  
  
Matlab = CreateObject("matlab.application")  
Matlab.MinimizeCommandWindow
```

'Now return the server window to its former state on  
'the desktop and make it the currently active window.

Matlab.MaximizeCommandWindow

## How To

- “MATLAB COM Automation Server Interface”
- “Controlling the Server Window”

# minres

---

## Purpose

Minimum residual method

## Syntax

```
x = minres(A,b)
minres(A,b,tol)
minres(A,b,tol,maxit)
minres(A,b,tol,maxit,M)
minres(A,b,tol,maxit,M1,M2)
minres(A,b,tol,maxit,M1,M2,x0)
[x,flag] = minres(A,b,...)
[x,flag,relres] = minres(A,b,...)
[x,flag,relres,iter] = minres(A,b,...)
[x,flag,relres,iter,resvec] = minres(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)
```

## Description

`x = minres(A,b)` attempts to find a minimum norm residual solution  $x$  to the system of linear equations  $A*x=b$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `minres` converges, a message to that effect is displayed. If `minres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual norm  $\|b-A*x\|/\|b\|$  and the iteration number at which the method stopped or failed.

`minres(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `minres` uses the default,  $1e-6$ .

`minres(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `minres` uses the default,  $\min(n,20)$ .

`minres(A,b,tol,maxit,M)` and `minres(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(\text{sqrt}(M))*A*\text{inv}(\text{sqrt}(M))*y =$

$\text{inv}(\text{sqrt}(M)) * b$  for  $y$  and then return  $x = \text{inv}(\text{sqrt}(M)) * y$ . If  $M$  is  $[]$  then `minres` applies no preconditioner.  $M$  can be a function handle `mfun`, such that `mfun(x)` returns  $M \backslash x$ .

`minres(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is  $[]$ , then `minres` uses the default, an all-zero vector.

`[x,flag] = minres(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	minres converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	minres iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	minres stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>minres</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = minres(A,b,...)` also returns the relative residual  $\text{norm}(b - A * x) / \text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = minres(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = minres(A,b,...)` also returns a vector of estimates of the `minres` residual norms at each iteration, including  $\text{norm}(b - A * x_0)$ .

`[x,flag,relres,iter,resvec,resvecg] = minres(A,b,...)` also returns a vector of estimates of the Conjugate Gradients residual norms at each iteration.

## Examples

### Using minres with a Matrix Input

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M1 = spdiags(4*on,0,n,n);

x = minres(A,b,tol,maxit,M1);
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

### Using minres with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_minres` that

- Calls `minres` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_minres` are available to `afun`.

The following shows the code for `run_minres`:

```
function x1 = run_minres
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M = spdiags(4*on,0,n,n);
x1 = minres(@afun,b,tol,maxit,M);

function y = afun(x)
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
y(1:n-1) = y(1:n-1) - 2 * x(2:n);
```

```

        end
    end

```

When you enter

```
x1=run_minres;
```

MATLAB software displays the message

```

minres converged at iteration 49 to a solution with relative
residual 4.7e-014

```

### Using minres instead of pcg

Use a symmetric indefinite matrix that fails with pcg.

```

A = diag([20:-1:1, -1:-1:-20]);
b = sum(A,2);           % The true solution is the vector of all ones.
x = pcg(A,b);          % Errors out at the first iteration.

```

displays the following message:

```

pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1

```

However, minres can handle the indefinite matrix A.

```

x = minres(A,b,1e-6,40);
minres converged at iteration 39 to a solution with relative
residual 1.3e-007

```

<b>Examples</b>	<p><b>Subtract Scalar from Array</b></p> <p>Create an array, A, and subtract a scalar value from it.</p>

## minus, -

---

```
A = [2 1; 3 5];  
C = A - 2
```

```
C =
```

```
    0    -1  
    1     3
```

The scalar is subtracted from each entry of A.

### Subtract Two Arrays

Create two arrays, A and B, and subtract the second, B, from the first, A.

```
A = [1 0; 2 4];  
B = [5 9; 2 1];  
C = A - B
```

```
C =
```

```
   -4   -9  
    0    3
```

The elements of B are subtracted from the corresponding elements of A.

Use the syntax `-C` to negate the elements of C.

```
-C
```

```
ans =
```

```
    4     9  
    0   -3
```

### See Also

`plusdiff` | `uminus`

**Purpose** Determine if function is locked in memory

**Syntax** `mislocked`  
`mislocked(fun)`

**Description** `mislocked` by itself returns logical 1 (`true`) if the currently running function is locked in memory, and logical 0 (`false`) otherwise. Functions that are locked cannot be removed with the `clear` function unless you first unlock them using the `munlock` function. You can use locking on functions that reside in MATLAB `.m` files or `.mex` files.

`mislocked(fun)` returns logical 1 (`true`) if the function named *fun* is locked in memory, and logical 0 (`false`) otherwise.

**See Also** `mlock` | `munlock` | `inmem`

# mkdir

---

**Purpose**            Make new folder

**Alternatives**    As an alternative to `mkdir`, use the Current Folder browser.

**Syntax**

```
mkdir('folderName')  
mkdir('parentFolder','folderName')  
status = mkdir(...)  
[status,message,messageid] = mkdir(...)
```

**Description**

`mkdir('folderName')` creates the folder `folderName`, where `folderName` can be an absolute or a relative path.

`mkdir('parentFolder','folderName')` creates the folder `folderName` in `parentFolder`, where `parentFolder` is an absolute or relative path. If `parentFolder` does not exist, MATLAB attempts to create it. See the Tips section.

`status = mkdir(...)` creates the specified folder. When the operation is successful, it returns a `status` of logical 1. When the operation is unsuccessful, it returns logical 0.

`[status,message,messageid] = mkdir(...)` creates the specified folder, and returns the `status`, message string, and MATLAB message ID. The value given to `status` is logical 1 for success, and logical 0 for error.

**Tips**

If an argument specifies a path that includes one or more nonexistent folders, MATLAB attempts to create the nonexistent folder. For example, for

```
mkdir('myFolder\folder1\folder2\targetFolder')
```

if `folder1` does not exist, MATLAB creates `folder1`, creates `folder2` within `folder1`, and creates `targetFolder` within `folder2`.

## **Examples**            **Creating a Subfolder in the Current Folder**

Create a subfolder called `newdir` in the current folder:

```
mkdir('newdir')
```

### **Creating a Subfolder in the Specified Parent Folder**

Create a subfolder called newFolder in the folder testdata, using a relative path, where newFolder is at the same level as the current folder:

```
mkdir('../testdata','newFolder')
```

### **Returning Status When Creating a Folder**

In this example, the first attempt to create newFolder succeeds, returning a status of 1, and no error or warning message or message identifier:

```
[s, mess, messid] = mkdir('../testdata', 'newFolder')
s =
    1
mess =
    ''
messid =
    ''
```

Attempt to create the same folder again. mkdir again returns a success status, and also a warning and message identifier informing you that the folder exists:

```
[s,mess,messid] = mkdir('../testdata','newFolder')
s =
    1
mess =
    Directory "newFolder" already exists.
messid =
    MATLAB:MKDIR:DirectoryExists
```

### **See Also**

### **How To**

- “Working with Files and Folders”

# FTP.mkdir

---

**Purpose** Create folder on FTP server

**Syntax** `mkdir(ftpobj, folder)`

**Description** `mkdir(ftpobj, folder)` creates the specified folder on the FTP server associated with `ftpobj`.

**Input Arguments**

**ftpobj**  
FTP object created by `ftp`.

**folder**  
String enclosed in single quotation marks that specifies a path relative to the current folder on the FTP server.

**Examples** Suppose that a hypothetical host, `ftp.testsite.com`, contains a folder named `testfolder`. Connect to the server and add a subfolder:

```
test=ftp('ftp.testsite.com');
mkdir(test, 'testfolder/newfolder');
close(test);
```

**See Also** `dir` | `ftp` | `rmdir`

**Purpose** Make piecewise polynomial

**Syntax**  
`pp = mkpp(breaks,coefs)`  
`pp = mkpp(breaks,coefs,d)`

**Description** `pp = mkpp(breaks,coefs)` builds a piecewise polynomial `pp` from its `breaks` and coefficients. `breaks` is a vector of length `L+1` with strictly increasing elements which represent the start and end of each of `L` intervals. `coefs` is an `L-by-k` matrix with each row `coefs(i,:)` containing the coefficients of the terms, from highest to lowest exponent, of the order `k` polynomial on the interval `[breaks(i),breaks(i+1)]`.

`pp = mkpp(breaks,coefs,d)` indicates that the piecewise polynomial `pp` is `d`-vector valued, i.e., the value of each of its coefficients is a vector of length `d`. `breaks` is an increasing vector of length `L+1`. `coefs` is a `d-by-L-by-k` array with `coefs(r,i,:)` containing the `k` coefficients of the `i`th polynomial piece of the `r`th component of the piecewise polynomial.

Use `ppval` to evaluate the piecewise polynomial at specific points. Use `unmkpp` to extract details of the piecewise polynomial.

**Note.** The *order* of a polynomial tells you the number of coefficients used in its description. A *k*th order polynomial has the form

$$c_1x^{k-1} + c_2x^{k-2} + \dots + c_{k-1}x + c_k$$

It has *k* coefficients, some of which can be 0, and maximum exponent *k* - 1. So the order of a polynomial is usually one greater than its degree. For example, a cubic polynomial is of order 4.

**Examples** The first plot shows the quadratic polynomial

$$1 - \left(\frac{x}{2} - 1\right)^2 = \frac{-x^2}{4} + x$$

shifted to the interval `[-8,-4]`. The second plot shows its negative

$$\left(\frac{x}{2}-1\right)^2-1=\frac{x^2}{4}-x$$

but shifted to the interval [-4,0].

The last plot shows a piecewise polynomial constructed by alternating these two quadratic pieces over four intervals. It also shows its first derivative, which was constructed after breaking the piecewise polynomial apart using unmkpp.

```
subplot(2,2,1)
cc = [-1/4 1 0];
pp1 = mkpp([-8 -4],cc);
xx1 = -8:0.1:-4;
plot(xx1,ppval(pp1,xx1),'k-')

subplot(2,2,2)
pp2 = mkpp([-4 0],-cc);
xx2 = -4:0.1:0;
plot(xx2,ppval(pp2,xx2),'k-')

subplot(2,1,2)
pp = mkpp([-8 -4 0 4 8],[cc;-cc;cc;-cc]);
xx = -8:0.1:8;
plot(xx,ppval(pp,xx),'k-')
[breaks,coefs,l,k,d] = unmkpp(pp);
dpp = mkpp(breaks,repmat(k-1:-1:1,d*1,1).*coefs(:,1:k-1),d);
hold on, plot(xx,ppval(dpp,xx),'r-'), hold off
```

**See Also**`ppval` | `spline` | `unmkpp`

# mldivide, \

---

**Purpose** Solve systems of linear equations  $Ax = B$  for  $x$

**Syntax**  
 $x = A \setminus B$   
 $x = \text{mldivide}(A,B)$

**Description**  $x = A \setminus B$  solves the system of linear equations  $A * x = B$ . The matrices  $A$  and  $B$  must have the same number of rows. MATLAB displays a warning message if  $A$  is badly scaled or nearly singular, but performs the calculation regardless.

- If  $A$  is a scalar, then  $A \setminus B$  is equivalent to  $A . \setminus B$ .
- If  $A$  is a square  $n$ -by- $n$  matrix and  $B$  is a matrix with  $n$  rows, then  $x = A \setminus B$  is a solution to the equation  $A * x = B$ , if it exists.
- If  $A$  is a rectangular  $m$ -by- $n$  matrix with  $m \sim n$ , and  $B$  is a matrix with  $m$  rows, then  $A \setminus B$  returns a least-squares solution to the system of equations  $A * x = B$ .

$x = \text{mldivide}(A,B)$  is an alternative way to execute  $x = A \setminus B$ , but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Coefficient matrix**  
vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If  $A$  has  $m$  rows, then  $B$  must have  $m$  rows.

**Data Types**  
single | double  
**Complex Number Support:** Yes

**B - Right-hand side**  
vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If  $B$  has  $m$  rows, then  $A$  must have  $m$  rows.

**Data Types**

single | double

**Complex Number Support:** Yes**Output Arguments****x - Solution**

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If A is an m-by-n matrix and B is an m-by-p matrix, then x is an n-by-p matrix, including the case when p==1.

x is sparse only if both A and B are sparse matrices.

**Examples****System of Equations**

Solve a simple system of linear equations,  $A*x = B$ .

```
A = magic(3);  
B = [15; 15; 15];  
x = A\B
```

```
x =
```

```
    1.0000  
    1.0000  
    1.0000
```

**Linear System with Singular Matrix**

Solve a linear system of equations  $A*x = b$  involving a singular matrix, A.

```
A = magic(4);  
b = [34; 34; 34; 34];  
x = A\b
```

```
Warning: Matrix is close to singular or badly scaled. Results may be  
1.306145e-17.
```

# mldivide, \

---

```
x =  
  
    1.5000  
    2.5000  
   -0.5000  
    0.5000
```

When `rcond` is between 0 and `eps`, MATLAB issues a nearly singular warning, but proceeds with the calculation. When working with ill-conditioned matrices, an unreliable solution can result even though the residual ( $\mathbf{b}-\mathbf{A}^*\mathbf{x}$ ) is relatively small. In this particular example, the norm of the residual is zero, and an exact solution is obtained, although `rcond` is small.

When `rcond` is equal to 0, the singular warning appears.

```
A = [1 0; 0 0];  
b = [1; 1];  
x = A\b
```

```
Warning: Matrix is singular to working precision.
```

```
x =  
  
    1  
   Inf
```

In this case, division by zero leads to computations with `Inf` and/or `NaN`, making the computed result unreliable.

## Least-Squares Solution of Underdetermined System

Solve a system of linear equations,  $\mathbf{A}^*\mathbf{x} = \mathbf{b}$ .

```
A = [1 2 0; 0 4 3];  
b = [8; 18];  
x = A\b
```

```
ans =
```

```

0
4.0000
0.6667

```

### Linear System with Sparse Matrix

Solve a simple system of linear equations using sparse matrices.

Consider the matrix equation  $A*x = B$ .

