**Examples** To set the `myStaticProperty` in the given class and namespace, use the syntax:

```
NET.setStaticProperty('MyTestObject.MyClass.myStaticProperty', 5);
```

<b>Purpose</b>	Create variable in NetCDF file
<b>Syntax</b>	<code>nccreate(filename,varname)</code> <code>nccreate(filename,varname,Name,Value)</code>
<b>Description</b>	<p><code>nccreate(filename,varname)</code> creates a scalar double variable named <code>varname</code> in the NetCDF file <code>filename</code>. If <code>filename</code> does not exist, <code>nccreate</code> creates the file using the <code>netcdf4_classic</code> format. To create a nonscalar variable, use the <code>Dimensions</code> argument.</p> <p><code>nccreate(filename,varname,Name,Value)</code> creates a variable named <code>varname</code> with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>filename</b></p> <p>Text string specifying a NetCDF file, or the name you want to assign to a new NetCDF file.</p> <p><b>varname</b></p> <p>Text string specifying the name you want to assign to a variable in a NetCDF file.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>'Dimensions'</b></p> <p>Cell array specifying dimensions for the variable in the NetCDF file. The cell array lists the dimension name as a string followed by its numerical length: <code>{dname1,dlength1,dname2,dlength2,...}</code>. If a dimension exists, specifying its length is optional. Use <code>Inf</code> to specify an unlimited dimension.</p>

All formats other than `netcdf4` format files can have only one unlimited dimension per file and it has to be the last in the list specified. A `netcdf4` format file can have any number of unlimited dimensions in any order.

A single-dimension variable is always treated as a column vector.

## 'Datatype'

Text string specifying a MATLAB data type. When `nccreate` creates the variable in the NetCDF file, it uses a corresponding NetCDF datatype. The following table describes how MATLAB datatypes map to NetCDF datatypes.

<b>MATLAB Data Type</b>	<b>Corresponding NetCDF Variable Type</b>
<code>double</code>	<code>NC_DOUBLE</code>
<code>single</code>	<code>NC_FLOAT</code>
<code>int64</code>	<code>NC_INT64*</code>
<code>uint64</code>	<code>NC_UINT64*</code>
<code>int32</code>	<code>NC_INT</code>
<code>uint32</code>	<code>NC_UINT*</code>
<code>int16</code>	<code>NC_SHORT</code>
<code>uint16</code>	<code>NC_USHORT*</code>
<code>int8</code>	<code>NC_BYTE</code>
<code>uint8</code>	<code>NC_UBYTE*</code>
<code>char</code>	<code>NC_CHAR</code>

\* These data types are only available when the file is a `netcdf4` format file.

## 'Format'

Text string specifying the type of NetCDF file you want to create.

Format String	Description
classic	NetCDF 3
64bit	NetCDF 3, with 64-bit offsets
netcdf4_classic	NetCDF 4 classic model
netcdf4	NetCDF 4 model (Use this to enable group hierarchy)

If varname specifies a group (e.g., '/grid3/temperature'), nccreate sets the value of format to 'netcdf4'.

**Default:** netcdf4\_classic

#### **'FillValue'**

A scalar specifying the value to use for missing values. To disable fill values, set FillValue to the text string 'disable'. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Value specified by the NetCDF library

#### **'ChunkSize'**

Vector specifying the size of the chunk along each dimension, [num\_rows,num\_cols,..., num\_ndims]. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Set by the NetCDF library

#### **'DeflateLevel'**

Numeric value between 0 (least) and 9 (most) specifying the compression setting for the deflate filter, or the text string disable. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Disabled

## **'Shuffle'**

Boolean flag to turn on the shuffle filter. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** False

## **Examples**

Create a new 2-D variable in a classic format file. Write data to this variable

```
nccreate('myncclassic.nc', 'peaks', ...
        'Dimensions', {'r' 200 'c' 200}, ...
        'Format', 'classic');
ncwrite('myncclassic.nc', 'peaks', peaks(200));
ncdisp('myncclassic.nc');
```

## **See Also**

## **Tutorials**

- “Exporting to Network Common Data Form (NetCDF) Files”

**Purpose** Display contents of NetCDF data source in Command Window

**Syntax**  
ncdisp(source)  
ncdisp(source,location)  
ncdisp(source,location,dispFormat)

**Description** ncdisp(source) displays all the groups, dimensions, variable definitions, and all attributes in the NetCDF data source, source, as text in the Command Window.

ncdisp(source,location) displays information about the variable or group specified by location.

ncdisp(source,location,dispFormat) displays the contents of the NetCDF data source, in the display format specified by dispFormat.

## Input Arguments

### **source - Name of NetCDF file**

string

Name of a NetCDF file, specified as a string. source also can be the URL of an OPeNDAP NetCDF data source that resolves to a NetCDF file or a variable in a NetCDF file.

**Example:** 'myNetCDFfile.nc'

### **Data Types**

char

### **location - Location of variable or group**

'/' (default) | string

Location of a variable or group in the NetCDF file, specified as a string. Set location to '/' (forward slash) to display the entire contents of the file.

### **Data Types**

char

## dispFormat - Display format

'full' (default) | 'min'

Display format, specified as one of the following strings.

'full'	Display group hierarchy with dimensions, attributes, and variable definitions.
'min'	Display group hierarchy and variable definitions.

## Data Types

char

## Examples

### Display Contents of NetCDF File

Display the contents of the example NetCDF file, `example.nc`.

```
ncdisp('example.nc')
```

Source:

```
matlabroot\toolbox\matlab\demos\example.nc
```

Format:

```
netcdf4
```

Global Attributes:

```
creation_date = '29-Mar-2010'
```

Dimensions:

```
x = 50
```

```
y = 50
```

```
z = 5
```

Variables:

```
avagadros_number
```

```
Size: 1x1
```

```
Dimensions:
```

```
Datatype: double
```

```
Attributes:
```

```
description = 'this variable has no dimensions'
```

```
temperature
```

```
Size: 50x1
```

```
Dimensions: x
```

```

    Datatype:  int16
    Attributes:
                scale_factor = 1.8
                add_offset   = 32
                units        = 'degrees_fahrenheit'
peaks
    Size:      50x50
    Dimensions: x,y
    Datatype:  int16
    Attributes:
                description = 'z = peaks(50);'
Groups:
  /grid1/
    Attributes:
                description = 'This is a group attribute.'
    Dimensions:
        x      = 360
        y      = 180
        time = 0      (UNLIMITED)
    Variables:
        temp
                Size:      []
                Dimensions: x,y,time
                Datatype:  int16

  /grid2/
    Attributes:
                description = 'This is another group attribute.'
    Dimensions:
        x      = 360
        y      = 180
        time = 0      (UNLIMITED)
    Variables:
        temp
                Size:      []
                Dimensions: x,y,time
                Datatype:  int16
```

MATLAB displays all the groups, dimensions, and variable definitions in `example.nc`.

## Display Contents of NetCDF Variable

Display the contents of the variable `peaks` in the file, `example.nc`.

```
ncdisp('example.nc','peaks')
```

Source:

```
matlabroot\toolbox\matlab\demos\example.nc
```

Format:

```
netcdf4
```

Dimensions:

```
x = 50
```

```
y = 50
```

Variables:

```
peaks
```

```
Size:      50x50
```

```
Dimensions: x,y
```

```
Datatype:  int16
```

```
Attributes:
```

```
description = 'z = peaks(50);'
```

## Display Contents of NetCDF File and Hide Attributes

Display only the group hierarchy and variable definitions of the example file, `example.nc`.

```
ncdisp('example.nc','/','min')
```

Source:

```
matlabroot\toolbox\matlab\demos\example.nc
```

Format:

```
netcdf4
```

Variables:

```
avagadros_number
```

```
Size:      1x1
```

```
Dimensions:
```

```
Datatype:  double
```

```

    temperature
      Size:      50x1
      Dimensions: x
      Datatype:  int16
    peaks
      Size:      50x50
      Dimensions: x,y
      Datatype:  int16
Groups:
  /grid1/
    Variables:
      temp
      Size:      []

      Datatype:  int16

  /grid2/
    Variables:
      temp
      Size:      []
      Dimensions: x,y,time
      Datatype:  int16

```

**Tips**

- If source is an OPeNDAP URL with string constraints, use the syntax, `ncdisp(source)` with no other input arguments.

**See Also**

`ncwrite` | `ncinfo` | `ncread` | `netcdf` | `ncreadatt`

**Concepts**

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

# ncinfo

---

**Purpose** Return information about NetCDF data source

**Syntax**

```
finfo = ncinfo(source)
vinfo = ncinfo(source,varname)
ginfo = ncinfo(source,groupname)
```

**Description**

`finfo = ncinfo(source)` returns information in the structure `finfo` about the entire NetCDF data source specified by `source`, where `source` can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

`vinfo = ncinfo(source,varname)` returns information in the structure `vinfo` about the variable `varname` in `source`.

`ginfo = ncinfo(source,groupname)` returns information in the structure `ginfo` about the group `groupname` in `source` (only NetCDF4 data sources).

---

**Note** Use `ncdisp` for visual inspection of a NetCDF source.

---

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **varname**

Text string specifying the name of a variable in a NetCDF file or OPeNDAP data source.

### **groupname**

Text string specifying the name of a group in a NetCDF file or OPeNDAP data source.

## Output Arguments

### finfo

A structure with the following fields.

Field	Description	
Filename	NetCDF file name or OPeNDAP URL	
Name	' / ', indicating the full file	
Dimensions	An array of structures with these fields:	
	Name	Dimension name
	Length	Current length of dimension
	Unlimited	Boolean flag, true for unlimited dimensions
Variables	An array of structures with these fields:	
	Name	Variable name
	Dimensions	Associated dimensions
	Size	Current variable size
	Datatype	MATLAB datatype
	Attributes	Associated variable attributes
	ChunkSize	Chunk size, if defined. [ ] otherwise
	FillValue	Fill value of the variable.
	DeflateLevel	Deflate filter level, if enabled.
	Shuffle	Shuffle filter enabled flag
Attributes	An array of global attributes with these fields:	
	Name	Attribute name
	Value	Attribute value

Field	Description	
Groups	An array of groups present in the file, for netcdf4 files; An empty array ([]) for all other NetCDF file formats.	
Format	The format of the NetCDF file	

## **vinfo**

A structure containing only the variable fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the variable
Dimensions	Dimensions of the variable
Size	Size of the current variable
Datatype	MATLAB datatype
Attributes	Attributes associated with the variable
ChunkSize	Chunk size, if defined. [] otherwise.
FillValue	Fill value used in the variable.
DeflateLevel	Deflate filter level, if enabled.
Shuffle	Shuffle filter enabled flag
Format	The format of the NetCDF file

## **ginfo**

A structure containing only the group fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the group

Field	Description
Dimensions	Only dimensions defined in the specified group
Variables	Only variables defined in the specified group
Attributes	Attributes associated with the variable
Groups	Names of groups, if defined. [] otherwise.
Format	The format of the NetCDF file

## Examples

Search for dimensions with names that start with the character x in the file.

```

finfo = ncinfo('example.nc');
disp(finfo);
dimNames = {finfo.Dimensions.Name};
dimMatch = strncmpi(dimNames,'x',1);
disp(finfo.Dimensions(dimMatch));

```

Obtain the size of a variable and check if it has any unlimited dimensions.

```

vinfo = ncinfo('example.nc','peaks');
varSize = vinfo.Size;
disp(vinfo);
hasUnLimDim = any([vinfo.Dimensions.Unlimited]);

```

Find all unlimited dimensions defined in a group.

```

ginfo = ncinfo('example.nc','/grid2/');
unlimDims = [ginfo.Dimensions.Unlimited];
disp(ginfo.Dimensions(unlimDims));

```

**Tutorials**

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

---

<b>Purpose</b>	Read data from variable in NetCDF data source
<b>Syntax</b>	<pre>vardata = ncread(source,varname) vardata = ncread(source,varname,start,count,stride)</pre>
<b>Description</b>	<p><code>vardata = ncread(source,varname)</code> reads data from the variable <code>varname</code> in <code>source</code>, which can be either the name of a NetCDF file or an OPeNDAP NetCDF data source.</p> <p><code>vardata = ncread(source,varname,start,count,stride)</code> reads data from the variable <code>varname</code> in <code>source</code> beginning at the location given by <code>start</code>. <code>count</code> specifies the number of elements to read along the corresponding dimension. The optional argument <code>stride</code> specifies the inter-element spacing along each dimension.</p>
<b>Input Arguments</b>	<p><b>source</b></p> <p>Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.</p> <p><b>varname</b></p> <p>Text string specifying the name of a variable in the NetCDF file or OPeNDAP NetCDF data source.</p> <p><b>start</b></p> <p>For an <math>N</math>-dimensional variable, <code>start</code> is a vector of length <math>N</math> of indices specifying the starting location. Indices are 1-based.</p> <p><b>count</b></p> <p>Vector of length <math>N</math> specifying the number of elements to read along the corresponding dimensions. If a particular element of <code>count</code> is <code>Inf</code>, <code>ncread</code> reads data until the end of the corresponding dimension.</p> <p><b>stride</b></p>

Optional argument that specifies the inter-element spacing along each dimension.

**Default:** Vector of 1s (ones)

## Output Arguments

### **vardata**

The data in the variable. `ncread` uses the MATLAB datatype that is the closest type to the corresponding NetCDF datatype, except when at least one of `_FillValue`, `scale_offset`, and `add_offset` variables attribute is present. `ncread` applies the following attribute conventions, in sequence, to `vardata` if the corresponding attribute exists for this variable:

- If the `_FillValue` attribute exists, `ncread` replaces values in `vardata` equal to the value of `_FillValue` with NaNs. If the `_FillValue` attribute does not exist, `ncread` queries the NetCDF library for the variable's fill value.
- If the `scale_factor` attribute exists, `ncread` multiplies `vardata` by the value of the `scale_factor` attribute.
- If the `add_offset` attribute exists, `ncread` adds the value of the `add_offset` attribute to `vardata`.

## Examples

Read and display the data in the `peaks` variable in the example file.

```
ncdisp('example.nc','peaks');  
peaksData = ncread('example.nc','peaks');  
peaksDesc = ncreadatt('example.nc','peaks','description');  
surf(double(peaksData));  
title(peaksDesc);
```

---

Subsample the `peaks` data by a factor of 2 (read every other value along each dimension).

```
subsetdata = ncread('example.nc','peaks',...  
                  [1 1], [Inf Inf], [2 2]);
```

```
surf(double(subsetdata));
```

**Tutorials**

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

# ncreadatt

---

**Purpose** Read attribute value from NetCDF data source

**Syntax** `attvalue = ncreadatt(source,location,attname)`

**Description** `attvalue = ncreadatt(source,location,attname)` reads the attribute `attname` from the group or variable specified by `location` in `source`, where `source` is the name of a NetCDF file or the URL of a NetCDF data source.

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **location**

Text string specifying a group or variable in the NetCDF data source. To read global attributes, set `location` to `'/'` (forward slash).

### **attname**

Text string specifying the name of an attribute that you want to read in the NetCDF data source.

## Output Arguments

### **attvalue**

Data associated with the attribute.

## Examples

Read a global attribute.

```
creation_date = ncreadatt('example.nc','/','creation_date');  
disp(creation_date);
```

---

Read an attribute associated with a variable.

```
scale_factor = ncreadatt('example.nc','temperature','scale_factor');  
disp(scale_factor);
```

---

Read an attribute associated with a group (netcdf4 format files only).

```
desc_value = ncreadatt('example.nc', '/grid2', 'description');  
disp(desc_value);
```

## See Also

`ncdisp` | `ncinfo` | `ncread` | `netcdf` | `ncwriteatt`

## Tutorials

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

# ncwrite

---

## Purpose

Write data to NetCDF file

## Syntax

```
ncwrite(filename,varname,vardata)
ncwrite(filename,varname,vardata,start, stride)
```

## Description

`ncwrite(filename,varname,vardata)` writes the numerical or char data in `vardata` to an existing variable `varname` in the NetCDF file `filename`. `ncwrite` writes the data in `vardata` starting at the beginning of the variable and extends unlimited dimensions automatically, if needed.

If the NetCDF file or the variable do not exist, use `nccreate` to create them first.

`ncwrite(filename,varname,vardata,start, stride)` writes `vardata` to an existing variable `varname` in file `filename` beginning at the location given by `start`. `stride` is an optional argument that specifies the inter-element spacing of the data written. Use this syntax to append data to an existing variable or write partial data.

## Tips

- If the variable `varname` already exists, `ncwrite` expects the datatype of `vardata` to match the NetCDF variable data type.
- If the variable `varname` has a `_FillValue`, `scale_factor` or `add_offset` attribute, `ncwrite` expects data in double format and casts `vardata` to the NetCDF data type, after applying the following attribute conventions in sequence:
  - 1 Subtract the value of the `add_offset` attribute from `vardata`.
  - 2 Divide `vardata` by the value of the `scale_factor` attribute.
  - 3 Replace NaNs in `vardata` by the value of the `_FillValue` attribute. If this attribute does not exist, `ncwrite` tries to use the fill value for this variable as reported by the NetCDF library.

## Input Arguments

### **filename**

Text string specifying the name of a NetCDF file. If the file does not exist, use `nccreate` to create it first.

**varname**

Text string specifying the name of a variable in a NetCDF file. If the variable does not exist, use `nccreate` to create it first.

**vardata**

Data to write to the variable in the NetCDF file.

**start**

For an  $N$ -dimensional variable, `start` is a vector of indices of length  $N$  specifying the starting location. Indices are 1-based.

**stride**

(Optional) Vector of length  $N$ , specifying the inter-element spacing.

**Default:** Vector of ones

## Examples

Create a new `netcdf4_classic` file, and write a scalar variable with no dimensions. Add the creation time as a global attribute.

```
nccreate('myfile.nc', 'pi');
ncwrite('myfile.nc', 'pi', 3.1);
ncwriteatt('myfile.nc', '/', 'creation_time', datestr(now));
% overwrite existing data
ncwrite('myfile.nc', 'pi', 3.1416);
ncdisp('myfile.nc');
```

Create a `netcdf4_classic` file with a variable defined on an unlimited dimension. Write data incrementally to the variable.

```
nccreate('mynctest.nc', 'vmark', ...
        'Dimensions', {'time', inf, 'cols', 6}, ...
        'ChunkSize', [3 3], ...
        'DeflateLevel', 2);
ncwrite('mynctest.nc', 'vmark', eye(3), [1 1]);
```

# ncwrite

---

```
varData = ncread('myncfile.nc','vmark');  
disp(varData);  
ncwrite('myncfile.nc','vmark',fliplr(eye(3)),[1 4]);  
varData = ncread('myncfile.nc','vmark');  
disp(varData);
```

## Tutorials

- “Exporting to Network Common Data Form (NetCDF) Files”

---

<b>Purpose</b>	Write attribute to NetCDF file
<b>Syntax</b>	<code>ncwriteatt(filename,location,attname,attvalue)</code>
<b>Description</b>	<code>ncwriteatt(filename,location,attname,attvalue)</code> creates or modifies the attribute specified by <code>attname</code> in the group or variable specified by <code>location</code> , in the NetCDF file specified by <code>filename</code> . <code>attvalue</code> can be a numeric vector or a string.
<b>Input Arguments</b>	<p><b>filename</b> Text string specifying the name of a NetCDF file</p> <p><b>location</b> Text string specifying a group or variable in the NetCDF file. To write global attributes, set <code>location</code> to <code>'/'</code> (forward slash).</p> <p><b>attname</b> Text string specifying the name of an existing attribute in a NetCDF file or the name of the attribute that you want to create.</p> <p><b>attvalue</b> Numeric vector or a string.</p>
<b>Examples</b>	<p>Create a global attribute.</p> <pre>copyfile(which('example.nc'),'myfile.nc'); fileattrib('myfile.nc','+w'); ncdisp('myfile.nc'); ncwriteatt('myfile.nc','/','creation_date',datestr(now)); ncdisp('myfile.nc');</pre> <hr/> <p>Modify an existing attribute.</p>

# ncwriteatt

---

```
copyfile(which('example.nc'),'myfile.nc');  
fileattrib('myfile.nc','+w');  
ncdisp('myfile.nc','peaks');  
ncwriteatt('myfile.nc','peaks','description','Output of PEAKS');  
ncdisp('myfile.nc','peaks');
```

## Tutorials

- “Exporting to Network Common Data Form (NetCDF) Files”

**Purpose**

Add NetCDF schema definitions to NetCDF file

**Syntax**

```
ncwritschema(filename,schema)
```

**Description**

`ncwritschema(filename,schema)` creates or adds attributes, dimensions, variable definitions and group structure defined in `schema` to the file `filename`.

Use `ncwritschema` in combination with `ncinfo` to create a new NetCDF file based on the schema of an existing file. You can also use `ncwritschema` to add variable definitions, attributes, dimensions, or group structure to an existing file.

---

**Note** `ncwritschema` does not write variable data. Use `ncwrite` to write data to the created variables. Created unlimited dimensions will have an initial size of 0 until you write data.

---

---

**Note** `ncwritschema` cannot change the format of an existing file. It cannot redefine existing variables and dimensions in `filename`. If your schema contains attributes, dimensions, variable definitions, or a group structure that already exist in the file, `writschema` issues a warning but continues processing.

---

**Input Arguments****filename**

Text string specifying the name of a NetCDF file. If `filename` does not exist, `ncwritschema` creates a new file using the `netcdf4_classic` format, unless the `Format` field in `schema` specifies another format.

**schema**

A structure, or array of structures, representing either a dimension, variable, an entire NetCDF file, or a `netcdf4` group. A group or file schema can contain a dimension or variable schema, or both. You can

# ncwritschema

---

use the output returned by `ncinfo` as a schema structure. The following table lists the fields in the various types of schema structures. Optional fields are marked with asterisk (\*).

Schema Type	Structure Field	Description
Group/File Schema	Name	Text string identifying the group name. Use '/' to indicate the entire file.
	Dimensions*	Dimension schema
	Variables*	Variable schema
	Attributes*	Structure array of group/global attributes with Name and Value fields
	Format*	Text string identifying a NetCDF file format
Dimension schema	Name	Text string identifying the dimension
	Length	Length of the dimension. Can be Inf.
	Unlimited*	Boolean flag indicating if the dimension is unlimited
	Format*	Text string identifying a NetCDF file format
Variable schema	Name	Text string identifying a variable name
	Dimensions	Variable's dimension schema
	Datatype	Text string identifying a MATLAB datatype
	Attributes*	Structure array of variable attributes with Name and Value fields

Schema Type	Structure Field	Description
	ChunkSize*	Numeric value specifying chunk size of the variable
	FillValue*	Character or numeric fill value
	DeflateValue*	Deflate compression level
	Shuffle*	Boolean flag to turn on the Shuffle filter
	Format*	Text string identifying a NetCDF file format

## Examples

Create a classic format file with two dimension definitions.

```
mySchema.Name = '/';
mySchema.Format = 'classic';
mySchema.Dimensions(1).Name = 'time';
mySchema.Dimensions(1).Length = Inf;
mySchema.Dimensions(2).Name = 'rows';
mySchema.Dimensions(2).Length = 10;
ncwritescema('emptyFile.nc', mySchema);
ncdisp('emptyFile.nc');
```

Create a netcdf4\_classic format file to store a single variable from an existing file. First use ncinfo to get the schema of the peaks variable from the file. Then use ncwritescema to create a NetCDF file, defining the peaks variable. Use ncread to get the data associated with the peaks variable and then use ncwrite to write the data to the variable in the new NetCDF file.

```
myVarSchema = ncinfo('example.nc', 'peaks');
ncwritescema('peaksFile.nc', myVarSchema);
peaksData = ncread('example.nc', 'peaks');
ncwrite('peaksFile.nc', 'peaks', peaksData);
ncdisp('peaksFile.nc');
```

# ncwritschema

---

## **Tutorials**

- “Exporting to Network Common Data Form (NetCDF) Files”

**Purpose** Summary of MATLAB Network Common Data Form (NetCDF) capabilities

**Description** MATLAB provides both high- and low-level access to NetCDF files:

- High-level access functions make it easy to read a data set from a NetCDF file or write a variable from the MATLAB workspace into a NetCDF file
- Low-level access functions provide interfaces to dozens of functions in the NetCDF library

---

**Note** For information about MATLAB support for the Common Data Format (CDF), which is a completely separate and incompatible format, see `cdflib`.

---

### High-Level Access

These functions provide high-level access to NetCDF files.

<code>nccreate</code>	Create variable in NetCDF file
<code>ncinfo</code>	Return information about NetCDF data source
<code>ncread</code>	Read data from variable in NetCDF data source
<code>ncreadatt</code>	Read attribute value from NetCDF data source
<code>ncwrite</code>	Write data to NetCDF file
<code>ncwriteatt</code>	Write attribute to NetCDF file
<code>ncwritschema</code>	Add NetCDF schema definitions to NetCDF file

## Low-Level Access

The MATLAB low-level functions provide an API that you can use to enable reading data from and writing data to NetCDF files (known as *data sets* in NetCDF terminology). To use these functions, you should be familiar with the information about NetCDF contained in the [NetCDF C Interface Guide](#).

MATLAB supports NetCDF version 4.1.3.

In most cases, the syntax of the MATLAB function matches the syntax of the NetCDF library function. The functions are implemented as a package called `netcdf`. To use these functions, prefix the function name with package name `netcdf`. For example, to call the NetCDF library routine used to open existing NetCDF files, use the following MATLAB syntax:

```
ncid = netcdf.open(ncfile, mode);
```

## Library Functions

<code>netcdf</code>	Summary of MATLAB Network Common Data Form (NetCDF) capabilities
<code>netcdf.getChunkCache</code>	Retrieve chunk cache settings for NetCDF library
<code>netcdf.inqLibVers</code>	Return NetCDF library version information
<code>netcdf.setChunkCache</code>	Set default chunk cache settings for NetCDF library
<code>netcdf.setDefaultFormat</code>	Change default netCDF file format

## File Operations

<code>netcdf.abort</code>	Revert recent netCDF file definitions
<code>netcdf.close</code>	Close netCDF file

---

netcdf.create	Create new NetCDF dataset
netcdf.endDef	End netCDF file define mode
netcdf.inq	Return information about netCDF file
netcdf.inqFormat	Determine format of NetCDF file
netcdf.inqGrps	Retrieve array of child group IDs
netcdf.inqUnlimDims	Return list of unlimited dimensions in group
netcdf.open	Open NetCDF data source
netcdf.reDef	Put open netCDF file into define mode
netcdf.setFill	Set netCDF fill mode
netcdf.sync	Synchronize netCDF file to disk

**Dimensions**

netcdf.defDim	Create netCDF dimension
netcdf.inqDim	Return netCDF dimension name and length
netcdf.inqDimID	Return dimension ID
netcdf.renameDim	Change name of netCDF dimension

**Variables**

netcdf.defVar	Create NetCDF variable
netcdf.defVarChunking	Define chunking behavior for NetCDF variable
netcdf.defVarDeflate	Define compression parameters for NetCDF variable
netcdf.defVarFill	Define fill parameters for NetCDF variable

<code>netcdf.defVarFletcher32</code>	Define checksum parameters for NetCDF variable
<code>netcdf.getVar</code>	Return data from netCDF variable
<code>netcdf.inqVar</code>	Information about variable
<code>netcdf.inqVarChunking</code>	Determine chunking settings for NetCDF variable
<code>netcdf.inqVarDeflate</code>	Determine compression settings for NetCDF variable
<code>netcdf.inqVarFill</code>	Determine values of fill parameters for NetCDF variable
<code>netcdf.inqVarFletcher32</code>	Fletcher32 checksum setting for NetCDF variable
<code>netcdf.inqVarID</code>	Return ID associated with variable name
<code>netcdf.putVar</code>	Write data to netCDF variable
<code>netcdf.renameVar</code>	Change name of netCDF variable
<b>Attributes</b>	
<code>netcdf.copyAtt</code>	Copy attribute to new location
<code>netcdf.delAtt</code>	Delete netCDF attribute
<code>netcdf.getAtt</code>	Return netCDF attribute
<code>netcdf.inqAtt</code>	Return information about netCDF attribute
<code>netcdf.inqAttID</code>	Return ID of netCDF attribute
<code>netcdf.inqAttName</code>	Return name of netCDF attribute
<code>netcdf.putAtt</code>	Write netCDF attribute
<code>netcdf.renameAtt</code>	Change name of attribute

**Utilities**`netcdf.getConstant`

Return numeric value of named constant

`netcdf.getConstantNames`

Return list of constants known to netCDF library

# netcdf.abort

---

**Purpose** Revert recent netCDF file definitions

**Syntax** `netcdf.abort(ncid)`

**Description** `netcdf.abort(ncid)` reverts a netCDF file to its previous state, backing out any definitions made since the file last entered define mode. A file enters define mode when you create it (using `netcdf.create`) or when you explicitly enter define mode (using `netcdf.redef`). Once you leave define mode (using `netcdf.endDef`), you cannot revert the definitions you made while in define mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. A call to `netcdf.abort` closes the file.