```

A = sparse([0 2 0 1 0; 4 -1 -1 0 0; 0 0 0 3 -6; -2 0 0 0 2; 0 0 4 2 0]);
B = sparse([8; -1; -18; 8; 20]);
x = A\B

```

x =

```

(1,1)    1.0000
(2,1)    2.0000
(3,1)    3.0000
(4,1)    4.0000
(5,1)    5.0000

```

### Tips

- If A is a square matrix,  $A\backslash B$  is roughly equal to  $\text{inv}(A)*B$ , but MATLAB processes  $A\backslash B$  differently and more robustly.
- If the rank of A is less than the number of columns in A, then  $x = A\backslash B$  is not necessarily the minimum norm solution. The more computationally expensive  $x = \text{pinv}(A)*B$  computes the minimum norm least-squares solution.
- For full singular inputs, you can compute the least-squares solution using the function `linsolve`.

### See Also

`mrdivide` | `ldivide` | `rdivide` | `inv` | `pinv` | `chol` | `lu` | `qr` | `linsolve` | `ldl`

### Concepts

- “Systems of Linear Equations”
- “Implementing Operators for Your Class”

# mrdivide, /

---

**Purpose** Solve systems of linear equations  $xA = B$  for  $x$

**Syntax**  
 $x = B/A$   
 $x = \text{mrdivide}(B,A)$

**Description**  $x = B/A$  solves the system of linear equations  $x*A = B$  for  $x$ . The matrices **A** and **B** must contain the same number of columns. MATLAB displays a warning message if **A** is badly scaled or nearly singular, but performs the calculation regardless.

- If **A** is a scalar, then  $B/A$  is equivalent to  $B ./ A$ .
- If **A** is a square  $n$ -by- $n$  matrix and **B** is a matrix with  $n$  columns, then  $x = B/A$  is a solution to the equation  $x*A = B$ , if it exists.
- If **A** is a rectangular  $m$ -by- $n$  matrix with  $m \sim n$ , and **B** is a matrix with  $n$  columns, then  $x = B/A$  returns a least-squares solution of the system of equations  $x*A = B$ .

$x = \text{mrdivide}(B,A)$  is an alternative way to execute  $x = B/A$ , but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Coefficient matrix**  
vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If **A** has  $n$  columns, then **B** must have  $n$  columns.

**Data Types**  
single | double  
**Complex Number Support:** Yes

**B - Right-hand side**  
vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If **B** has  $n$  columns, then **A** must have  $n$  columns.

**Data Types**

single | double

**Complex Number Support:** Yes**Output Arguments****x - Solution**

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If A is an m-by-n matrix and B is a p-by-n matrix, then x is a p-by-m matrix.

x is sparse only if both A and B are sparse matrices.

**Examples****System of Equations**

Solve a system of equations that has a unique solution,  $x*A = B$ .

```
A = [1 1 3; 2 0 4; -1 6 -1];
```

```
B = [2 19 8];
```

```
x = B/A
```

```
x =
```

```
    1.0000    2.0000    3.0000
```

**Least-Squares on an Underdetermined System**

Solve an underdetermined system,  $x*C = D$ .

```
C = [1 0; 2 0; 1 0];
```

```
D = [1 2];
```

```
x = D/C
```

```
Warning: Rank deficient, rank = 1, tol = 6.280370e-16.
```

```
x =
```

```
    0    0.5000    0
```

MATLAB issues a warning but proceeds with calculation.

# mrdivide, /

---

Verify that  $x$  is not an exact solution.

```
x*C-D
```

```
ans =
```

```
0    -2
```

## Tips

- The operators `/` and `\` are related to each other by the equation  $B/A = (A' \setminus B)'$ .
- If  $A$  is a square matrix,  $B/A$  is roughly equal to  $B \cdot \text{inv}(A)$ , but MATLAB processes  $B/A$  differently and more robustly.

## Concepts

- “Systems of Linear Equations”

**Purpose** Check MATLAB code files for possible problems

---

**Note** `mlint` is not recommended. Use `checkcode` instead.

---

**Alternatives** For information on using the graphical user interface to the Code Analyzer, see “Check Code for Errors and Warnings”.

**Syntax**

```
mlint('filename')
mlint('filename', '-config=settings.txt')
mlint('filename', '-config=factory')
inform=mlint('filename', '-struct')
msg=mlint('filename', '-string')
[inform, filepaths]=mlint('filename')
inform=mlint('filename', '-id')
inform=mlint('filename', '-fullpath')
inform=mlint('filename', '-notok')
mlint('filename', '-cyc')
mlint('filename', '-codegen')
mlint('filename', '-eml')
```

**Description** `mlint('filename')` displays Code Analyzer messages about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `mlint(F1,F2,F3,...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `mlint` messages is subject to some change between versions.

`mlint('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

---

**Note** If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

---

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `mlint` returns a message indicating that it cannot open or read the file you specified. In that case, `mlint` uses the factory default settings.

`mlint('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=mlint('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
<code>message</code>	Message describing the suspicious construct that code analysis caught.
<code>line</code>	Vector of file line numbers to which the message refers.
<code>column</code>	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=mlint('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each

file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **-struct** or **-string** argument and you specify an output argument, the default behavior is **-struct**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepath]=mlint('filename')` additionally returns `filepath`, the absolute paths to the file names, in the same order as you specified them.

`inform=mlint('filename','-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=mlint('filename','-fullpath')` assumes that the input file names are absolute paths, so that `mlint` does not try to locate them.

`inform=mlint('filename','-notok')` runs `mlint` for all lines in `filename`, even those lines that end with the `mlint` suppression directive, `%#ok`.

`mlint('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`mlint('filename','-codegen')` enables code generation messages for display in the Command Window.

`mlint('filename','-eml')` `-eml` is not recommended. Use `-codegen` instead.

## Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in

`matlabroot/help/techdoc/matlab_env/examples`. If you want to run the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

## Running mlint on a File with No Options

To run `mlint` on the example file, `lengthofline.m`, run

```
mlint('lengthofline')
```

MATLAB displays the M-Lint messages for `lengthofline.m` in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
                Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

## Running mlint with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=mlint('lengthofline', '-id')
```

MATLAB returns

```
inform =
```

```
19x1 struct array with fields:
```

```
    message  
     line  
   column  
     id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =
```

```
    message: 'The value assigned here to variable 'nohandle' might never be used.'  
         line: 22  
    column: [1 9]  
         id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned here to variable 'nohandle' might never be used.'.

## Displaying McCabe Complexity with mlint

To display the McCabe complexity of a MATLAB code file, run `mlint` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
mlint lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the M-Lint messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more in
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

## See Also

mlintrpt, profile

## How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

**Purpose**

Run checkcode for file or folder, reporting results in browser

**Syntax**

```
mlintrpt
mlintrpt('filename','file')
mlintrpt('dirname','dir')
mlintrpt('filename','file','settings.txt')
mlintrpt('dirname','dir','settings.txt')
```

**Description**

mlintrpt scans all files with an .m file extension in the current folder for Code Analyzer messages and reports the results in a MATLAB Web browser.

mlintrpt('filename','file') scans filename for Code Analyzer messages and reports results. You can omit 'file' in this form of the syntax because it is the default.

mlintrpt('dirname','dir') scans the specified folder. Here, dirname can be in the current folder or can be a full path.

mlintrpt('filename','file','settings.txt') applies the Code Analyzer preference settings to enable or suppress messages as indicated in the specified settings.txt file.

mlintrpt('dirname','dir','settings.txt') applies the settings indicated in the specified settings.txt file.

---

**Note** If you specify a settings.txt file, you must specify the full path to the file.

---

**Examples**

lengthofline.m is an example file with code that can be improved. It is found in *matlabroot*/matlab/help/techdoc/matlab\_env/examples.

**Run Report for All Files in a Folder**

Run

```
mlintrpt(fullfile(matlabroot,'help','techdoc','matlab_env','examples'),'dir')
```

and MATLAB displays a report of potential problems and improvements for all files with an `.m` file extension in the `examples` folder.

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages”.

## Run Report Using Code Analyzer Preference Settings

You can save preference settings to a text file by clicking the **Preferences** button in the **Environment** section on the **Home** tab and selecting **Code Analyzer** in the left pane. To save a preferences file, select **Save as** under the  drop-down list. To apply those settings when you run `mlintrpt`, use the `file` option and supply the full path to the settings file name as shown in this example:

```
mlintrpt('lengthofline.m', 'file', ...  
'C:\WINNT\Profiles\me\Application Data\MathWorks\MATLAB\R2012b\mymlint.txt')
```

Alternatively, use `fullfile` if the settings file is stored in the preferences folder:

```
mlintrpt('lengthofline.m', 'file', fullfile(prefdir,'mymlint.txt'))
```

Assuming that in that example `mymlint.txt` file, the setting for **Terminate statement with semicolon to suppress output** has been disabled, the results of `mlintrpt` for `lengthofline` do not show that message for line 49.

When `mlintrpt` cannot locate the settings file, the first message in the report is

```
0: Unable to open or read the configuration file 'mymlint.txt'--using default settings.
```

`checkcode`

## Concepts

- “Check Code for Errors and Warnings”

---

<b>Purpose</b>	Prevent clearing function from memory
<b>Syntax</b>	<code>mlock</code>
<b>Description</b>	<p><code>mlock</code> locks the currently running function in memory so that subsequent <code>clear</code> functions do not remove it. Locking a function in memory also prevents any persistent variables defined in the file from getting reinitialized.</p> <p>Use the <code>munlock</code> function to return the file to its normal, clearable state.</p>
<b>Examples</b>	<p>The function <code>testfun</code> begins with an <code>mlock</code> statement.</p> <pre>function testfun mlock   .   .</pre> <p>When you execute this function, it becomes locked in memory. You can check this using the <code>mislocked</code> function.</p> <pre>testfun  mislocked('testfun') ans =      1</pre> <p>Using <code>munlock</code>, you unlock the <code>testfun</code> function in memory. Checking its status with <code>mislocked</code> shows that it is indeed unlocked at this point.</p> <pre>munlock('testfun')  mislocked('testfun') ans =      0</pre>
<b>See Also</b>	<code>mislocked</code>   <code>munlock</code>   <code>inmem</code>   <code>persistent</code>

# mmfileinfo

---

**Purpose** Information about multimedia file

**Syntax** `info = mmfileinfo(filename)`

**Description** `info = mmfileinfo(filename)` returns a structure, `info`, with fields containing information about the contents of the multimedia file identified by `filename`. The `filename` input is a string enclosed in single quotation marks.

If `filename` is a URL, `mmfileinfo` might take a long time to return because it must first download the file. For large files, downloading can take several minutes. To avoid blocking the MATLAB command line while this processing takes place, download the file before calling `mmfileinfo`.

The `info` structure contains the following fields, listed in the order they appear in the structure.

Field	Description
Filename	String indicating the name of the file.
Path	String indicating the absolute path to the file.
Duration	Length of the file in seconds.
Audio	Structure containing information about the audio data in the file. See “Audio Data” on page 1-3915 for more information about this data structure.
Video	Structure containing information about the video data in the file. See “Video Data” on page 1-3915 for more information about this data structure.

### Audio Data

The Audio structure contains the following fields, listed in the order they appear in the structure. If the file does not contain audio data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the audio format.
NumberOfChannels	Number of audio channels.

### Video Data

The Video structure contains the following fields, listed in the order they appear in the structure. If the file does not contain video data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the video format.
Height	Height of the video frame.
Width	Width of the video frame.

## Examples

Display information about the example file `xylophone.mpg`:

```
info = mmfileinfo('xylophone.mpg')
audio = info.Audio
video = info.Video
```

MATLAB returns:

```
info =
  Filename: 'xylophone.mpg'
    Path: [1x75 char]
  Duration: 4.7020
    Audio: [1x1 struct]
    Video: [1x1 struct]
```

# mmfileinfo

---

```
audio =  
    Format: 'MPEG'  
    NumberOfChannels: 2  
  
video =  
    Format: 'MPEG1'  
    Height: 240  
    Width: 320
```

where Path is system-dependent.

## See Also

[get](#) | [VideoReader](#)

**Purpose** Create object for reading video files

---

**Note** mmreader will be removed in a future release. Use VideoReader instead. The mmreader class has been renamed VideoReader.

---

**Description** Use mmreader with the read method to read video data from a multimedia file into the MATLAB workspace.

The file formats that mmreader supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	Motion JPEG 2000 (.mj2)
Windows	AVI (.avi), MPEG-1 (.mpg), Windows Media Video (.wmv, .asf, .asx), and any format supported by Microsoft DirectShow.
Macintosh	AVI (.avi), MPEG-1 (.mpg), MPEG-4 (.mp4, .m4v), Apple QuickTime Movie (.mov), and any format supported by QuickTime as listed on <a href="http://support.apple.com/kb/HT3775">http://support.apple.com/kb/HT3775</a> .
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on <a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> , including AVI (.avi) and Ogg Theora (.ogg).

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

**Construction** `obj = mmreader(filename)` constructs `obj` to read video data from the file named `filename`. The mmreader constructor searches for the file on the MATLAB path. If it cannot construct the object for any reason, mmreader generates an error.

`obj = mmreader(filename, 'PropertyName', PropertyValue)`  
constructs the object using options, specified as property name/value pairs. Property name/value pairs can be in any format that the `set` method supports: name/value string pairs, structures, or name/value cell array pairs.

## Properties

### **BitsPerPixel**

Bits per pixel of the video data. (Read-only)

### **Duration**

Total length of the file in seconds. (Read-only)

### **FrameRate**

Frame rate of the video in frames per second. (Read-only)

### **Height**

Height of the video frame in pixels. (Read-only)

### **Name**

Name of the file associated with the object. (Read-only)

### **NumberOfFrames**

Total number of frames in the video stream. (Read-only)

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `mmreader` cannot determine the number of frames until you read the last frame. When you construct the object, `mmreader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = mmreader('varFrameRateFile.wmv');  
lastFrame = read(vidObj, inf);  
numFrames = vidObj.NumberOfFrames;
```

For more information, see “Read Variable Frame Rate Video” in the MATLAB Data Import and Export documentation.

**Path**

String containing the full path to the file associated with the reader. (Read-only)

**Tag**

User-defined string to identify the object.

**Default:** ''

**Type**

Class name of the object: 'mmreader'. (Read-only)

**UserData**

Generic field for user-defined data.

**Default:** []

**VideoFormat**

String indicating the MATLAB representation of the video format, such as 'RGB24'. (Read-only)

**Width**

Width of the video frame in pixels. (Read-only)

**Methods**

For backward compatibility, mmreader supports the following VideoReader methods:

get	Query property values for video reader object
getFileFormats	File formats that VideoReader supports

# mmreader

---

read	Read video frame data from file
set	Set property values for video reader object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## Examples

Construct an `mmreader` object for the example movie file `xylophone.mpg` and view its properties:

```
xyloObj = mmreader('xylophone.mpg', 'Tag', 'My reader object');  
get(xyloObj)
```

---

Read and play back the movie file `xylophone.mpg`:

```
xyloObj = mmreader('xylophone.mpg');  
  
nFrames = xyloObj.NumberOfFrames;  
vidHeight = xyloObj.Height;  
vidWidth = xyloObj.Width;  
  
% Preallocate movie structure.  
mov(1:nFrames) = ...  
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...  
          'colormap', []);  
  
% Read one frame at a time.  
for k = 1 : nFrames  
    mov(k).cdata = read(xyloObj, k);  
end  
  
% Size a figure based on the video's width and height.  
hf = figure;  
set(hf, 'position', [150 150 vidWidth vidHeight])
```

```
% Play back the movie once at the video's frame rate.  
movie(hf, mov, 1, xyloObj.FrameRate);
```

## How To

- “Read Video Files”

# mod

---

**Purpose** Modulus after division

**Syntax** `M = mod(X,Y)`

**Description** `M = mod(X,Y)` returns the modulus after division of `X` by `Y`. In general, if `Y` does not equal 0, `M = mod(X,Y)` returns `X - n.*Y`, where `n = floor(X./Y)`. If `Y` is not an integer and the quotient `X./Y` is within roundoff error of an integer, then `n` is that integer. Inputs `X` and `Y` must have the same dimensions unless one is a scalar double. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar double.

The following are true by convention:

- `mod(X,0)` is `X`.
- `mod(X,X)` is 0.
- `mod(X,Y)` for `X~=Y` and `Y~=0` has the same sign as `Y`.

## Input Arguments

### **X - Dividend**

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

### **Y - Divisor**

scalar | vector | matrix | multidimensional array

Divisor, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

**Examples****Modulus of Two Scalars**

Compute 23 modulo 5.

```
X = 23;
Y = 5;
M = mod(X,Y)
```

M =

3

**Modulus of a Vector**

Create a vector, then use `mod` to find the modulus after dividing a scalar into each element of the vector.

```
X = 1:5;
Y = 3;
M = mod(X,Y)
```

M =

1 2 0 1 2

When you specify one or more of the inputs as an array, the `mod` function acts on each array element independently.

**Modulus of Two Arrays**

Create two 3-by-3 matrices, then use `mod` to find the modulus after dividing Y into X.

```
X = [1 2 3;4 5 6;7 8 9];
Y = [9 8 7;6 5 4;3 2 1];
M = mod(X,Y)
```

M =

1 2 3

# mod

---

```
4    0    2
1    0    0
```

Inputs  $X$  and  $Y$  must have the same dimensions unless one is a scalar double.

## Forced Rounding in mod

If  $Y$  is not an integer and  $X./Y$  is within roundoff error of an integer, then `mod` rounds to that integer for its calculation. The size of the roundoff error is very small.

```
X = 2;
Y = 2 - eps(2)
```

```
Y =
```

```
2.0000
```

It looks like  $Y$  is trivially equal to 2, but in fact there is an infinitesimal difference.

```
2 - Y
```

```
ans =
```

```
4.4409e-16
```

This difference is forced to zero by `mod` if it is small enough.

```
M = mod(X,Y)
```

```
M =
```

```
0
```

Make the difference a little larger and the forced rounding disappears.

```
Y = 2 - eps(4);
```

```
M = mod(X,Y)
```

```
M =
```

```
8.8818e-16
```

### Difference Between mod and rem

Define X and Y with different signs.

```
X = 5;
```

```
Y = -2;
```

Compute the modulus after division with `mod`, then compute the remainder after division with `rem`.

```
M = mod(X,Y)
```

```
M =
```

```
-1
```

```
R = rem(X,Y)
```

```
R =
```

```
1
```

`mod(X,Y)` and `rem(X,Y)` are equal if X and Y have the same sign, but differ by Y if X and Y have different signs. Notice that `mod` retains the sign of Y, while `rem` retains the sign of X.

### Tips

- The `mod` function is useful for congruence relationships: *x* and *y* are congruent (mod *m*) if and only if `mod(x,m) == mod(y,m)`. For example, 23 and 13 are congruent (mod 5).

### See Also

`rem`

# mode

---

**Purpose** Most frequent values in array

**Syntax**  
`M = mode(X)`  
`M = mode(X, dim)`

`[M, F] = mode( ___ )`  
`[M, F, C] = mode( ___ )`

**Description** `M = mode(X)` returns the sample mode of `X`, which is the most frequently occurring value in `X`. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, the smallest value is the first value in a sorted list.

- If `X` is a vector, then `mode(X)` returns the most frequent value of `X`.
- If `X` is a nonempty matrix, then `mode(X)` returns a row vector containing the mode of each column of `X`.
- If `X` is an empty 0-by-0 matrix, `mode(X)` returns NaN.
- If `X` is a multidimensional array, then `mode(X)` acts along the first nonsingleton dimension and returns an array of most frequent values. The size of this dimension reduces to 1 while the sizes of all other dimensions remain the same.

`M = mode(X, dim)` returns the mode of elements along dimension `dim`. For example, if `X` is a matrix, then `mode(X, 2)` is a column vector containing the most frequent value of each row

`[M, F] = mode( ___ )` also returns a frequency array `F`, using any of the input arguments in the previous syntaxes. `F` is the same size as `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

`[M, F, C] = mode( ___ )` also returns a cell array `C` of the same size as `M` and `F`. Each element of `C` is a sorted vector of all values that have the same frequency as the corresponding element of `M`.

## Input Arguments

### X - Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

NaN values in the input array, X, are ignored.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(M,dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, X.

- If `dim = 1`, then `mode(X,1)` returns a row vector containing the most frequent value in each column.
- If `dim = 2`, then `mode(X,2)` returns a column vector containing the most frequent value in each row.

`mode` returns X if `dim` is greater than `ndims(X)`.

# mode

---

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## Output Arguments

### M - Most frequent values

scalar | vector | matrix | multidimensional array

Most frequent values returned as a scalar, vector, matrix, or multidimensional array. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, this is taken to be the first value in a sorted list of values.

The class of `M` is the same as the class of the input array, `X`.

### F - Frequency array

scalar | vector | matrix | multidimensional array

Frequency array returned as a scalar, vector, matrix, or multidimensional array. The size of `F` is the same as the size of `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

The class of `F` is always `double`.

### C - Most frequent values with multiplicity

cell array

Most frequent values with multiplicity returned as a cell array. The size of `C` is the same as the size of `M` and `F`, and each element of `C` is a sorted column vector of all values that have the same frequency as the corresponding element of `M`.

## Definitions

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If  $X$  is a 1-by- $n$  row vector, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

## Tips

- The mode function is most useful with discrete or coarsely rounded data. The mode for a continuous probability distribution is defined as the peak of its density function. Applying the mode function to a sample from that distribution is unlikely to provide a good estimate of the peak; it would be better to compute a histogram or density estimate and calculate the peak of that estimate. Also, the mode function is not suitable for finding peaks in distributions having multiple modes.

## Examples

### Mode of Matrix Columns

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

X =

```

     3     3     1     4
     0     0     1     1
     0     1     2     4
```

Find the most frequent value of each column.

```
M = mode(X)
```

M =

```

     0     0     1     4
```

## Mode of Matrix Rows

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```
     3     3     1     4
     0     0     1     1
     0     1     2     4
```

Find the most frequent value of each row.

```
M = mode(X,2)
```

```
M =
```

```
     3
     0
     0
```

## Mode of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
X = gallery('integerdata',10,[1,3,4],1)
```

```
X(:,:,1) =
```

```
     10     8     10
```

```
X(:,:,2) =
```

```
     6     9     5
```

```
X(:,:,3) =
```

```
9 6 1
```

```
X(:,:,4) =
```

```
4 9 5
```

Find the most frequent values of this 3-D array along the second dimension.

```
M = mode(X)
```

```
M(:,:,1) =
```

```
10
```

```
M(:,:,2) =
```

```
5
```

```
M(:,:,3) =
```

```
1
```

```
M(:,:,4) =
```

```
4
```

This operation produces a 1-by-1-by-4 array by finding the most frequent value along the second dimension. The size of the second dimension reduces to 1.

Compute the mode along the first dimension of X.

# mode

---

```
M = mode(X,1);  
isequal(X,M)
```

```
ans =
```

```
1
```

This returns the same array as X because the size of the first dimension is 1.

## Mode of Matrix Columns with Frequency Information

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```
3     3     1     4  
0     0     1     1  
0     1     2     4
```

Find the most frequent value of each column, as well as how often it occurs.

```
[M,F] = mode(X)
```

```
M =
```

```
0     0     1     4
```

```
F =
```

```
2     1     2     2
```

F(1) is 2 since M(1) occurs twice in the first column.

### Mode of Matrix Rows with Frequency and Multiplicity Information

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

X =

```

     3     3     1     4
     0     0     1     1
     0     1     2     4
```

Find the most frequent value of each row, how often it occurs, and which values in that row occur with the same frequency.

```
[M,F,C] = mode(X,2)
```

M =

```

     3
     0
     0
```

F =

```

     2
     2
     1
```

C =

```

     [          3]
     [2x1 double]
     [4x1 double]
```

$C\{2\}$  is the 2-by-1 vector  $[0;1]$  since values 0 and 1 in the second row occur with frequency  $F(2)$ .

$C\{3\}$  is the 4-by-1 vector  $[0;1;2;4]$  since all values in the third row occur with frequency  $F(3)$ .

## Mode of 16-bit Unsigned Integer Array

Define a 1-by-4 vector of 16-bit unsigned integers.

```
X = gallery('integerdata',10,[1,4],3,'uint16')
```

```
X =
```

```
     6     3     2     3
```

Find the most frequent value, as well as the number of times it occurs.

```
[M,F] = mode(X),  
class(M)
```

```
M =
```

```
     3
```

```
F =
```

```
     2
```

```
ans =
```

```
uint16
```

$M$  is the same class as the input,  $X$ .

[mean](#) | [median](#) | [hist](#) | [histc](#) | [sort](#)

**Purpose**

Control paged output for Command Window

**Syntax**

```
more on
more off
more(n)
A = more(state)
```

**Description**

`more on` enables paging of the output in the MATLAB Command Window. MATLAB displays output one page at a time. Use the keys defined in the table below to control paging.

`more off` disables paging of the output in the MATLAB Command Window.

`more(n)` defines the length of a page to be *n* lines.

`A = more(state)` returns in *A* the number of lines that are currently defined to be a page. The `state` input can be one of the quoted strings 'on' or 'off', or the number of lines to set as the new page length.

By default, the length of a page is equal to the number of lines available for display in the MATLAB Command Window. Manually changing the size of the command window adjusts the page length accordingly.

If you set the page length to a specific value, MATLAB uses that value for the page size, regardless of the size of the command window. To have MATLAB return to matching page size to window size, type `more off` followed by `more on`.

To see the status of `more`, type `get(0, 'More')`. MATLAB returns either `on` or `off`, indicating the `more` status.

When you have enabled `more` and are examining output, you can do the following.

## more

---

Press the...	To...
Return key	Advance to the next line of output.
Space bar	Advance to the next page of output.
Q (for quit) key	Terminate display of the text. Do not use <b>Ctrl+C</b> to terminate <code>more</code> or you might generate error messages in the Command Window.

`more` is in the **off** state, by default.

diary

**Purpose** Move or resize control in parent window

**Syntax**  
`V = h.move(position)`  
`V = move(h, position)`

**Description** `V = h.move(position)` moves the control to the position specified by the `position` argument. When you use `move` with only the handle argument, `h`, it returns a four-element vector indicating the current position of the control.

`V = move(h, position)` is an alternate syntax.

The `position` argument is a four-element vector specifying the position and size of the control in the parent figure window. The elements of the vector are:

```
[x, y, width, height]
```

where `x` and `y` are offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control, and `width` and `height` are the size of the control itself.

**Examples** This example moves the control:

```
f = figure('Position', [100 100 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.1', [0 0 200 200], f);  
pos = h.move([50 50 200 200])  
pos =  
    50    50   200   200
```

The next example resizes the control to always be centered in the figure as you resize the figure window. Start by creating the script `resizectl.m` that contains

```
% Get the new position and size of the figure window  
fpos = get(gcbo, 'position');  
  
% Resize the control accordingly
```

## move

---

```
h.move([0 0 fpos(3) fpos(4)]);
```

Now execute the following:

```
f = figure('Position', [100 100 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.1', [0 0 200 200]);  
set(f, 'ResizeFcn', 'resizectrl');
```

As you resize the figure window, notice that the circle moves so that it is always positioned in the center of the window.

<b>Purpose</b>	Move file or folder
<b>Alternatives</b>	As an alternative to the <code>movefile</code> function, use the Current Folder browser. For more information, see “Working with Files and Folders”.
<b>Syntax</b>	<pre>movefile('source') movefile('source','destination') movefile('source','destination','f') [status,message,messageid]=movefile(...)</pre>
<b>Description</b>	<p><code>movefile('source')</code> moves the file or folder named <code>source</code> to the current folder, where <code>source</code> is the absolute or relative path name for the folder or file. To move multiple files or folders, use one or more wildcard characters (*) after the last file separator in <code>source</code>. The <code>source</code> argument permits a wildcard character in a path string. <code>movefile</code> does not preserve the archive attribute of <code>source</code>.</p> <p><code>movefile('source','destination')</code> moves the file or folder named <code>source</code> to the location <code>destination</code>, where <code>source</code> and <code>destination</code> are the absolute or relative paths for the folder or file. To move multiple files or folders, you can use one or more wildcard characters (*) after the last file separator in <code>source</code>. You cannot use a wildcard character in <code>destination</code>. To rename a file or folder when moving it, make <code>destination</code> a different name than <code>source</code>, and specify only one file for <code>source</code>. When <code>source</code> and <code>destination</code> have the same location, <code>movefile</code> renames <code>source</code> to <code>destination</code>.</p> <p><code>movefile('source','destination','f')</code> moves the file or folder named <code>source</code> to the location <code>destination</code>, regardless of the read-only attribute of <code>destination</code>.</p> <p><code>[status,message,messageid]=movefile(...)</code> moves the file or folder named <code>source</code> to the location <code>destination</code>, returning the status, a message, and the MATLAB message ID. Here, <code>status</code> is logical 1 for success or logical 0 for error. <code>movefile</code> requires only one output argument.</p>

## Examples

### Moving a File to the Current Folder

Assuming `myfiles` is a subfolder within the current folder, move the file `myfunction.m` to the current folder:

```
movefile('myfiles/myfunction.m')
```

Assuming `projects/testcases` is the current folder, move `projects/myfiles` and its contents to the current folder:

```
movefile('../myfiles')
```

### Renaming a File in the Current Folder

In the current folder, rename `myfunction.m` to `oldfunction.m`:

```
movefile('myfunction.m','oldfunction.m')
```

### Using a Wildcard to Move All Matching Files

Assuming `myfiles` is a subfolder of the current folder, move all files whose names that begin with `my` from the `myfiles` folder, to the current folder:

```
movefile('myfiles/my*')
```

### Moving a File to a Different Folder

Assuming `projects` and the current folder are at the same level, move the file `myfunction.m` from the current folder to the folder `projects`:

```
movefile('myfunction.m','../projects')
```

### Moving a Folder Down One Level

Assuming `projects` is a subfolder of the current folder, move the folder `projects/testcases` and all its contents down a level in `projects` into `projects/myfiles`:

```
movefile('projects/testcases','projects/myfiles/')
```

### Moving a File to a Read-Only Folder and Renaming the File

Move the file `myfile.m` from the current folder to `d:/work/restricted`, assigning it the name `test1.m`, where `restricted` is a read-only folder:

```
movefile('myfile.m','d:/work/restricted/test1.m','f')
```

The read-only file `myfile.m` is no longer in the current folder. The file `test1.m` is in `d:/work/restricted` and is read only.

### Returning Status When Moving Files

Move all files in the folder `myfiles` whose names start with `new` to the current folder, when there is an error. You mistype `new*` as `nex*` and no items in the current folder start with `nex*`:

```
[s,mess,messid]=movefile('myfiles/nex*')
```

```
s =  
    0
```

```
mess =
```

```
No matching files were found.
```

```
messid =
```

```
MATLAB:MOVEFILE:FileDoesNotExist
```

### How To

- “Creating, Opening, Changing, and Deleting Files and Folders”

# movegui

---

**Purpose** Move GUI figure to specified location on screen

**Syntax** `movegui(h, 'position')`  
`movegui(position)`  
`movegui(h)`  
`movegui`

**Description** `movegui(h, 'position')` moves the figure identified by handle `h` to the specified screen location, preserving the figure's size. The `position` argument is a string or a two-element vector, as defined in the following tables.

`movegui(position)` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the specified position.

`movegui(h)` moves the figure identified by the handle `h` to the onscreen position.

`movegui` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the onscreen position. You can specify 'movegui' as a `CreateFcn` callback for a figure. It ensures after you save it, the figure appears on screen when you reload it, regardless of its saved position. See the following example.

When it is a string, `position` is one of the following descriptors.

Position String	Description
north	Top center edge of screen
south	Bottom center edge of screen
east	Right center edge of screen
west	Left center edge of screen
northeast	Top right corner of screen
northwest	Top left corner of screen
southeast	Bottom right corner of screen

Position String	Description
southwest	Bottom left corner
center	Centered on screen
onscreen	Nearest location to current location that is entirely on screen

You can also specify the *position* argument as a two-element vector,  $[h, v]$ . Depending on sign,  $h$  specifies the figure's offset from the left or right edge of the screen, and  $v$  specifies the figure's offset from the top or bottom of the screen, in pixels. The following table summarizes the possible values.

$h$ (for $h \geq 0$ )	Offset of left side from left edge of screen
$h$ (for $h < 0$ )	Offset of right side from right edge of screen
$v$ (for $v \geq 0$ )	Offset of bottom edge from bottom of screen
$v$ (for $v < 0$ )	Offset of top edge from top of screen

Applying `movegui` to a maximized figure window moves the window towards the task bar and creates a gap on the opposite side of the screen about as wide as the task bar. The window might shrink in size by a few pixels. If you use the `onscreen` option with a maximized figure window, then `movegui` creates a gap on both the left and upper sides of the screen so that the top-left corner of the figure is visible.

`GUIDE` and `openfig` call `movegui` when loading figures to ensure they are visible.

## Examples

Use `movegui` to ensure that a saved GUI appears on screen you reload it, regardless of the target computer screen size and resolution. Create

a figure that is off the screen, assign `movegui` as its `CreateFcn` callback, save it, and then reload the figure.