This function corresponds to the `nc_abort` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new file, performs an operation on the file, and then reverts the file back to its original state. To run this example, you must have write permission in your current directory.

```
% Create a netCDF file
ncid = netcdf.create('foo.nc','NC_NOCLlobber');

% Perform an operation, such as defining a dimension.
dimid = netcdf.defDim(ncid, 'lat', 50);

% Revert the file back to its previous state.
netcdf.abort(ncid)

% Verify that the file is now closed.
dimid = netcdf.defDim(ncid, 'lat', 50); % should fail
??? Error using ==> netcdflib
NetCDF: Not a valid ID

Error in ==> defDim at 22
dimid = netcdflib('def_dim', ncid,dimname,dimlen);
```

## See Also

[netcdf.create](#) | [netcdf.endDef](#) | [netcdf.reDef](#)

# netcdf.close

---

**Purpose** Close netCDF file

**Syntax** `netcdf.close(ncid)`

**Description** `netcdf.close(ncid)` terminates access to the netCDF file identified by `ncid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_close` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new netCDF file, and then closes the file. You must have write permission in your current directory to run this example.

```
ncid = netcdf.open('foo.nc', 'NC_WRITE')
```

```
netcdf.close(ncid)
```

**See Also** `netcdf.create` | `netCDF.open`

<b>Purpose</b>	Copy attribute to new location
<b>Syntax</b>	<code>netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)</code>
<b>Description</b>	<p><code>netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)</code> copies an attribute from one variable to another, possibly across files. <code>ncid_in</code> and <code>ncid_out</code> are netCDF file identifiers returned by <code>netcdf.create</code> or <code>netcdf.open</code>. <code>varid_in</code> identifies the variable with an attribute that you want to copy. <code>varid_out</code> identifies the variable to which you want to associate a copy of the attribute.</p> <p>This function corresponds to the <code>nc_copy_att</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>This example makes a copy of the attribute associated with the first variable in the netCDF example file, <code>example.nc</code>, in a new file. To run this example, you must have write permission in your current directory.</p> <pre>% Open example file. ncid = netcdf.open('example.nc','NC_NOWRITE');  % Get identifier for a variable in the file. varid = netcdf.inqVarID(ncid,'avagadros_number');  % Create new netCDF file. ncid2 = netcdf.create('foo.nc','NC_NOCLlobber');  % Define a dimension in the new file. dimid2 = netcdf.defDim(ncid2,'x',50);  % Define a variable in the new file. varid2 = netcdf.defVar(ncid2,'myvar','double',dimid2);  % Copy the attribute named 'description' into the new file, % associating the attribute with the new variable. netcdf.copyAtt(ncid,varid,'description',ncid2,varid2);</pre>

# netcdf.copyAtt

---

```
%  
% Check the name of the attribute in new file.  
attname = netcdf.inqAttName(ncid2,varid2,0)  
  
attname =  
  
description
```

## See Also

```
netcdf.inqAtt | netcdf.inqAttID | netcdf.inqAttName |  
netcdf.putAtt | netcdf.renameAtt
```

**Purpose** Create new NetCDF dataset

**Syntax**

```
ncid = netcdf.create(filename,mode)
[chunksize_out,ncid] = netcdf.create(filename,mode,initSZ,
    chunksize)
```

**Description** `ncid = netcdf.create(filename,mode)` creates a new NetCDF file according to the file creation mode. The return value `ncid` is a file ID. The mode parameter is a text string that describes the type of file access, which can have any of the following values.

Value	Description
NOCLOBBER	Prevent overwriting of existing file with the
CLOBBER	Overwrite any existing file with the same name.
SHARE	Allow synchronous file updates.
64BIT_OFFSET	Allow easier creation of files and variables which are larger than two gigabytes.
NETCDF4	Create a NetCDF-4/HDF5 file
CLASSIC_MODEL	Enforce the classic model; has no effect unless used in a bitwise-or with NETCDF4

**Note** You can specify the mode as a numeric value, retrieved using the `netcdf.getConstant` function. To specify more than one mode, use a bitwise-OR of the numeric values of the modes.

`[chunksize_out,ncid] = netcdf.create(filename,mode,initSZ, chunksize)` creates a new netCDF file, but with additional performance tuning parameters. `initSZ` sets the initial size of the file. `chunksize` can affect I/O performance. The actual value chosen by the NetCDF library might not correspond to the input value.

# netcdf.create

---

This function corresponds to the `nc_create` and `nc__create` functions in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a netCDF dataset named `foo.nc`, only if no other file with the same name exists in the current directory. To run this example, you must have write permission in your current directory.

```
ncid = netcdf.create('foo.nc', 'NOCLOBBER');
```

---

This example creates a netCDF-4 file that uses the classic model.

```
mode = netcdf.getConstant('NETCDF4');  
mode = bitor(mode, netcdf.getConstant('CLASSIC_MODEL'));  
ncid = netcdf.create('myfile.nc', mode);  
netcdf.close(ncid);
```

## See Also

`netcdf.getConstant` | `netcdf.open`

<b>Purpose</b>	Create netCDF dimension
<b>Syntax</b>	<code>dimid = netcdf.defDim(ncid,dimname,dimlen)</code>
<b>Description</b>	<p><code>dimid = netcdf.defDim(ncid,dimname,dimlen)</code> creates a new dimension in the netCDF file specified by <code>ncid</code>, where <code>dimname</code> is a character string that specifies the name of the dimension and <code>dimlen</code> is a numeric value that specifies its length. To define an unlimited dimension, specify the predefined constant <code>'NC_UNLIMITED'</code> for <code>dimlen</code>, using <code>netcdf.getConstant</code> to retrieve the value.</p> <p><code>netcdf.defDim</code> returns <code>dimid</code>, a numeric ID corresponding to the new dimension.</p> <p>This function corresponds to the <code>nc_def_dim</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>
<b>Examples</b>	<p>Create a new file and define two dimensions in the file. One dimension is an unlimited dimension. To run this example, you must have write permission in your current folder.</p> <pre>% Create a netCDF file. ncid = netcdf.create('foo.nc','NC_NOCLlobber')  % Define a dimension. lat_dimID = netcdf.defDim(ncid,'latitude',360);  % Define an unlimited dimension. long_dimID = netcdf.defDim(ncid,'longitude',...     netcdf.getConstant('NC_UNLIMITED'));</pre>
<b>See Also</b>	<code>netcdf.getConstant</code>

# netcdf.defGrp

---

<b>Purpose</b>	Create group in NetCDF file
<b>Syntax</b>	<code>childGrpID = netcdf.defGrp(parentGroupId,childGroupName)</code>
<b>Description</b>	<code>childGrpID = netcdf.defGrp(parentGroupId,childGroupName)</code> creates a child group with the name specified by <code>childGroupName</code> , that is the child of the parent group specified by <code>parentGroupId</code>
<b>Input Arguments</b>	<b>parentGroupId</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> . <b>childGroupName</b> Text string specifying the name that you want to assign to the group.
<b>Output Arguments</b>	<b>childGrpID</b> Identifier of a NetCDF group.
<b>Examples</b>	This example creates a NetCDF dataset and then defines a group. <pre>ncid = netcdf.create('myfile.nc','netcdf4'); childGroupId = netcdf.defGrp(ncid,'mygroup'); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_def_grp</code> function in the NetCDF library C API. For copyright information, read the files <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> .
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqGrps</code>

<b>Purpose</b>	Create NetCDF variable
<b>Syntax</b>	<code>varid = netcdf.defVar(ncid,varname,xtype,dimids)</code>
<b>Description</b>	<p><code>varid = netcdf.defVar(ncid,varname,xtype,dimids)</code> creates a new variable in the dataset identified by <code>ncid</code>.</p> <p><code>varname</code> is a character string that specifies the name of the variable. <code>xtype</code> can be either a character string specifying the data type of the variable, such as <code>'double'</code>, or it can be the numeric equivalent returned by the <code>netcdf.getConstant</code> function. <code>dimids</code> specifies a list of dimension IDs.</p> <p><code>netcdf.defVar</code> returns <code>varid</code>, a numeric identifier for the new variable.</p> <p>This function corresponds to the <code>nc_def_var</code> function in the NetCDF library C API. Because MATLAB uses FORTRAN-style ordering, the fastest-varying dimension comes first and the slowest comes last. Any unlimited dimension is therefore last in the list of dimension IDs. This ordering is the reverse of that found in the C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>This example creates a new netCDF file, defines a dimension in the file, and then defines a variable on that dimension. (In netCDF files, you must create a dimension before you can create a variable.) To run this example, you must have write permission in your current directory.</p> <pre>% Create netCDF file. ncid = netcdf.create('foo.nc','NC_NOCLlobber'); % % Define a dimension in the new file. dimid = netcdf.defDim(ncid,'x',50);  % Define a variable in the new file. varid = netcdf.defVar(ncid,'myvar','double',dimid)</pre>
<b>See Also</b>	<code>netCDF.getConstant</code>   <code>netCDF.inqVar</code>   <code>netCDF.putVar</code>

# netcdf.defVarChunking

---

<b>Purpose</b>	Define chunking behavior for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarChunking(ncid,varid,storage,chunkDims)</code>
<b>Description</b>	<p><code>netcdf.defVarChunking(ncid,varid,storage,chunkDims)</code>. sets the chunk settings for the variable specified by <code>varid</code>. Chunking is a technique to improve performance. <code>storage</code> specifies the type of chunking to use and <code>chunkDims</code> specifies the extents of the chunk size. You must specify the chunk size used with a variable after creating the variable but before you write data to the variable.</p> <p>You cannot specify the chunk size for variables in a NetCDF file created with the netCDF-3 mode (<code>CLASSIC_MODEL</code>).</p>
<b>Input Arguments</b>	<p><b>ncid</b></p> <p>Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b></p> <p>Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>storage</b></p> <p>Text string specifying whether NetCDF should break the variable into chunks when writing to a file. If set to <code>CHUNKED</code>, NetCDF breaks the variable into chunks; if set to <code>CONTIGUOUS</code>, NetCDF does not break the data into chunks.</p> <p><b>chunkDims</b></p> <p>Array specifying the dimensions of the chunk.</p> <p>Because MATLAB uses FORTRAN-style ordering, the order of dimensions in <code>chunkdims</code> is reversed relative to what would be in the C API.</p> <p>If <code>storage</code> is <code>CONTIGUOUS</code>, you can omit <code>chunkDims</code>.</p>

**Default:** Chunk size determined by the NetCDF library.

## Examples

This example creates a NetCDF file and specifies the chunking behavior of a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
latdimid = netcdf.defDim(ncid, 'lat', 1800);
londimid = netcdf.defDim(ncid, 'col', 3600);
varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]);
netcdf.defVarChunking(ncid, varid, 'CHUNKED', [180 360]);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_chunking` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexncopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqVarChunking`

# netcdf.defVarDeflate

---

<b>Purpose</b>	Define compression parameters for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)</code>
<b>Description</b>	<code>netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)</code> sets the compression parameters for the NetCDF variable specified by <code>varid</code> in the location specified by <code>ncid</code> .
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>shuffle</b> Boolean value. To turn on the shuffle filter, set this argument to <code>true</code>. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.</p> <p><b>deflate</b> Boolean value. To turn on compression, set this argument to <code>true</code> and set the <code>deflateLevel</code> argument to the desired compression level.</p> <p><b>deflateLevel</b> Numeric value between 0 and 9 specifying the amount of compression, where 0 is no compression and 9 is the most compression.</p>

## Examples

This example create a variable with dimensions [1800 3600] and a compression level of 5. This results in a chunked layout that is a 10-by-10 grid.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');  
latdimid = netcdf.defDim(ncid, 'lat', 1800);
```

```
londimid = netcdf.defDim(ncid,'col',3600);  
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);  
netcdf.defVarDeflate(ncid,varid,true,true,5);  
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_deflate` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexncopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqVarDeflate`

# netcdf.defVarFill

---

**Purpose** Define fill parameters for NetCDF variable

**Syntax** `netcdf.defVarFill(ncid, varid, noFillMode, fillValue)`

**Description** `netcdf.defVarFill(ncid, varid, noFillMode, fillValue)` sets the fill parameters for the NetCDF variable identified by `varid`. `ncid` specifies the location.

For netCDF-4 files, you can only specify fill values when the NetCDF is in definition mode (before calling `netcdf.endDef`). For NetCDF files in classic and 64-bit offset modes, you can turn no-fill mode on and off at any time.

## Input Arguments

### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

### **noFillMode**

Boolean value. When set to `true`, turns off use of fill values for the variable, which can be helpful in high performance applications. When `true`, `netcdf.defVarFill` ignores the value of the `fillValue` argument. To use the fill value, set this to `false`.

### **fillValue**

Specifies the value to use in the variable when no other value is specified. The data type must be the same data type as the variable.

## Examples

This example creates a NetCDF file and defines a fill value for a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');  
dimid = netcdf.defDim(ncid, 'latitude', 180);
```

```
varid = netcdf.defVar(ncid,'latitude','double',dimid);  
netcdf.defVarFill(ncid,varid,false,-999);  
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_fill` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf` | `netcdf.setFill` | `netcdf.inqVarFill`

# netcdf.defVarFletcher32

---

<b>Purpose</b>	Define checksum parameters for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarFletcher32(ncid,varid,setting)</code>
<b>Description</b>	<code>netcdf.defVarFletcher32(ncid,varid,setting)</code> defines the checksum settings for the NetCDF variable specified by <code>varid</code> in the file specified by <code>ncid</code> .
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>setting</b> Text string specifying whether Fletcher32 checksum error detection is used with the variable. To turn on Fletcher32 checksum, specify the value <code>FLETCHER32</code>. To turn off the use of checksum error detection, specify the value <code>NOCHECKSUM</code>.</p>
<b>Examples</b>	<p>This example creates a NetCDF dataset and turns on the Fletcher32 checksum for a variable.</p> <pre>ncid = netcdf.create('myfile.nc', 'NETCDF4'); latdimid = netcdf.defDim(ncid, 'lat', 1800); londimid = netcdf.defDim(ncid, 'col', 3600); varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]); netcdf.defVarFletcher32(ncid, varid, 'FLETCHER32'); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_def_var_fletcher32</code> function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

### **See Also**

`netcdf` | `netcdf.inqVarFletcher32`

# netcdf.delAtt

---

**Purpose** Delete netCDF attribute

**Syntax** `netcdf.delAtt(ncid,varid,attName)`

**Description** `netcdf.delAtt(ncid,varid,attName)` deletes the attribute identified by the text string `attName`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric value that identifies the variable. To delete a global attribute, use `netcdf.getConstant('GLOBAL')` for the `varid`. You must be in define mode to delete an attribute.

This function corresponds to the `nc_del_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Determine number of global attributes in file.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

    1

% Get name of attribute; it is needed for deletion.
attname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

% Put file in define mode to delete an attribute.
netcdf.reDef(ncid);

% Delete the global attribute in the netCDF file.
```

```
netcdf.delAtt(ncid,netcdf.getConstant('GLOBAL'),attname);

% Verify that the global attribute was deleted.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

    0
```

## See Also

[netcdf.getConstant](#) | [netcdf.inqAttName](#)

# netcdf.endDef

---

**Purpose** End netCDF file define mode

**Syntax** `netcdf.endDef(ncid)`  
`netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)`

**Description** `netcdf.endDef(ncid)` takes a netCDF file out of define mode and into data mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)` takes a netCDF file out of define mode, specifying four additional performance tuning parameters. For example, one reason for using the performance parameters is to reserve extra space in the netCDF file header using the `h_minfree` parameter:

```
ncid = netcdf.endDef(ncid,20000,4,0,4);
```

This reserves 20,000 bytes in the header, which can be used later when adding attributes. This can be extremely efficient when working with very large files. To understand how to use these performance tuning parameters, see the netCDF library documentation.

This function corresponds to the `nc_enddef` and `nc__enddef` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

When you create a file using `netcdf.create`, the functions opens the file in define mode. This example uses `netcdf.endDef` to take the file out of define mode.

```
% Create a netCDF file.
ncid = netcdf.create('foo.c','NC_NOGLOBBER');

% Define a dimension.
dimid = netcdf.defDim(ncid, 'lat', 50);

% Leave define mode.
netcdf.endDef(ncid)
```

```
% Test if still in define mode.  
dimid = netcdf.defDim(ncid, 'lon', 50); % should fail  
??? Error using ==> netcdflib  
NetCDF: Operation not allowed in data mode
```

```
Error in ==> defDim at 22  
dimid = netcdflib('def_dim', ncid,dimname,dimlen);
```

## See Also

[netcdf.create](#) | [netcdf.reDef](#)

# netcdf.getAtt

---

**Purpose** Return netCDF attribute

**Syntax**  
`attrvalue = netcdf.getAtt(ncid,varid,attname)`  
`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)`

**Description** `attrvalue = netcdf.getAtt(ncid,varid,attname)` returns `attrvalue`, the value of the attribute specified by the text string `attname`. When it chooses the data type of `attrvalue`, MATLAB attempts to match the netCDF class of the attribute. For example, if the attribute has the netCDF data type `NC_INT`, MATLAB uses the `int32` class for the output data. If an attribute has the netCDF data type `NC_BYTE`, the class of the output data is `int8` value.

`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)` returns `attrvalue`, the value of the attribute specified by the text string `attname`, using the output class specified by `output_datatype`. You can specify any of the following strings for the output data type.

'int'	'double'	'int16'
'short'	'single'	'int8'
'float'	'int32'	'uint8'

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and gets the value of the attribute associated with the first variable. The example also gets the value of the global variable in the file.

```
% Open a netCDF file.  
ncid = netcdf.open('example.nc','NC_NOWRITE');  
  
% Get name of first variable.
```

```
[varname vartype vardimIDs varatts] = netcdf.inqVar(ncid,0);

% Get ID of variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get attribute name, given variable id.
attname = netcdf.inqAttName(ncid,varid,0);

% Get value of attribute.
attval = netcdf.getAtt(ncid,varid,attname);

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get value of global attribute.
gattval = netcdf.getAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname);

gattval =

09-Jun-2008
```

# netcdf.getChunkCache

---

<b>Purpose</b>	Retrieve chunk cache settings for NetCDF library
<b>Syntax</b>	<code>[csize, nelems, premp] = netcdf.getChunkCache()</code>
<b>Description</b>	<code>[csize, nelems, premp] = netcdf.getChunkCache()</code> returns the default chunk cache settings.
<b>Output Arguments</b>	<p><b>csize</b></p> <p>Scalar double specifying the total size of the raw data chunk cache in bytes.</p> <p><b>nelems</b></p> <p>Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.</p> <p><b>premp</b></p> <p>Double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of zero means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.</p>
<b>Examples</b>	<p>Determine information about the chunk cache size used by the NetCDF library.</p> <pre>[csize, nelems, premp] = netcdf.getChunkCache();</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_get_chunk_cache</code> function in the NetCDF library C API.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.setChunkCache</code>

**Purpose** Return numeric value of named constant

**Syntax** `val = netcdf.getConstant(param_name)`

**Description** `val = netcdf.getConstant(param_name)` returns the numeric value corresponding to the name of a constant defined by the netCDF library. For example, `netcdf.getConstant('NC_NOCLOBBER')` returns the numeric value corresponding to the netCDF constant `NC_NOCLOBBER`.

The value for `param_name` can be either upper- or lowercase, and does not need to include the leading three characters `'NC_'`. To retrieve a list of all the names defined by the netCDF library, use the `netcdf.getConstantNames` function.

This function has no direct equivalent in the netCDF C interface. To find out more about NetCDF, see `netcdf`.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Determine contents of the file.
[ndims nvars natts dimm] = netcdf.inq(ncid);

% Get name of global attribute.
% Note: You must use netcdf.getConstant to specify NC_GLOBAL.
attname = netcdf.inqattname(ncid,netcdf.getConstant('NC_GLOBAL'),0)

attname =

creation_date
```

**See Also** `netcdf.getConstantNames`

# netcdf.getConstantNames

---

**Purpose** Return list of constants known to netCDF library

**Syntax** `val = netcdf.getConstantNames(param_name)`

**Description** `val = netcdf.getConstantNames(param_name)` returns a list of names of netCDF library constants, definitions, and enumerations. When these strings are supplied as actual parameters to MATLAB netCDF package functions, the functions automatically convert the constant to the appropriate numeric value.

This MATLAB function has no direct equivalent in the netCDF C interface. To find out more about netCDF, see `netcdf`.

**Examples** `nc_constants = netcdf.getConstantNames`

```
nc_constants =  
  
    'NC2_ERR'  
    'NC_64BIT_OFFSET'  
    'NC_BYTE'  
    'NC_CHAR'  
    'NC_CLOBBER'  
    'NC_DOUBLE'  
    'NC_EBADDIM'  
    'NC_EBADID'  
    'NC_EBADNAME'  
    'NC_EBADTYPE'  
    ...
```

**See Also** `netCDF.getConstantNames`

## Purpose

Return data from netCDF variable

## Syntax

```
data = netcdf.getVar(ncid,varid)
data = netcdf.getVar(ncid,varid,start)
data = netcdf.getVar(ncid,varid,start,count)
data = netcdf.getVar(ncid,varid,start,count,stride)
data = netcdf.getVar(...,output_type)
```

## Description

`data = netcdf.getVar(ncid,varid)` returns data, the value of the variable specified by `varid`. MATLAB attempts to match the class of the output data to netCDF class of the variable.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`data = netcdf.getVar(ncid,varid,start)` returns a single value starting at the specified index, `start`.

`data = netcdf.getVar(ncid,varid,start,count)` returns a contiguous section of a variable. `start` specifies the starting point and `count` specifies the amount of data to return.

`data = netcdf.getVar(ncid,varid,start,count,stride)` returns a subset of a section of a variable. `start` specifies the starting point, `count` specifies the extent of the section, and `stride` specifies which values to return.

`data = netcdf.getVar(...,output_type)` specifies the data type of the return value `data`. You can specify any of the following strings for the output data type.

'int8'
--------

'uint8'
---------

'int16'
---------

'int32'
---------

'single'
----------

'double'
----------

# netcdf.getVar

---

This function corresponds to several functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

Open the example netCDF file and get the value of a variable in the file.

```
% Open example file.
ncid = netcdf.open('example.nc', 'NC_NOWRITE');

% Get the name of the first variable.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get the value of the first variable, given its ID.
data = netcdf.getVar(ncid,varid)

data =

    6.0221e+023

% Determine the data type of the output value
whos data
  Name      Size      Bytes  Class  Attributes
  data      1x1          8  double

% Get the value again, this time specifying the output data type
data = netcdf.getVar(ncid,varid,'single');

% Determine the data type of the output value
whos data
  Name      Size      Bytes  Class  Attributes
  data      1x1          4  single
```

**See Also**

[netcdf.create](#) | [netcdf.inqVarID](#) | [netcdf.open](#)

# netcdf.inq

---

**Purpose** Return information about netCDF file

**Syntax** [ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)

**Description** [ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid) returns the number of dimensions, variables, and global attributes in a netCDF file. The function also returns the ID of the dimension defined with unlimited length, if one exists.

ncid is a netCDF file identifier returned by netcdf.create or netcdf.open. You can call netcdf.inq in either define mode or data mode.

This function corresponds to the nc\_inq function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See netcdf for more information.

**Examples** This example opens the example netCDF file included with MATLAB, example.nc, and uses the netcdf.inq function to get information about the contents of the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE')

% Get information about the contents of the file.
[numdims, numvars, numglobalatts, unlimdimID] = netcdf.inq(ncid)

numdims =

     4

numvars =

     4

numglobalatts =
```

# netcdf.inqDimIDs

---

<b>Purpose</b>	Retrieve list of dimension identifiers in group
<b>Syntax</b>	<pre>dimIDs = netcdf.inqDimIDs(ncid) dimIDs = netcdf.inqDimIDs(ncid,includeParents)</pre>
<b>Description</b>	<p><code>dimIDs = netcdf.inqDimIDs(ncid)</code> returns a list of dimension identifiers in the group specified by <code>ncid</code>.</p> <p><code>dimIDs = netcdf.inqDimIDs(ncid,includeParents)</code> includes all dimensions in all parent groups if <code>includeParents</code> is true.</p>
<b>Input Arguments</b>	<p><b>ncid</b></p> <p>Identifier of a NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>includeParents</b></p> <p>Boolean value. If set to true, <code>netcdf.inqDimIDs</code> includes the dimensions of all parent groups.</p> <p><b>Default:</b> false</p>
<b>Output Arguments</b>	<p><b>dimIDs</b></p> <p>Array of dimension IDs</p>
<b>Examples</b>	<p>This example opens the NetCDF sample file and gets the IDs of all the dimensions.</p> <pre>ncid = netcdf.open('example.nc','NOWRITE'); gid = netcdf.inqNcid(ncid,'grid1'); dimids = netcdf.inqDimIDs(gid); dimids_all = netcdf.inqDimIDS(gid, true); netcdf.close(ncid);</pre>

**See Also**

`netcdf` | `netcdf.inqVarIDs`

# netcdf.inqFormat

---

**Purpose** Determine format of NetCDF file

**Syntax** `format = netcdf.inqFormat(ncid)`

**Description** `format = netcdf.inqFormat(ncid)` returns the format for the file specified by NetCDF file identifier, `ncid`.

**Input Arguments** **ncid**  
Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Output Arguments** **format**  
Text string that specifies the format of the NetCDF file. Values include:

Format String	Description
FORMAT_CLASSIC	Classic format — Original NetCDF format, used by all NetCDF files created between 1989 and 2004
FORMAT_64BIT	Classic format, 64-bit — Original format with 64-bit addressing capability to allow creation and access of much larger files.
FORMAT_NETCDF4	Enhanced model, HDF5-based — Introduced in 2008, NetCDF, version 4, extends the classic model and is based on HDF5.
FORMAT_NETCDF4_CLASSIC	Classic model, HDF5-based — Introduced in 2008, NetCDF, version 4, implements classic model but is based on HDF5.

**Examples** This example opens the sample NetCDF file and determines the format.