```
f = figure('Position',[10000,10000,400,300]);
% The figure does not display because it is created offscreen
set(f,'CreateFcn','movegui')
hgsave(f,'onscreenfig')
close(f)
f2 = hgload('onscreenfig');
% The reloaded figure is now visible
```

---

<b>Purpose</b>	Play recorded movie frames
<b>Syntax</b>	<pre>movie(M) movie(M,n) movie(M,n,fps) movie(h,...) movie(h,M,n,fps,loc)</pre>
<b>Description</b>	<p>The <code>movie</code> function plays the movie defined by a matrix whose columns are movie frames (usually produced by <code>getframe</code>).</p> <p><code>movie(M)</code> plays the movie in matrix <code>M</code> once, using the current axes as the default target. If you want to play the movie in the figure instead of the axes, specify the figure handle (or <code>gcf</code>) as the first argument: <code>movie(<i>figure_handle</i>,...)</code>. <code>M</code> must be an array of movie frames (usually from <code>getframe</code>).</p> <p><code>movie(M,n)</code> plays the movie <code>n</code> times. If <code>n</code> is negative, each cycle is shown forward then backward. If <code>n</code> is a vector, the first element is the number of times to play the movie, and the remaining elements make up a list of frames to play in the movie.</p> <p>For example, if <code>M</code> has four frames then <code>n = [10 4 4 2 1]</code> plays the movie ten times, and the movie consists of frame 4 followed by frame 4 again, followed by frame 2 and finally frame 1.</p> <p><code>movie(M,n,fps)</code> plays the movie at <code>fps</code> frames per second. The default is 12 frames per second. Computers that cannot achieve the specified speed play as fast as possible.</p> <p><code>movie(h,...)</code> plays the movie centered in the figure or axes identified by the handle <code>h</code>. Specifying the figure or axes enables MATLAB to fit the movie to the available size.</p> <p><code>movie(h,M,n,fps,loc)</code> specifies <code>loc</code>, a four-element location vector, <code>[x y 0 0]</code>, where the lower left corner of the movie frame is anchored (only the first two elements in the vector are used). The location is relative to the lower left corner of the figure or axes specified by handle <code>h</code> and in units of pixels, regardless of the object's <code>Units</code> property.</p>

## Tips

The `movie` function uses a default figure size of 560-by-420 and does not resize figures to fit movies with larger or smaller frames. To accommodate other frame sizes, you can resize the figure to fit the movie, as shown in the second example below.

`movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale or 24-bit truecolor image frames.

Buffering the movie places all frames in memory. As a result, on Microsoft Windows and perhaps other platforms, a long movie (on the order of several hundred frames) can exhaust memory, depending on system resources. In such cases an error message is issued that says

```
??? Error using ==> movie
Could not create movie frame
```

You can abort a movie by typing **Ctrl-C**.

`movie` is not a built-in function. Therefore, you cannot call `movie` using the `builtin` function.

## Limitations with Renderer on Windows Systems

Setting the figure `Renderer` property to `zbuffer` or `painters` works around limitations of using `getframe` with the OpenGL renderer on some Windows systems.

## Examples

Animate the `peaks` function as you scale the values of `Z`:

```
figure('Renderer','zbuffer')
Z = peaks;
surf(Z);
axis tight
set(gca,'NextPlot','replaceChildren');
% Preallocate the struct array for the struct returned by getframe
F(20) = struct('cdata',[],'colormap',[]);
% Record the movie
for j = 1:20
    surf(.01+sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
```

```
end
```

Now play the movie ten times. The twelfth frame looks like the following plot.

```
movie(F,10)
```

With larger frames, first adjust the figure's size to fit the movie:

```
figure('Position',[100 100 850 600])
```

```
Z = peaks; surf(Z);
axis tight
set(gca,'NextPlot','replacechildren');
% Record the movie
for j = 1:20
    surf(sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
end
% use 1st frame to get dimensions
[h, w, p] = size(F(1).cdata);
hf = figure;
% resize figure based on frame's w x h, and place at (150, 150)
set(hf,'Position', [150 150 w h]);
axis off
% Place frames at bottom left
movie(hf,F,4,30,[0 0 0 0]);
```

## How To

- [Example – Visualizing an FFT as a Movie](#)

**Purpose** Create Audio/Video Interleaved (AVI) file from MATLAB movie

**Syntax** `movie2avi(mov, filename)`  
`movie2avi(mov, filename, ParameterName, ParameterValue)`

**Description** `movie2avi(mov, filename)` creates the AVI file `filename` from the MATLAB movie `mov`. The `filename` input is a string. The `mov` input is a 1-by- $n$  structure array, where  $n$  is the number of frames. Each frame is a structure with two fields: `cdata` and `colormap`. For more information, see `getframe`.

`movie2avi(mov, filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. The following table lists the available parameters and values.

Parameter Name	Value	Default
'colormap'	An $m$ -by-3 matrix defining the colormap for indexed AVI movies, where $m$ is no more than 256 (236 for Indeo compression).  Valid only when the 'compression' is 'MSVC', 'RLE', or 'None'.	No default
'compression'	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of 'None'.  On UNIX operating systems, the only valid value is 'None'.  On Windows systems, valid values include: <ul style="list-style-type: none"> <li>• 'MSVC'</li> <li>• 'RLE'</li> <li>• 'Cinepak' on 32-bit systems.</li> </ul>	'Indeo5' on Windows systems.  'None' on UNIX systems.

Parameter Name	Value	Default
	<ul style="list-style-type: none"> <li>'Indeo3' or 'Indeo5' on 32-bit Windows XP systems.</li> </ul> <p>Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.</p>	
'fps'	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
'keyframe'	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
'quality'	A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.  Valid only for compressed movies.	75
'videoname'	A descriptive name for the video stream, no more than 64 characters.	<i>filename</i>

## Tips

- On some Windows systems, including all 64-bit systems, the default Indeo 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer. Consider specifying a compression value of 'None'.

**Examples**

Create a movie and write to an uncompressed AVI file, `myPeaks.avi`:

```
nFrames = 20;

% Preallocate movie structure.
mov(1:nFrames) = struct('cdata', [],...
                       'colormap', []);

% Create movie.
Z = peaks; surf(Z);
axis tight
set(gca, 'nextplot', 'replacechildren');
for k = 1:nFrames
    surf(sin(2*pi*k/20)*Z,Z)
    mov(k) = getframe(gcf);
end

% Create AVI file.
movie2avi(mov, 'myPeaks.avi', 'compression', 'None');
```

# mpower, ^

---

**Purpose** Matrix power

**Syntax**  
 $C = A^B$   
`C = mpower(A,B)`

**Description**  $C = A^B$  computes  $A$  to the  $B$  power and returns the result in  $C$ .

`C = mpower(A,B)` is an alternate way to execute  $A^B$ , but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Base**  
scalar | matrix

Base, specified as a scalar or matrix. Inputs  $A$  and  $B$  must be one of the following:

- Base  $A$  is a square matrix and exponent  $B$  is a scalar. If  $B$  is a positive integer, the power is computed by repeated squaring. For other values of  $B$  the calculation involves eigenvalues and eigenvectors.
- Base  $A$  is a scalar and exponent  $B$  is a square matrix. The calculation uses eigenvalues and eigenvectors.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### B - Exponent

scalar | matrix

Exponent, specified as a scalar or matrix. Inputs  $A$  and  $B$  must be one of the following:

- Base  $A$  is a square matrix and exponent  $B$  is a scalar. If  $B$  is a positive integer, the power is computed by repeated squaring. For other values of  $B$  the calculation involves eigenvalues and eigenvectors.

- Base **A** is a scalar and exponent **B** is a square matrix. The calculation uses eigenvalues and eigenvectors.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**Examples**

**Square a Matrix**

Create a 2-by-2 matrix and square it.

```
A = [1 2; 3 4];
C = A^2
```

C =

```
     7     10
    15     22
```

The syntax  $A^2$  is equivalent to  $A*A$ .

**Matrix Exponents**

Create a 2-by-2 matrix and use it as the exponent for a scalar.

```
B = [0 1; 1 0];
C = 2^B
```

C =

```
    1.2500    0.7500
    0.7500    1.2500
```

Compute **C** by first finding the eigenvalues **D** and eigenvectors **V** of the matrix **B**.

```
[V,D] = eig(B)
```

# mpower, ^

---

V =

```
-0.7071    0.7071
 0.7071    0.7071
```

D =

```
-1    0
 0    1
```

Next, use the formula  $2^B = V*2^D/V$  to compute the power.

C = V\*2^D/V

C =

```
1.2500    0.7500
 0.7500    1.2500
```

## See Also

`power` | `mtimes` | `times`

<b>Purpose</b>	Upload file or folder to FTP server
<b>Syntax</b>	<code>mput(ftpobj,contents)</code> <code>paths = mput(ftpobj,contents)</code>
<b>Description</b>	<code>mput(ftpobj,contents)</code> uploads the file or folder specified by <code>contents</code> to the current folder on an FTP server.  <code>paths = mput(ftpobj,contents)</code> returns a cell array that lists the paths to the uploaded files on the server.
<b>Input Arguments</b>	<p><b>ftpobj</b> FTP object created by <code>ftp</code>.</p> <p><b>contents</b> String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (*).</p>
<b>Output Arguments</b>	<p><b>paths</b> Cell array that includes the paths to the uploaded files on the server.</p>
<b>Examples</b>	<p>Suppose that your current MATLAB folder contains files <code>myfile1.m</code> through <code>myfile10.m</code>, and that you want to upload to a hypothetical FTP server, <code>ftp.testsite.com</code>. Connect to the server and upload the files:</p> <pre>test = ftp('ftp.testsite.com'); mput(test, 'myfile*.m'); close(test);</pre>
<b>See Also</b>	<code>mget</code>   <code>ftp</code>   <code>mkdir</code>   <code>rename</code>

# msgbox

---

**Purpose** Create and open message dialog box

**Syntax**

```
h = msgbox(Message)
h = msgbox(Message,Title)
h = msgbox(Message,Title,Icon)
h = msgbox(Message,Title,'custom',IconData,IconCMap)
h = msgbox( __ ,CreateMode)
```

**Description** `h = msgbox(Message)` creates a message dialog box that automatically wraps `Message` to fit an appropriately sized figure.

`h = msgbox(Message,Title)` specifies the title of the message box.

`h = msgbox(Message,Title,Icon)` specifies which built-in icon to display in the message dialog box.

`h = msgbox(Message,Title,'custom',IconData,IconCMap)` specifies a custom icon to include in the message dialog box. `IconData` is the image data that defines the icon. `IconCMap` is the colormap used for the image. If `IconData` is a true-color image, you do not need to specify an `IconCMap`.

`h = msgbox( __ ,CreateMode)` specifies whether the message box is modal. Additionally, you can specify a TeX interpreter for `Message` and `Title`.

**Input Arguments** **Message - Message dialog box text**

string vector | string matrix | cell array

Dialog box text specified as a string vector, string matrix, or cell array.

**Example:** 'Operation Completed'

**Example:** ['Operation ', 'Completed']

**Example:** {'Operation', 'Completed'}

**Title - Message dialog box title bar text**

string vector

Dialog box title bar text specified as a string vector.

**Example:** 'Success'

**Icon - Icon to include in message dialog box**

'none' (default) | 'error' | 'help' | 'warn' | 'custom'

Icon to include in message dialog box specified as a string.

Built-in icons appear as follows:

-  Error
-  Help
-  Warn

**IconData - Image data defining a custom icon**

matrix

Image data defining a custom icon specified as a matrix. Each element of the matrix specifies the color of a rectangular segment in the image. Use `imread` to get the `IconData` value for an image that you want to use as a message dialog box icon.

**Example:** `[1:64]'*[1:64])/64`

**IconCMap - Colormap for a custom icon that is not true-color**

m-by-3 matrix | MATLAB built-in colormap

Colormap for a custom icon that is not true-color, specified as a m-by-3 matrix of real numbers between 0.0 and 1.0, or as a MATLAB built-in colormap. Use `imread` to get the `IconCMap` value for an image that you want to use as a message dialog box icon.

**Example:** `[0.5 0.5 0.5]`

**Example:** `hot(64)`

## **CreateMode - Message dialog box mode**

Structure | 'nonmodal' (default) | 'modal' | 'replace'

Mode in which message dialog box is created, specified as a string or a structure.

- If `CreateMode` is a structure, it can have the fields `WindowStyle` and `Interpreter`. The `WindowStyle` field must be one of the strings listed in the list items that follow this one. The `Interpreter` field must be the string 'tex' or 'none'. If the `Interpreter` value is 'tex', MATLAB interprets the `Message` and `Title` values as TeX. The default value for `Interpreter` is 'none'.
- If `CreateMode` is 'nonmodal', MATLAB creates a new nonmodal message box with the specified parameters. Existing message boxes with the same `Title` remain.
- If `CreateMode` is 'modal', MATLAB replaces the existing message box with the specified `Title` that was last created or clicked on with the specified modal dialog box. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.
- If `CreateMode` is 'replace', MATLAB replaces the message box having the specified `Title` that was last created or clicked on with a nonmodal message box as specified. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.

**Example:** `CreateStruct.Interpreter='tex';`

## **Output Arguments**

### **h - Message dialog box handle**

scalar

Message dialog box handle returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific message dialog box.

## Tips

- Program execution continues even when a modal dialog box is active. To block MATLAB program execution until the user responds to the modal dialog box, use the `uiwait` function.
- If you open a dialog box with `errordlg`, `msgbox`, or `warn dlg` using `'CreateMode','modal'` and a nonmodal dialog box that was created with any of these functions is already present and *has the same title as the modal dialog box*, then the nonmodal dialog box closes when the modal one opens.

## Definitions

### modal dialog box

A modal dialog box prevents a user from interacting with other windows before responding to the modal dialog box.

For more information about modal dialog boxes, see `WindowState` in the [Figure Properties](#) topic.

## Examples

### Simple Message Dialog Box

Specify the text you want displayed in the message dialog box.

```
h = msgbox('Operation Completed');
```

### Message Dialog Box with a Title

Specify the message dialog box text and give the dialog box the title `Success`.

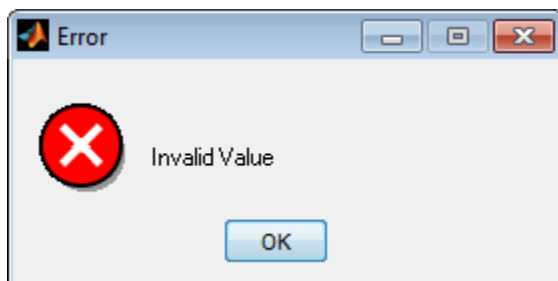

```
h = msgbox('Operation Completed', 'Success');
```

## Message Dialog Box that Uses a Built-in Icon

Include a built-in error icon with an error message in a message dialog box entitled Error.

```
h = msgbox('Invalid Value', 'Error','error');
```

## Message Dialog Box that Uses a True-Color Custom Icon

Use a .png file as an icon in your message dialog box. True-color images, such as .png files, do not use colormaps.

Copy a .png file to a folder on your MATLAB search path.

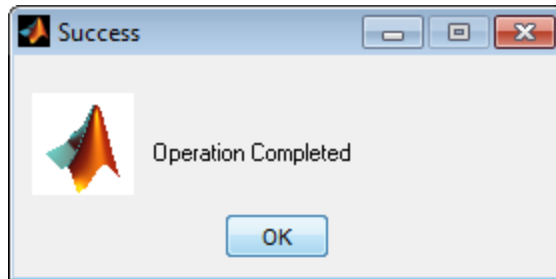

```
copyfile(fullfile(matlabroot,...  
    'toolbox','matlab','demos','html','logodemo_01.png'));
```

Determine the value to specify for `IconData` by passing the image file to `imread`.

```
[cdata] = imread('logodemo_01.png');
```

Create the message dialog box, including the custom icon. Because .png files are true-color, you do not specify a colormap.

```
h=msgbox('Operation Completed','Success','custom',cdata);
```

### Message Dialog Box that Uses an Indexed Custom Icon

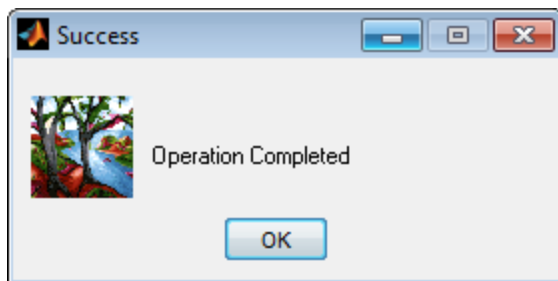

Use `trees.tif` (which is on the MATLAB path) as an icon in your message dialog box. Because .tif images use a colormap to define the colors, you must specify a colormap. Change the colormap to change the image colors.

Determine the value to specify for `IconData` by passing the image file to `imread`.

```
[cdata,map] = imread('trees.tif');
```

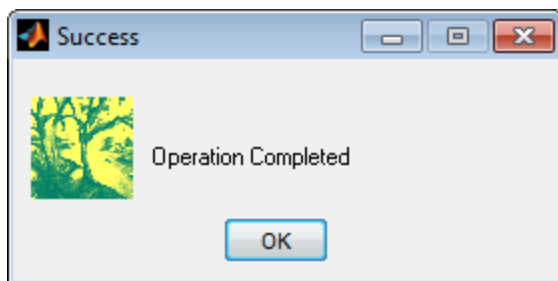

Create the message dialog box, including the custom icon.

```
h=msgbox('Operation Completed','Success','custom',cdata,map);
```

Adjust the image colors by specifying a different colormap. For instance, specify the MATLAB built-in colormap, `summer`

```
h=msgbox('Operation Completed','Success','custom',cdata,summer);
```

## Modal Message Dialog Box

Create a modal message dialog box, wrapping the call to `msgbox` with `uiwait` to make the message dialog box block MATLAB execution until the user responds to the message dialog box.

```
uiwait(msgbox('Operation Completed','Success','modal'));
```

### Modal Message Dialog Box that Uses a TeX Formatted Message

Create a structure to specify that the user must click OK before interacting with another window and that MATLAB interpret the message text as TeX format.

```
CreateStruct.Interpreter = 'tex';  
CreateStruct.WindowStyle = 'modal';
```

Create the message dialog box.

```
h=msgbox('Z = X^2 + Y^2','Value',CreateStruct);
```

### Concepts

- “Reading Image Data”

# mtimes, \*

---

**Purpose** Matrix Multiplication

**Syntax**  
`C = A*B`  
`C = mtimes(A,B)`

**Description** `C = A*B` is the matrix product of `A` and `B`. If `A` is an `m`-by-`p` and `B` is a `p`-by-`n` matrix, then `C` is an `m`-by-`n` matrix defined by

$$C(i,j) = \sum_{k=1}^p A(i,k)B(k,j).$$

This definition says that `C(i,j)` is the inner product of the `i`th row of `A` with the `j`th column of `B`. You can write this definition using the MATLAB colon operator as

$$C(i,j) = A(i,:) * B(:,j)$$

For nonscalar `A` and `B`, the number of columns of `A` must equal the number of rows of `B`. Matrix multiplication is *not* universally commutative for nonscalar inputs. That is, `A*B` is typically not equal to `B*A`. If at least one input is scalar, then `A*B` is equivalent to `A.*B` and is commutative.

`C = mtimes(A,B)` is an alternative way to execute `A*B`, but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Left Array**  
scalar | vector | matrix

Left Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in `A` must be equal to the number of rows in `B`.

**Data Types**  
single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**B - Right Array**

scalar | vector | matrix

Right Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in A must be equal to the number of rows in B.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes**Output Arguments****C - Product Array**

scalar | vector | matrix

Product Array, returned as a scalar, vector, or matrix. Array C has the same number of rows as input A and the same number of columns as input B. For example, if A is an m-by-0 empty matrix and B is a 0-by-n empty matrix, then A\*B is an m-by-n matrix of zeros.

**Examples****Multiply Two Vectors**

Create a 1-by-4 row vector, A, and a 4-by-1 column vector, B.

```
A = [1 1 0 0];
B = [1; 2; 3; 4];
```

Multiply A times B.

```
C = A*B
```

```
C =
```

```
3
```

The result is a 1-by-1 scalar, also called the *dot product* or *inner product* of the vectors A and B. Alternatively, you can calculate the dot product  $A \cdot B$  with the syntax `dot(A,B)`.

Multiply B times A.

```
C = B*A
```

```
C =
```

```
     1     1     0     0
     2     2     0     0
     3     3     0     0
     4     4     0     0
```

The result is a 4-by-4 matrix, also called the *outer product* of the vectors A and B. The outer product of two vectors,  $A \otimes B$ , returns a matrix.

## Multiply Two Arrays

Create two arrays, A and B.

```
A = [1 3 5; 2 4 7];
```

```
B = [-5 8 11; 3 9 21; 4 0 8];
```

Calculate the product of A and B.

```
C = A*B
```

```
C =
```

```
    24    35   114
    30    52   162
```

Calculate the inner product of the second row of A and the third column of B.

```
A(2,:) * B(:,3)
```

```
ans =
```

```
    162
```

This answer is the same as `C(2,3)`.

**See Also**

`colontimes` | `dot` | `cross`

# mu2lin

---

**Purpose** Convert mu-law audio signal to linear

**Syntax** `y = mu2lin(mu)`

**Description** `y = mu2lin(mu)` converts mu-law encoded 8-bit audio signals, stored as “flints” in the range  $0 \leq \mu \leq 255$ , to linear signal amplitude in the range  $-s < Y < s$  where  $s = 32124/32768 \approx .9803$ . The input `mu` is often obtained using `fread(..., 'uchar')` to read byte-encoded audio files. “Flints” are MATLAB integers — floating-point numbers whose values are integers.

**See Also** `auread` | `lin2mu`

## Purpose

Read band-interleaved data from binary file

## Syntax

```
X = multibandread(filename, size, precision, offset,
    interleave, byteorder)
X = multibandread(...,subset1,subset2,subset3)
```

## Description

`X = multibandread(filename, size, precision, offset, interleave, byteorder)` reads band-sequential (BSQ), band-interleaved-by-line (BIL), or band-interleaved-by-pixel (BIP) data from the binary file `filename`. The `filename` input is a string enclosed in single quotes. This function defines *band* as the third dimension in a 3-D array, as shown in this figure.

You can use the parameters to `multibandread` to specify many aspects of the read operation, such as which bands to read. See “Parameters” on page 1-3970 for more information.

`X` is a 2-D array if only one band is read; otherwise it is 3-D. `X` is returned as an array of data type `double` by default. Use the `precision` parameter to map the data to a different data type.

`X = multibandread(...,subset1,subset2,subset3)` reads a subset of the data in the file. You can use up to three subsetting parameters to specify the data subset along row, column, and band dimensions. See “Subsetting Parameters” on page 1-3971 for more information.

# multibandread

---

---

**Note** In addition to BSQ, BIL, and BIP files, multiband imagery may be stored using the TIFF file format. In that case, use the `imread` function to import the data.

---

## Parameters

This table describes the arguments accepted by `multibandread`.

Argument	Description
<code>filename</code>	String containing the name of the file to be read.
<code>size</code>	Three-element vector of integers consisting of [height, width, N], where <ul style="list-style-type: none"><li>• height is the total number of rows</li><li>• width is the total number of elements in each row</li><li>• N is the total number of bands.</li></ul> This will be the dimensions of the data if it is read in its entirety.
<code>precision</code>	String specifying the format of the data to be read, such as 'uint8', 'double', 'integer*4', or any of the other precisions supported by the <code>fread</code> function.  Note: You can also use the <code>precision</code> parameter to specify the format of the output data. For example, to read <code>uint8</code> data and output a <code>uint8</code> array, specify a precision of 'uint8=>uint8' (or '*uint8'). To read <code>uint8</code> data and output it in the MATLAB software in single precision, specify 'uint8=>single'. See <code>fread</code> for more information.

<b>Argument</b>	<b>Description</b>
offset	Scalar specifying the zero-based location of the first data element in the file. This value represents the number of bytes from the beginning of the file to where the data begins.
interleave	String specifying the format in which the data is stored <ul style="list-style-type: none"> <li>• 'bsq' — Band-Sequential</li> <li>• 'bil' — Band-Interleaved-by-Line</li> <li>• 'bip' — Band-Interleaved-by-Pixel</li> </ul> <p>For more information about these interleave methods, see the <code>multibandwrite</code> reference page.</p>
byteorder	String specifying the byte ordering (machine format) in which the data is stored, such as <ul style="list-style-type: none"> <li>• 'ieee-le' — Little-endian</li> <li>• 'ieee-be' — Big-endian</li> </ul> <p>See <code>fopen</code> for a complete list of supported formats.</p>

## Subsetting Parameters

You can specify up to three subsetting parameters. Each subsetting parameter is a three-element cell array, `{dim, method, index}`, where

<b>Parameter</b>	<b>Description</b>
<i>dim</i>	Text string specifying the dimension to subset along. It can have any of these values: <ul style="list-style-type: none"> <li>• 'Column'</li> <li>• 'Row'</li> </ul>

# multibandread

---

Parameter	Description
<i>method</i>	<ul style="list-style-type: none"><li>• 'Band'</li></ul> Text string specifying the subsetting method. It can have either of these values: <ul style="list-style-type: none"><li>• 'Direct'</li><li>• 'Range'</li></ul>
<i>index</i>	If you leave out this element of the subset cell array, <code>multibandread</code> uses 'Direct' as the default. If method is 'Direct', <i>index</i> is a vector specifying the indices to read along the Band dimension. If method is 'Range', <i>index</i> is a three-element vector of [start, increment, stop] specifying the range and step size to read along the dimension specified in <i>dim</i> . If <i>index</i> is a two-element vector, <code>multibandread</code> assumes that the value of increment is 1.

## Examples

### Example 1

Setup initial parameters for a data set.

```
rows=3; cols=3; bands=5;  
filename = tempname;
```

Define the data set.

```
fid = fopen(filename, 'w', 'ieee-le');  
fwrite(fid, 1:rows*cols*bands, 'double');  
fclose(fid);
```

Read every other band of the data using the Band-Sequential format.

```
im1 = multibandread(filename, [rows cols bands], ...  
    'double', 0, 'bsq', 'ieee-le', ...  
    {'Band', 'Range', [1 2 bands]} )
```

Read the first two rows and columns of data using Band-Interleaved-by-Pixel format.

```
im2 = multibandread(filename, [rows cols bands], ...  
    'double', 0, 'bip', 'ieee-le', ...  
    {'Row', 'Range', [1 2]}, ...  
    {'Column', 'Range', [1 2]} )
```

Read the data using Band-Interleaved-by-Line format.

```
im3 = multibandread(filename, [rows cols bands], ...  
    'double', 0, 'bil', 'ieee-le')
```

Delete the file created in this example.

```
delete(filename);
```

## Example 2

Read int16 BIL data from the FITS file `tst0012.fits`, starting at byte 74880.

```
im4 = multibandread('tst0012.fits', [31 73 5], ...  
    'int16', 74880, 'bil', 'ieee-be', ...  
    {'Band', 'Range', [1 3]} );  
im5 = double(im4)/max(max(max(im4)));  
imagesc(im5);
```

## See Also

[fread](#) | [fwrite](#) | [imread](#) | [memmapfile](#) | [multibandwrite](#)

# multibandwrite

---

**Purpose** Write band-interleaved data to file

**Syntax** `multibandwrite(data,filename,interleave)`  
`multibandwrite(data,filename,interleave,start,totalsize)`  
`multibandwrite(...,param,value...)`

**Description** `multibandwrite(data,filename,interleave)` writes `data`, a two- or three-dimensional numeric or logical array, to the binary file specified by `filename`. The `filename` input is a string enclosed in single quotes. The length of the third dimension of `data` determines the number of bands written to the file. The bands are written to the file in the form specified by `interleave`. See “Interleave Methods” on page 1-3976 for more information about this argument.

If `filename` already exists, `multibandwrite` overwrites it unless you specify the optional `offset` parameter. See the last alternate syntax for `multibandwrite` for information about other optional parameters.

`multibandwrite(data,filename,interleave,start,totalsize)` writes `data` to the binary file `filename` in chunks. In this syntax, `data` is a subset of the complete data set.

`start` is a 1-by-3 array [`firstrow firstcolumn firstband`] that specifies the location to start writing data. `firstrow` and `firstcolumn` specify the location of the upper left image pixel. `firstband` gives the index of the first band to write. For example, `data(I,J,K)` contains the data for the pixel at [`firstrow+I-1, firstcolumn+J-1`] in the (`firstband+K-1`)-th band.

`totalsize` is a 1-by-3 array, [`totalrows,totalcolumns,totalbands`], which specifies the full, three-dimensional size of the data to be written to the file.

---

**Note** In this syntax, you must call `multibandwrite` multiple times to write all the data to the file. The first time it is called, `multibandwrite` writes the complete file, using the fill value for all values outside the data subset. In each subsequent call, `multibandwrite` overwrites these fill values with the data subset in `data`. The parameters `filename`, `interleave`, `offset`, and `totalsize` must remain constant throughout the writing of the file.

---

`multibandwrite(..., param, value...)` writes the multiband data to a file, specifying any of these optional parameter/value pairs.

Parameter	Description
'precision'	String specifying the form and size of each element written to the file. See the help for <code>fwrite</code> for a list of valid values. The default precision is the class of the data.
'offset'	The number of bytes to skip before the first data element. If the file does not already exist, <code>multibandwrite</code> writes ASCII null values to fill the space. To specify a different fill value, use the parameter <code>'fillvalue'</code> .  This option is useful when you are writing a header to the file before or after writing the data. When writing the header to the file after the data is written, open the file with <code>fopen</code> using <code>'r+'</code> permission.

# multibandwrite

Parameter	Description
'machfmt'	String to control the format in which the data is written to the file. Typical values are 'ieee-le' for little endian and 'ieee-be' for big endian. See the help for <code>fopen</code> for a complete list of available formats. The default machine format is the local machine format.
'fillvalue'	A number specifying the value to use in place of missing data. 'fillvalue' can be a single number, specifying the fill value for all missing data, or a 1-by-Number-of-bands vector of numbers specifying the fill value for each band. This value is used to fill space when data is written in chunks.

## Interleave Methods

`interleave` is a string that specifies how `multibandwrite` interleaves the bands as it writes data to the file. If data is two-dimensional, `multibandwrite` ignores the `interleave` argument. The following table lists the supported methods and uses this example multiband file to illustrate each method.

Supported methods of interleaving bands include those listed below.

Method	String	Description	Example
Band-Interleaved-by-Line	'bil'	Write an entire row from each band	AAAAABBBBBCCCC AAAAABBBBBCCCC AAAAABBBBBCCCC
Band-Interleaved-by-Pixel	'bip'	Write a pixel from each band	ABCABCABCABC...
Band-Sequential	'bsq'	Write each band in its entirety	AAAAA AAAAA AAAAA BBBBB BBBBB BBBBB CCCCC CCCCC CCCCC

## Examples

---

**Note** To run these examples successfully, you must be in a writable directory.

---

### Example 1

Write all data (interleaved by line) to the file in one call.