```
ncid = netcdf.open('example.nc', 'NOWRITE');  
fmt = netcdf.inqFormat(ncid)
```

```
format =  
FORMAT_NETCDF4  
netcdf.close(ncid);
```

# netcdf.inqGrpName

---

<b>Purpose</b>	Retrieve name of group
<b>Syntax</b>	<code>groupName = netcdf.inqGrpName(ncid)</code>
<b>Description</b>	<code>groupName = netcdf.inqGrpName(ncid)</code> returns the name of a group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>groupName</b> Text string specifying name of a group. The root group has the name <code>'/'</code> .
<b>Examples</b>	This example opens the NetCDF sample file and gets the names of groups in the dataset. <pre>ncid = netcdf.open('example.nc','nowrite'); name = netcdf.inqGrpName(ncid); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_inq_grpname</code> function in the NetCDF library C API. For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqGrpNameFull</code>

<b>Purpose</b>	Complete pathname of group
<b>Syntax</b>	<code>groupName = netcdf.inqGrpNameFull(ncid)</code>
<b>Description</b>	<code>groupName = netcdf.inqGrpNameFull(ncid)</code> returns the complete pathname of the group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>groupName</b> Text string specifying complete path of group.  The root group has the name <code>'/'</code> . The names of parent groups and child groups use the forward slash <code>'/'</code> separator, as in UNIX folder names, for example, <code>/group1/subgrp2/subsubgrp3</code> .
<b>Examples</b>	Open the NetCDF sample dataset and retrieve the names of all groups.  <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid2'); fullName = netcdf.inqGrpNameFull(gid); netcdf.close(ncid);</pre>

# netcdf.inqGrpParent

---

<b>Purpose</b>	Retrieve ID of parent group.
<b>Syntax</b>	<code>parentGroupID = netcdf.inqGrpParent(ncid)</code>
<b>Description</b>	<code>parentGroupID = netcdf.inqGrpParent(ncid)</code> returns the ID of the parent group given the location of the child group, specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of a NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>parentGroupID</b> Identifier of the NetCDF group or file that is the parent of the specified file or group.
<b>Examples</b>	<p>This example opens the NetCDF sample file and gets the full path of the parent of the specified group.</p> <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid2'); parentId = netcdf.inqGrpParent(gid); fullName = netcdf.inqGrpNameFull(parentId); netcdf.close(ncid);</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_inq_grp_parent</code> function in the NetCDF library C API.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>

# netcdf.inqVarIDs

---

<b>Purpose</b>	IDs of all variables in group
<b>Syntax</b>	<code>varids = netcdf.inqVarIDs(ncid)</code>
<b>Description</b>	<code>varids = netcdf.inqVarIDs(ncid)</code> returns IDs of the all the variables in the group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>varids</b> Array containing identifiers of variables in a NetCDF file or group.
<b>Examples</b>	This example opens the NetCDF sample file and gets the IDs of all the variables in a group. <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid1'); varids = netcdf.inqVarIDs(gid); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_inq_varids</code> function in the NetCDF library C API. For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqDimIDs</code>   <code>netcdf.inqVarID</code>

<b>Purpose</b>	Determine chunking settings for NetCDF variable
<b>Syntax</b>	<code>[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)</code>
<b>Description</b>	<code>[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)</code> returns the type of chunking and the dimensions of a chunk for the NetCDF variable specified by <code>varid</code> , in the file or group specified by <code>ncid</code> .
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of NetCDF variable, returned by <code>netcdf.defVar</code>.</p>
<b>Output Arguments</b>	<p><b>storage</b> Text string specifying if NetCDF breaks the data into chunks when writing to a file. <code>CHUNKED</code> indicates the data is chunked; <code>CONTIGUOUS</code> indicates that the data is not chunked.</p> <p><b>chunkSizes</b> Array specifying the dimensions of the chunk. Because MATLAB uses FORTRAN-style ordering, the order of dimensions in <code>chunkdims</code> is reversed relative to what would be in the NetCDF C API. If the storage type specified is <code>CONTIGUOUS</code>, <code>netcdf.inqVarChunking</code> returns an empty array, <code>[]</code>.</p>
<b>Examples</b>	<p>This example opens the NetCDF sample dataset and gets the values of chunking parameters associated with a variable.</p> <pre>ncid = netcdf.open('example.nc','NOWRITE');</pre>

# netcdf.inqVarChunking

---

```
groupid = netcdf.inqNcid(ncid,'grid1');
varid = netcdf.inqVarID(groupid,'temp');
[storage,chunkSize] = netcdf.inqVarChunking(groupid,varid);
netcdf.close(ncid);
```

# netcdf.inqVarFletcher32

---

## See Also

[netcdf](#) | [netcdf.defVarFletcher32](#)

**Purpose** Return information about netCDF attribute

**Syntax** `[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)`

**Description** `[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)` returns the data type, `xtype`, and length, `attlen`, of the attribute identified by the text string `attname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable that the attribute is associated with. To get information about a global attribute, specify `netcdf.getConstant('NC_GLOBAL')` in place of `varid`.

This function corresponds to the `nc_inq_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and gets information about an attribute in the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NOWRITE');

% Get identifier of a variable in the file, given its name.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Get attribute name, given variable id and attribute number.
attname = netcdf.inqAttName(ncid,varid,0);

% Get information about the attribute.
[xtype,attlen] = netcdf.inqAtt(ncid,varid,'description')

xtype =
```

```

## See Also

[netcdf.inqAttID](#) | [netcdf.inqAttName](#)

## Purpose

Return ID of netCDF attribute

## Syntax

```
attnum = netcdf.inqAttID(ncid,varid,attname)
```

## Description

`attnum = netcdf.inqAttID(ncid,varid,attname)` retrieves `attnum`, the identifier of the attribute specified by the text string `attname`.

`varid` specifies the variable the attribute is associated with.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_attid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the netCDF example file included with MATLAB, `example.nc`.

```
% Open the netCDF example file.
```

```
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

```
% Get the identifier of a variable in the file.
```

```
varid = netcdf.inqVarID(ncid,'avagadros_number');
```

```
% Retrieve the identifier of the attribute associated with the variable.
```

```
attid = netcdf.inqAttID(ncid,varid,'description');
```

## See Also

`netcdf.inqAtt` | `netcdf.inqAttName`

# netcdf.inqAttName

---

**Purpose** Return name of netCDF attribute

**Syntax** `attname = netcdf.inqAttName(ncid,varid,attnum)`

**Description** `attname = netcdf.inqAttName(ncid,varid,attnum)` returns `attname`, a text string specifying the name of an attribute.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric identifier of a variable in the file. If you want to get the name of a global attribute in the file, use `netcdf.getConstant('NC_GLOBAL')` in place of `attnum` is a zero-based numeric value specifying the attribute, with 0 indicating the first attribute, 1 the second attribute, and so on.

This function corresponds to the `nc_inq_attname` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number')

% Get the name of the attribute associated with the variable.
attname = netcdf.inqAttName(ncid,varid,0)

attname =

description

% Get the name of the global attribute associated with the variable.
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

# netcdf.inqDim

---

**Purpose** Return netCDF dimension name and length

**Syntax** [dimname, dimlen] = netcdf.inqDim(ncid,dimid)

**Description** [dimname, dimlen] = netcdf.inqDim(ncid,dimid) returns the name, dimname, and length, dimlen, of the dimension specified by dimid. If ndims is the number of dimensions defined for a netCDF file, each dimension has an ID between 0 and ndims-1. For example, the dimension identifier of the first dimension is 0, the second dimension is 1, and so on.

ncid is a netCDF file identifier returned by netcdf.create or netcdf.open.

This function corresponds to the nc\_inq\_dim function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See netcdf for more information.

**Examples** The example opens the example netCDF file include with MATLAB, example.nc.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

```
% Get name and length of first dimension  
[dimname, dimlen] = netcdf.inqDim(ncid,0)
```

```
dimname =
```

```
x
```

```
dimlen =
```

```
50
```

**See Also** netcdf.inqDimID

**Purpose** Return dimension ID

**Syntax** `dimid = netcdf.inqDimID(ncid,dimname)`

**Description** `dimid = netcdf.inqDimID(ncid,dimname)` returns `dimid`, the identifier of the dimension specified by the character string `dimname`. You can use the `netcdf.inqDim` function to retrieve the dimension name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dimid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0);

% Retrieve identifier of dimension.
dimid = netcdf.inqDimID(ncid,dimname)

dimid =

     0
```

**See Also** `netcdf.inqDim`

# netcdf.inqLibVers

---

**Purpose** Return NetCDF library version information

**Syntax** `libvers = netcdf.inqLibVers`

**Description** `libvers = netcdf.inqLibVers` returns a string identifying the version of the NetCDF library.

This function corresponds to the `nc_inq_libvers` function in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** `libvers = netcdf.inqLibVers`

```
libvers =
```

```
4.1.3
```

<b>Purpose</b>	Information about variable
<b>Syntax</b>	<code>[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)</code>
<b>Description</b>	<p><code>[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)</code> returns information about the variable identified by <code>varid</code>. The argument, <code>ncid</code>, is a netCDF file identifier returned by <code>netcdf.create</code> or <code>netcdf.open</code>.</p> <p>The output argument, <code>varname</code>, is the name of the variable. <code>xtype</code> is the data type, <code>dimids</code> is the dimension IDs, and <code>natts</code> is the number of attributes associated with the variable. Dimension IDs are zero-based.</p> <p>This function corresponds to the <code>nc_inq_var</code> function in the netCDF library C API. Because MATLAB uses FORTRAN-style ordering, however, the order of the dimension IDs is reversed relative to what would be obtained from the C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>

**Examples** Open the example netCDF file included with MATLAB, `example.nc`, and get information about a variable in the file.

```
% Open the example netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about third variable in the file.
[varname, xtype, dimids, numatts] = netcdf.inqVar(ncid,2)

## See Also

[netcdf.create](#) | [netcdf.inqVarID](#) | [netcdf.open](#)

**Purpose** Return ID associated with variable name

**Syntax** `varid = netcdf.inqVarID(ncid,varname)`

**Description** `varid = netcdf.inqVarID(ncid,varname)` returns `varid`, the ID of a netCDF variable specified by the text string, `varname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_varid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and uses several inquiry functions to get the ID of the first variable.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about first variable in the file.
[varname, xtype, dimids, atts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name
varid = netcdf.inqVarID(ncid,varname)

varid =

    0
```

**See Also** `netcdf.create` | `netcdf.inqVar` | `netcdf.open`

# netcdf.open

---

**Purpose** Open NetCDF data source

**Syntax**

```
ncid = netcdf.open(source)
ncid = netcdf.open(source,mode)
[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)
```

**Description** `ncid = netcdf.open(source)` opens `source`, which can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source, for read-only access. Returns a NetCDF ID in `ncid`.

`ncid = netcdf.open(source,mode)` opens `source` with the type of access specified by `mode`, which can have any of the following values.

Value	Description
'WRITE'	Read-write access
'SHARE'	Synchronous file updates
'NOWRITE'	Read-only access (Default)

You can also specify `mode` as a numeric value that can be retrieved using `netcdf.getConstant`. Use these numeric values when you want to specify a bitwise-OR of several modes.

```
[chosen_chunksize, ncid] =
netcdf.open(source,mode,chunksize)
```

opens `source`, an existing netCDF data source, specifying the additional I/O performance tuning parameter, `chunksize`. The actual value used by the NetCDF library might not correspond to the input value you specify.

This function corresponds to the `nc_open` and `nc__open` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example NetCDF file included with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NOWRITE');
netcdf.close(ncid);
```

[netcdf.close](#) | [netcdf](#) | [netcdf.getConstant](#)

# netcdf.putAtt

---

**Purpose** Write netCDF attribute

**Syntax** `netcdf.putAtt(ncid,varid,attrname,attrvalue)`

**Description** `netcdf.putAtt(ncid,varid,attrname,attrvalue)` writes the attribute named `attrname` with value `attrvalue` to the netCDF variable specified by `varid`. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

`ncid` is a netCDF file identifier returned by `netCDF.create` or `netCDF.open`.

---

**Note** You cannot use `netcdf.putAtt` to set the `'_FillValue'` attribute of NetCDF4 files. Use the `netcdf.defVarFill` function to set the fill value for a variable.

---

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a new netCDF file, defines a dimension and a variable, adds data to the variable, and then creates an attribute associated with the variable. To run this example, you must have writer permission in your current directory.

```
% Create a variable in the workspace.
my_vardata = linspace(0,50,50);

% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');

% Define a dimension in the file.
dimid = netcdf.defDim(ncid,'my_dim',50);

% Define a new variable in the file.
```

```
varid = netcdf.defVar(ncid,'my_var','double',dimid);

% Leave define mode and enter data mode to write data.
netcdf.endDef(ncid);

% Write data to variable.
netcdf.putVar(ncid,varid,my_vardata);

% Re-enter define mode.
netcdf.reDef(ncid);

% Create an attribute associated with the variable.
netcdf.putAtt(ncid,0,'my_att',10);

% Verify that the attribute was created.
[xtype xlen] = netcdf.inqAtt(ncid,0,'my_att')

xtype =

     6

xlen =

     1
```

---

This example creates a new netCDF file, specifies a global attribute, and assigns a value to the attribute.

```
ncid = netcdf.create('myfile.nc','CLOBBER');
varid = netcdf.getConstant('GLOBAL');
netcdf.putAtt(ncid,varid,'creation_date',datestr(now));
netcdf.close(ncid);
```

## See Also

[netcdf.getAtt](#) | [netcdf.defVarFill](#) | [netcdf.getConstant](#)

# netcdf.putVar

---

**Purpose** Write data to netCDF variable

**Syntax**

```
netcdf.putVar(ncid,varid,data)
netcdf.putVar(ncid,varid,start,data)
netcdf.putVar(ncid,varid,start,count,data)
netcdf.putVar(ncid,varid,start,count,stride,data)
```

**Description** `netcdf.putVar(ncid,varid,data)` writes data to a netCDF variable identified by `varid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.putVar(ncid,varid,start,data)` writes a single data value into the variable at the index specified by `start`.

`netcdf.putVar(ncid,varid,start,count,data)` writes a section of values into the netCDF variable at the index specified by the vector `start` to the extent specified by the vector `count`, along each dimension of the specified variable.

`netcdf.putVar(ncid,varid,start,count,stride,data)` writes the subsection specified by sampling interval, `stride`, of the values in the section of the variable beginning at the index `start` and to the extent specified by `count`.

This function corresponds to several variable I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## **Examples**      **Write Variable to New netCDF File**

Create a new netCDF file and write a variable to the file.

Create a 50 element vector for a variable.

```
my_vardata = linspace(0,50,50);
```

Open the netCDF file.

```
ncid = netcdf.create('foo.nc', 'NOCLOBBER');
```

Define the dimensions of the variable.

```
dimid = netcdf.defDim(ncid, 'my_dim', 50);
```

Define a new variable in the file.

```
my_varID = netcdf.defVar(ncid, 'my_var', 'double', dimid);
```

Leave define mode and enter data mode to write data.

```
netcdf.endDef(ncid);
```

Write data to variable.

```
netcdf.putVar(ncid, my_varID, my_vardata);
```

Verify that the variable was created.

```
[varname xtype dimid natts ] = netcdf.inqVar(ncid, 0)
```

```
varname =
```

```
my_var
```

```
xtype =
```

```
6
```

```
dimid =
```

```
0
```

```
natts =
```

# netcdf.putVar

---

0

Close the file.

```
netcdf.close(ncid)
```

## Write Elements of Variable

Write to the first ten elements of the example temperature variable.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.nc');  
copyfile(srcFile,'myfile.nc');  
fileattrib('myfile.nc','+w');  
ncid = netcdf.open('myfile.nc','WRITE');  
varid = netcdf.inqVarID(ncid,'temperature');  
data = [100:109];  
netcdf.putVar(ncid,varid,0,10,data);  
netcdf.close(ncid);
```

## See Also

```
netcdf.getVar
```

<b>Purpose</b>	Put open netCDF file into define mode
<b>Syntax</b>	<code>netcdf.reDef(ncid)</code>
<b>Description</b>	<p><code>netcdf.reDef(ncid)</code> puts an open netCDF file into define mode so that dimensions, variables, and attributes can be added or renamed. Attributes can also be deleted in define mode. <code>ncid</code> is a valid NetCDF file ID, returned from a previous call to <code>netcdf.open</code> or <code>netcdf.create</code>.</p> <p>This function corresponds to the <code>nc_redef</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>This example opens a local copy of the example netCDF file included with MATLAB, <code>example.nc</code>.</p> <pre>% Open a netCDF file. ncid = netcdf.open('my_example.nc','NC_WRITE')  % Try to define a dimension. dimid = netcdf.defdim(ncid, 'lat', 50); % should fail. ??? Error using ==&gt; netcdflib NetCDF: Operation not allowed in data mode  Error in ==&gt; defDim at 22 dimid = netcdflib('def_dim', ncid,dimname,dimlen);  % Put file in define mode. netcdf.reDef(ncid);  % Try to define a dimension again. Should succeed. dimid = netcdf.defDim(ncid, 'lat', 50);</pre>

# netcdf.renameAtt

---

**Purpose** Change name of attribute

**Syntax** `netcdf.renameAtt(ncid,varid,oldName,newName)`

**Description** `netcdf.renameAtt(ncid,varid,oldName,newName)` changes the name of the attribute specified by the character string `oldName`.

`newName` is a character string that specifies the new name.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable to which the attribute is associated. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

This function corresponds to the `nc_rename_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Get the ID of a variable the attribute is associated with.
varID = netcdf.inqVarID(ncid,'avagadros_number')

% Rename the attribute.
netcdf.renameAtt(ncid,varID,'description','Description');

% Verify that the name changed.
attname = netcdf.inqAttName(ncid,varID,0)

attname =

Description
```

**See Also**      `netcdf.inqAttName`

# netcdf.renameDim

---

**Purpose** Change name of netCDF dimension

**Syntax** `netcdf.renameDim(ncid,dimid,newName)`

**Description** `netcdf.renameDim(ncid,dimid,newName)` renames the dimension identified by the dimension identifier, `dimid`.

`newName` is a character string specifying the new name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`

This function corresponds to the `nc_rename_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This examples modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file is define mode.
netcdf.reDef(ncid)

% Get the identifier of a dimension to rename.
dimid = netcdf.inqDimID(ncid,'x');

% Rename the dimension.
netcdf.renameDim(ncid,dimid,'Xdim')

% Verify that the name changed.
data = netcdf.inqDim(ncid,dimid)

data =

Xdim
```

<b>Purpose</b>	Set default chunk cache settings for NetCDF library
<b>Syntax</b>	<code>netcdf.setChunkCache(csize, nelems, premp)</code>
<b>Description</b>	<p><code>netcdf.setChunkCache(csize, nelems, premp)</code> sets the default chunk cache settings used by the NetCDF library.</p> <p>Settings apply for subsequent file open or create operations, for the remainder of the MATLAB session or until you issue a <code>clear mex</code> call. This function does not change the chunk cache settings of files already open.</p>
<b>Input Arguments</b>	<p><b>csize</b></p> <p>Scalar double specifying the total size of the raw data chunk cache in bytes.</p> <p><b>nelems</b></p> <p>Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.</p> <p><b>premp</b></p> <p>Scalar double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of 0 means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.</p>
<b>Examples</b>	<p>This example sets the cache chunk size used by the NetCDF library.</p> <pre>netcdf.setChunkCache(32000000, 2003, .75)</pre>
<b>References</b>	This function corresponds to the <code>nc_set_chunk_cache</code> function in the NetCDF library C API.

# netcdf.setChunkCache

---

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.getChunkCache`

**Purpose** Change default netCDF file format

**Syntax** `oldFormat = netcdf.setDefaultFormat(newFormat)`

**Description** `oldFormat = netcdf.setDefaultFormat(newFormat)` changes the default format used by `netCDF.create` when creating new netCDF files, and returns the value of the old format. You can use this function to change the format used by a netCDF file without having to change the creation mode flag used in each call to `netCDF.create`.

`newFormat` can be either of the following values.

Value	Description
'NC_FORMAT_CLASSIC'	Original netCDF file format
'NC_FORMAT_64BIT'	64-bit offset format; relaxes limitations on creating very large files

You can also specify the numeric equivalent of these values, as retrieved by `netcdf.getConstant`.

This function corresponds to the `nc_set_default_format` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** `oldFormat = netcdf.setDefaultFormat('NC_FORMAT_64BIT');`

**See Also** `netcdf.create`

# netcdf.setFill

---

**Purpose** Set netCDF fill mode

**Syntax** `old_mode = netcdf.setFill(ncid,new_mode)`

**Description** `old_mode = netcdf.setFill(ncid,new_mode)` sets the fill mode for a netCDF file identified by `ncid`.

`new_mode` can be either 'FILL' or 'NOFILL' or their numeric equivalents, as retrieved by `netcdf.getConstant`. The default mode is 'FILL'. netCDF pre-fills data with fill values. Specifying 'NOFILL' can be used to enhance performance, because it avoids the duplicate writes that occur when the netCDF writes fill values that are later overwritten with data.

This function corresponds to the `nc_set_fill` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new file and specifies the fill mode used by netCDF with the file.

```
ncid = netcdf.open('foo.nc','NC_WRITE');  
  
% Set filling behavior  
old_mode = netcdf.setFill(ncid,'NC_NOFILL');
```

**See Also** `netcdf.getConstant`

**Purpose** Synchronize netCDF file to disk

**Syntax** `netcdf.sync(ncid)`

**Description** `netcdf.sync(ncid)` synchronizes the state of a netCDF file to disk. The netCDF library normally buffers accesses to the underlying netCDF file, unless you specify the `NC_SHARE` mode when you opened the file with `netcdf.open` or `netcdf.create`. To call `netcdf.sync`, the netCDF file must be in data mode.

This function corresponds to the `nc_sync` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new netCDF file for write access, performs an operation on the file, takes the file out of define mode, and then synchronizes the file to disk.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');

% Perform an operation.
dimid = netcdf.defDim(ncid,'Xdim',50);

% Take file out of define mode.
netcdf.endDef(ncid);

% Synchronize the file to disk.
netcdf.sync(ncid)
```

**See Also** `netcdf.close` | `netcdf.create` | `netcdf.open` | `netcdf.endDef`

# newplot

---

**Purpose** Determine where to draw graphics objects

**Syntax**

```
newplot
h = newplot
h = newplot(hsave)
```

**Description** `newplot` prepares a figure and axes for subsequent graphics commands.

`h = newplot` prepares a figure and axes for subsequent graphics commands and returns a handle to the current axes.

`h = newplot(hsave)` prepares and returns an axes, but does not delete any objects whose handles you have assigned to the `hsave` argument, which can be a vector of handles. If `hsave` is not empty, the figure and axes containing `hsave` are prepared for plotting instead of the current axes of the current figure. If `hsave` is empty, `newplot` behaves as if it were called without any inputs.

**Tips** To create a simple 2-D plot, use the `plot` function instead.

Use `newplot` at the beginning of high-level graphics code to determine which figure and axes to target for graphics output. Calling `newplot` can change the current figure and current axes. Basically, there are three options when you are drawing graphics in existing figures and axes:

- Add the new graphics without changing any properties or deleting any objects.
- Delete all existing objects whose handles are not hidden before drawing the new objects.
- Delete all existing objects regardless of whether or not their handles are hidden, and reset most properties to their defaults before drawing the new objects (refer to the following table for specific information).

The figure and axes `NextPlot` properties determine how `newplot` behaves. The following two tables describe this behavior with various property values.

First, `newplot` reads the current figure's `NextPlot` property and acts accordingly.

NextPlot	What Happens
new	Create a new figure and use it as the current figure.
add	Draw to the current figure without clearing any graphics objects already present.
replacechildren	<p>Remove all child objects whose HandleVisibility property is set to on and reset figure NextPlot property to add.</p> <p>This clears the current figure and is equivalent to issuing the clf command.</p>
replace	<p>Remove all child objects (regardless of the setting of the HandleVisibility property) and reset figure properties to their defaults, except NextPlot is reset to add regardless of user-defined defaults.</p> <ul style="list-style-type: none"> <li>• Position, Units, PaperPosition, and PaperUnits are not reset.</li> </ul> <p>This clears and resets the current figure and is equivalent to issuing the clf reset command.</p>

After newplot establishes which figure to draw in, it reads the current axes' NextPlot property and acts accordingly.

NextPlot	Description
add	Draw into the current axes, retaining all graphics objects already present.
replacechildren	Remove all child objects whose HandleVisibility property is set to on, but do not reset axes properties. This clears the current axes like the cla command.
replace	Remove all child objects (regardless of the setting of the HandleVisibility property) and reset axes properties to their defaults, except Position and Units.  This clears and resets the current axes like the cla reset command.

## How To

- Controlling Graphics Output

**Purpose** Make next IFD current IFD

**Syntax** `tiffobj.nextDirectory()`

**Description** `tiffobj.nextDirectory()` makes the next image file directory (IFD) in the file the current IFD. `Tiff` object methods operate on the current IFD. Use this method to navigate among IFDs in a TIFF file containing multiple images.

**Examples**      **Make Next Directory the Current Directory**

Open a `Tiff` object and change the current IFD to the next IFD in the file.

```
t = Tiff('example.tif', 'r');
t.nextDirectory();
t.close();
```

**References** This method corresponds to the `TIFFReadDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.setDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# nextpow2

---

**Purpose** Exponent of next higher power of 2

**Syntax** `P = nextpow2(A)`

**Description** `P = nextpow2(A)` returns the exponents for the smallest powers of two that satisfy

$$2^p \geq |A|$$

for each element in A.

You can use `nextpow2` to pad the signal you pass to `fft`. Doing so can speed up the computation of the FFT when the signal length is not an exact power of 2.

## Input Arguments

### A - Input values

scalar, vector, or array of real numbers

Input values, specified as a scalar, vector, or array of real numbers of any numeric type.

**Example:** 15

**Example:** `[-15.123 32.456 63.111]`

**Example:** `int16([-15 32 63])`

### Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Examples

### Next Power of 2 of Double Integer Values

Define a vector of double integer values and calculate the exponents for the next power of 2 higher than those values.

```
a = [1 -2 3 -4 5 9 519];  
p = nextpow2(a)
```

```
p =
```

```

0      1      2      2      3      4      10

```

Calculate the positive next powers of 2.

```
np2 = 2.^p
```

```
np2 =
```

```

1      2      4      4      8      16      1024

```

Preserve the sign of the original input values.

```
np2.*sign(a)
```

```
ans =
```

```

1      -2      4      -4      8      16      1024

```

### Next Power of 2 of Unsigned Integer Values

Define a vector of unsigned integers and calculate the exponents for the next power of 2 higher than those values.

```
a = uint32([1020 4000 32700]);
p = nextpow2(a)
```

```
p =
```

```

10      12      15

```

Calculate the next powers of 2 higher than the values in a.

```
2.^p
```

```
ans =
```

```

1024      4096      32768

```

## Optimize FFT with Padding

Use `nextpow2` to increase the performance of `fft` when the length of your signal is not a power of 2.

Create a 1-D vector containing 8191 sample values.

```
x = gallery('uniformdata',[1,8191],0);
```

Calculate the next power of 2 higher than 8191.

```
p = nextpow2(8191);
```

```
n = 2^p
```

```
n =
```

```
8192
```

Pass the signal and the next power of 2 to the `fft` function.

```
y = fft(x,n);
```

## See Also

[fft](#) | [log2](#) | [pow2](#)

**Purpose**            Number of nonzero matrix elements

**Syntax**            `n = nnz(X)`

**Description**        `n = nnz(X)` returns the number of nonzero elements in matrix `X`.  
The density of a sparse matrix is `nnz(X)/prod(size(X))`.

**Examples**            The matrix

```
w = sparse(wilkinson(21));
```

is a tridiagonal matrix with 20 nonzeros on each of three diagonals, so `nnz(w) = 60`.

**See Also**            `find` | `isa` | `nonzeros` | `nzmax` | `size` | `whos`

# noanimate

---

**Purpose** Change EraseMode of all objects to normal

---

**Note** noanimate will be removed in a future release.

---

**Syntax** noanimate(state, fig\_handle)  
noanimate(state)

**Description** noanimate(state, fig\_handle) sets the EraseMode of all image, line, patch, surface, and text graphics objects in the specified figure to normal. state can be the following strings:

- 'save' — Set the values of the EraseMode properties to normal for all the appropriate objects in the designated figure.
- 'restore' — Restore the EraseMode properties to the previous values (i.e., the values before calling noanimate with the 'save' argument).

noanimate(state) operates on the current figure.

noanimate is useful if you want to print the figure to a TIFF or JPEG format.

**See Also** print

**Purpose** Nonzero matrix elements

**Syntax** `s = nonzeros(A)`

**Description** `s = nonzeros(A)` returns a full column vector of the nonzero elements in A, ordered by columns.

This gives the s, but not the i and j, from `[i,j,s] = find(A)`.  
Generally,

`length(s) = nnz(A) <= nzmax(A) <= prod(size(A))`

**See Also** `find` | `isa` | `nnz` | `nzmax` | `size` | `whos`

# norm

---

**Purpose** Vector and matrix norms

**Syntax**  
`n = norm(X)`  
`n = norm(X,p)`

**Description** `n = norm(X)` returns the 2-norm of input `X` and is equivalent to `norm(X,2)`. If `X` is a vector, this is equal to the Euclidean distance. If `X` is a matrix, this is equal to the largest singular value of `X`.

`n = norm(X,p)` returns the  $p$ -norm of input `X`.

**Input Arguments**  
**X - Numeric array**  
scalar | vector | matrix

Numeric array, specified as a scalar, vector, or matrix. If `X` is sparse, then `norm(X)` returns an error.

**Data Types**  
single | double  
**Complex Number Support:** Yes

**p - Norm type**  
2 (default) | positive integer scalar | Inf | -Inf | 'fro'

Norm type, specified as 2 (default), a positive integer scalar, Inf, -Inf, or 'fro'. Whether `X` is a matrix or vector determines the allowed values of  $p$  (and what they return). The following table lists the calculated values for each allowed value of  $p$ .

---

**Note** The table does not reflect the actual algorithms used in calculations.

---

<b>p</b>	<b>Matrix</b>	<b>Vector</b>
1	$\max(\text{sum}(\text{abs}(X)))$	$\text{sum}(\text{abs}(X))$
2	$\max(\text{svd}(X))$	$\text{sum}(\text{abs}(X).^2)^{(1/2)}$
positive, real-valued numeric p	–	$\text{sum}(\text{abs}(X).^p)^{(1/p)}$
Inf	$\max(\text{sum}(\text{abs}(X')))$	$\max(\text{abs}(X))$
-Inf	–	$\min(\text{abs}(X))$
'fro'	$\text{sqrt}(\text{sum}(\text{diag}(X'*X)))$	$\text{norm}(X)$

## Output Arguments

### **n** - Matrix or vector norm

scalar

Matrix or vector norm, returned as a scalar. The norm gives a measure of the magnitude of the elements. By convention, norm returns NaN if the input contains NaN values.

## Examples

### **1- and 2- Norm of Vector**

Create a vector corresponding to the point (-2,3,-1) in 3-D space.

```
X = [-2 3 -1];
```

Calculate the 2-norm of the vector.

```
n = norm(X)
```

```
n =
```

```
3.7417
```

The 2-norm is equal to the Euclidean length of the vector.

Calculate the 1-norm of the vector.

```
n = norm(X,1)
```

```
n =
```

```
6
```

The 1-norm is equal to the sum of the element magnitudes.

## **2-Norm of Matrix**

Create a matrix.

```
X = [2 0 1; -1 1 0; -3 3 0];
```

The matrix has  $\text{rank}(X) = 2$ , so it has two nonzero singular values.

Calculate the 2-norm of the matrix.

```
n = norm(X)
```

```
n =
```

```
4.7234
```

The 2-norm is equal to the largest singular value of X.

## **Frobenius Norm of Sparse Matrix**

Create a sparse identity matrix, S.

```
S = sparse(1:25,1:25,1);
```

Attempt to use `norm(S)` to calculate the 2-norm of S.

```
n = norm(S)
```

```
Error using norm
```

```
Sparse norm(S,2) is not available.
```

When the input matrix is sparse, `norm(S)` returns an error.

Now use `'fro'` to calculate the Frobenius norm of the sparse matrix.

```
n = norm(S, 'fro')
```

```
n =
```

```
5
```

This calculates the 2-norm of the column vector,  $S(:)$ .

**See Also**

[cond](#) | [rcond](#) | [condest](#) | [normest](#) | [hypot](#)

# normest

---

**Purpose** 2-norm estimate

**Syntax**  
`nrm = normest(S)`  
`nrm = normest(S,tol)`  
`[nrm,count] = normest(...)`

**Description** This function is intended primarily for sparse matrices, although it works correctly and may be useful for large, full matrices as well.

`nrm = normest(S)` returns an estimate of the 2-norm of the matrix  $S$ .

`nrm = normest(S,tol)` uses relative error `tol` instead of the default tolerance  $1.e-6$ . The value of `tol` determines when the estimate is considered acceptable.

`[nrm,count] = normest(...)` returns an estimate of the 2-norm and also gives the number of power iterations used.

**Algorithms** The power iteration involves repeated multiplication by the matrix  $S$  and its transpose,  $S'$ . The iteration is carried out until two successive estimates agree to within the specified relative tolerance.

**See Also** `cond` | `condest` | `norm` | `rcond` | `svd`

**Purpose** Find logical NOT of array or scalar input

**Syntax** `~A`  
`not(A)`

**Description** `~A` performs a logical NOT of input array `A`, and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if the input array contains a zero value element at that same array location. Otherwise, that element is set to 0.

The input of the expression can be an array or can be a scalar value. If the input is an array, then the output is an array of the same dimensions. If the input is scalar, then the output is scalar.

`not(A)` is called for the syntax `~A` when `A` is an object.

**Examples** If matrix `A` is

0	29	0	36	0
23	34	35	0	39
0	24	31	27	0
0	29	0	0	34

then

`~A`  
ans =

1	0	1	0	1
0	0	0	1	0
1	0	0	0	1
1	0	1	1	0

**See Also** `bitcmp` | `and` | `or` | `xor` | `any` | `all`

**How To**

- “Bit-Wise Functions”

# notebook

---

**Purpose** Open MATLAB Notebook in Microsoft Word software (on Microsoft Windows platforms)

**Syntax** `notebook`  
`notebook('filename')`  
`notebook('-setup')`

**Description** `notebook` starts Microsoft Word software and creates a new MATLAB Notebook titled Document 1.

`notebook('filename')` starts Microsoft Word and opens the notebook `filename`, where `filename` is either in the MATLAB current folder or is a full path. If `filename` does not exist, MATLAB creates a new notebook titled `filename`. If the file name extension is not specified, MATLAB assumes `.doc`.

`notebook('-setup')` runs an interactive setup function for MATLAB Notebook. It copies the notebook template, `m-book.dot`, to the Microsoft Word template folder, whose location MATLAB automatically determines from the Windows system registry. Upon completion, MATLAB displays a message indicating whether or not the setup was successful.

**How To**

- “Create a MATLAB Notebook with Microsoft Word”
- “Publishing MATLAB Code”

**Purpose** Notify listeners that event is occurring

**Syntax** `notify(Hobj, 'EventName')`  
`notify(Hobj, 'EventName', data)`

**Description** `notify(Hobj, 'EventName')` notifies listeners that the specified event is taking place on the specified handle objects.

`notify(Hobj, 'EventName', data)` includes user-defined event data.

### **Input Arguments**

`Hobj`

Array of handle objects triggering the specified event.

`EventName`

Name of the event.

`data`

An `event.EventData` object encapsulating information about the event. You can define custom event data by subclassing `event.EventData` and passing an instance of your subclass as the data argument. See “Defining Event-Specific Data” for information on defining event data.

### **See Also**

See “Events and Listeners — Syntax and Techniques”

`handle`, `addlistener`

# now

---

**Purpose** Current date and time as serial date number

**Syntax** `t = now`

**Description** `t = now` returns the current date and time as a serial date number. A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`floor(now)` returns the current date as a serial date number, and `rem(now,1)` returns the current time as a serial date number. `datestr(now)` returns the current date and time as a string.

**Examples** `t1 = now, t2 = rem(now,1)`

```
t1 =  
  
    7.2908e+05
```

```
t2 =  
  
    0.4013
```

**See Also** `clock` | `date` | `datenum` | `datestr`

---

<b>Purpose</b>	Real nth root of real numbers
<b>Syntax</b>	$y = \text{nthroot}(X, n)$
<b>Description</b>	$y = \text{nthroot}(X, n)$ returns the real nth root of the elements of $X$ . Both $X$ and $n$ must be real and $n$ must be a scalar. If $X$ has negative entries, $n$ must be an odd integer.
<b>Examples</b>	$\text{nthroot}(-2, 3)$  returns the real cube root of -2.  ans =  -1.2599  By comparison,  $(-2)^{(1/3)}$  returns a complex cube root of -2.  ans =  0.6300 + 1.0911i
<b>See Also</b>	power   sqrt

# null

---

**Purpose** Null space

**Syntax** `Z = null(A)`  
`Z = null(A, 'r')`

**Description** `Z = null(A)` is an orthonormal basis for the null space of  $A$  obtained from the singular value decomposition. That is,  $A*Z$  has negligible elements, `size(Z,2)` is the nullity of  $A$ , and  $Z'*Z = I$ .

`Z = null(A, 'r')` is a “rational” basis for the null space obtained from the reduced row echelon form.  $A*Z$  is zero, `size(Z,2)` is an estimate for the nullity of  $A$ , and, if  $A$  is a small matrix with integer elements, the elements of the reduced row echelon form (as computed using `rref`) are ratios of small integers.

The orthonormal basis is preferable numerically, while the rational basis may be preferable pedagogically.

## Examples

### Example 1

Compute the orthonormal basis for the null space of a matrix  $A$ .

```
A = [1    2    3
      1    2    3
      1    2    3];
```

```
Z = null(A);
A*Z
```

```
ans =
  1.0e-015 *
    0.2220    0.2220
    0.2220    0.2220
    0.2220    0.2220
```

```
Z'*Z
```

```
ans =
```

```
1.0000 -0.0000
-0.0000 1.0000
```

### Example 2

Compute the 1-norm of the matrix  $A*Z$  and determine that it is within a small tolerance.

```
norm(A*Z,1) < 1e-12
ans =
1
```

### Example 3

Compute the rational basis for the null space of the same matrix A.

```
ZR = null(A, 'r')
```

```
ZR =
-2 -3
1 0
0 1
```

```
A*ZR
```

```
ans =
0 0
0 0
0 0
```

### See Also

# num2cell

---

**Purpose** Convert array to cell array with consistently sized cells

**Syntax**  
`C = num2cell(A)`  
`C = num2cell(A,dim)`

**Description** `C = num2cell(A)` converts array `A` into cell array `C` by placing each element of `A` into a separate cell in `C`. Array `A` need not be numeric.

`C = num2cell(A,dim)` splits the contents of `A` into separate cells of `C`, where `dim` specifies which dimensions of `A` to include in each cell. `dim` can be a scalar or a vector of dimensions. For example, if `A` has 2 rows and 3 columns, then:

- `num2cell(A,1)` creates a 1-by-3 cell array `C`, where each cell contains a 2-by-1 column of `A`.
- `num2cell(A,2)` creates a 2-by-1 cell array `C`, where each cell contains a 1-by-3 row of `A`.
- `num2cell(A,[1 2])` creates a 1-by-1 cell array `C`, where the cell contains the entire array `A`.

## Input Arguments

**A - Input**  
any type of multidimensional array

Input, specified as any type of multidimensional array.

**Data Types**  
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell` | `function_handle`

**dim - Dimension of A**  
positive integer | positive vector of integers

Dimension of `A`, specified as a positive integer or a vector of positive integers. `dim` must be between 1 and `ndims(A)`.

Elements need not be in numeric order. However, num2cell permutes the dimensions of the arrays in each cell of C to match the order of the specified dimensions.

**Data Types**

double

**Output Arguments**

**C - Resulting array**

cell array

Resulting array, returned as a cell array. The size of C depends on the size of A and the values of dim.

- If dim is not specified, then C is the same size as A.
- If dim is a scalar, then C contains numel(A)/size(A,dim) cells. If dim is 1 or 2, then each cell contains a column or row vector, respectively. If dim > 2, then each cell contains an array whose dimth dimensional length is size(A,dim), and whose other dimensions are all singletons.

For example, given a 4-by-7-by-3 array, A, this figure shows how num2cell creates cells corresponding to dim values of 1, 2, and 3.

- If dim is a vector containing N values, then C has numel(A)/prod([size(A,dim(1)), ..., size(A, vdim(N))]) cells. Each cell contains an array whose dim(i)th dimension has a length of size(A, dim(i)) and whose other dimensions are singletons.

For example, given a 4-by-7-by-3 array, you can specify dim as an positive integer vector to create cell arrays of different dimensions.

# num2cell

## Examples

### Convert Arrays to Cell Array

Place all elements of a numeric array into separate cells.

```
a = magic(3)
c = num2cell(a)
```

a =

```
8     1     6
3     5     7
4     9     2
```

c =

```
[8]    [1]    [6]
[3]    [5]    [7]
[4]    [9]    [2]
```

Place individual letters of a word into separate cells of an array.

```
a = ['four'; 'five'; 'nine']
c = num2cell(a)
```

a =

```
four
```

```
five
nine
```

```
c =
```

```
    'f'    'o'    'u'    'r'
    'f'    'i'    'v'    'e'
    'n'    'i'    'n'    'e'
```

### Create Cell Array of Numeric Arrays

Generate a 4-by-3-by-2 numeric array, and then create a 1-by-3-by-2 cell array of 4-by-1 column vectors.

```
A = reshape(1:12,4,3);
A(:,:,2) = A*10
C = num2cell(A,1)
```

```
A(:,:,1) =
```

```
    1    5    9
    2    6   10
    3    7   11
    4    8   12
```

```
A(:,:,2) =
```

```
   10   50   90
   20   60  100
   30   70  110
   40   80  120
```

```
C(:,:,1) =
```

```
 [4x1 double] [4x1 double] [4x1 double]
```

# num2cell

---

```
C(:,:,2) =  
    [4x1 double]    [4x1 double]    [4x1 double]
```

Each 4-by-1 vector contains elements from along the *first* dimension of A:

```
C{1}
```

```
ans =
```

```
    1  
    2  
    3  
    4
```

Create a 4-by-1-by-2 cell array of 1-by-3 numeric arrays.

```
C = num2cell(A,2)
```

```
C(:,:,1) =  
    [1x3 double]  
    [1x3 double]  
    [1x3 double]  
    [1x3 double]
```

```
C(:,:,2) =  
    [1x3 double]  
    [1x3 double]  
    [1x3 double]  
    [1x3 double]
```

Each 1-by-3 row vector contains elements from along the *second* dimension of A:

```
C{1}
```

```
ans =
```

```
    1    5    9
```

Finally, create a 4-by-3 cell array of 1-by-1-by-2 numeric arrays.

```
C = num2cell(A,3)
```

```
C =
```

```

    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
```

Each 1-by-1-by-2 vector contains elements from along the *third* dimension of A:

```
C{1}
```

```
ans(:,:,1) =
```

```
    1
```

```
ans(:,:,2) =
```

```
   10
```

### Combine Across Multiple Dimensions

Create a cell array by combining elements into numeric arrays along several dimensions.

```
a = reshape(1:12,4,3);
```

```
a(:,:,2) = a*10
```

```
c = num2cell(A,[1 3])
```

# num2cell

---

```
a(:,:,1) =
```

```
    1    5    9
    2    6   10
    3    7   11
    4    8   12
```

```
a(:,:,2) =
```

```
   10   50   90
   20   60  100
   30   70  110
   40   80  120
```

```
c =
```

```
 [4x1x2 double]  [4x1x2 double]  [4x1x2 double]
```

Each 4-by-1-by-2 array contains elements from along the first and third dimension of A:

```
c{1}
```

```
ans(:,:,1) =
```

```
    1
    2
    3
    4
```

```
ans(:,:,2) =
```

```
   10
   20
```

```
30  
40
```

```
c = num2cell(A,[2 3])
```

```
c =
```

```
[1x3x2 double]  
[1x3x2 double]  
[1x3x2 double]  
[1x3x2 double]
```

```

# num2hex

---

**Purpose** Convert singles and doubles to IEEE hexadecimal strings

**Syntax** num2hex(X)

**Description** If X is a single or double precision array with n elements, num2hex(X) is an n-by-8 or n-by-16 char array of the hexadecimal floating-point representation. The same representation is printed with format hex.

**Examples**

```
num2hex([1 0 0.1 -pi Inf NaN])

returns

ans =

3ff0000000000000
0000000000000000
3fb999999999999a
c00921fb54442d18
7ff0000000000000
fff8000000000000
num2hex(single([1 0 0.1 -pi Inf NaN]))
```

returns

ans =

```
3f800000
00000000
3dcccccd
c0490fdb
7f800000
ffc00000
```

**See Also** hex2num | dec2hex | format

**Purpose** Convert number to string

**Syntax**

```
str = num2str(A)
str = num2str(A,precision)
str = num2str(A,formatSpec)
```

**Description** `str = num2str(A)` converts array `A` into a string representation `str`. The output format depends upon the magnitude of the original values and sometimes includes exponents. `num2str` is useful for labeling and titling plots with numeric values.

`str = num2str(A,precision)` returns a string representation with the maximum number of digits specified by `precision`.

`str = num2str(A,formatSpec)` applies a format specified by `formatSpec` to all elements of `A`.

## Input Arguments

### **A - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array of real or complex numbers.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **precision - Numeric precision**

positive integer

Numeric precision of the output string, specified as a positive integer. This is the maximum number of digits in the output string.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## formatSpec - Format of the output fields

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F
Floating-point number	%f	Fixed-point notation
	%e	Exponential notation, such as 3.141593e+00
	%E	Same as %e, but uppercase, such as 3.141593E+00
	%g	The more compact of %e or %f, with no trailing zeros
	%G	The more compact of %E or %f, with no trailing zeros
	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value Example: %bx prints pi as 400921fb54442d18

Value Type	Conversion	Details
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value Example: %tx prints pi as 40490fdb
Characters	%c	Single character
	%s	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Identifier

Order for processing inputs. Use the syntax `n$`, where `n` represents the position of the value in the input list.

For example, `'%3$s %2$s %1$s %2$s'` prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

- ' ' Left-justify. Example: `%-5.2f`
- '+' Print sign character (+) for positive values. Example:  `%+5.2f`
- ' ' Pad to field width with spaces before the value. Example:  `% 5.2f`

'0' Pad to field width with zeros. Example: %05.2f

'#' Modify selected numeric conversions:

- For %o, %x, or %X, print 0, 0x, or 0X prefix.
- For %f, %e, or %E, print decimal point even when precision is 0.
- For %g or %G, do not remove trailing zeros or decimal point.

Example: %#5.0f

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

- Precision

For %f, %e, or %E: Number of digits to the right of the decimal point.

Example: '%6.4f' prints pi as '3.1416'

For %g or %G: Number of significant digits.

Example: '%6.4g' prints pi as ' 3.142'

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%6.4f', pi) is equivalent to ('%\*.\*f', 6, 4, pi).

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include '' in formatSpec.
- Control characters, including:

<code>%%</code>	Percent character
<code>\\</code>	Backslash
<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\xN</code>	Character whose ASCII code is the hexadecimal number, <i>N</i>
<code>\W</code>	Character whose ASCII code is the octal number, <i>N</i>

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.
- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, `'%s'` converts `[65 66 67]` to `ABC`.

## Output Arguments

### **str** - String representation of input array

character array

String representation of the input array, *A*, returned as a character array.

## Algorithms

num2str trims any leading spaces from a string, even when formatSpec includes a space character flag. For example, num2str(42.67, '%10.2f') returns a 1-by-5 character array '42.67'.

## Examples

### Default Conversions of Floating-Point Values

Convert pi and eps to text strings.

```
str = num2str(pi)
```

```
str =  
3.1416
```

```
str = num2str(eps)
```

```
str =  
2.2204e-16
```

### Specifying Precision

Specify the number of significant digits for floating-point values.

```
A = gallery('normaldata',[2,2],0);  
precision = 3;  
str = num2str(A,precision)
```

```
str =  
-0.433    0.125  
-1.67     0.288
```

### Specifying Formatting

Specify the width, precision, and other formatting for an array of floating-point values.

```
A = gallery('uniformdata',[2,3],0) * 9999;  
formatSpec = '%10.5e\n';  
str = num2str(A,formatSpec)
```

```
str =  
9.50034e+03
```

```
6.06782e+03
8.91210e+03
2.31115e+03
4.85934e+03
7.62021e+03
```

The format `'%10.5e'` prints each value in exponential format with five decimal places, and `'\n'` prints a new line character.

# Tiff.numberOfStrips

---

**Purpose** Total number of strips in image

**Syntax** `numStrips = tiffobj.numberOfStrips()`

**Description** `numStrips = tiffobj.numberOfStrips()` returns the total number of strips in the image.

## **Examples Determine Number of Strips in Image**

Determine the number of strips in the second image of a file.

Create a Tiff object associated with the example file, `example.tif`.

```
t = Tiff('example.tif', 'r');
```

When the Tiff object is created, the first image in the file is the current image file directory.

Make the second image the current directory.

```
t.nextDirectory();
```

Get the number of strips in the image if the image has a stripped organization.

```
if ~t.isTiled()
    numStrips = t.numberOfStrips()
end
```

```
numStrips =
```

```
7
```

The image has 7 strips.

Close the Tiff object.

```
t.close();
```

## References

This method corresponds to the `TIFFNumberOfStrips` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# Tiff.numberOfTiles

---

**Purpose** Total number of tiles in image

**Syntax** `numTiles = tiffobj.numberOfTiles()`

**Description** `numTiles = tiffobj.numberOfTiles()` returns the total number of tiles in the image.

## **Examples** **Determine Number of Tiles in Image**

Create a `Tiff` object associated with the example file, `example.tif`. Get the number of tiles in the image if the image has a tiled organization.

```
t = Tiff('example.tif', 'r');
if t.isTiled()
    nTiles = t.numberOfTiles()
end
```

```
nTiles =
```

```
    110
```

The image has 110 tiles.

Close the `Tiff` object.

```
t.close();
```

**References** This method corresponds to the `TIFFNumberOfTiles` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Number of array elements

**Syntax** `n = numel(A)`

**Description** `n = numel(A)` returns the number of elements, `n`, in array `A`, equivalent to `prod(size(A))`.

**Input Arguments** **A - Input array**  
 scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, tables, structure arrays, cell arrays, and object arrays.

**Examples** **Number of Elements in 3-D Matrix**

Create a 4-by-4-by-2 matrix.

```
A = magic(4);
A(:,:,2) = A'
```

```
A(:,:,1) =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

```
A(:,:,2) =
    16     5     9     4
     2    11     7    14
     3    10     6    15
    13     8    12     1
```

`numel` counts 32 elements in the matrix.

```
n = numel(A)
```

```
n =  
  
    32
```

## Number of Elements in Cell Array of Strings

Create a cell array of strings.

```
A = {'dog','cat','fish','horse'};
```

numel counts 4 string elements in the array.

```
n = numel(A)
```

```
n =  
  
    4
```

## Number of Elements in Table

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};  
Age = [38;43;38;40;49];  
Height = [71;69;64;67;64];  
Weight = [176;163;131;133;119];  
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
A = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
A =  
  
    Age      Height      Weight      BloodPressure  
    ---      -
```

---

Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the number of elements in the table.