```
data = reshape(uint16(1:600), [10 20 3]);
multibandwrite(data, 'data.bil', 'bil');
```

# multibandwrite

---

## Example 2

Write a single-band tiled image with one call for each tile. This is only useful if a subset of each band is available at each call to `multibandwrite`.

```
numBands = 1;
dataDims = [1024 1024 numBands];
data = reshape(uint32(1:(1024 * 1024 * numBands)), dataDims);

for band = 1:numBands
    for row = 1:2
        for col = 1:2

            subsetRows = ((row - 1) * 512 + 1):(row * 512);
            subsetCols = ((col - 1) * 512 + 1):(col * 512);

            upperLeft = [subsetRows(1), subsetCols(1), band];
            multibandwrite(data(subsetRows, subsetCols, band), ...
                'banddata.bsq', 'bsq', upperLeft, dataDims);

        end
    end
end
```

## See Also

`multibandread` | `fwrite` | `fread`

**Purpose** Allow clearing functions from memory

**Syntax**

```
munlock
munlock fun
munlock('fun')
```

**Description** `munlock` unlocks the currently running `.m` or `.mex` function in memory so that subsequent `clear` functions can remove it.

`munlock fun` unlocks the `.m` or `.mex` file named `fun` from memory. By default, these files are unlocked so that changes to the file are picked up. Calls to `munlock` are needed only to unlock `.m` or `.mex` functions that have been locked with `mlock`.

`munlock('fun')` is the function form of `munlock`.

**Examples** The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
.
.
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked testfun
ans =
     1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock testfun

mislocked testfun
ans =
```

# **munlock**

---

0

## **See Also**

`mlock` | `mislocked` | `inmem` | `persistent`

**Purpose** Maximum identifier length

**Syntax** `len = namelengthmax`

**Description** `len = namelengthmax` returns the maximum length allowed for MATLAB identifiers, which include:

- Variable names
- Structure field names
- Script, function, and class names
- Model names

Rather than hard-coding a specific maximum name length into your programs, use the `namelengthmax` function. This saves you the trouble of having to update these limits should the identifier length change in some future MATLAB release.

**Examples** Call `namelengthmax` to get the maximum identifier length:

```
maxid = namelengthmax
maxid =
    63
```

**See Also** `isvarname` | `genvarname`

# NaN

---

**Purpose** Not-a-Number

**Syntax** NaN  
NaN('double')  
NaN('single')  
NaN(n)  
NaN(m,n)  
NaN([m,n])  
NaN(m,n,p,...)  
NaN([m,n,p,...])  
NaN(...,'like',p)

**Description** NaN returns the IEEE arithmetic representation for Not-a-Number (NaN). These result from operations which have undefined numerical results.

NaN('double') is the same as NaN with no inputs.

NaN('single') is the single precision representation of NaN.

NaN(n) is an n-by-n matrix of NaNs.

NaN(m,n) or NaN([m,n]) is an m-by-n matrix of NaNs.

NaN(m,n,p,...) or NaN([m,n,p,...]) is an m-by-n-by-p-by-... array of NaNs.

---

**Note** The size inputs m, n, p, ... should be nonnegative integers. Negative integers are treated as 0.

---

NaN(...,classname) is an array of NaNs of class specified by the string classname. classname can be either 'single' or 'double'.

NaN(...,'like',p) is an array of NaNs of the same data type, sparsity, and complexity (real or complex) as the single or double precision numeric variable p.

**Examples**

These operations produce NaN:

- Any arithmetic operation on a NaN, such as `sqrt(NaN)`
- Addition or subtraction, such as magnitude subtraction of infinities as `(+Inf)+(-Inf)`
- Multiplication, such as `0*Inf`
- Division, such as `0/0` and `Inf/Inf`
- Remainder, such as `rem(x,y)` where `y` is zero or `x` is infinity

**Tips**

Because two NaNs are not equal to each other, logical operations involving NaNs always return false, except `~=` (not equal). Consequently,

```
NaN ~= NaN
ans =
    1
NaN == NaN
ans =
    0
```

and the NaNs in a vector are treated as different unique elements.

```
unique([1 1 NaN NaN])
ans =
    1 NaN NaN
```

Use the `isnan` function to detect NaNs in an array.

```
isnan([1 1 NaN NaN])
ans =
    0    0    1    1
```

**See Also**

`Inf` | `isnan`

# nargchk

---

**Purpose** Validate number of input arguments

---

**Note** `nargchk` will be removed in a future version. Use `narginchk` instead.

---

**Syntax**

```
msgstring = nargchk(minargs, maxargs, numargs)
msgstring = nargchk(minargs, maxargs, numargs, 'string')
msgstruct = nargchk(minargs, maxargs, numargs, 'struct')
```

**Description** Use `nargchk` inside a function to check that the desired number of input arguments is specified in the call to that function.

`msgstring = nargchk(minargs, maxargs, numargs)` returns an error message string `msgstring` if the number of inputs specified in the call `numargs` is less than `minargs` or greater than `maxargs`. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty matrix.

It is common to use the `nargin` function to determine the number of input arguments specified in the call.

`msgstring = nargchk(minargs, maxargs, numargs, 'string')` is essentially the same as the command shown above, as `nargchk` returns a string by default.

`msgstruct = nargchk(minargs, maxargs, numargs, 'struct')` returns an error message structure `msgstruct` instead of a string. The fields of the return structure contain the error message string and a message identifier. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty structure.

When too few inputs are supplied, the message string and identifier are

```
message: 'Not enough input arguments.'
identifier: 'MATLAB:nargchk:notEnoughInputs'
```

When too many inputs are supplied, the message string and identifier are

```
message: 'Too many input arguments.'  
identifier: 'MATLAB:nargchk:tooManyInputs'
```

**Tips**

nargchk is often used together with the error function. The error function accepts either type of return value from nargchk: a message string or message structure. For example, this command provides the error function with a message string and identifier regarding which error was caught:

```
error(nargchk(2, 4, nargin, 'struct'))
```

If nargchk detects no error, it returns an empty string or structure. When nargchk is used with the error function, as shown here, this empty string or structure is passed as an input to error. When error receives an empty string or structure, it simply returns and no error is generated.

**Examples**

Given the function CheckInputs,

```
function CheckInputs(x, y, z)  
error(nargchk(2, 3, nargin))
```

Then typing CheckInputs(1) produces

```
Not enough input arguments.
```

**See Also**

```
narginchk | nargoutchk | nargin | nargout | varargin | varargout  
| error
```

# nargin

---

**Purpose**            Number of function input arguments

**Syntax**            nargin  
                      nargin(fx)

**Description**       nargin returns the number of input arguments passed in the call to the currently executing function. Use this nargin syntax only in the body of a function.

nargin(fx) returns the number of input arguments that appear in the definition statement for function fx. If the function includes varargin in its definition, then nargin returns the negative of the number of inputs. For example, if function foo declares inputs a, b, and varargin, then nargin('foo') returns -3.

**Input Arguments**       **fx**  
                          Either a function handle or a string in single quotes that specifies the name of a function.

**Examples**            **Inputs to Current Function**

Create a function in a file named addme.m that accepts up to two inputs, and identify the number of inputs with nargin.

```
function c = addme(a,b)
```

```
switch nargin
    case 2
        c = a + b;
    case 1
        c = a + a;
    otherwise
        c = 0;
end
```

**Inputs Defined for a Function**

Determine how many inputs a function can accept.

The function `addme` created in the previous example has two inputs in its declaration statement (a and b).

```
fx = 'addme';  
nargin(fx)
```

```
ans =  
     2
```

### Function with `varargin` Input

Determine how many inputs a function that uses `varargin` can accept.

Define a function in a file named `mynewplot.m` that accepts numeric inputs `x` and `y` and any number of additional plot inputs using `varargin`.

```
function mynewplot(x,y,varargin)  
    figure  
    plot(x,y,varargin{:})  
    title('My New Plot')
```

At the command line, query how many inputs `newplot` can accept.

```
fx = 'mynewplot';  
nargin(fx)
```

```
ans =  
    -3
```

The minus sign indicates that the third input is `varargin`. The `mynewplot` function can accept an indeterminate number of additional input arguments.

### See Also

`nargout` | `narginchk` | `nargoutchk` | `varargin` | `varargout` | `inputname`

# narginchk

---

**Purpose** Validate number of input arguments

**Syntax** narginchk(minargs, maxargs)

**Description** narginchk(minargs, maxargs) throws an error if the number of inputs specified in the call to the currently executing function is less than minargs or greater than maxargs. If the number of inputs is between minargs and maxargs (inclusive), narginchk does nothing.

When too few inputs are supplied, the message identifier and message are:

```
identifier: 'MATLAB:narginchk:notEnoughInputs'  
message: 'Not enough input arguments.'
```

When too many inputs are supplied, the message identifier and message are:

```
identifier: 'MATLAB:narginchk:tooManyInputs'  
message: 'Too many input arguments.'
```

## Examples

This function uses narginchk to verify that a minimum of 2 and maximum of 5 input arguments are received from the calling function:

```
function check_inputs(A, B, varargin)  
minargs=2; maxargs=5;  
  
% Number of inputs must be >=minargs and <=maxargs.  
narginchk(minargs, maxargs)  
  
fprintf('Received 2 required, %d optional inputs.\n\n', ...  
        size(varargin, 2))
```

Call the example function, passing 1 input argument:

```
check_inputs(23)  
Error using check_inputs  
Not enough input arguments.
```

Call the function, passing 5 arguments:

```
check_inputs(23, 9, 15, 34, 62)
Received 2 required, 3 optional inputs.
```

Call the function, passing 6 arguments:

```
check_inputs(23, 9, 15, 34, 62, 6)
Error using check_inputs
Too many input arguments.
```

# nargout

---

<b>Purpose</b>	Number of function output arguments
<b>Syntax</b>	<code>nargout</code> <code>nargout(fx)</code>
<b>Description</b>	<p><code>nargout</code> returns the number of output arguments specified in the call to the currently executing function. Use this <code>nargout</code> syntax only in the body of a function.</p> <p><code>nargout(fx)</code> returns the number of outputs that appear in the definition statement of function <code>fx</code>. If the function includes <code>varargout</code> in its definition, then <code>nargout</code> returns the negative of the number of outputs. For example, if function <code>foo</code> declares outputs <code>a</code>, <code>b</code>, and <code>varargout</code>, then <code>nargout('foo')</code> returns <code>-3</code>.</p>
<b>Input Arguments</b>	<p><b>fx</b></p> <p>Either a function handle or a string in single quotes that specifies the name of a function.</p>
<b>Examples</b>	<p><b>Outputs for Current Function</b></p> <p>Create a function in a file named <code>subtract.m</code> that calculates a second return value only when requested.</p> <pre>function [dif,absdif] = subtract(y,x) dif = y - x; if nargout &gt; 1     disp('Calculating absolute value')     absdif = abs(dif); end</pre> <p><b>Outputs Defined for a Function</b></p> <p>Determine how many outputs a function can return.</p> <p>The function named <code>subtract</code> created in the previous example has two outputs in its declaration statement (<code>dif</code> and <code>absdif</code>).</p>

```
fx = 'subtract';  
nargout(fx)
```

```
ans =  
     2
```

### Function with varargout Output

Determine how many outputs a function that uses `varargout` can return.

Define a function in a file named `mysize.m` that returns a vector of dimensions from the `size` function and the individual dimensions using `varargout`.

```
function [sizeVector,varargout] = mysize(x)  
    sizeVector = size(x);  
    varargout = cell(1,nargout-1);  
    for k = 1:length(varargout)  
        varargout{k} = sizeVector(k);  
    end
```

At the command line, query how many outputs `mysize` can return.

```
fx = 'mysize';  
nargout(fx)
```

```
ans =  
    -2
```

The minus sign indicates that the second output is `varargout`. The `mysize` function can return an indeterminate number of additional outputs.

### Tips

- When you use a function as part of an expression, MATLAB calls the function with one output argument, so `nargout` within the function returns 1. For example, given the following `if` statement and the `subtract` function defined in the Examples section, the value of `nargout` within the `subtract` function is 1.

# nargout

---

```
a = 1; b = 2;  
if subtract(a,b) < 0  
    disp('Result is negative')  
end
```

## See Also

nargin | nargoutchk | narginchk | varargout | varargin |  
inputname

**Purpose** Validate number of output arguments

**Syntax** nargoutchk(minargs, maxargs)

**Description** nargoutchk(minargs, maxargs) throws an error if the number of outputs specified in the call is less than minargs or greater than maxargs. If the number of outputs is between minargs and maxargs (inclusive), nargoutchk does nothing.

When too few outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:notEnoughOutputs'  
message: 'Not enough output arguments.'
```

When too many outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:tooManyOutputs'  
message: 'Too many output arguments.'
```

## Examples

This function uses nargoutchk to verify that a minimum of 2 and maximum of 5 input arguments are passed back to the calling function:

```
function [varargout] = check_outputs(array_in)  
minargs=2; maxargs=5;  
  
% Number of outputs must be >=minargs and <=maxargs.  
nargoutchk(minargs, maxargs)  
  
for k=1:nargout  
    varargout{k} = array_in(k)*3;  
end
```

Initialize input array X to a vector of 6 elements:

```
X = 5:7:40  
X =  
     5     12     19     26     33     40
```

# nargoutchk

---

Call the example function with 1 output argument. This is less than the minimum (2) that was specified by `nargoutchk` and results in an error:

```
A = check_outputs(X);
```

```
Error using check_outputs  
Not enough output arguments.
```

Call the function with 4 output arguments. This is within the allowable bounds (2 to 5) specified by `nargoutchk`:

```
[A, B, C, D] = check_outputs(X);
```

```
[A, B, C, D]  
ans =  
    15    36    57    78
```

Call the function with 6 output arguments. This exceeds the maximum (5) that was specified by `nargoutchk` and results in an error:

```
[A, B, C, D, E, F] = check_outputs(X);
```

```
Error using check_outputs  
Too many output arguments.
```

## See Also

`narginchk` | `nargout` | `nargin` | `varargout` | `varargin`

**Purpose** Convert numeric bytes to Unicode character representation

**Syntax** `unicodestr = native2unicode(bytes)`  
`unicodestr = native2unicode(bytes, encoding)`

**Description** `unicodestr = native2unicode(bytes)` converts a numeric vector, `bytes`, from the user default encoding to Unicode character representation. `bytes` is treated as a stream of 8-bit bytes, and each value must be in the range `[0,255]`. Return value `unicodestr` is a char vector having the same general array shape as `bytes`.