```
n = numel(A)
```

```
n =
```

```
20
```

numel returns a value equivalent to `prod(size(A))` corresponding to the 5 rows and 4 variables.

## Limitations

- If `A` is a table, `numel` returns the number of elements in the table, `A`, equivalent to `prod(size(A))`. Variables in a table can have multiple columns, but `numel(A)` only accounts for the number of rows and number of variables.

## See Also

`prod` | `size` | `subsref`

## Concepts

- “Caution When Customizing Classes”

# nzmax

---

**Purpose** Amount of storage allocated for nonzero matrix elements

**Syntax** `n = nzmax(S)`

**Description** `n = nzmax(S)` returns the amount of storage allocated for nonzero elements.

If `S` is a sparse matrix... `nzmax(S)` is the number of storage locations allocated for the nonzero elements in `S`.

If `S` is a full matrix... `nzmax(S) = prod(size(S))`.

Often, `nnz(S)` and `nzmax(S)` are the same. But if `S` is created by an operation which produces fill-in matrix elements, such as sparse matrix multiplication or sparse LU factorization, more storage may be allocated than is actually required, and `nzmax(S)` reflects this. Alternatively, `sparse(i,j,s,m,n,nzmax)` or its simpler form, `spalloc(m,n,nzmax)`, can set `nzmax` in anticipation of later fill-in.

**See Also** `find` | `isa` | `nnz` | `nonzeros` | `size` | `whos`

**Purpose** Solve fully implicit differential equations, variable order method

**Syntax**

```
[T,Y] = ode15i(odefun,tspan,y0,yp0)
[T,Y] = ode15i(odefun,tspan,y0,yp0,options)
[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)
sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)
```

**Arguments** The following table lists the input arguments for `ode15i`.

<code>odefun</code>	A function handle that evaluates the left side of the differential equations, which are of the form $f(t,y,y') = 0$ .
<code>tspan</code>	A vector specifying the interval of integration, $[t_0, t_f]$ . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .
<code>y0, yp0</code>	Vectors of initial conditions for $y$ and $y'$ respectively.
<code>options</code>	Optional integration argument created using the <code>odeset</code> function. See <code>odeset</code> for details.

The following table lists the output arguments for `ode15i`.

<code>T</code>	Column vector of time points
<code>Y</code>	Solution array. Each row in $y$ corresponds to the solution at a time returned in the corresponding row of $t$ .

**Description** `[T,Y] = ode15i(odefun,tspan,y0,yp0)` with `tspan = [t0 tf]` integrates the system of differential equations  $f(t,y,y') = 0$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$  and  $yp_0$ . `odefun` is a function handle. Function `ode15i` solves ODEs and DAEs of index 1. The initial conditions must be consistent, meaning that  $f(t_0,y_0,yp_0) = 0$ . You can use the function `decic` to compute consistent initial conditions close to guessed values. Function `odefun(t,y,yp)`, for a scalar  $t$  and column vectors  $y$  and  $yp$ , must return a column vector corresponding to  $f(t,y,y')$ . Each row in the solution array  $Y$  corresponds to a time returned in the

column vector  $T$ . To obtain solutions at specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $tspan = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`[T,Y] = ode15i(odefun,tspan,y0,yp0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used options include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components  $1e-6$  by default). See `odeset` for details.

`[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)` with the 'Events' property in `options` set to a function `events`, solves as above while also finding where functions of  $(t,y,y')$ , called event functions, are zero. The function `events` is of the form `[value,isterminal,direction] = events(t,y,yp)` and includes the necessary event functions. Code the function `events` so that the  $i$ th element of each output vector corresponds to the  $i$ th event. For the  $i$ th event function in `events`:

- `value(i)` is the value of the function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Output `TE` is a column vector of times at which events occur. Rows of `YE` are the corresponding solutions, and indices in vector `IE` specify which event occurred. See “Integrator Options” in the MATLAB Mathematics documentation for more information.

`sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)` returns a structure that can be used with `deval` to evaluate the solution at any point between `t0` and `tfinal`. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver. If you specify the <code>Events</code> option and a terminal event is detected, <code>sol.x(end)</code> contains the end of the step at which the event occurred.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

## Options

`ode15i` accepts the following parameters in options. For more information, see `odeset` and [Changing ODE Integration Properties](#) in the MATLAB Mathematics documentation.

Error control	<code>RelTol</code> , <code>AbsTol</code> , <code>NormControl</code>
Solver output	<code>OutputFcn</code> , <code>OutputSel</code> , <code>Refine</code> , <code>Stats</code>
Event location	<code>Events</code>
Step size	<code>MaxStep</code> , <code>InitialStep</code>
Jacobian matrix	<code>Jacobian</code> , <code>JPattern</code> , <code>Vectorized</code>

## Solver Output

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, and `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

## Jacobian Matrices

The Jacobian matrices  $\partial f/\partial y$  and  $\partial f/\partial y'$  are critical to reliability and efficiency. You can provide these matrices as one of the following:

- Function of the form `[dfdy,dfdyp] = FJAC(t,y,yp)` that computes the Jacobian matrices. If `FJAC` returns an empty matrix `[]` for either `dfdy` or `dfdyp`, then `ode15i` approximates that matrix by finite differences.
- Cell array of two constant matrices `{dfdy,dfdyp}`, either of which could be empty.

Use `odeset` to set the `Jacobian` option to the function or cell array. If you do not set the `Jacobian` option, `ode15i` approximates both Jacobian matrices by finite differences.

For `ode15i`, `Vectorized` is a two-element cell array. Set the first element to `'on'` if `odefun(t,[y1,y2,...],yp)` returns `[odefun(t,y1,yp),odefun(t,y2,yp),...]`. Set the second element to `'on'` if `odefun(t,y,[yp1,yp2,...])` returns `[odefun(t,y,yp1),odefun(t,y,yp2),...]`. The default value of `Vectorized` is `{'off','off'}`.

For `ode15i`, `JPattern` is also a two-element sparse matrix cell array. If  $\partial f/\partial y$  or  $\partial f/\partial y'$  is a sparse matrix, set `JPattern` to the sparsity patterns, `{SPDY, SPDYP}`. A sparsity pattern of  $\partial f/\partial y$  is a sparse matrix `SPDY` with `SPDY(i,j) = 1` if component `i` of  $f(t,y,yp)$  depends on component `j` of  $y$ , and 0 otherwise. Use `SPDY = []` to indicate that  $\partial f/\partial y$  is a full matrix. Similarly for  $\partial f/\partial y'$  and `SPDYP`. The default value of `JPattern` is `{[], []}`.

## Examples

### Example 1

This example uses a helper function `decic` to hold fixed the initial value for  $y(t_0)$  and compute a consistent initial value for  $y'(t_0)$  for the Weissinger implicit ODE. The Weissinger function evaluates the residual of the implicit ODE.

```
t0 = 1;
y0 = sqrt(3/2);
yp0 = 0;
[y0,yp0] = decic(@weissinger,t0,y0,1,yp0,0);
```

The example uses `ode15i` to solve the ODE, and then plots the numerical solution against the analytical solution.

```
[t,y] = ode15i(@weissinger,[1 10],y0,yp0);
ytrue = sqrt(t.^2 + 0.5);
plot(t,y,t,ytrue,'o');
```

## Other Examples

The files, `ihb1dae.m` and `iburgersode.m`, are examples of implicit ODEs.

## See Also

`decic` | `deval` | `odeget` | `odeset` | `function_handle` | `ode45` | `ode23` | `ode113` | `ode15s` | `ode23s` | `ode23t` | `ode23tb`

**Purpose** Solve stiff differential equations and DAEs; variable order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

T	Column vector of time points.
Y	Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T.
TE	The time at which an event occurs.
YE	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
 sol          Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

# ode15s

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4213 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode15s

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose** Solve nonstiff differential equations; low order method

**Syntax**  
`[T,Y] = solver(odefun,tspan,y0)`  
`[T,Y] = solver(odefun,tspan,y0,options)`  
`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)`  
`sol = solver(odefun,[t0 tf],y0...)`

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
---------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .
--------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
sol           Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t,y)$ , for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to  $f(t,y)$ . Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0, t1, ..., tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the *i*th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4228 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

## ode23

---

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode23

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## See Also

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

**Purpose**

Solve stiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

T	Column vector of time points.
Y	Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T.
TE	The time at which an event occurs.
YE	The solution at the time of the event.

IE	The index <i>i</i> of the event function that vanishes.
sol	Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4243 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode23s

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.'
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

deval | ode15i | odeget | odeset | function\_handle

**Purpose** Solve moderately stiff ODEs and DAEs; trapezoidal rule

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
sol           Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4258 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode23t

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

**Purpose**

Solve stiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

T	Column vector of time points.
Y	Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T.
TE	The time at which an event occurs.
YE	The solution at the time of the event.

IE	The index <i>i</i> of the event function that vanishes.
sol	Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i, j) = 1` if for any `k`, the `(i, k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4273 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode23tb

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose** Solve nonstiff differential equations; medium order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.

IE	The index <i>i</i> of the event function that vanishes.
sol	Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4288 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode45

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

# ode45

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## See Also

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

**Purpose** Solve nonstiff differential equations; variable order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0` A vector of initial conditions.

`options` Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

T	Column vector of time points.
Y	Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T.
TE	The time at which an event occurs.
YE	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
 sol          Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to  $f(t,y)$ . Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1`, ..., `tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the *i*th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4303 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode113

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

# odeget

---

**Purpose** Ordinary differential equation options parameters

**Syntax**  
`o = odeget(options, 'name')`  
`o = odeget(options, 'name', default)`

**Description** `o = odeget(options, 'name')` extracts the value of the property specified by string 'name' from integrator options structure `options`, returning an empty matrix if the property value is not specified in `options`. It is only necessary to type the leading characters that uniquely identify the property name. Case is ignored for property names.

`o = odeget(options, 'name', default)` returns `o = default` if the named property is not specified in `options`.

The empty matrix `[]` is a valid `options` argument, and the syntax `odeget([], 'name', default)` always returns `default`.

**Examples** Having constructed an ODE options structure,

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-3 2e-3 3e-3]);
```

you can view these property settings with `odeget`.

```
odeget(options,'RelTol')  
ans =
```

```
1.0000e-04
```

```
odeget(options,'AbsTol')  
ans =
```

```
0.0010    0.0020    0.0030
```

```
odeget([], 'RelTol', 1e-3)  
ans =
```

```
1.0000e-03
```

**See Also**

odeset

# odeset

---

**Purpose** Create or alter options structure for ordinary differential equation solvers

**Syntax**

```
options = odeset('name1',value1,'name2',value2,...)
options = odeset(olddopts,'name1',value1,...)
options = odeset(olddopts,newopts)
odeset
```

**Description** The odeset function lets you adjust the integration parameters of the following ODE solvers.

For solving fully implicit differential equations:

```
ode15i
```

For solving initial value problems:

```
ode23, ode45, ode113, ode15s, ode23s, ode23t, ode23tb
```

See below for information about the integration parameters.

`options = odeset('name1',value1,'name2',value2,...)` creates an options structure that you can pass as an argument to any of the ODE solvers. In the resulting structure, `options`, the named properties have the specified values. For example, 'name1' has the value `value1`. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify a property name. Case is ignored for property names.

`options = odeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This sets `options` equal to the existing structure `olddopts`, overwrites any values in `olddopts` that are respecified using name/value pairs, and adds any new pairs to the structure. The modified structure is returned as an output argument.

`options = odeset(olddopts,newopts)` alters an existing options structure `olddopts` by combining it with a new options structure `newopts`. Any new options not equal to the empty matrix overwrite corresponding options in `olddopts`.

odeset with no input arguments displays all property names as well as their possible and default values.

## ODE Properties

The following sections describe the properties that you can set using odeset. The available properties depend on the ODE solver you are using. There are several categories of properties:

- “Error Control Properties” on page 1-4309
- “Solver Output Properties” on page 1-4311
- “Step-Size Properties” on page 1-4314
- “Event Location Property” on page 1-4316
- “Jacobian Matrix Properties” on page 1-4317
- “Mass Matrix and DAE Properties” on page 1-4321
- “ode15s and ode15i-Specific Properties” on page 1-4323

---

**Note** This reference page describes the ODE properties for MATLAB, Version 7. The Version 5 properties are supported only for backward compatibility. For information on the Version 5 properties, type at the MATLAB command line: `more on`, `type odeset`, `more off`.

---

## Error Control Properties

At each step, the solver estimates the local error  $e$  in the  $i$ th component of the solution. This error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

$$|e(i)| \leq \max(\text{RelTol} * \text{abs}(y(i)), \text{AbsTol}(i))$$

For routine problems, the ODE solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For

the absolute error tolerance, the scaling of the solution components is important: if  $|y|$  is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in  $y$ . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component  $y(i)$  when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in  $y(i)$  so that you can accurately compute more interesting components.

The following table describes the error control properties. Further information on each property is given following the table.

Property	Value	Description
<code>RelTol</code>	Positive scalar {1e-3}	Relative error tolerance that applies to all components of the solution vector $y$ .
<code>AbsTol</code>	Positive scalar or vector {1e-6}	Absolute error tolerances that apply to the individual components of the solution vector.
<code>NormControl</code>	on   {off}	Control error relative to norm of solution.

## Description of Error Control Properties

**RelTol** — This tolerance is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components, except those smaller than thresholds `AbsTol(i)`.

The default, `1e-3`, corresponds to 0.1% accuracy.

**AbsTol** — `AbsTol(i)` is a threshold below which the value of the  $i$ th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero.

If `AbsTol` is a vector, the length of `AbsTol` must be the same as the length of the solution vector `y`. If `AbsTol` is a scalar, the value applies to all components of `y`.

**NormControl** — Set this property on to request that the solvers control the error in each integration step with  $\text{norm}(e) \leq \max(\text{RelTol} \cdot \text{norm}(y), \text{AbsTol})$ . By default the solvers use a more stringent componentwise error control.

## Solver Output Properties

The following table lists the solver output properties that control the output that the solvers generate. Further information on each property is given following the table.

Property	Value	Description
NonNegative	Vector of integers	Specifies which components of the solution vector must be nonnegative. The default value is <code>[]</code> .
OutputFcn	Function handle	A function for the solver to call after every successful integration step.
OutputSel	Vector of indices	Specifies which components of the solution vector are to be passed to the output function.
Refine	Positive integer	Increases the number of output points by a factor of <code>Refine</code> .
Stats	on   {off}	Determines whether the solver should display statistics about its computations. By default, <code>Stats</code> is off.

### Description of Solver Output Properties

**NonNegative** — The `NonNegative` property is not available in `ode23s`, `ode15i`. In `ode15s`, `ode23t`, and `ode23tb`, `NonNegative` is not available for problems where there is a mass matrix.

**OutputFcn** — To specify an output function, set 'OutputFcn' to a function handle. For example,

```
options = odeset('OutputFcn',@myfun)
```

sets 'OutputFcn' to @myfun, a handle to the function myfun. See the [function\\_handle](#) reference page for more information.

The output function must be of the form

```
status = myfun(t,y,flag)
```

“Parameterizing Functions” explains how to provide additional parameters to myfun, if necessary.

The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:

Flag	Description
init	The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> and <code>y0</code> are the input arguments to the ODE solver.
{[]}	The solver calls <code>status = myfun(t,y,[])</code> after each integration step on which output is requested. <code>t</code> contains points where output was generated during the step, and <code>y</code> is the numerical solution at the points in <code>t</code> . If <code>t</code> is a vector, the <i>i</i> th column of <code>y</code> corresponds to the <i>i</i> th element of <code>t</code> .  When <code>length(tspan) &gt; 2</code> the output is produced at every point in <code>tspan</code> . When <code>length(tspan) = 2</code> the output is produced according to the <code>Refine</code> option.

Flag	Description
	myfun must return a status output value of 0 or 1. If status = 1, the solver halts integration. You can use this mechanism, for instance, to implement a <b>Stop</b> button.
done	The solver calls myfun([],[], 'done') when integration is complete to allow the output function to perform any cleanup chores.

You can use these general purpose output functions or you can edit them to create your own. Type `help` function at the command line for more information.

- `odeplot` — Time series plotting (default when you call the solver with no output arguments and you have not specified an output function)
- `odephas2` — Two-dimensional phase plane plotting
- `odephas3` — Three-dimensional phase plane plotting
- `odeprint` — Print solution as it is computed

---

**Note** If you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history.

---

**OutputSel** — Use `OutputSel` to specify which components of the solution vector you want passed to the output function. For example, if you want to use the `odeplot` output function, but you want to plot only the first and third components of the solution, you can do this using

```
options = ...
odeset('OutputFcn',@odeplot,'OutputSel',[1 3]);
```

By default, the solver passes all components of the solution to the output function.

**Refine** — If `Refine` is 1, the solver returns solutions only at the end of each time step. If `Refine` is  $n > 1$ , the solver subdivides each time step into  $n$  smaller intervals and returns solutions at each time point. `Refine` does not apply when `length(tspan) > 2` or the ODE solver returns the solution as a structure.

---

**Note** In all the solvers, the default value of `Refine` is 1. Within `ode45`, however, the default is 4 to compensate for the solver's large step sizes. To override this and see only the time steps chosen by `ode45`, set `Refine` to 1.

---

The extra values produced for `Refine` are computed by means of continuous extension formulas. These are specialized formulas used by the ODE solvers to obtain accurate solutions between computed time steps without significant increase in computation time.

**Stats** — By default, `Stats` is off. If it is on, after solving the problem the solver displays

- Number of successful steps
- Number of failed attempts
- Number of times the ODE function was called to evaluate  $f(t,y)$

Solvers based on implicit methods, including `ode23s`, `ode23t`, `ode15s`, and `ode15i`, also display

- Number of times that the partial derivatives matrix  $\partial f/\partial x$  was formed
- Number of LU decompositions
- Number of solutions of linear systems

## Step-Size Properties

The step-size properties specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step-size properties. Further information on each property is given following the table.

Property	Value	Description
InitialStep	Positive scalar	Suggested initial step size.
MaxStep	Positive scalar {0.1*abs(t0-tf)}	Upper bound on solver step size.

### Description of Step-Size Properties

**InitialStep** — InitialStep sets an upper bound on the magnitude of the first step size the solver tries. If you do not set InitialStep, the initial step size is based on the slope of the solution at the initial time `tspan(1)`, and if the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable InitialStep.

**MaxStep** — If the differential equation has periodic coefficients or solutions, it might be a good idea to set MaxStep to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce MaxStep for any of the following purposes:

- To produce more output points. This can significantly slow down solution time. Instead, use `Refine` to compute additional outputs by continuous extension at very low cost.
- When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. See “Error Control Properties” on page 1-4309 for a description of the error tolerance properties.
- To make sure that the solver doesn’t step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into

two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbsTol`. Use `MaxStep` as a last resort.

## Event Location Property

In some ODE problems the times of specific events are important, such as the time at which a ball hits the ground, or the time at which a spaceship returns to the earth. While solving a problem, the ODE solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the Events property. Further information on each property is given following the table.

### ODE Events Property

String	Value	Description
Events	Function handle	Handle to a function that includes one or more event functions.

### Description of Event Location Properties

**Events** — The function is of the form

```
[value, isterminal, direction] = events(t,y)
```

`value`, `isterminal`, and `direction` are vectors for which the `ith` element corresponds to the `ith` event function:

- `value(i)` is the value of the `ith` event function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function, otherwise, 0.
- `direction(i) = 0` if all zeros are to be located (the default), +1 if only zeros where the event function is increasing, and -1 if only zeros where the event function is decreasing.

If you specify an events function and events are detected, the solver returns three additional outputs:

- A column vector of times at which events occur
- Solution values corresponding to these times
- Indices into the vector returned by the events function. The values indicate which event the solver detected.

If you call the solver as

```
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as TE, YE, and IE respectively. If you call the solver as

```
sol = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as sol.xe, sol.ye, and sol.ie, respectively.

For examples that use an event function, see “Event Location” and “Advanced Event Location” in the MATLAB Mathematics documentation.

## Jacobian Matrix Properties

The stiff ODE solvers often execute faster if you provide additional information about the Jacobian matrix  $\partial f/\partial y$ , a matrix of partial derivatives of the function that defines the differential equations.

$$\frac{\partial f}{\partial y} = \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} & \dots \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} & \dots \\ \vdots & \vdots & \ddots \end{bmatrix}$$

The Jacobian matrix properties pertain only to those solvers for stiff problems (ode15s, ode23s, ode23t, ode23tb, and ode15i) for which the Jacobian matrix  $\partial f/\partial y$  can be critical to reliability and efficiency. If you do not provide a function to calculate the Jacobian, these solvers

approximate the Jacobian numerically using finite differences. In this case, you might want to use the `Vectorized` or `JPattern` properties.

The following table describes the Jacobian matrix properties for all implicit solvers except `ode15i`. Further information on each property is given following the table. See [Jacobian Properties for `ode15i`](#) on page 1-4320 for `ode15i`-specific information.

### Jacobian Properties for All Implicit Solvers Except `ode15i`

Property	Value	Description
Jacobian	Function handle   constant matrix	Matrix or function that evaluates the Jacobian.
JPattern	Sparse matrix of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Allows the solver to reduce the number of function evaluations required.

### Description of Jacobian Properties

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function `FJac`, where `FJac(t,y)` computes  $\partial f/\partial y$ , or to the constant value of  $\partial f/\partial y$ .

The Jacobian for the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, can be coded as

```
function J = vdp1000jac(t,y)
J = [ 0 1
      (-2000*y(1)*y(2)-1) (1000*(1-y(1)^2)) ];
```

**JPattern** — `JPattern` is a sparsity pattern with 1s where there might be nonzero entries in the Jacobian.

---

**Note** If you specify `Jacobian`, the solver ignores any setting for `JPattern`.

---

Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if component  $i$  of  $f(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. The solver uses this sparsity pattern to generate a sparse Jacobian matrix numerically. If the Jacobian matrix is large and sparse, this can greatly accelerate execution. For an example using the `JPattern` property, see Example: Large, Stiff, Sparse Problem in the MATLAB Mathematics documentation.

**Vectorized** — The `Vectorized` property allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

Set `on` to inform the solver that you have coded the ODE function `F` so that `F(t,[y1 y2 ...])` returns `[F(t,y1) F(t,y2) ...]`. This allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

---

**Note** If you specify `Jacobian`, the solver ignores a setting of `'on'` for `'Vectorized'`.

---

With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. For example, you can vectorize the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, by introducing colon notation into the subscripts and by using the array power (`.`<sup>`^`</sup>) and array multiplication (`.`<sup>`*`</sup>) operators.

```
function dydt = vdp1000(t,y)
dydt = [y(2,:); 1000*(1-y(1,:).^2).*y(2,:)-y(1,:)];
```

---

**Note** Vectorization of the ODE function used by the ODE solvers differs from the vectorization used by the boundary value problem (BVP) solver, `bvp4c`. For the ODE solvers, the ODE function is vectorized only with respect to the second argument, while `bvp4c` requires vectorization with respect to the first and second arguments.

---

The following table describes the Jacobian matrix properties for `ode15i`.

### Jacobian Properties for `ode15i`

Property	Value	Description
Jacobian	Function handle   Cell array of constant values	Function that evaluates the Jacobian or a cell array of constant values.
JPattern	Sparse matrices of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Vectorized ODE function

### Description of Jacobian Properties for `ode15i`

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function

$$[dFd_y, dFd_p] = Fjac(t, y, y_p)$$

or to a cell array of constant values  $[\partial F/\partial y, (\partial F/\partial y)']$ .

**JPattern** — `JPattern` is a sparsity pattern with 1's where there might be nonzero entries in the Jacobian.

Set this property to `{dFd_yPattern, dFd_pPattern}`, the sparsity patterns of  $\partial F/\partial y$  and  $\partial F/\partial y'$ , respectively.

**Vectorized** —

Set this property to {yVect, ypVect}. Setting yVect to 'on' indicates that

```
F(t, [y1 y2 ...], yp)
```

returns

```
[F(t,y1,yp), F(t,y2,yp) ...]
```

Setting ypVect to 'on' indicates that

```
F(t,y,[yp1 yp2 ...])
```

returns

```
[F(t,y,yp1) F(t,y,yp2) ...]
```

## Mass Matrix and DAE Properties

This section describes mass matrix and differential-algebraic equation (DAE) properties, which apply to all the solvers except `ode15i`. These properties are not applicable to `ode15i` and their settings do not affect its behavior.

The solvers of the ODE suite can solve ODEs of the form

$$M(t,y)y' = f(t,y) \tag{1-3}$$

with a mass matrix  $M(t,y)$  that can be sparse.

When  $M(t,y)$  is nonsingular, the equation above is equivalent to  $y' = M^{-1}f(t,y)$  and the ODE has a solution for any initial values  $y_0$  at  $t_0$ . The more general form (Equation 1-3) is convenient when you express a model naturally in terms of a mass matrix. For large, sparse  $M(t,y)$ , solving Equation 1-3 directly reduces the storage and run-time needed to solve the problem.

When  $M(t,y)$  is singular, then  $M(t,y)$  times  $M(t,y)y' = f(t,y)$  is a DAE. A DAE has a solution only when  $y_0$  is consistent; that is, there exists an initial slope  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . If  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve

the problem. For DAEs of index 1, solving an initial value problem with consistent initial conditions is much like solving an ODE.

The `ode15s` and `ode23t` solvers can solve DAEs of index 1. For examples of DAE problems, see Example: Differential-Algebraic Problem, in the MATLAB Mathematics documentation, and the examples `amp1dae` and `hb1dae`.

The following table describes the mass matrix and DAE properties. Further information on each property is given following the table.

## Mass Matrix and DAE Properties (Solvers Other Than `ode15i`)

Property	Value	Description
Mass	Matrix   function handle	Mass matrix or a function that evaluates the mass matrix $M(t,y)$ .
MStateDependence	none   {weak}   strong	Dependence of the mass matrix on $y$ .
MvPattern	Sparse matrix	$\partial(M(t,y)v)/\partial y$ sparsity pattern.
MassSingular	yes   no   {maybe}	Indicates whether the mass matrix is singular.
InitialSlope	Vector {zero vector}	Vector representing the consistent initial slope $yp_0$ .

## Description of Mass Matrix and DAE Properties

**Mass** — For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a mass matrix  $M$ . For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a function handle `@Mfun`, where `Mfun(t,y)` evaluates the mass matrix  $M(t,y)$ . The `ode23s` solver can only solve problems with a constant mass matrix  $M$ . When solving DAEs, using `ode15s` or `ode23t`, it is advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semiexplicit DAE).

For example problems, see “Finite Element Discretization” in the MATLAB Mathematics documentation, or the examples `fem2ode` or `batonode`.

**MStateDependence** — Set this property to `none` for problems

$M(t)y' = f(t,y)$ . Both `weak` and `strong` indicate  $M(t,y)$ , but `weak` results in implicit solvers using approximations when solving algebraic equations.

**MvPattern** — Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if, for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. For use with the `ode15s`, `ode23t`, and `ode23tb` solvers when `MStateDependence` is `strong`. See `burgersode` as an example.

**MassSingular** — Set this property to `no` if the mass matrix is not singular and you are using either the `ode15s` or `ode23t` solver. The default value of `maybe` causes the solver to test whether the problem is a DAE, by testing whether  $M(t_0,y_0)$  is singular.

**InitialSlope** — Vector representing the consistent initial slope  $yp_0$ , where  $yp_0$  satisfies  $M(t_0,y_0) \cdot yp_0 = f(t_0,y_0)$ . The default is the zero vector.

This property is for use with the `ode15s` and `ode23t` solvers when solving DAEs.

## ode15s and ode15i-Specific Properties

`ode15s` is a variable-order solver for stiff problems. It is based on the numerical differentiation formulas (NDFs). The NDFs are generally more efficient than the closely related family of backward differentiation formulas (BDFs), also known as Gear’s methods. The `ode15s` properties let you choose among these formulas, as well as specifying the maximum order for the formula used.

`ode15i` solves fully implicit differential equations of the form

$$f(t,y,y') = 0$$

using the variable order BDF method.

The following table describes the `ode15s` and `ode15i`-specific properties. Further information on each property is given following the table. Use `odeset` to set these properties.

## ode15s and ode15i-Specific Properties

Property	Value	Description
MaxOrder	1   2   3   4   {5}	Maximum order formula used to compute the solution.
BDF (ode15s only)	on   {off}	Specifies whether you want to use the BDFs instead of the default NDFs.

## Description of ode15s and ode15i-Specific Properties

**MaxOrder** — Maximum order formula used to compute the solution.

**BDF** (ode15s only) — Set BDF on to have `ode15s` use the BDFs.

For both the NDFs and BDFs, the formulas of orders 1 and 2 are A-stable (the stability region includes the entire left half complex plane). The higher order formulas are not as stable, and the higher the order the worse the stability. There is a class of stiff problems (stiff oscillatory) that is solved more efficiently if `MaxOrder` is reduced (for example to 2) so that only the most stable formulas are used.

`deval` | `odeget` | `ode45` | `ode23` | `ode23t` | `ode23tb` | `ode113` | `ode15s` | `ode23s` | `function_handle`

**Purpose** Extend solution of initial value problem for ordinary differential equation

**Syntax**

```

solext = odextend(sol, odefun, tfinal)
solext = odextend(sol, [], tfinal)
solext = odextend(sol, odefun, tfinal, yinit)
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
solext = odextend(sol, odefun, tfinal, yinit, options)

```

**Description** `solext = odextend(sol, odefun, tfinal)` extends the solution stored in `sol` to an interval with upper bound `tfinal` for the independent variable. Specify `odefun` as a function handle. Specify `sol` as an ODE solution structure created using an ODE solver. The lower bound for the independent variable in `solext` is the same as in `sol`. If you created `sol` with an ODE solver other than `ode15i`, the function `odefun` computes the right-hand side of the ODE equation, which is of the form  $y' = f(t,y)$ . If you created `sol` using `ode15i`, the function `odefun` computes the left-hand side of the ODE equation, which is of the form  $f(t,y,y') = 0$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`odextend` extends the solution by integrating `odefun` from the upper bound for the independent variable in `sol` to `tfinal`, using the same ODE solver that created `sol`. By default, `odextend` uses

- The initial conditions `y = sol.y(:,end)` for the subsequent integration
- The same integration properties and additional input arguments the ODE solver originally used to compute `sol`. This information is stored as part of the solution structure `sol` and is subsequently passed to `solext`. Unless you want to change these values, you do not need to pass them to `odextend`.

`solext = odextend(sol, [], tfinal)` uses the same ODE function that the ODE solver uses to compute `sol` to extend the solution. It is

# odextend

---

not necessary to pass in `odefun` explicitly unless it differs from the original ODE function.

`solext = odextend(sol, odefun, tfinal, yinit)` uses the column vector `yinit` as new initial conditions for the subsequent integration, instead of the vector `sol.y(end)`.

---

**Note** To extend solutions obtained with `ode15i`, use the following syntax, in which the column vector `ypinit` is the initial derivative of the solution:

---

```
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
```

---

`solext = odextend(sol, odefun, tfinal, yinit, options)` uses the integration properties specified in `options` instead of the options the ODE solver originally used to compute `sol`. The new options are then stored within the structure `solext`. See `odeset` for details on setting options properties. Set `yinit = []` as a placeholder to specify the default initial conditions.

## Examples

The following command

```
sol=ode45(@vdp1,[0 10],[2 0]);
```

uses `ode45` to solve the system  $y' = \text{vdp1}(t, y)$ , where `vdp1` is an example of an ODE function provided with MATLAB software, on the interval `[0 10]`. Then, the commands

```
sol=odextend(sol,@vdp1,20);  
plot(sol.x,sol.y(1,:));
```

extend the solution to the interval `[0 20]` and plot the first component of the solution on `[0 20]`.

<b>Purpose</b>	Cleanup tasks upon function completion
<b>Syntax</b>	<code>cleanupObj = onCleanup(cleanupFun)</code>
<b>Description</b>	<p><code>cleanupObj = onCleanup(cleanupFun)</code> creates an object that, when destroyed, executes the function <code>cleanupFun</code>. MATLAB implicitly clears all local variables at the termination of a function, whether by normal completion, or a forced exit, such as an error, or <b>Ctrl+C</b>.</p> <p>If you reference or pass <code>cleanupObj</code> outside your function, then <code>cleanupFun</code> does not run when that function terminates. Instead, it runs whenever the MATLAB destroys the object.</p>
<b>Input Arguments</b>	<p><b>cleanupFun - Clean-up task</b> function handle</p> <p>Clean-up task, specified as a function handle to an anonymous function. Your clean-up function should never rely on variables that are defined outside of the scope of that function.</p> <p>You can declare any number of <code>onCleanup</code> objects in a program file. However, if the clean-up tasks depend on the order of execution, then you should define only one object that calls a script or function, containing the relevant clean-up commands.</p> <p>You should use an anonymous function handle to call your clean-up task. This allows you to pass arguments to your clean-up function.</p> <p><b>Example:</b> <code>@() fclose(file.m)</code></p> <p><b>Example:</b> <code>@() user_script</code></p> <p><b>Example:</b> <code>@() function(input)</code></p> <p><b>Data Types</b> function_handle</p>

## Examples

### Close a File After Executing Function

Save the following code in `action.m` and type `action` in the Command Window.

```
function [] = action()
    file = fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', ...
        'examples', 'collatz.m');
    fid = fopen(file);
    finishup = onCleanup(@() fclose(fid));
    disp('Execute code');
    disp('then close file')
end
```

```
Execute code
then close file
```

### Switch Directories After Executing Function

Pass your own script to the `onCleanup` object so that it executes when MATLAB destroys the cleanup object.

Save the following code in `cleanup.m`.

```
cd(matlabroot);
disp('You are now in the MATLAB root directory')
```

Save the following code in `youraction.m` and type `youraction` in the Command Window.

```
function [] = youraction
    changeup = onCleanup(@() cleanup);
    disp('Execute Code');
end
```

```
Execute Code
You are now in the MATLAB root directory
```

## Tips

- If your program contains multiple cleanup objects, MATLAB does not guarantee the order that it destroys these objects.

- If the order of your cleanup functions matters, define one `onCleanup` object for all the tasks.

## Concepts

- “Clean Up When Functions Complete”
- “Object Lifecycle”
- “Function Handles”
- “What Are Anonymous Functions?”

**Purpose**

Create array of all ones

**Syntax**

```
X = ones
X = ones(n)
X = ones(sz1, ..., szN)
X = ones(sz)

X = ones(classname)
X = ones(n, classname)
X = ones(sz1, ..., szN, classname)
X = ones(sz, classname)

X = ones('like', p)
X = ones(n, 'like', p)
X = ones(sz1, ..., szN, 'like', p)
X = ones(sz, 'like', p)
```

**Description**

`X = ones` returns the scalar 1.

`X = ones(n)` returns an n-by-n matrix of ones.

`X = ones(sz1, ..., szN)` returns an sz1-by-...-by-szN array of ones where sz1, ..., szN indicates the size of each dimension. For example, `ones(2,3)` returns a 2-by-3 array of ones.

`X = ones(sz)` returns an array of ones where the size vector, `sz`, defines `size(X)`. For example, `ones([2,3])` returns a 2-by-3 array of ones.

`X = ones(classname)` returns a scalar 1 where the string, `classname`, specifies the data type. For example, `ones('int8')` returns a scalar, 8-bit integer 1.

`X = ones(n, classname)` returns an n-by-n array of ones of data type `classname`.

`X = ones(sz1,...,szN,classname)` returns an `sz1`-by-...-by-`szN` array of ones of data type `classname`.

`X = ones(sz,classname)` returns an array of ones where the size vector, `sz`, defines `size(X)` and `classname` defines `class(X)`.

`X = ones('like',p)` returns a scalar 1 with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = ones(n,'like',p)` returns an `n`-by-`n` array of ones like `p`.

`X = ones(sz1,...,szN,'like',p)` returns an `sz1`-by-...-by-`szN` array of ones like `p`.

`X = ones(sz,'like',p)` returns an array of ones like `p` where the size vector, `sz`, defines `size(X)`.

## Input Arguments

### **n** - Size of square matrix

integer value

Size of square matrix, specified as an integer value, defines the output as a square, `n`-by-`n` matrix of ones.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### **sz1,...,szN** - Size of each dimension

two or more integer values

Size of each dimension, specified as two or more integer values, defines `X` as a `sz1`-by-...-by-`szN` array.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### sz - Output size

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

**Example:** `sz = [2,3,4]` defines X as a 2-by-3-by-4 array.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### classname - Output class

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

### Data Types

char

### p - Prototype

numeric variable

Prototype, specified as a numeric variable.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**Complex Number Support:** Yes

## Examples

### Square Array of Ones

Create a 4-by-4 array of ones.

```
X = ones(4)
```

```
X =
```

```
     1     1     1     1
     1     1     1     1
     1     1     1     1
     1     1     1     1
```

### 3-D Array of Ones

Create a 2-by-3-by-4 array of ones.

```
X = ones(2,3,4);
```

```
size(X)
```

```
ans =
```

```
     2     3     4
```

### Size Defined by Existing Array

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)
```

```
sz =
```

```
     3     2
```

Create an array of ones that is the same size as A

```
X = ones(sz)
```

```
X =
```

```
     1     1
     1     1
     1     1
```

## Nondefault Numeric Data Type

Create a 1-by-3 vector of ones whose elements are 16-bit unsigned integers.

```
X = ones(1,3,'uint16'),
class(X)
```

```
X =
```

```
     1     1     1
```

```
ans =
```

```
uint16
```

## Complex One

Create a scalar 1 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar 1 that is complex like p.

```
X = ones('like',p)
```

```
X =
```

```
1.0000 + 0.0000i
```

### Size and Numeric Data Type of Defined by Existing Array

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of ones that is the same size and data type as p.

```
X = ones(size(p),'like',p),  
class(X)
```

```
X =
```

```
1 1 1  
1 1 1
```

```
ans =
```

```
uint8
```

### Concepts

- “Preallocating Arrays”

# open

---

**Purpose** Open file in appropriate application

**Syntax** `open(name)`  
`output = open(name)`

**Description** `open(name)` opens the specified file or variable in the appropriate application.

`output = open(name)` returns an empty `output` (`[]`) for most cases. If opening a MAT-file, `output` is a structure that contains the variables in the file. If opening a figure, `output` is a handle to that figure.

**Tips** The `open` function opens files based on their extension. You can extend the functionality of `open` by defining your own file handling function of the form `openxxx`, where `xxx` is a file extension. For example, if you create a function `openlog`, the `open` function calls `openlog` to process any files with the `.log` extension. The `open` function returns any single `output` defined by your function.

**Input Arguments** **name**  
Name of file or variable to open. If `name` does not include an extension, the `open` function:

- 1 Searches for a variable named `name`. If the variable exists, `open` opens it in the Variables editor.
- 2 Searches the MATLAB path for `name.mdl`, `name.slx`, or `name.m`. If `name.mdl` or `name.slx` exists, then `open` opens the model in Simulink. If only `name.m` exists, `open` opens the file in the MATLAB Editor.

If more than one file named `name` exists on the MATLAB path, the `open` function opens the file returned by `which(name)`.

The `open` function performs the following actions based on the file extension:

**(Continued)**

.m	Open in MATLAB Editor.
.mat	Return variables in structure <i>st</i> when called with the syntax:  <code>st = open(name)</code>
.fig	Open figure in Handle Graphics.
.mdl or .slx	Open model in Simulink.
.prj	Open project in the MATLAB Compiler Deployment Tool.
.doc*	Open document in Microsoft Word.
.exe	Run executable file (only on Windows systems).
.pdf	Open document in Adobe® Acrobat®.
.ppt*	Open document in Microsoft PowerPoint.
.xls*	Start MATLAB Import Wizard.
.htm or .html	Open document in MATLAB browser.
.url	Open file in your default Web browser.

**Examples**

Open `Contents.m` in the MATLAB Editor by typing:

```
open Contents.m
```

Generally, MATLAB opens `matlabroot\toolbox\matlab\general\Contents.m`. However, if you have a file called `Contents.m` in a directory that is before `toolbox\matlab\general` on the MATLAB path, then `open` opens that file instead.

---

Open a file not on the MATLAB path by including the complete file specification:

```
open('D:\temp\data.mat')
```

If the file does not exist, MATLAB displays an error message.

---

Create a function called `opentxt` to handle files with extension `.txt`:

```
function opentxt(filename)

    fprintf('You have requested file: %s\n', filename);

    wh = which(filename);
    if exist(filename, 'file') == 2
        fprintf('Opening in MATLAB Editor: %s\n', filename);
        edit(filename);
    elseif ~isempty(wh)
        fprintf('Opening in MATLAB Editor: %s\n', wh);
        edit(wh);
    else
        warning('MATLAB:fileNotFound', ...
            'File was not found: %s', filename);
    end

end
```

Open the file `ngc6543a.txt` (a description of `ngc6543a.jpg`, located in `matlabroot\toolbox\matlab\demos`):

```
photo_text = 'ngc6543a.txt';
open(photo_text)
```

`open` calls your function with the following syntax:

```
opentxt(photo_text)
```

## See Also

`edit` | `load` | `openfig` | `openvar` | `path` | `uiopen` | `which` | `winopen`

<b>Purpose</b>	Open file for writing video data
<b>Syntax</b>	<code>open(writerObj)</code>
<b>Description</b>	<code>open(writerObj)</code> opens the file associated with <code>writerObj</code> for writing. When you open the file, all properties of the object become read only. <code>open</code> discards any existing contents of the file.
<b>Input Arguments</b>	<b>writerObj</b> VideoWriter object created by the <code>VideoWriter</code> function.
<b>Examples</b>	Open a new AVI file: <pre>myObj = VideoWriter('newfile.avi'); open(myObj);</pre>
<b>See Also</b>	<code>writeVideo</code>   <code>VideoWriter</code>   <code>close</code>

# openfig

---

**Purpose** Open new copy or raise existing copy of saved figure

**Syntax**

```
openfig('filename.fig')
openfig('filename.fig','new')
openfig('filename.fig','reuse')
openfig('filename.fig','new','invisible')
openfig('filename.fig','reuse','invisible')
openfig('filename.fig','new','visible')
openfig('filename.fig','reuse','visible')
figure_handle = openfig(...)
```

**Description** `openfig('filename.fig')` and `openfig('filename.fig','new')` opens the figure contained in the FIG-file, `filename.fig`, and ensures it is visible and positioned completely on screen. You do not have to specify the full path to the FIG-file as long as it is on your MATLAB path. The `.fig` extension is optional.

`openfig('filename.fig','reuse')` opens the figure contained in the FIG-file only if a copy of the figure is not currently open. Otherwise, `openfig` brings the existing copy forward, making sure it is still visible and completely on screen.

`openfig('filename.fig','new','invisible')` or `openfig('filename.fig','reuse','invisible')` opens the figure as in the preceding example, while forcing the figure to be invisible.

`openfig('filename.fig','new','visible')` or `openfig('filename.fig','reuse','visible')` opens the figure, while forcing the figure to be visible.

`figure_handle = openfig(...)` returns the handle to the figure.

**Tips** `openfig` is designed for use with GUI figures. Use this function to:

- Open the FIG-file creating the GUI and ensure it is displayed on screen. This provides compatibility with different screen sizes and resolutions.

- Control whether the MATLAB software displays one or multiple instances of the GUI at any given time.
- Return the handle of the figure created, which is typically hidden for GUI figures.

If the FIG-file contains an invisible figure, `openfig` returns its handle and leaves it invisible. The caller should make the figure visible when appropriate.

Do not use `openfig` or double-click a FIG-file to open a GUI created with GUIDE. Instead open the GUI code file by typing its name in the command window or by right-clicking its name in the Current Folder Browser and selecting **Run File**. To open a GUIDE GUI, for example one called `guifile.m`, in an invisible state, specify the `Visible` property in your command:

```
guifile('Visible','off')
```

Your code should then make the figure visible at an appropriate time.

## See Also

`guide` | `guihandles` | `movegui` | `open` | `hgload` | `save`

**Purpose** Control OpenGL rendering

**Syntax**

```
opengl info
s = opengl('data')
opengl software
opengl hardware
opengl verbose
opengl quiet
opengl DriverBugWorkaround
opengl('DriverBugWorkaround',WorkaroundState)
```

**Description** The OpenGL autoselection mode applies when the `RendererMode` of the figure is `auto`. Possible values for `selection_mode` are

- `autoselect` – allows OpenGL to be automatically selected if OpenGL is available and if there is graphics hardware on the host machine.
- `neverselect` – disables autoselection of OpenGL.
- `advise` – prints a message to the command window if OpenGL rendering is advised, but `RenderMode` is set to `manual`.

`opengl`, by itself, returns the current autoselection state.

Note that the autoselection state only specifies whether OpenGL should or should not be considered for rendering; it does not explicitly set the rendering to OpenGL. You can do this by setting the `Renderer` property of the figure to `OpenGL`. For example,

```
set(figure_handle,'Renderer','OpenGL')
```

`opengl info` prints information with the version and vendor of the OpenGL on your system. Also indicates whether your system is currently using hardware or software OpenGL and the state of various driver bug workarounds. Note that calling `opengl info` loads the OpenGL Library.

For example, the following output is generated on a Windows XP computer that uses ATI Technologies graphics hardware:

```
>> opengl info
Version          = 1.3.4010 WinXP Release
Vendor           = ATI Technologies Inc.
Renderer        = RADEON 9600SE x86/SSE2
MaxTextureSize  = 2048
Visual          = 05 (RGB 16 bits(05 06 05 00) zdepth 16, Hardware
Accelerated, Opengl, Double Buffered, Window)
Software        = false
# of Extensions = 85
Driver Bug Workarounds:
OpenGLBitmapZbufferBug    = 0
OpenGLWobbleTesselatorBug = 0
OpenGLLineSmoothingBug   = 0
OpenGLDockingBug         = 0
OpenGLClippedImageBug    = 0
```

Note that different computer systems may not list all OpenGL bugs.

`s = opengl('data')` returns a structure containing the same data that is displayed when you call `opengl info`, with the exception of the driver bug workaround state.

`opengl software` forces the MATLAB software to use software OpenGL rendering instead of hardware OpenGL. Note that Macintosh systems do not support software OpenGL.

`opengl hardware` reverses the `opengl software` command and enables MATLAB to use hardware OpenGL rendering if it is available. If your computer does not have OpenGL hardware acceleration, MATLAB automatically switches to software OpenGL rendering (except on Macintosh systems, which do not support software OpenGL).

Note that on UNIX systems, the `software` or `hardware` options with the `opengl` command works only if MATLAB has not yet used the OpenGL renderer or you have not issued the `opengl info` command (which attempts to load the OpenGL Library).

`opengl verbose` displays verbose messages about OpenGL initialization (if OpenGL is not already loaded) and other runtime messages.

`opengl quiet` disables verbose message setting.

`opengl DriverBugWorkaround` queries the state of the specified driver bug workaround. Use the command `opengl info` to see a list of all driver bug workarounds. See “Driver Bug Workarounds” on page 1-4344 for more information.

`opengl('DriverBugWorkaround',WorkaroundState)` sets the state of the specified driver bug workaround. You can set `WorkaroundState` to one of three values:

- 0 – Disable the specified *DriverBugWorkaround* (if enabled) and do not allow MATLAB to autoselect this workaround.
- 1 – Enable the specified *DriverBugWorkaround*.
- -1 – Set the specified *DriverBugWorkaround* to autoselection mode, which allows MATLAB to enable this workaround if the requisite conditions exist.

## Driver Bug Workarounds

The MATLAB software enables various OpenGL driver bug workarounds when it detects certain known problems with installed hardware. However, because there are many versions of graphics drivers, you might encounter situations when MATLAB does not enable a workaround that would solve a problem you are having with OpenGL rendering.

This section describes the symptoms that each workaround is designed to correct so you can decide if you want to try using one to fix an OpenGL rendering problem.

Use the `opengl info` command to see what driver bug workarounds are available on your computer.

---

**Note** These workarounds have not been tested under all driver combinations and therefore might produce undesirable results under certain conditions.

---

### **OpenGLBitmapZbufferBug**

Symptom: text with background color (including data tips) and text displayed on image, patch, or surface objects is not visible when using OpenGL renderer.

Possible side effect: text is always on top of other objects.

Command to enable:

```
opengl('OpenGLBitmapZbufferBug',1)
```

### **OpenGLWobbleTessellatorBug**

Symptom: Rendering complex patch object causes segmentation violation and returns a tessellator error message in the stack trace.

Command to enable:

```
opengl('OpenGLWobbleTessellatorBug',1)
```

### **OpenGLLineSmoothingBug**

Symptom: Lines with a LineWidth greater than 3 look bad.

Command to enable:

```
opengl('OpenGLLineSmoothingBug',1)
```

### **OpenGLDockingBug**

Symptom: MATLAB crashes when you dock a figure that has its Renderer property set to opengl.

Command to enable:

```
opengl('OpenGLDockingBug',1)
```

## **OpenGLClippedImageBug**

Symptom: Images (as well as colorbar displays) do not display when the `Renderer` property set to `opengl`.

Command to enable:

```
opengl('OpenGLClippedImageBug',1)
```

## **OpenGLEraseModeBug**

Symptom: Graphics objects with `EraseMode` property set to non-normal erase modes (`xor`, `none`, or `background`) do not draw when the figure `Renderer` property is set to `opengl`.

Command to enable:

```
opengl('OpenGLEraseModeBug',1)
```

## **See Also**

`Renderer`

**Purpose** Open workspace variable in Variables editor or other graphical editing tool

**Syntax** `openvar(varname)`

**Description** `openvar(varname)` opens the workspace variable named by the string, `varname`, in the Variables editor for graphical editing. Changes that you make to variables in the Variables editor occur in the workspace as soon as you enter them.

In some toolboxes, `openvar` opens a tool appropriate for viewing or editing objects indicated by `varname` instead of opening the Variables editor.

MATLAB does not impose any limitation on the size of a variable that you can open in the Variables editor. However, your operating system or the amount of physical memory installed on your computer can impose such limits.

## Input Arguments

### **varname - Variable name**

string

Variable name, specified as a string. The named variable can be an array, character string, cell array, structure, or an object and its properties. If the named variable is a multidimensional array, then you can only view the array in the Variables editor, and not edit it.

**Example:** `'myVariable'`

**Example:** `'A'`

## Examples

### **Identify Outliers in a Linked Graph**

Use data brushing to identify observations in a vector or matrix that might warrant further analysis.

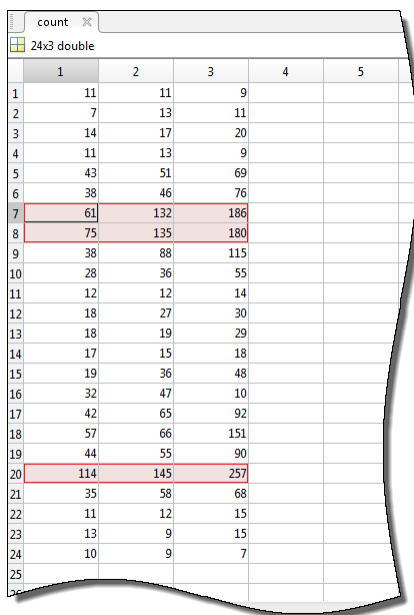

Make a scatter plot of data in the sample MAT-file `count.dat`, and open the variable `count` in the Variables editor.

```
load count.dat
```

```
scatter(count(:,1),count(:,2))  
openvar('count')
```

Right-click a cell in the Variables editor and select **Brushing > Brushing On**. This turns on data brushing in the Variables editor.

Select the rows 7, 8, and 20. (Select noncontiguous rows by holding down the **Ctrl** key and clicking in each row.)

	1	2	3	4	5
1	11	11	9		
2	7	13	11		
3	14	17	20		
4	11	13	9		
5	43	51	69		
6	38	46	76		
7	61	132	186		
8	75	135	180		
9	38	88	115		
10	28	36	55		
11	12	12	14		
12	18	27	30		
13	18	19	29		
14	17	15	18		
15	19	36	48		
16	32	47	10		
17	42	65	92		
18	57	66	151		
19	44	55	90		
20	114	145	257		
21	35	58	68		
22	11	12	15		
23	13	9	15		
24	10	9	7		
25					

In the Figure window with the scatter plot, click **Brush/Select Data**  to enable data brushing, and **Link Plot**  to enable data linking.

The data observations you brushed in the Variables editor appear highlighted in the scatter plot.

As long as data linking is enabled in the figure, observations that you brush in the scatter plot are highlighted in the Variables editor. When a figure is not linked to its data sources, you can still brush its graphs and you can brush the same data in the Variables editor, but only the display that you brush responds by highlighting.

## Tips

- As an alternative to the `openvar` function, double-click a variable in the Workspace browser.

# optimget

---

**Purpose** Optimization options values

**Syntax**

```
val = optimget(options,'param')  
val = optimget(options,'param',default)
```

**Description**

`val = optimget(options,'param')` returns the value of the specified parameter in the optimization options structure `options`. You need to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`val = optimget(options,'param',default)` returns `default` if the specified parameter is not defined in the optimization options structure `options`. Note that this form of the function is used primarily by other optimization functions.

**Examples**

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options`.

```
val = optimget(my_options,'Display')
```

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options` (as in the previous example) except that if the `Display` parameter is not defined, it returns the value `'final'`.

```
optnew = optimget(my_options,'Display','final');
```

**See Also** `optimset` | `fminbnd` | `fminsearch` | `fzero` | `lsqnonneg`

**Purpose**

Create or edit optimization options structure

**Syntax**

```
options = optimset('param1',value1,'param2',value2,...)
optimset
options = optimset
options = optimset(optimfun)
options = optimset(olddopts,'param1',value1,...)
options = optimset(olddopts,newopts)
```

**Description**

The function `optimset` creates an `options` structure that you can pass as an input argument to the following four MATLAB optimization functions:

- `fminbnd`
- `fminsearch`
- `fzero`
- `lsqnonneg`

You can use the `options` structure to change the default parameters for these functions.

---

**Note** If you have an Optimization Toolbox™ license, you can also use `optimset` to create an expanded `options` structure containing additional options specifically designed for the functions provided in that toolbox. For more information about these additional options, see the reference page for the enhanced Optimization Toolbox `optimset` function.

---

`options = optimset('param1',value1,'param2',value2,...)` creates an optimization options structure called `options`, in which the specified parameters (`param`) have specified values. Any unspecified parameters are set to `[]` (parameters with value `[]` indicate to use the default value for that parameter when `options` is passed to the optimization function). It is sufficient to type only enough leading

# optimset

---

characters to define the parameter name uniquely. Case is ignored for parameter names.

`optimset` with no input or output arguments displays a complete list of parameters with their valid values.

`options = optimset` (with no input arguments) creates an options structure `options` where all fields are set to `[]`.

`options = optimset(optimfun)` creates an options structure `options` with all parameter names and default values relevant to the optimization function `optimfun`.

`options = optimset(oldopts, 'param1', value1, ...)` creates a copy of `oldopts`, modifying the specified parameters with the specified values.

`options = optimset(oldopts, newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any parameters in `newopts` with nonempty values overwrite the corresponding old parameters in `oldopts`.

## Options

The following table lists the available options for the MATLAB optimization functions.

Option	Value	Description	Solvers
Display	'off'   'iter'   {'final'}   'notify'	Level of display. 'off' displays no output; 'iter' displays output at each iteration (not available for <code>lsqnonneg</code> ); 'final' displays just the final output; 'notify' displays output only if	fminbnd, fminsearch,fzero, lsqnonneg

Option	Value	Description	Solvers
		the function does not converge.	
FunValCheck	'off'   'on'	Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is complex or NaN. 'off' displays no error.	fminbnd, fminsearch, fzero
MaxFunEvals	positive integer	Maximum number of function evaluations allowed.	fminbnd, fminsearch
MaxIter	positive integer	Maximum number of iterations allowed.	fminbnd, fminsearch
OutputFcn	function   {}	User-defined function that an optimization function calls at each iteration.	fminbnd, fminsearch, fzero
PlotFcns	function   {}	User-defined or built-in plot function that an optimization function calls at each iteration. Built-in functions: <ul style="list-style-type: none"> <li>• @optimplotx plots the current point</li> <li>• @optimplotfval plots the function value</li> <li>• @optimplotfunccount plots the function</li> </ul>	fminbnd, fminsearch, fzero

# optimset

Option	Value	Description	Solvers
		count (not available for fzero)	
TolFun	positive scalar	Termination tolerance on the function value. See “Tolerances and Stopping Criteria”.	fminsearch
TolX	positive scalar	Termination tolerance on $x$ , the current point. See “Tolerances and Stopping Criteria”.	fminbnd, fminsearch, fzero, lsqnonneg

## Examples

This statement creates an optimization options structure called `options` in which the `Display` parameter is set to `'iter'` and the `TolFun` parameter is set to `1e-8`.

```
options = optimset('Display','iter','TolFun',1e-8)
```

This statement makes a copy of the options structure called `options`, changing the value of the `TolX` parameter and storing new values in `optnew`.

```
optnew = optimset(options,'TolX',1e-4);
```

This statement returns an optimization options structure that contains all the parameter names and default values relevant to the function `fminbnd`.