`unicodestr = native2unicode(bytes, encoding)` converts `bytes` to Unicode representation assuming that the byte stream is in the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string ( `' '` ) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. If `encoding` is unspecified or is the empty string ( `' '` ), the default encoding scheme is used.

---

**Note** If `bytes` is a char vector, it is returned unchanged.

---

**Examples** This example begins with a vector of bytes in an unknown character encoding scheme. The user-written function `detect_encoding` determines the encoding scheme. If successful, it returns the encoding scheme name or alias as a string. If unsuccessful, it throws an error represented by an `MException` object, `ME`. The example calls `native2unicode` to convert the bytes to Unicode representation:

```
try
    enc = detect_encoding(bytes);
    str = native2unicode(bytes, enc);
    disp(str);
catch ME
    rethrow(ME);
end
```

# native2unicode

---

Note that the computer must be configured to display text in a language represented by the detected encoding scheme for the output of `disp(str)` to be correct.

## See Also

`unicode2native`

**Purpose** Binomial coefficient or all combinations

**Syntax**  
`b = nchoosek(n,k)`  
`C = nchoosek(v,k)`

**Description** `b = nchoosek(n,k)` returns the binomial coefficient, defined as  $n!/((n-k)! k!)$ . This is the number of combinations of  $n$  items taken  $k$  at a time.

`C = nchoosek(v,k)` returns a matrix containing all possible combinations of the elements of vector  $v$  taken  $k$  at a time. Matrix  $C$  has  $k$  columns and  $n!/((n-k)! k!)$  rows, where  $n$  is `length(v)`.

## Input Arguments

### **n - Number of possible choices**

scalar, real, nonnegative value

Number of possible choices, specified as a scalar value of any numeric type that is real and nonnegative.

**Example:** 10

**Example:** `int16(10)`

### **Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **k - Number of selected choices**

scalar, real, nonnegative value

Number of selected choices, specified as a scalar value that is real and nonnegative.  $k$  can be any numeric type. However, `nchoosek(n,k)` requires that  $n$  and  $k$  be the same type or that at least one of them be of type `double`.

There are no restrictions on combining inputs of different types for `nchoosek(v,k)`.

**Example:** 3

**Example:** `int16(3)`

## Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **v** - Set of all choices

vector of numeric, logical, or char values

Set of all choices, specified as a vector of numeric, logical, or char values.

**Example:** `[1 2 3 4 5]`

**Example:** `[1+1i 2+1i 3+1i 4+1i]`

**Example:** `int16([1 2 3 4 5])`

**Example:** `[true false true false]`

**Example:** `['abcd']`

## Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

**Complex Number Support:** Yes

## Output Arguments

### **b** - Binomial coefficient

nonnegative scalar value

Binomial coefficient, returned as a nonnegative scalar value. `b` is the same type as `n` and `k`. If `n` and `k` are of different types, then `b` is returned as the nondouble type.

### **C** - All combinations of `v`

matrix

All combinations of `v`, returned as a matrix of the same type as `v`. Matrix `C` has `k` columns and  $n!/((n-k)! k!)$  rows, where `n` is `length(v)`.

Each row of **C** contains a combination of **k** items chosen from **v**. The elements in each row of **C** are listed in the same order as they appear in **v**.

## Limitations

- When **b** = `nchoosek(n,k)` is sufficiently large, `nchoosek` displays a warning that the result might not be exact. In this case, the result is only accurate to 15 digits for double-precision inputs, or 8 digits for single-precision inputs.
- **C** = `nchoosek(v,k)` is only practical for situations where `length(v)` is less than about 15.

## Examples

### Binomial Coefficient, "5 Choose 4"

```
b = nchoosek(5,4)
```

```
b =
```

```
5
```

### All Combinations of Five Numbers Taken Four at a Time

```
v = 2:2:10;
C = nchoosek(v,4)
```

```
C =
```

```
2     4     6     8
2     4     6    10
2     4     8    10
2     6     8    10
4     6     8    10
```

### All Combinations of Three Unsigned Integers Taken Two at a Time

```
v = uint16([10 20 30]);
C = nchoosek(v,uint16(2))
```

# nchoosek

---

C =

10	20
10	30
20	30

<b>Purpose</b>	Rectangular grid in N-D space
<b>Syntax</b>	$[X1, X2, X3, \dots, Xn] = \text{ndgrid}(x1gv, x2gv, x3gv, \dots, xngv)$ $[X1, X2, \dots, Xn] = \text{ndgrid}(xgv)$
<b>Description</b>	<p><math>[X1, X2, X3, \dots, Xn] = \text{ndgrid}(x1gv, x2gv, x3gv, \dots, xngv)</math> replicates the grid vectors <math>x1gv, x2gv, x3gv, \dots, xngv</math> to produce a full grid. This grid is represented by the output coordinate arrays <math>X1, X2, X3, \dots, Xn</math>. The <math>i</math>th dimension of any output array <math>Xi</math> contains copies of the grid vector <math>xigv</math>.</p> <p><math>[X1, X2, \dots, Xn] = \text{ndgrid}(xgv)</math> is the same as <math>[X1, X2, \dots, Xn] = \text{ndgrid}(xgv, xgv, \dots, xgv)</math>. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.</p> <p>The coordinate arrays <math>[X1, X2, X3, \dots, Xn]</math> are typically used to evaluate functions of several variables and to create surface and volumetric plots.</p>
<b>Input Arguments</b>	<p><b>xigv</b> Grid vector specifying a series of grid point coordinates in the <math>i</math>th dimension.</p> <p><b>xgv</b> Generic grid vector specifying a series of point coordinates.</p>
<b>Output Arguments</b>	<p><b><math>Xi</math></b> The <math>i</math>th dimension of the output array <math>Xi</math> are copies of elements of the grid vector <math>xigv</math>. The output arrays specify the full grid.</p>
<b>Tips</b>	The <code>ndgrid</code> function is similar to <code>meshgrid</code> , however <code>ndgrid</code> supports 1-D to N-D while <code>meshgrid</code> is restricted to 2-D and 3-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors $x1gv$ ,

# ndgrid

---

`x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `ndgrid(x1gv, x2gv)` will output arrays of size `M-by-N` while `meshgrid(x1gv, x2gv)` outputs arrays of size `N-by-M`. Similarly, `ndgrid(x1gv, x2gv, x3gv)` will output arrays of size `M-by-N-by-P` while `meshgrid(x1gv, x2gv, x3gv)` outputs arrays of size `N-by-M-by-P`. See “Grid Representation” in the MATLAB Mathematics documentation for more information.

## Examples

Evaluate the function  $x_1 e^{-x_1^2 - x_2^2}$  over the range  $-2 < x_1 < 2, -2 < x_2 < 2$ :

```
[X1,X2] = ndgrid(-2:.2:2, -2:.2:2);  
Z = X1 .* exp(-X1.^2 - X2.^2);  
mesh(X1,X2,Z)
```

## How To

- “Interpolating Gridded Data”

**Purpose**            Number of array dimensions

**Syntax**            `n = ndims(A)`

**Description**        `n = ndims(A)` returns the number of dimensions in the array `A`. The number of dimensions in an array is always greater than or equal to 2. Trailing singleton dimensions are ignored. A singleton dimension is any dimension for which `size(A,dim) = 1`.

**Algorithms**        `ndims(x)` is `length(size(x))`.

**See Also**            `size`

**Purpose** Determine inequality

**Syntax** A ~= B  
eq(A,B)

**Description** A ~= B returns a logical array with elements set to logical 1 (true) where arrays A and B are not equal; otherwise, it returns logical 0 (false). The test compares both real and imaginary parts of numeric arrays. ne returns logical 1 (true) where A or B have NaN or undefined categorical elements.

eq(A,B) is an alternative way to execute A ~= B, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Left array

numeric array | logical array | character array | categorical array

Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### B - Right array

numeric array | logical array | character array | categorical array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Inequality of Two Vectors

Create two vectors containing both real and imaginary numbers.

```
A = [1+i 3 2 4+i];
B = [1 3+i 2 4+i];
```

Compare the two vectors for inequality.

```
A ~= B
```

```
ans =
```

```
     1     1     0     0
```

The `ne` function tests both real and imaginary parts for inequality, and returns logical 1 (true) where one or both parts are not equal.

### Find Characters in String

Create a string of characters.

```
M = 'masterpiece';
```

Test the string for the presence of a specific character using ~=.

```
M ~= 'n'
```

```
ans =
```

```
     1     1     1     1     1     1     1     1     1     1     1
```

The value of logical 1 (true) in the vector indicates the absence of the character 'n'. The character is not present in the string.

### **Find Values in Categorical Array**

Create a categorical array.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =
```

```
     heads     heads     tails  
     tails     heads     tails
```

The array has two categories: 'heads' and 'tails'.

Find all values not in the 'heads' category.

```
A ~= 'heads'
```

```
ans =
```

```
     0     0     1  
     1     0     1
```

A value of logical 1 (true) indicates a value not in the category. Since A only has two categories, A ~= 'heads' returns the same answer as A == 'tails'.

Compare the rows of A for inequality.

```
A(1,:) ~= A(2, :)
```

```
ans =
```

```
     1     0     0
```

The function returns logical 1 (true) where the rows have unequal category values.

### Compare Floating-Point Numbers

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `~=` operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in `C`.

```
C = 0.5-0.4-0.1
```

```
C =
```

```
-2.7756e-17
```

Intuitively, `C` should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare `C` to zero for inequality.

```
C ~= 0
```

```
ans =
```

```
     1
```

The result is logical 1 (true).

Compare floating-point numbers using a tolerance, `tol`, instead of `~=`.

```
tol = eps;
```

## ne, ~=

---

```
abs(C-0) > tol
```

```
ans =
```

```
0
```

The two numbers, `C` and `0`, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

**Purpose** (Will be removed) Point closest to specified location

---

**Note** nearestNeighbor(DelaunayTri) will be removed in a future release. Use nearestNeighbor(delaunayTriangulation) instead.

DelaunayTri will be removed in a future release. Use delaunayTriangulation instead.

---

**Syntax**

```
PI = nearestNeighbor(DT,QX)
PI = nearestNeighbor(DT,QX,QY)
PI = nearestNeighbor(DT,QX,QY,QZ)
[PI,D] = nearestNeighbor(DT,QX,...)
```

**Description**

PI = nearestNeighbor(DT,QX) returns the index of the nearest point in DT.X for each query point location in QX.

PI = nearestNeighbor(DT,QX,QY) and PI = nearestNeighbor(DT,QX,QY,QZ) allow the query points to be specified in column vector format when working in 2-D and 3-D.

[PI,D] = nearestNeighbor(DT,QX,...) returns the index of the nearest point in DT.X for each query point location in QX. The corresponding Euclidean distances between the query points and their nearest neighbors are returned in D.

---

**Note** Note: nearestNeighbor is not supported for 2-D triangulations that have constrained edges.

---

**Input Arguments**

DT	Delaunay triangulation.
QX	The matrix QX is of size mpts-by-ndim, mpts being the number of query points and ndim the dimension of the space where the points reside.

# DelaunayTri.nearestNeighbor

---

## Output Arguments

PI                    PI is a column vector of point indices that index into the points DT.X. The length of PI is equal to the number of query points mpts

D                     D is a column vector of length mpts.

## Examples

Create a Delaunay triangulation:

```
x = rand(10,1);  
y = rand(10,1);  
dt = DelaunayTri(x,y);
```

Create query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
```

Find the nearest neighbors to the query points:

```
pid = nearestNeighbor(dt, qrypts)
```

<b>Purpose</b>	Compare scalar MException objects for inequality
<b>Syntax</b>	<code>eObj1 ~= eObj2</code>
<b>Description</b>	<code>eObj1 ~= eObj2</code> tests MException objects <code>eObj1</code> and <code>eObj2</code> for inequality, returning logical 1 (true) if the two objects are not identical, otherwise returning logical 0 (false).
<b>See Also</b>	<code>try</code>   <code>catch</code>   <code>error</code>   <code>assert</code>   <code>MException</code>   <code>isequal(MException)</code>   <code>eq(MException)</code>   <code>getReport(MException)</code>   <code>disp(MException)</code>   <code>throw(MException)</code>   <code>rethrow(MException)</code>   <code>throwAsCaller(MException)</code>   <code>addCause(MException)</code>   <code>last(MException)</code>

# TriRep.neighbors

---

**Purpose** (Will be removed) Simplex neighbor information

---

**Note** `neighbors(TriRep)` will be removed in a future release. Use `neighbors(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `SN = neighbors(TR, SI)`

**Description** `SN = neighbors(TR, SI)` returns the simplex neighbor information for the specified simplices `SI`.

**Input Arguments**

`TR` Triangulation representation.

`SI` `SI` is a column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`. If `SI` is not specified the neighbor information for the entire triangulation is returned, where the neighbors associated with simplex `i` are defined by the `i`'th row of `SN`.

**Output Arguments**

`SN` `SN` is an `m`-by-`n` matrix, where `m = length(SI)`, the number of specified simplices, and `n` is the number of neighbors per simplex. Each row `SN(i,:)` represents the neighbors of the simplex `SI(i)`.

By convention, the simplex opposite vertex `(j)` of simplex `SI(i)` is `SN(i,j)`. If a simplex has one or more boundary facets, the nonexistent neighbors are represented by `NaN`.

## Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

## Examples

### Example 1

Load a 3-D triangulation and use `TriRep` to compute the neighbors of all tetrahedra.

```
load tetmesh
trep = TriRep(tet, X)
nbrs = neighbors(trep)
```

### Example 2

Query a 2-D triangulation created using `DelaunayTri`.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
```

Find the neighbors of the first triangle:

```
n1 = neighbors(dt, 1)
```

## Purpose

Summary of functions in MATLAB .NET interface

## Description

Use the following functions to bring assemblies from the Microsoft .NET Framework into the MATLAB environment. The functions are implemented as a package called NET. To use these functions, prefix the function name with package name NET.

BeginInvoke	Initiate asynchronous .NET delegate call
cell	Create cell array
Combine	Convenience function for static .NET System.Delegate Combine method
enableNETfromNetworkDrive	Enable access to .NET commands from network drive
EndInvoke	Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method
NET.addAssembly	Make .NET assembly visible to MATLAB
NET.Assembly	Members of .NET assembly
NET.convertArray	Convert numeric MATLAB array to .NET array
NET.createArray	Array for nonprimitive .NET types
NET.createGeneric	Create instance of specialized .NET generic type
NET.disableAutoRelease	Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

---

NET.enableAutoRelease	Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object
NET.GenericClass	Represent parameterized generic type definitions
NET.invokeGenericMethod	Invoke generic method of object
NET.isNETSupported	Check for supported Microsoft .NET Framework
NET.NetException	Capture error information for .NET exception
NET.setStaticProperty	Static property or field name
Remove	Convenience function for static .NET System.Delegate Remove method
RemoveAll	Convenience function for static .NET System.Delegate RemoveAll method

**How To**

- “.NET Libraries”

# NET.addAssembly

---

<b>Purpose</b>	Make .NET assembly visible to MATLAB
<b>Syntax</b>	<pre>asmInfo = NET.addAssembly(globalName) asmInfo = NET.addAssembly(privateName)</pre>
<b>Description</b>	<p><code>asmInfo = NET.addAssembly(globalName)</code> loads a global .NET assembly into MATLAB.</p> <p><code>asmInfo = NET.addAssembly(privateName)</code> loads a private .NET assembly.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• MATLAB dynamically loads the <code>mscorlib.dll</code> and <code>system.dll</code> assemblies from the .NET Framework class library the first time you type "NET." or "System.". You do not need to call <code>NET.addAssembly</code> to access classes in these assemblies.</li><li>• Refer to your .NET product documentation for the name of the assembly and its deployment type (global or private).</li></ul>
<b>Limitations</b>	<ul style="list-style-type: none"><li>• <code>NET.addAssembly</code> does not support assemblies generated by the MATLAB Builder NE product.</li></ul>
<b>Input Arguments</b>	<p><b>globalName</b></p> <p>One of the following:</p> <ul style="list-style-type: none"><li>• String representing the name of a global assembly.</li><li>• Instance of <code>System.Reflection.AssemblyName</code> class.</li></ul> <p><b>privateName</b></p> <p>String representing the full path of a private assembly.</p>
<b>Output Arguments</b>	<p><b>asmInfo</b></p> <p>NET.Assembly object containing names of the members of the assembly.</p>

## Examples

Display today's date using `System.DateTime` in the `mscorlib` assembly.