```
optimset('fminbnd')
```

**Purpose** Find logical OR of array or scalar inputs

**Syntax** `A | B | ...`  
`or(A, B)`

**Description** `A | B | ...` performs a logical OR of all input arrays A, B, etc., and returns an array containing elements set to either logical 1 (true) or logical 0 (false). An element of the output array is set to 1 if any input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input A is a 3-by-5 matrix and input B is the number 1, then B is treated as if it were a 3-by-5 matrix of ones.

`or(A, B)` is called for the syntax `A | B` when either A or B is an object.

---

**Note** The symbols `|` and `||` perform different operations in a MATLAB application. The element-wise OR operator described here is `|`. The short-circuit OR operator is `||`.

---

**Examples** If matrix A is

0.4235	0.5798	0	0.7942	0
0.5155	0	0	0	0.8744
0	0	0	0.4451	0.0150
0.4329	0.6405	0.6808	0	0

and matrix B is

# or

---

0	1	0	1	0
1	1	0	0	1
0	0	0	1	0
0	1	0	0	1

then

A		B			
ans	=				
1		1	0	1	0
1		1	0	0	1
0		0	0	1	1
1		1	1	0	1

## How To

- logical operators

**Purpose** Eigenvalues of quasitriangular matrices

**Syntax** E = ordeig(T)  
E = ordeig(AA,BB)

**Description** E = ordeig(T) takes a quasitriangular Schur matrix T, typically produced by schur, and returns the vector E of eigenvalues in their order of appearance down the diagonal of T.

E = ordeig(AA,BB) takes a quasitriangular matrix pair AA and BB, typically produced by qz, and returns the generalized eigenvalues in their order of appearance down the diagonal of  $AA - \lambda BB$ .

ordeig is an order-preserving version of eig for use with ordschur and ordqz. It is also faster than eig for quasitriangular matrices.

## Examples

### Example 1

```
T=diag([1 -1 3 -5 2]);
```

ordeig(T) returns the eigenvalues of T in the same order they appear on the diagonal.

```
ordeig(T)
```

```
ans =
```

```
    1  
   -1  
    3  
   -5  
    2
```

eig(T), on the other hand, returns the eigenvalues in order of increasing magnitude.

```
eig(T)
```

```
ans =
```

```
-5  
-1  
1  
2  
3
```

## Example 2

```
A = rand(10);  
[U, T] = schur(A);  
abs(ordeig(T))
```

```
ans =
```

```

0.5855

**See Also**

schur | qz | ordschur | ordqz | eig

# orderfields

---

**Purpose** Order fields of structure array

**Syntax**

```
s = orderfields(s1)
s = orderfields(s1, s2)
s = orderfields(s1, c)
s = orderfields(s1, perm)
[s, perm] = orderfields(...)
```

**Description** `s = orderfields(s1)` orders the fields in `s1` so that the new structure array `s` has field names in ASCII dictionary order.

`s = orderfields(s1, s2)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in `s2`. Structures `s1` and `s2` must have the same fields.

`s = orderfields(s1, c)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in the cell array of field name strings `c`. Structure `s1` and cell array `c` must contain the same field names.

`s = orderfields(s1, perm)` orders the fields in `s1` so that the new structure array `s` has fieldnames in the order specified by the indices in permutation vector `perm`.

If `s1` has `N` fieldnames, the elements of `perm` must be an arrangement of the numbers from 1 to `N`. This is particularly useful if you have more than one structure array that you would like to reorder in the same way.

`[s, perm] = orderfields(...)` returns a permutation vector representing the change in order performed on the fields of the structure array that results in `s`.

**Tips** `orderfields` only orders top-level fields. It is not recursive.

**Examples** Create a structure `s`. Then create a new structure from `s`, but with the fields ordered alphabetically:

```
s = struct('b', 2, 'c', 3, 'a', 1)
s =
```

```
b: 2  
c: 3  
a: 1
```

```
snew = orderfields(s)  
snew =  
  a: 1  
  b: 2  
  c: 3
```

Arrange the fields of `s` in the order specified by the second (cell array) argument of `orderfields`. Return the new structure in `snew` and the permutation vector used to create it in `perm`:

```
[snew, perm] = orderfields(s, {'b', 'a', 'c'})  
snew =  
  b: 2  
  a: 1  
  c: 3  
perm =  
  1  
  3  
  2
```

Now create a new structure, `s2`, having the same fieldnames as `s`. Reorder the fields using the permutation vector returned in the previous operation:

```
s2 = struct('b', 3, 'c', 7, 'a', 4)  
s2 =  
  b: 3  
  c: 7  
  a: 4  
  
snew = orderfields(s2, perm)  
snew =  
  b: 3  
  a: 4
```

# orderfields

---

c: 7

## How To

- dynamic field names

**Purpose** Reorder eigenvalues in QZ factorization

**Syntax**  
`[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)`  
`[...] = ordqz(AA,BB,Q,Z,keyword)`  
`[...] = ordqz(AA,BB,Q,Z,clusters)`

**Description** `[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)` reorders the QZ factorizations  $Q^*A^*Z = AA$  and  $Q^*B^*Z = BB$  produced by the `qz` function for a matrix pair  $(A,B)$ . It returns the reordered pair  $(AAS,BBS)$  and the cumulative orthogonal transformations `QS` and `ZS` such that  $QS^*A^*ZS = AAS$  and  $QS^*B^*ZS = BBS$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular pair  $(AAS,BBS)$ , and the corresponding invariant subspace is spanned by the leading columns of `ZS`. The logical vector `select` specifies the selected cluster as  $E(\text{select})$  where  $E$  is the vector of eigenvalues as they appear along the diagonal of  $AA - \lambda BB$ .

---

**Note** To extract  $E$  from `AA` and `BB`, use `ordeig(BB)`, instead of `eig`. This ensures that the eigenvalues in  $E$  occur in the same order as they appear on the diagonal of  $AA - \lambda BB$ .

---

`[...] = ordqz(AA,BB,Q,Z,keyword)` sets the selected cluster to include all eigenvalues in the region specified by `keyword`:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

`[...] = ordqz(AA,BB,Q,Z,clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices commensurate with  $E = \text{ordeig}(AA,BB)$ , such that all eigenvalues with the same `clusters`

# ordqz

---

value from one cluster, `ordqz` sorts the specified clusters in descending order along the diagonal of  $(AAS, BBS)$ . The cluster with highest index appears in the upper left corner.

## See Also

`ordeig` | `ordschur` | `qz`

**Purpose** Reorder eigenvalues in Schur factorization

**Syntax**

```
[US,TS] = ordschur(U,T,select)
[US,TS] = ordschur(U,T,keyword)
[US,TS] = ordschur(U,T,clusters)
```

**Description** `[US,TS] = ordschur(U,T,select)` reorders the Schur factorization  $X = U^*T^*U'$  produced by the `schur` function and returns the reordered Schur matrix `TS` and the cumulative orthogonal transformation `US` such that  $X = US^*TS^*US'$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular Schur matrix `TS`, and the corresponding invariant subspace is spanned by the leading columns of `US`. The logical vector `select` specifies the selected cluster as `E(select)` where `E` is the vector of eigenvalues as they appear along `T`'s diagonal.

---

**Note** To extract `E` from `T`, use `E = ordeig(T)`, instead of `eig`. This ensures that the eigenvalues in `E` occur in the same order as they appear on the diagonal of `TS`.

---

`[US,TS] = ordschur(U,T,keyword)` sets the selected cluster to include all eigenvalues in one of the following regions:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

`[US,TS] = ordschur(U,T,clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices, commensurate with `E = ordeig(T)`, and such that all eigenvalues with the same `clusters` value form one cluster, `ordschur` sorts the specified clusters

# ordschur

---

in descending order along the diagonal of  $TS$ , the cluster with highest index appearing in the upper left corner.

<b>Purpose</b>	Hardcopy paper orientation
<b>Alternatives</b>	Use <b>File</b> → <b>Print Preview</b> on the figure window menu to directly manipulate print layout, paper size, headers, fonts and other properties when printing figures. For details, see Using Print Preview in the MATLAB Graphics documentation.
<b>Syntax</b>	<pre>orient orient landscape orient portrait orient tall orient(fig_handle), orient(simulink_model) orient(fig_handle,orientation), orient(simulink_model,     orientation)</pre>
<b>Description</b>	<p><code>orient</code> returns a string with the current paper orientation: <code>portrait</code>, <code>landscape</code>, or <code>tall</code>.</p> <p><code>orient landscape</code> sets the paper orientation of the current figure to full-page landscape, orienting the longest page dimension horizontally. The figure is centered on the page and scaled to fit the page with a 0.25 inch border.</p> <p><code>orient portrait</code> sets the paper orientation of the current figure to portrait, orienting the longest page dimension vertically. The <code>portrait</code> option returns the page orientation to the MATLAB default. (Note that the result of using the <code>portrait</code> option is affected by changes you make to figure properties. See the "Algorithm" section for more specific information.)</p> <p><code>orient tall</code> maps the current figure to the entire page in portrait orientation, leaving a 0.25 inch border.</p> <p><code>orient(fig_handle)</code>, <code>orient(simulink_model)</code> returns the current orientation of the specified figure or Simulink model.</p> <p><code>orient(fig_handle,orientation)</code>, <code>orient(simulink_model,orientation)</code> sets the orientation for the specified figure or Simulink model to the specified orientation (<code>landscape</code>, <code>portrait</code>, or <code>tall</code>).</p>

## Algorithms

orient sets the PaperOrientation, PaperPosition, and PaperUnits properties of the current figure. Subsequent print operations use these properties. The result of using the portrait option can be affected by default property values as follows:

- If the current figure PaperType is the same as the default figure PaperType and the default figure PaperOrientation has been set to landscape, then the orient portrait command uses the current values of PaperOrientation and PaperPosition to place the figure on the page.
- If the current figure PaperType is the same as the default figure PaperType and the default figure PaperOrientation has been set to landscape, then the orient portrait command uses the default figure PaperPosition with the x, y and width, height values reversed (i.e., [y,x,height,width]) to position the figure on the page.
- If the current figure PaperType is different from the default figure PaperType, then the orient portrait command uses the current figure PaperPosition with the x, y and width, height values reversed (i.e., [y,x,height,width]) to position the figure on the page.

**Purpose** Orthonormal basis for range of matrix

**Syntax** `Q = orth(A)`

**Description** `Q = orth(A)` returns an orthonormal basis for the range of A. The columns of Q are vectors, which span the range of A. The number of columns in Q is equal to the rank of A.

**Input Arguments** **A - Input matrix**  
scalar | vector | matrix

Input matrix, specified as a scalar, vector, or matrix.

**Data Types**

single | double

**Complex Number Support:** Yes

**Examples** **Basis for Full Rank Matrix**

Calculate and verify the orthonormal basis vectors for the range of a full rank matrix.

Define a matrix and find the rank.

```
A = [1 0 1; -1 -2 0; 0 1 -1];  
r = rank(A)
```

```
r =
```

```
3
```

Since A is a square matrix of full rank, the orthonormal basis calculated by `orth(A)` matches the matrix U calculated in the singular value decomposition, `[U,S] = svd(A, 'econ')`. This is because the singular values of A are all nonzero.

Calculate the orthonormal basis for the range of A using `orth`.

```
Q = orth(A)
```

```
Q =
```

```
-0.1200 -0.8097 0.5744  
0.9018 0.1531 0.4042  
-0.4153 0.5665 0.7118
```

The number of columns in  $Q$  is equal to  $\text{rank}(A)$ . Since  $A$  is of full rank,  $Q$  and  $A$  are the same size.

Verify that the basis,  $Q$ , is orthogonal and normalized within a reasonable error range.

```
E = norm(eye(r) - Q' * Q, 'fro')
```

```
E =
```

```
9.6228e-16
```

The error is on the order of  $\text{eps}$ .

## **Basis for Rank Deficient Matrix**

Calculate and verify the orthonormal basis vectors for the range of a rank deficient matrix.

Define a singular matrix and find the rank.

```
A = [1 0 1; 0 1 0; 1 0 1];
```

```
r = rank(A)
```

```
r =
```

```
2
```

Since  $A$  is rank deficient, the orthonormal basis calculated by  $\text{orth}(A)$  matches only the first  $r = 2$  columns of matrix  $U$  calculated in the

singular value decomposition,  $[U,S] = \text{svd}(A, 'econ')$ . This is because the singular values of  $A$  are *not* all nonzero.

Calculate the orthonormal basis for the range of  $A$  using `orth`.

$Q = \text{orth}(A)$

$Q =$

```
-0.7071    0
         0    1.0000
-0.7071    0
```

Since  $A$  is rank deficient,  $Q$  contains one fewer column than  $A$ .

## Definitions

### Range

The column space, or *range*, of a matrix  $A$  is the collection of all linear combinations of the columns of  $A$ . Any vector,  $b$ , that is a solution to the linear equation,  $A*x = b$ , is included in the range of  $A$  since you can also write it as a linear combination of the columns of  $A$ .

### Rank

The rank of a matrix is equal to the dimension of the range.

## Algorithms

`orth` is obtained from  $U$  in the singular value decomposition,  $[U,S] = \text{svd}(A, 'econ')$ . If  $r = \text{rank}(A)$ , the first  $r$  columns of  $U$  form an orthonormal basis for the range of  $A$ .

## See Also

`null` | `svd` | `rank`

# otherwise

---

**Purpose** Optional keyword in switch statement

**Syntax**

```
switch switch_expression
    case case_expression
        statements
    case case_expression
        statements
    ...
    otherwise
        statements
end
```

**Description** A switch block conditionally executes one set of statements from several choices. Each choice is a case.

An evaluated *switch\_expression* is a scalar or string. An evaluated *case\_expression* is a scalar, a string, or a cell array of scalars or strings. The switch block tests each case until one of the cases is true. A case is true when:

- For numbers, `eq(case_expression,switch_expression)`.
- For strings, `strcmp(case_expression,switch_expression)`.
- For objects that support the eq function, `eq(case_expression,switch_expression)`.
- For a cell array *case\_expression*, at least one of the elements of the cell array matches *switch\_expression*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the switch block.

*otherwise* is optional, and executes only when no case is true.

For more information, see the switch reference page.

**Examples**

Decide which plot to create based on the value of the string `plottype`:

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
    case 'bar'
        bar(x)
        title('Bar Graph')
    case {'pie','pie3'}
        pie3(x)
        title('Pie Chart')
        legend('First','Second','Third')
    otherwise
        warning('Unexpected plot type. No plot created.');
```

end

`switch` | `end` | `if` | `for` | `while`

# outerjoin

---

**Purpose** Outer join between two tables

**Syntax**  
`C = outerjoin(A,B)`  
`C = outerjoin(A,B,Name,Value)`  
`[C,ia,ib] = outerjoin( ___ )`

**Description** `C = outerjoin(A,B)` creates the table, `C`, as the outer join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The outer join includes the rows that match between `A` and `B`, and also unmatched rows from either `A` or `B`, all with respect to the key variables. `C` contains all variables from both `A` and `B`, including the key variables.

`C = outerjoin(A,B,Name,Value)` performs the outer-join operation with additional options specified by one or more `Name,Value` pair arguments.

`[C,ia,ib] = outerjoin( ___ )` also returns index vectors, `ia` and `ib`, indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

## Input Arguments

**A,B - Input tables**  
tables

Input tables, specified as tables.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' ' ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Keys',2` uses the second variable in `A` and the second variable in `B` as key variables.

**'Keys' - Variables to use as keys**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of 'Keys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the 'Keys' name-value pair argument with the 'LeftKeys' and 'RightKeys' name-value pair arguments.

**Example:** 'Keys', [1 3] uses the first and third variables in A and B as a key variables.

**'LeftKeys' - Variables to use as keys in A**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. outerjoin pairs key values based on their order.

**Example:** 'LeftKeys', 1 uses only the first variable in A as a key variable.

**'RightKeys' - Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of 'RightKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'RightKeys' name-value pair argument in conjunction with the 'LeftKeys' name-value pair argument.

# outerjoin

---

'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `outerjoin` pairs key values based on their order.

**Example:** 'RightKeys',3 uses only the third variable in B as a key variable.

## 'MergeKeys' - Merge keys flag

false (default) | true | 0 | 1

Merge keys flag, specified as the comma-separated pair consisting of 'MergeKeys' and either false, true, 0 or 1.

**false**                      `outerjoin` includes two separate variables in the output table, C, for each key variable pair from tables A and B.

This is the default behavior.

**true**                        `outerjoin` includes a single variable in the output table, C, for each key variable pair from tables A and B.

`outerjoin` creates the single variable by merging the key values from A and B, taking values from A where a corresponding row exists in A, and taking values from B otherwise.

If you specify, 'MergeKeys', true, then `outerjoin` includes all key variables in the output table, C, and overrides the inclusion or exclusion of key variables specified via the 'LeftVariables' and 'RightVariables' name-value pair arguments.

## 'LeftVariables' - Variables from A to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of 'LeftVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'LeftVariables'` to include or exclude key variables as well as nonkey variables from the output, `C`.

By default, `outerjoin` includes all variables from `A`.

#### **'RightVariables' - Variables from B to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from `B` to include in `C`, specified as the comma-separated pair consisting of `'RightVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'RightVariables'` to include or exclude key variables as well as nonkey variables from the output, `C`.

By default, `outerjoin` includes all the variables from `B`.

#### **'Type' - Type of outer join operation**

'full' (default) | 'left' | 'right'

Type of outer-join operation, specified as the comma-separated pair consisting of `'Type'` and either `'full'`, `'left'`, or `'right'`.

- For a left outer join, `C` contains rows corresponding to key values in `A` that do not match any values in `B`, but not vice-versa.
- For a right outer join, `C` contains rows corresponding to key values in `B` that do not match any values in `A`, but not vice-versa.

By default, `outerjoin` does a full outer join and includes unmatched rows from both `A` and `B`.

## **Output Arguments**

### **C - Outer join from A and B**

table

Outer join from `A` and `B`, returned as a table. The output table, `C`, contains one row for each pair of rows in tables `A` and `B` that share the same combination of key values. If `A` and `B` contain variables with the same name, `outerjoin` adds a unique suffix to the corresponding variable names in `C`. Variables in `C` that came from `A` contain null values

in those rows that had no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

In general, if there are  $m$  rows in table A and  $n$  rows in table B that all contain the same combination of values in the key variables, table C contains  $m*n$  rows for that combination. C also contains rows corresponding to key value combinations in one input table that do not match any row the other input table.

C contains the horizontal concatenation of  $A(ia, LeftVars)$  and  $B(ib, RightVars)$  sorted by the values in the key variables. By default, `LeftVars` consists of all the variables of A, and `RightVars` consists of all the from B. Otherwise, `LefttVars` consists of the variables specified by the 'LeftVariables' name-value pair argument, and `RightVars` consists of the variables specified by the 'RightVariables' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

## **ia - Index to A**

column vector

Index to A, returned as a column vector. Each element of `ia` identifies the row in table A that corresponds to that row in the output table, C. The vector `ia` contains zeros to indicate the rows in C that do not correspond to rows in A.

## **ib - Index to B**

column vector

Index to B, returned as a column vector. Each element of `ib` identifies the row in table B that corresponds to that row in the output table, C. The vector `ib` contains zeros to indicate the rows in C that do not correspond to rows in B.

**Definitions****Key Variable**

Variable used to match and combine data between the input tables, A and B.

**Examples****Outer-Join Operation of Tables with One Variable in Common**

Create a table, A.

```
A = table([5;12;23;2;15;6],...
         {'cheerios';'pizza';'salmon';'oreos';'lobster';'pizza'},...
         'VariableNames',{'Age','FavoriteFood'},...
         'RowNames',{'Amy','Bobby','Holly','Harry','Marty','Sally'})
```

A =

	Age	FavoriteFood
Amy	5	'cheerios'
Bobby	12	'pizza'
Holly	23	'salmon'
Harry	2	'oreos'
Marty	15	'lobster'
Sally	6	'pizza'

Create a table, B, with one variable in common with A, called FavoriteFood.

```
B = table({'cheerios';'oreos';'pizza';'salmon';'cake'},...
         [110;160;140;367;243],...
         {'A-';'D';'B';'B';'C-'},...
         'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

B =

FavoriteFood	Calories	NutritionGrade
--------------	----------	----------------

# outerjoin

---

'cheerios'	110	'A-'
'oreos'	160	'D'
'pizza'	140	'B'
'salmon'	367	'B'
'cake'	243	'C-'

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`.

```
C = outerjoin(A,B)
```

```
C =
```

Age	FavoriteFood_A	FavoriteFood_B	Calories	NutritionGrade
NaN	''	'cake'	243	'C-'
5	'cheerios'	'cheerios'	110	'A-'
15	'lobster'	''	NaN	''
2	'oreos'	'oreos'	160	'D'
12	'pizza'	'pizza'	140	'B'
6	'pizza'	'pizza'	140	'B'
23	'salmon'	'salmon'	367	'B'

Table `C` contains a separate variable for the key variable from `A`, called `FavoriteFood_A`, and the key variable from `B`, called `FavoriteFood_B`.

## Merge Key Variable Pair to Single Variable

Create a table, `A`.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...  
         'VariableNames',{'Key1' 'Var1'})
```

```
A =
```

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a','b','d','e'},[4;5;6;7],...
         'VariableNames',{'Key1' 'Var2'})
```

B =

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, C, with data from tables A and B. Merge the key values into a single variable in the output table, C.

```
C = outerjoin(A,B,'MergeKeys',true)
```

C =

Key1	Var1	Var2
'a'	1	4

# outerjoin

---

'b'	2	5
'c'	3	NaN
'd'	NaN	6
'e'	11	7
'h'	17	NaN

Variables in table C that came from A contain null values in the rows that have no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

## Outer-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...  
        'VariableNames',{'Key1' 'Var1'})
```

A =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a','b','d','e'},[4;5;6;7]',...  
        'VariableNames',{'Key1' 'Var2'})
```

B =

Key1	Var2
------	------

```
'a'    4
'b'    5
'd'    6
'e'    7
```

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Match up rows with common values in the key variable, `Key1`, but also retain rows whose key values don't have a match.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B)
```

```
C =
```

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	' '	NaN
' '	NaN	'd'	6
'e'	11	'e'	7
'h'	17	' '	NaN

```
ia =
```

```
1
2
3
0
4
5
```

# outerjoin

---

```
ib =  
  
    1  
    2  
    0  
    3  
    4  
    0
```

The index vectors `ia` and `ib` contain zeros to indicate the rows in table C that do not correspond to rows in tables A or B, respectively.

## Left Outer-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17],...  
        'VariableNames',{'Key1' 'Var1'})
```

A =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable `Key1` between tables A and B, but also containing rows with values of `Key1` not present in A.

```
B = table({'a','b','d','e'},[4;5;6;7],...  
        'VariableNames',{'Key1' 'Var2'})
```

B =

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Ignore rows in `B` whose key values do not match any rows in `A`.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B,'Type','left')
```

`C =`

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	' '	NaN
'e'	11	'e'	7
'h'	17	' '	NaN

`ia =`

```
1
2
3
4
5
```

# outerjoin

---

```
ib =
```

```
  1  
  2  
  0  
  4  
  0
```

All values of `ia` are nonzero indicating that all rows in `C` have corresponding rows in `A`.

## See Also

`join` | `outerjoin`

**Purpose**

Consolidate workspace memory

**Syntax**

```
pack
pack filename
pack('filename')
```

**Description**

`pack` frees up needed space by reorganizing information so that it only uses the minimum memory required. All variables from your base and global workspaces are preserved. Any persistent variables that are defined at the time are set to their default value (the empty matrix, `[]`).

The MATLAB software temporarily stores your workspace data in a file called `tp#####.mat` (where `#####` is a numeric value) that is located in your temporary folder. (You can use the command `dir(tempdir)` to see the files in this folder).

`pack filename` frees space in memory, temporarily storing workspace data in a file specified by `filename`. This file resides in your current working folder and, unless specified otherwise, has a `.mat` file extension.

`pack('filename')` is the function form of `pack`.

**Tips**

You can only run `pack` from the MATLAB command line.

If you specify a `filename` argument, that file must reside in a folder for which you have write permission.

The `pack` function does not affect the amount of memory allocated to the MATLAB process. You must quit MATLAB to free up this memory.

Since MATLAB uses a heap method of memory management, extended MATLAB sessions may cause memory to become fragmented. When memory is fragmented, there may be plenty of free space, but not enough contiguous memory to store a new large variable.

If you get the `Out of memory` message from MATLAB, the `pack` function may find you some free memory without forcing you to delete variables.

The `pack` function frees space by

- Saving all variables in the base and global workspaces to a temporary file.
- Clearing all variables and functions from memory.
- Reloading the base and global workspace variables back from the temporary file and then deleting the file.

If you use `pack` and there is still not enough free memory to proceed, you must clear some variables. If you run out of memory often, you can allocate larger matrices earlier in the MATLAB session and use these system-specific tips:

- When running MATLAB on The Open Group UNIX platforms, ask your system manager to increase your swap space.
- On Microsoft Windows platforms, increase virtual memory using the Windows Control Panel.

To maintain persistent variables when you run `pack`, use `mlock` in the function.

## Examples

Change the current folder to one that is writable, run `pack`, and return to the previous folder.

```
cwd = pwd;  
cd(tempdir);  
pack  
cd(cwd)
```

# pagesetupdlg

**Purpose** Page setup dialog box

**Syntax** `dlg = pagesetupdlg(fig)`

---

**Note** `pagesetupdlg` is not recommended. Use `printpreview` instead.

---

**Description** `dlg = pagesetupdlg(fig)` creates a dialog box from which a set of pagelayout properties for the figure window, `fig`, can be set.

`pagesetupdlg` implements the "Page Setup..." option in the **Figure File Menu**.

`pagesetupdlg` supports setting the layout for a single figure. `fig` must be a single figure handle, not a vector of figures or a simulink diagram.

**See Also**      `printdlg` | `printpreview` | `printopt`

# pan

---

**Purpose** Pan view of graph interactively

**Syntax**

```
pan on
pan xon
pan yon
pan off
pan
pan(figure_handle,...)
h = pan(figure_handle)
```

**Description**

`pan on` turns on mouse-based panning in the current figure.

`pan xon` turns on panning only in the *x* direction in the current figure.

`pan yon` turns on panning only in the *y* direction in the current figure.

`pan off` turns panning off in the current figure.

`pan` toggles the pan state in the current figure on or off.

`pan(figure_handle,...)` sets the pan state in the specified figure.

`h = pan(figure_handle)` returns the figure's pan *mode object* for the figure *figure\_handle* for you to customize the mode's behavior.

## Using Pan Mode Objects

Access the following properties of pan mode objects via `get` and modify some of them using `set`:

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of panning enabled for the figure
- *FigureHandle* <handle> — The associated figure handle, a read-only property that cannot be set

## Pan Mode Callbacks

You can program the following callbacks for pan mode operations.

- `ButtonDownFilter` <function\_handle> — Function to intercept `ButtonDown` events

The application can inhibit the panning operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj          handle to the object that has been clicked on
% event_obj    event data (empty in this release)
% res [output] a logical flag to determine whether the pan
%              operation should take place(for 'res' set to 'false'
%              or the 'ButtonDownFcn' property of the object should
%              take precedence (when 'res' is 'true'))
```

- `ActionPreCallback` <function\_handle> — Function to execute before panning

Set this callback to if you need to execute code when a pan operation begins. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data
```

The event data struct has the following field:

Axes	The handle of the axes that is being panned
------	---------------------------------------------

- `ActionPostCallback` <function\_handle> — Function to execute after panning

Set this callback if you need to execute code when a pan operation ends. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

## Pan Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesPan(h,axes)` — Function querying permission to pan axes

Calling the function `isAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a pan operation is permitted on the axes objects.

- `setAllowAxesPan(h,axes,flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a pan operation on the axes objects.

- `info = getAxesPanMotion(h,axes)` — Function to get style of pan operations

Calling the function `getAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, as input will return a character cell array of the same dimension as the axes handle vector, which indicates the type of pan operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical' or 'both'.

- `setAxesPanMotion(h,axes,style)` — Function to set style of pan operations

Calling the function `setAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of panning on each axes.

## Examples

### Example 1 – Entering Pan Mode

Plot a graph and turn on Pan mode:

```
plot(magic(10));  
pan on  
% pan on the plot
```

### Example 2 – Constrained Pan

Constrain pan to  $x$ -axis using set:

```
plot(magic(10));  
h = pan;  
set(h,'Motion','horizontal','Enable','on');  
% pan on the plot in the horizontal direction.
```

### Example 3 – Constrained Pan in Subplots

Create four axes as subplots and give each one a different panning behavior:

```
ax1 = subplot(2,2,1);  
plot(1:10);  
h = pan;  
ax2 = subplot(2,2,2);  
plot(rand(3));  
setAllowAxesPan(h,ax2,false);  
ax3 = subplot(2,2,3);  
plot(peaks);  
setAxesPanMotion(h,ax3,'horizontal');  
ax4 = subplot(2,2,4);  
contour(peaks);  
setAxesPanMotion(h,ax4,'vertical');  
% pan on the plots.
```

### **Example 4 – Coding a ButtonDown Callback**

Create a `buttonDown` callback for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = pan;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
% Indicate what the target is
disp(['Clicked ' get(obj,'Type') ' object'])
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
    flag = true;
else
    flag = false;
end
```

### **Example 5 – Coding Pre- and Post-Callback Behavior**

Create callbacks for pre- and post-`ButtonDown` events for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Listen to pan events
plot(1:10);
h = pan;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
```

```
%  
function myprecallback(obj, evd)  
disp('A pan is about to occur.');
```

```
%  
function mypostcallback(obj, evd)  
newLim = get(evd.Axes, 'XLim');  
msgbox(sprintf('The new X-Limits are [%.2f %.2f].', newLim));
```

### Example 6 – Creating a Context Menu for Pan Mode

Coding a context menu that lets the user to switch to Zoom mode by right-clicking:

```
figure; plot(magic(10));  
hCM = uicontextmenu;  
hMenu = uimenu('Parent', hCM, 'Label', 'Switch to zoom', ...  
              'Callback', 'zoom(gcf, 'on')');
```

```
hPan = pan(gcf);  
set(hPan, 'UIContextMenu', hCM);  
pan('on')
```

You cannot add items to the built-in pan context menu, but you can replace it with your own.

### Tips

You can create a pan mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure’s callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure’s callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different pan behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the **Pan** tool  on the figure toolbar to enable and disable pan mode on a plot, or select **Pan** from the figure’s **Tools** menu. For details, see “Panning — Shifting Your View of the Graph”.

`zoom` | `linkaxes` | `rotate3d`

**Purpose**

Pareto chart

**Syntax**

```
pareto(Y)
pareto(Y, names)
pareto(Y, X)
H = pareto(...)
```

**Description**

Pareto charts display the values in the vector  $Y$  as bars drawn in descending order. Values in  $Y$  must be nonnegative and not include NaNs. Only the first 95% of the cumulative distribution is displayed.

`pareto(Y)` labels each bar with its element index in  $Y$  and also plots a line displaying the cumulative sum of  $Y$ .

`pareto(Y, names)` labels each bar with the associated name in the string matrix or cell array `names`.

`pareto(Y, X)` labels each bar with the associated value from  $X$ .

`pareto(ax, ...)` plots a Pareto chart in existing axes `ax` rather than GCA.

`H = pareto(...)` returns a combination of patch and line object handles.

**Examples****Create Pareto Chart**

Create a Pareto chart of vector `y`.