```
System.DateTime.Now.ToLongDateString
```

---

Call the `System.Windows.Forms.MessageBox.Show` method in the global assembly `System.Windows.Forms`.

```
asm = NET.addAssembly('System.Windows.Forms');  
import System.Windows.Forms.*;  
MessageBox.Show('Simple Message Box')
```

---

Display classes in the private assembly `NetSample.dll`.

```
asm = NET.addAssembly('c:\work\NetSample.dll');  
asm.Classes
```

## See Also

## How To

- [“An Assembly is a Library of .NET Classes”](#)

## Related Links

- [MSDN AssemblyName Class](#)

# NET.Assembly

---

<b>Purpose</b>	Members of .NET assembly
<b>Description</b>	NET.Assembly object returns names of the members of an assembly.
<b>Construction</b>	The NET.addAssembly function creates an instance of this class.
<b>Properties</b>	<b>AssemblyHandle</b> Instance of System.Reflection.Assembly class of the added assembly.
	<b>Classes</b> nClassx1 cell array of class names of the assembly, where nClass is the number of classes
	<b>Enums</b> nEnumx1 cell array of enums of the assembly, where nEnum is the number of enums
	<b>Structures</b> nStructx1 cell array of structures of the assembly, where nStruct is the number of structures
	<b>GenericTypes</b> nGenTypex1 cell array of generic types of the assembly, where nGenType is the number of generic types
	<b>Interfaces</b> nInterfacex1 cell array of interface names of the assembly, where nInterface is the number of interfaces
	<b>Delegates</b> nDelegatex1 cell array of delegates of the assembly, where nDelegate is the number of delegates
<b>Copy Semantics</b>	Handle. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.

**See Also**

`NET.addAssembly`

**How To**

- “What Classes Are in a .NET Assembly?”

# NET.convertArray

---

**Purpose** Convert numeric MATLAB array to .NET array

---

**Note** MATLAB automatically converts arrays to .NET types. For information, see “Using Arrays with .NET Applications”.

---

**Syntax** `arrObj = NET.convertArray(V, 'arrType', [m,n])`

**Description** `arrObj = NET.convertArray(V, 'arrType', [m,n])` converts a MATLAB array `V` to a .NET array. Optional value `arrType` is a string representing a namespace-qualified .NET array type. Use optional values `m,n` to convert a MATLAB vector to a two-dimensional .NET array (either 1-by-`n` or `m`-by-1). If `V` is a MATLAB vector and you do not specify the number of dimensions and their sizes, the output `arrObj` is a one-dimensional .NET array.

If you do not specify `arrType`, MATLAB converts the type according to the MATLAB Primitive Type Conversion Table. See “Pass Primitive .NET Types”.

**Examples** Create a list `aList` of random `System.Int32` integers using the `System.Collections.Generic.List` class, and then sort the results:

```
%Create array R of random integers
nInt = 5;
R = randi(100,1,nInt);
%Create .NET array A
A = NET.convertArray(R, 'System.Int32');
%Put A into aList, a generic collections list
aList = NET.createGeneric(...
    'System.Collections.Generic.List',...
    {'System.Int32'},A.Length);
aList.AddRange(A);
%Sort the values in aList
aList.Sort;
```

## See Also

`NET.createArray`

# NET.createArray

---

**Purpose** Array for nonprimitive .NET types

**Syntax**  
array = NET.createArray(typeName,[m,n,p,...])  
array = NET.createArray(typeName,m,n,p,...)

**Description** array = NET.createArray(typeName,[m,n,p,...]) creates an m-by-n-by-p-by-... array of type typeName, which is either a fully qualified .NET array type name (namespace and array type name) or an instance of the NET.GenericClass class, in case of arrays of generic type. m,n,p,... are the number of elements in each dimension of the array.

array = NET.createArray(typeName,m,n,p,...) alternative syntax for creating an array.

You cannot specify the lower bound of an array.

## Examples

### Create .NET Array of Generic Type

This example creates a .NET array of List<Int32> generic type.

```
genType = NET.GenericClass('System.Collections.Generic.List',...  
    'System.Int32');  
arr = NET.createArray(genType, 5)
```

```
arr =
```

```
List<System*Int32>[] with properties:
```

```
    Length: 5  
    LongLength: 5  
    Rank: 1  
    SyncRoot: [1x1 System.Collections.Generic.List<System*Int32>[]]  
    IsReadOnly: 0  
    IsFixedSize: 1  
    IsSynchronized: 0
```

## Create and Initialize Jagged Array

This example creates a jagged .NET array of 3 elements.

```
jaggedArray = NET.createArray('System.Double[]', 3)
```

```
jaggedArray =
```

```
    Double[][] with properties
```

```
        Length: 3
        LongLength: 3
        Rank: 1
        SyncRoot: [1x1 System.Double[][]]
        IsReadOnly: 0
        IsFixedSize: 1
        IsSynchronized: 0
```

Assign values:

```
jaggedArray(1) = [1, 3, 5, 7, 9];
jaggedArray(2) = [0, 2, 4, 6];
jaggedArray(3) = [11, 22];
```

Access first value of 3rd array:

```
jaggedArray(3,1)
```

```
ans =
    11
```

## Create Jagged Array of Generic Type

This example creates a jagged array of List<Double> generic type.

```
genCls = NET.GenericClass('System.Collections.Generic.List[]',...
    'System.Double');
```

Create the array, genArr.

# NET.createArray

---

```
genArr = NET.createArray(genCls,3)

genArr =

List<System*Double>[[]] with properties:

    Length: 3
    LongLength: 3
    Rank: 1
    SyncRoot: [1x1 System.Collections.Generic.List`1[[]]]
    IsReadOnly: 0
    IsFixedSize: 1
    IsSynchronized: 0
```

## Create Nested Jagged Array

This command creates a jagged array of type `System.Double[[][]]`.

```
netArr = NET.createArray('System.Double[[][]]', 3)
```

```
netArr =

Double[[][]] with properties:

    Length: 3
    LongLength: 3
    Rank: 1
    SyncRoot: [1x1 System.Double[[][]]]
    IsReadOnly: 0
    IsFixedSize: 1
    IsSynchronized: 0
```

## See Also

[NET.convertArray](#) | [NET.createGeneric](#)

**Purpose**

Create instance of specialized .NET generic type

**Syntax**

```
genObj = createGeneric(className,paramTypes,  
    varargin ctorArgs)
```

**Description**

genObj = createGeneric(className,paramTypes, varargin ctorArgs) creates an instance genObj of generic type className.

**Input Arguments**

className	Fully qualified string with the generic type name.
paramTypes	Allowed cell types are: strings with fully qualified parameter type names and instances of the NET.GenericClass class when parameterization with another parameterized type is needed.
ctorArgs	Optional, variable length (0 to N) list of constructor arguments matching the arguments of the .NET generic class constructor intended to be invoked.

**Output Arguments**

genObj	Handle to the specialized generic class instance.
--------	---------------------------------------------------

**Examples****Create a List of System.Double Objects**

Create a strongly typed list dblLst of objects of type System.Double:

```
t = NET.createGeneric('System.Collections.Generic.List',...  
    {'System.Double'},10);
```

# NET.createGeneric

---

## Create a List with Key/Value Pairs

Create the kvpType generic association where Key is of System.Int32 type and Value is a System.String:

```
kvpType = NET.GenericClass('System.Collections.Generic.KeyValuePair',...  
    'System.Int32', 'System.String');
```

Create the list kvpList with initial storage capacity for 10 key-value pairs:

```
st = NET.createGeneric('System.Collections.Generic.List',...  
    {kvpType}, 10);
```

## Add an Item to the List

Create a KeyValuePair item.

```
kvpItem = NET.createGeneric('System.Collections.Generic.KeyValuePair',...  
    {'System.Int32', 'System.String'}, 42, 'myString');
```

Add this item to the list kvpList.

```
kvpList.Add(kvpItem);
```

## See Also

NET.GenericClass

## Purpose

Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

## Syntax

```
A = NET.disableAutoRelease(obj)
```

## Description

A = NET.disableAutoRelease(obj) locks a .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release the COM object. obj is a .NET object representing a COM Wrapper.

Before passing a .NET object representing a COM Wrapper to another process, lock the object using this function so that MATLAB does not release it. After using the object, call NET.enableAutoRelease to release the COM object.

## Examples

The following user-defined function, GetComApp.m, has access to a COM object defined in the **pseudo-class** ComNamespace.ComClass. One of its methods is readData, with the signature:

```
System.String RetVal readData(ComNamespace.ComClass this, System.String strIn)
```

The input argument is defined in the **pseudo-class** NetDocTest.MyClass, which has a property named MyApp.

```
function GetComApp(obj)
comObj = ComNamespace.ComClass;
obj.MyApp = comObj;
% To pass a COM object to another process, lock the object
NET.disableAutoRelease(comObj);
end
```

The example in NET.enableAutoRelease shows how to call the GetComApp function.

## See Also

NET.enableAutoRelease

## How To

- “How MATLAB Handles System.\_\_ComObject”

# NET.enableAutoRelease

---

**Purpose** Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object

**Syntax** A = NET.enableAutoRelease(obj)

**Description** A = NET.enableAutoRelease(obj) releases the COM wrapper when the object goes out of scope, where obj is a .NET object representing a COM Wrapper.

Call this function only if the object was locked using NET.disableAutoRelease.

**Examples** The following **pseudo-code** shows how to call a function (GetComApp.m, described in NET.disableAutoRelease) which returns a COM object. The object, mainObj of type NetDocTest.MyClass, has a property, MyApp. Call GetComApp to get a COM object, and use its readData method.

```
mainObj = NetDocTest.MyClass;
GetComApp(mainObj);
app = mainObj.MyApp;
app.readData('hello');
% Unlock the COM object
NET.enableAutoRelease(mainObj.MyApp);
```

**See Also** NET.disableAutoRelease

**How To** • “How MATLAB Handles System.\_\_ComObject”

<b>Purpose</b>	Represent parameterized generic type definitions
<b>Description</b>	Instances of this class are used by the <code>NET.createGeneric</code> function when creation of generic specialization requires parameterization with another parameterized type.
<b>Construction</b>	<code>genType = NET.GenericClass (className, paramTypes)</code>
	<b>Input Arguments</b>
	<b>className</b> Fully qualified string containing the generic type name.
	<b>paramTypes</b> Optional, variable length (1 to N) list of types for the generic class parameterization. Allowed argument types are: <ul style="list-style-type: none"><li>• Fully qualified string containing the generic type name.</li><li>• Instance of the <code>NET.GenericClass</code> class when deeper nested parameterization with another parameterized type is needed.</li></ul>
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.
<b>Examples</b>	Create an instance of <code>System.Collections.Generic.List</code> of <code>System.Collections.Generic.KeyValuePair</code> generic associations where <code>Key</code> is of <code>System.Int32</code> type and <code>Value</code> is a <code>System.String</code> class with initial storage capacity for 10 key-value pairs. <pre>kvpType = NET.GenericClass(...     'System.Collections.Generic.KeyValuePair',...     'System.Int32', 'System.String'); kvpList = NET.createGeneric('System.Collections.Generic.List',...     { kvpType }, 10);</pre>
<b>See Also</b>	<code>NET.createGeneric</code>   <code>NET.createArray</code>   <code>NET.invokeGenericMethod</code>

# NET.GenericClass

---

## How To

- “.NET Generic Classes”

**Purpose**

Invoke generic method of object

**Syntax**

```
[varargout] = NET.invokeGenericMethod(obj,  
    'genericMethodName', paramTypes, args, ...)
```

**Description**

[varargout] = NET.invokeGenericMethod(obj, 'genericMethodName', paramTypes, args, ...) calls instance or static generic method *genericMethodName*.

**Input Arguments**

obj

Allowed argument types are:

- Instances of class containing the generic method
- Strings with fully qualified class name, if calling static generic methods
- Instances of NET.GenericClass definitions, if calling static generic methods of a generic class

*genericMethodName*

Generic method name to invoke

paramTypes

Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are:

- Strings with fully qualified parameter type name.
- Instances of NET.GenericClass definitions, if using nested parameterization with another parameterized type

args

Optional, variable length (0 to N) list of method arguments

# NET.invokeGenericMethod

---

## Output Arguments

varargout      Variable-length output argument list, varargout, from method *genericMethodName*

## Examples

Use the following syntax to call a generic method that takes two parameterized types and returns a parameterized type:

```
a = NET.invokeGenericMethod(obj, ...  
    'myGenericSwapMethod', ...  
    {'System.Double', 'System.Double'}, ...  
    5, 6);
```

---

To display generic methods in MATLAB, see the example “Display .NET Generic Methods Using Reflection”.

## How To

- “Call .NET Generic Methods”

**Purpose** Check for supported Microsoft .NET Framework

**Syntax** `tf = NET.isNETSupported`

**Description** `tf = NET.isNETSupported` returns logical 1 (true) if a supported version of the Microsoft .NET Framework is found. Otherwise, it returns logical 0 (false).

# NET.NetException

---

<b>Purpose</b>	Capture error information for .NET exception
<b>Description</b>	Process information from a NET.NetException object to handle .NET errors. This class is derived from MException.
<b>Construction</b>	<code>e = NET.NetException(msgID, errMsg, netObj)</code> constructs instance <code>e</code> of NET.NetException class.
<b>Input Arguments</b>	<b>msgID</b> message identifier <b>errMsg</b> error message string <b>netObj</b> System.Exception object that caused the exception
<b>Properties</b>	<b>ExceptionObject</b> System.Exception class causing the error.
<b>Methods</b>	<b>Inherited Methods</b> See the methods of the base class MException.
<b>Copy Semantics</b>	Handle. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.
<b>Examples</b>	Display error information after trying to load an unknown assembly: <pre>try NET.addAssembly('C:\Work\invalidfile.dll') catch e e.message; if(isa(e, 'NET.NetException')) eObj = e.ExceptionObject</pre>

```
end  
end
```

MATLAB displays:

```
ans =  
Message: Could not load file or assembly  
         'file:///C:\Work\invalidfile.dll' or  
         one of its dependencies. The system cannot  
         find the file specified.

## How To

- Class Attributes
- Property Attributes

# NET.setStaticProperty

---

**Purpose** Static property or field name

**Syntax** `NET.setStaticProperty('propName', value)`

**Description** `NET.setStaticProperty('propName', value)` sets the static property or field name specified in the string `propName` to the given value.