```
y = [90,75,30,60,5,40,40,5];
figure
pareto(y)
```

# pareto

---

`pareto` displays the elements in `y` as bars in descending order and labels each bar with its index in `y`. Since `pareto` displays only the first 95% of the cumulative distribution, some elements in `y` are not displayed.

## Label Bars in Pareto Chart

Examine the cumulative productivity of a group of programmers to see how normal its distribution is. Label each bar with the name of the programmer.

```
codelines = [200 120 555 608 1024 101 57 687];  
coders = {'Fred', 'Ginger', 'Norman', 'Max', 'Julia', 'Wally', 'Heidi', 'Pat'}  
  
figure  
pareto(codelines, coders)  
title('Lines of Code by Programmer')
```

**Tips**

You can use `pareto` to display the output of `hist`, even for vectors that include negative numbers. Because only the first 95 percent of values

## pareto

---

are displayed, one or more of the smallest bars may not appear. If you extend the `Xlim` of your chart, you can display all the values, but the new bars will not be labeled.

You cannot place datatips (use the Datacursor tool) on graphs created with `pareto`.

**Purpose**

Parallel for loop

**Syntax**

```
parfor loopvar = initval:endval; statements; end  
parfor (loopvar = initval:endval, M); statements; end
```

**Description**

`parfor loopvar = initval:endval; statements; end` executes a series of MATLAB statements for values of `loopvar` between `initval` and `endval`, inclusive, which specify a vector of increasing integer values. The loop occurs in parallel when you open a pool of workers with Parallel Computing Toolbox™ or when you create a MEX function with MATLAB Coder™. Unlike a traditional `for`-loop, iterations are not executed in a guaranteed order.

`parfor (loopvar = initval:endval, M); statements; end` executes statements in a loop using a maximum of `M` workers or threads, where `M` is a nonnegative integer.

**Tips**

- If you have Parallel Computing Toolbox software, see the function reference pages for `parfor` and `parpool` for additional information.
- If you have MATLAB Coder software, see the `parfor` function reference page for additional information.

**Examples**

Perform three large eigenvalue computations using three workers or cores with Parallel Computing Toolbox software:

```
parpool(3)  
parfor i=1:3, c(:,i) = eig(rand(1000)); end
```

**See Also**

`for`

# inputParser.parse

---

<b>Purpose</b>	Parse function inputs
<b>Syntax</b>	parse(p, argList)
<b>Description</b>	parse(p, argList) parses and validates the inputs in arglist.
<b>Input Arguments</b>	<b>p</b> Object of class inputParser. <b>argList</b> Comma separated list of inputs to parse and validate for your custom function. The class of each input depends upon your function definition.

## Examples **Input Parsing**

Parse and validate required and optional function inputs.

Create a custom function with required and optional inputs in the file findArea.m.

```
function a = findArea(width,varargin)
    p = inputParser;
    defaultHeight = 1;
    defaultUnits = 'inches';
    defaultShape = 'rectangle';
    expectedShapes = {'square','rectangle','parallelogram'};

    addRequired(p,'width',@isnumeric);
    addOptional(p,'height',defaultHeight,@isnumeric);
    addParameter(p,'units',defaultUnits);
    addParameter(p,'shape',defaultShape,...
        @(x) any(validatestring(x,expectedShapes)));

    parse(p,width,varargin{:});
    a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```
Error using findArea (line 14)  
The value of 'width' is invalid. It must satisfy the function: isnume
```

Specify an unsupported value for `shape`:

```
findArea(4, 'shape', 'circle')
```

```
Error using findArea (line 14)  
The value of 'shape' is invalid. Expected input to match one of these  
  
square, rectangle, parallelogram
```

```
The input, 'circle', did not match any of the valid strings.
```

# parseSoapResponse

---

**Purpose** Convert response string from SOAP server into MATLAB types

**Syntax** parseSoapResponse(response)

**Description** parseSoapResponse(response) extracts data from response a string returned by a SOAP server from the callSoapService function, and converts it to appropriate MATLAB classes (types).

**Examples** This example uses parseSoapResponse in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

---

**Note** The example does not use an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

---

```
% Create the message:
message = createSoapMessage(...
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'},...
'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
'http://test/soap/services/LibraryCatalog',...
'urn:LibraryCatalog#getAuthor',...
message)
%
% Extract MATLAB data from the response
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

# pascal

---

**Purpose** Pascal matrix

**Syntax**  
A = pascal(n)  
A = pascal(n,1)  
A = pascal(n,2)

**Description** A = pascal(n) returns the Pascal matrix of order n: a symmetric positive definite matrix with integer entries taken from Pascal's triangle. The inverse of A has integer entries.

A = pascal(n,1) returns the lower triangular Cholesky factor (up to the signs of the columns) of the Pascal matrix. It is *involutary*, that is, it is its own inverse.

A = pascal(n,2) returns a transposed and permuted version of pascal(n,1). A is a cube root of the identity matrix.

**Examples** pascal(4) returns

```
1   1   1   1
1   2   3   4
1   3   6  10
1   4  10  20
```

A = pascal(3,2) produces

```
A =
    1    1    1
   -2   -1    0
    1    0    0
```

**See Also** chol

**Purpose**

Create one or more filled polygons

**Syntax**

```
patch(X,Y,C)
patch(X,Y,Z,C)
patch(FV)
patch(X,Y,C, 'PropertyName',propertyvalue...)
patch('PropertyName',propertyvalue,...)
handle = patch(...)
```

**Properties**

For a list of properties, see [Patch Properties](#).

**Description**

`patch(X,Y,C)` adds a filled 2-D patch object to the current axes. A patch object is one or more polygons defined by the coordinates of its vertices. The elements of `X` and `Y` specify the vertices of a polygon. If `X` and `Y` are `m`-by-`n` matrices, MATLAB draws `n` polygons with `m` vertices. `C` determines the color of the patch. For more information on color input requirements, see “Coloring Patches” on page 1-4413.

MATLAB does not require each face to have the same number of vertices. In cases where they do not, pad the end of the `Faces` matrix with `NaNs`. To define a patch with faces that do not close, add one or more `NaNs` to the row in the `Vertices` matrix that defines the vertex you do not want connected.

See “Introduction to Patch Objects” for more information on using patch objects.

`patch(X,Y,Z,C)` creates a patch in 3-D coordinates. If the coordinate data does not define closed polygons, `patch` closes the polygons. The data can define concave or intersecting polygons. However, if the edges of an individual patch face intersect themselves, the resulting face might be only partly filled. In that case, it is better to divide the face into smaller polygons.

`patch(FV)` creates a patch using structure `FV`, which contains the fields `vertices`, `faces`, and optionally `facevertexcdata`. These fields correspond to the `Vertices`, `Faces`, and `FaceVertexCData` patch properties. Specifying only unique vertices and their connection matrix

can reduce the size of the data for patches having many faces. For an example of how to specify patches with this method, see “Specifying Patch Object Shapes” on page 1-4410.

`patch(X,Y,C,'PropertyName',propertyvalue...)` follows the `X`, `Y`, (`Z`), and `C` arguments with property name/property value pairs to specify additional patch properties. For a description of the properties, see [Patch Properties](#). You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the [set](#) and [get](#) reference pages for examples of how to specify these data types).

`patch('PropertyName',propertyvalue,...)` specifies all properties using property name/property value pairs. This form lets you omit the color specification because MATLAB uses the default face color and edge color unless you explicitly assign a value to the `FaceColor` and `EdgeColor` properties. This form also lets you specify the patch using the `Faces` and `Vertices` properties instead of `x`-, `y`-, and `z`-coordinates. See “Specifying Patch Object Shapes” on page 1-4410 for more information.

`handle = patch(...)` returns the handle of the patch object it creates.

Unlike high-level area creation functions, such as `fill` or `area`, `patch` does not check the settings of the figure and axes `NextPlot` properties. It simply adds the patch object to the current axes.

## Examples

### Specifying Patch Object Shapes

The next two examples create a patch object using two methods:

- Specifying `x`-, `y`-, and `z`-coordinates and color data (`XData`, `YData`, `ZData`, and `CData` properties)
- Specifying vertices, the connection matrix, and color data (`Vertices`, `Faces`, and `FaceVertexCData` properties)

Create five triangular faces, each having three vertices, by specifying the `x`-, `y`-, and `z`-coordinates of each vertex:

```
xdata = [2 2 0 2 5;  
         2 8 2 4 5;
```

```

        8 8 2 4 8];
ydata = [4 4 4 2 0;
        8 4 6 2 2;
        4 0 4 0 0];
zdata = ones(3,5);

% Red numbers denote the vertex indices.
% For this example:
% xindices = [1 4 7 10 13;
%            2 5 8 11 14;
%            3 6 9 12 15];
% Blue numbers denote the face numbers.
patch(xdata,ydata,zdata,'w')

```

Create the five triangular faces, specifying faces and vertices:

% The Vertices property contains the coordinates of each

# patch

---

```
% unique vertex defining the patch. The Faces property
% specifies how to connect these vertices to form each
% face of the patch. More than one face may
% use a given vertex.
% For this example, five triangles have 11 total vertices,
% instead of 15. Each row contains
% the x- and y-coordinates
% of each vertex.
verts = [2 4; ...
         2 8; ...
         8 4; ...
         8 0; ...
         0 4; ...
         2 6; ...
         2 2; ...
         4 2; ...
         4 0; ...
         5 2; ...
         5 0 ];

% There are five faces, defined by connecting the
% vertices in the order indicated.
faces = [ ...
         1 2 3; ...
         1 3 4; ...
         5 6 1; ...
         7 8 9; ...
         11 10 4 ];

% Create the patch by specifying the Faces, Vertices,
% and FaceVertexCData properties as well as the
% FaceColor property. Red numbers denote the vertex
% numbers, as defined in faces. Blue indicate face numbers.
p = patch('Faces',faces,'Vertices',verts,'FaceColor','w');
```

```
% Using the previous values for verts and faces, you can
% create the same patch object using a structure:
patchinfo.Vertices = verts;
patchinfo.Faces = faces;
patchinfo.FaceColor = 'w';
```

```
patch(patchinfo);
```

### Coloring Patches

There are many ways to customize your patch objects using colors. The appropriate input depends on:

- Whether you want to change the edge colors
- How you specified the patch faces:
  - Using face/vertex values
  - Using  $x$ -,  $y$ -, and  $z$ -coordinates

The following sections present the various options available.

## Specifying Edge Colors

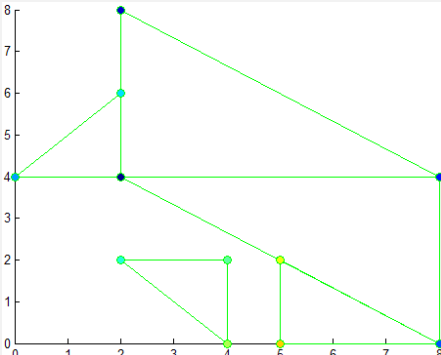

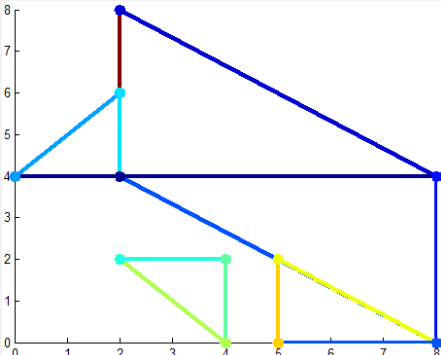

The following options apply to the edge colors of your patch object. The settings are independent of the face colors, but the colors themselves depend on the colors specified at each vertex. Markers show the color at each vertex. Specify the colors using the `EdgeColor` property. To explore the options using the Sample Input Code, create a base patch object:

```
xdata = [2     2     0     2     5;
         2     8     2     4     5;
         8     8     2     4     8];
ydata = [4     4     4     2     0;
         8     4     6     2     2;
         4     0     4     0     0];
cdata = [15    0     4     6    10;
         1     2     5     7     9;
         2     3     0     8     3];
p = patch(xdata,ydata,cdata,'Marker','o',...
         'MarkerFaceColor','flat',...
         'FaceColor','none')
```

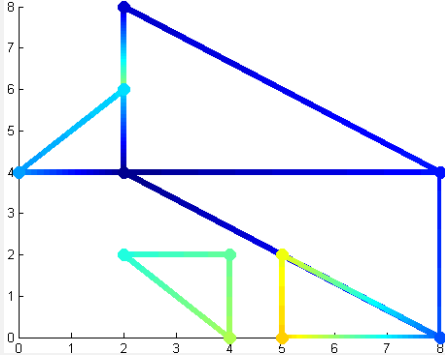

For more detailed information on how the `EdgeColor` property works, see the [Patch Properties](#) page.

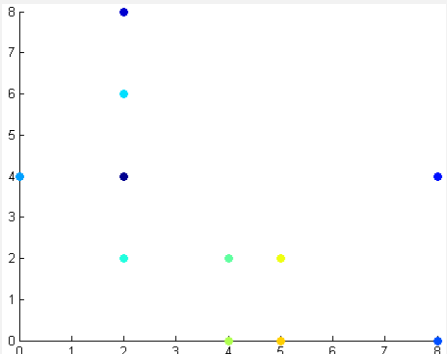

Desired Look	EdgeColor Value	Sample Code
All edges have the same color, around all faces. This option does not rely on the <code>FaceColor</code> value.	<code>ColorSpec</code>	<code>set(p, 'EdgeColor', 'g')</code>

Desired Look	EdgeColor Value	Sample Code
		
<p>Each edge corresponds to the color of the vertex that precedes the edge, with one color per edge. This option requires that the FaceColor property be flat or interp. By default, if you specify CData when creating the patch object, its FaceColor property is interp.</p> 	<p>'flat'</p>	<pre>set(p, 'EdgeColor', 'flat', ...     'LineWidth', 3)</pre>

# patch

Desired Look	EdgeColor Value	Sample Code
<p>Each edge corresponds to the vertex colors, interpolated between vertices. This option requires that the FaceColor property be flat or interp. By default, if you specify CData when creating the patch object, its FaceColor property is interp.</p> 	'interp'	<pre>set(gcf, 'Renderer', 'zbuffer') set(p, 'EdgeColor', 'interp', ... 'LineWidth', 5)</pre>
<p>Edges have no color. This option does not rely on the FaceColor value. If set, markers retain vertex colors.</p>	'none'	<pre>set(p, 'EdgeColor', 'none')</pre>

Desired Look	EdgeColor Value	Sample Code
		

### Specifying Face Colors Using Face/Vertex Input Matrices

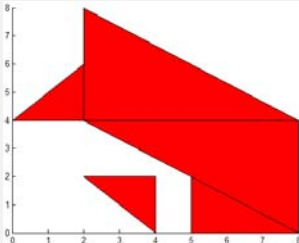

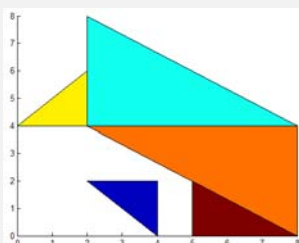

The following options apply to the face colors of your patch object when you specify the faces using face/vertex input matrices. To explore the options, start with a base patch object:

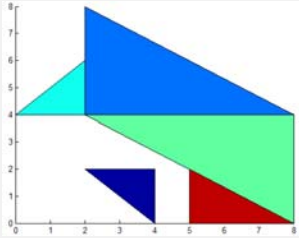

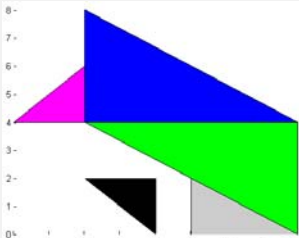

```
% For this example, there are five triangles (m = 5)
% sharing eleven unique vertices (k = 11).
verts = [2 4; ...
         2 8; ...
         8 4; ...
         8 0; ...
         0 4; ...
         2 6; ...
         2 2; ...
         4 2; ...
         4 0; ...
         5 2; ...
         5 0 ];
faces = [1 2 3; ...
        1 3 4; ...
        5 6 1; ...
        7 8 9; ...
        11 10 4];
```

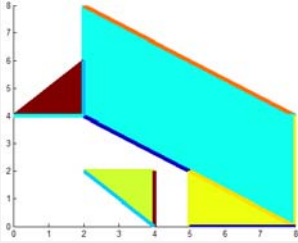

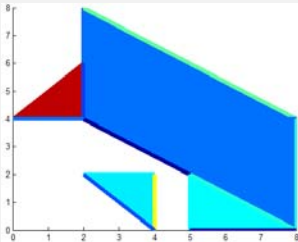

# patch

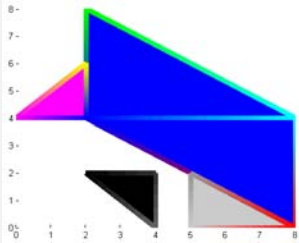

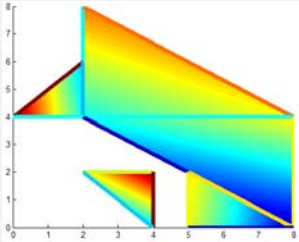

```
p = patch('Faces',faces,'Vertices',verts,'FaceColor','b');
```

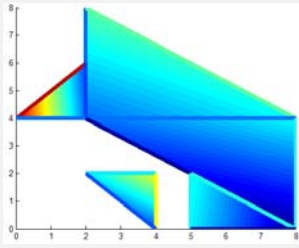

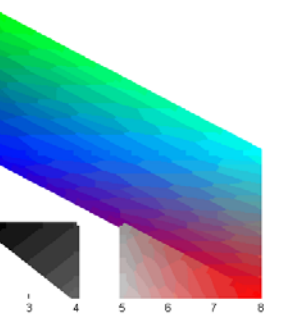

For more information on the relevant properties, see [FaceColor](#), [FaceVertexCData](#), and [CDataMapping](#).

Desired Look	Parameter Values	Sample Code
<p>All faces have the same color.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> ColorSpec</li> <li>• <b>FaceVertexCData:</b> [] (no input) An empty array is the default value, and patch ignores any input until you set FaceColor to 'flat' or 'interp'.</li> <li>• <b>Color source:</b> truecolor</li> <li>• <b>CDataMapping:</b> 'direct' or 'scaled'. 'scaled' is the default value, but neither affects the outcome.</li> </ul>	<pre>set(p,'FaceColor','r')  or  set(p,'FaceColor',[1 0 0])</pre>
<p>Each face has a single, unique color, indexed from a selected section of the colormap.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> 'flat'</li> <li>• <b>FaceVertexCData:</b> m-by-1 matrix of index values</li> <li>• <b>Color source:</b> A selected portion of the colormap</li> <li>• <b>CDataMapping:</b> 'scaled'</li> </ul>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60]; set(p,'FaceColor','flat',...     'FaceVertexCData',cdata,...     'CDataMapping','scaled')</pre>

Desired Look	Parameter Values	Sample Code
<p>Each face has a single, unique color, indexed from the whole colormap.</p> 	<ul style="list-style-type: none"> <li>• FaceColor: 'flat'</li> <li>• FaceVertexCData: m-by-1 matrix of index values</li> <li>• Color source: colormap</li> <li>• CDataMapping: 'direct'</li> </ul> <p>'scaled' is the default value when you input CData values. If you want to change the axes CLim property, but want your patch object to index the entire colormap, use 'CDataMapping', 'direct'.</p>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60]'; set(p,'FaceColor','flat',... 'FaceVertexCData',cdata,...     'EdgeColor','interp',...     'LineWidth',5)</pre>

### Specifying Face Colors Using x-, y-, and z-Coordinate Input

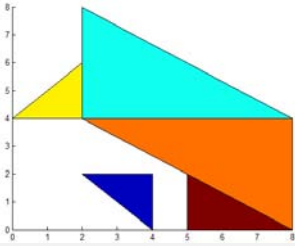

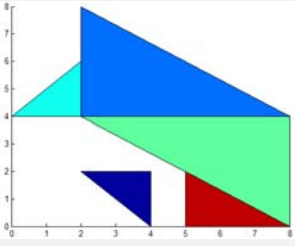

The following options apply to the face colors of your patch object when you specify the faces using x-, y-, and z-coordinates. To explore the options, start with a base patch object:

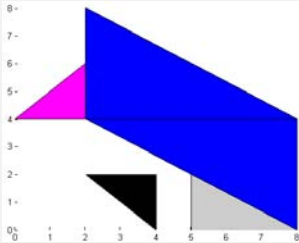

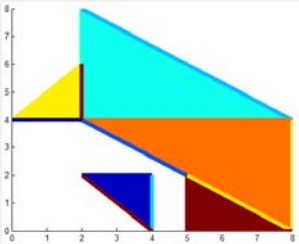

```
% For this example, there are five (m=5) triangles (n=3).
% The total number of vertices is mxn, or k = 15.
xdata = [2 2 0 2 5;
         2 8 2 4 5;
         8 8 2 4 8];
ydata = [4 4 4 2 0;
         8 4 6 2 2;
         4 0 4 0 0];
zdata = ones(3,5);
p = patch(xdata,ydata,zdata,'b')
```

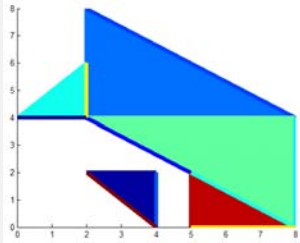

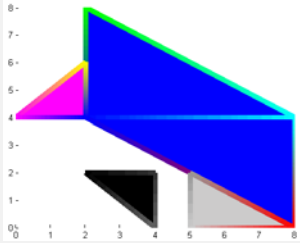

For more information on the relevant properties, see `FaceColor`, `CData`, and `CDataMapping`.

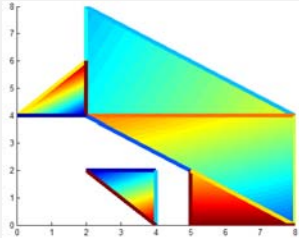

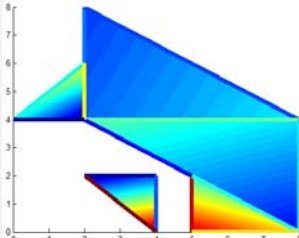

Desired Look	Parameter Values	Sample Code
<p>All faces have the same color.</p> 	<ul style="list-style-type: none"> <li>• <code>FaceColor</code>: <code>ColorSpec</code></li> <li>• <code>CData</code>: <code>[]</code> (no input)</li> <li>• Color source: <code>truecolor</code></li> <li>• <code>CDataMapping</code>: <code>'direct'</code> or <code>'scaled'</code>.</li> </ul> <p><code>'scaled'</code> is the default value, but neither affects the outcome.</p>	<pre>set(p,'FaceColor','r')  or  set(p,'FaceColor',[1 0 0])</pre>
<p>Each face has a single, unique color, indexed from a selected section of the colormap.</p>	<ul style="list-style-type: none"> <li>• <code>FaceColor</code>: <code>'flat'</code></li> <li>• <code>CData</code>: m-by-1 matrix of index values</li> </ul>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60];</pre>

# patch

## Tutorials

- “Introduction to Patch Objects”

## Purpose

Patch properties

## Creating Patch Objects

Use patch to create patch objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Patch Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

AlphaDataMapping  
none | {scaled} | direct

*Transparency mapping method.* Determines how the MATLAB software interprets indexed alpha data.

- none — The transparency values of FaceVertexAlphaData are between 0 and 1 or are clamped to this range.
- scaled — Transform the FaceVertexAlphaData to span the portion of the alphamap indicated by the axes ALim property, linearly mapping data values to alpha values.
- direct — Use the FaceVertexAlphaData as indices directly into the alphamap. When not scaled, the data are usually integer values ranging from 1 to length(alphamap). MATLAB maps values less than 1 to the first alpha value in the

# Patch Properties

---

alphamap, and values greater than `length(alphamap)` to the last alpha value in the alphamap. Values with a decimal portion are fixed to the nearest lower integer. If `FaceVertexAlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the alphamap).

## AmbientStrength

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the patch `DiffuseStrength` and `SpecularStrength` properties.

## Annotation

hg.Annotation object (read-only)

*Handle of Annotation object.* The Annotation property enables you to specify whether this patch object is represented in a figure legend.

Querying the Annotation property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the patch object is displayed in a figure legend:

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Represent this patch object in a legend (default)
off	Do not include this patch object in a legend
children	Same as on because patch objects do not have children

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

## Selecting which objects to display in legend

Some graphics functions create multiple objects. For example, `contour3` uses patch objects to create a 3D contour graph. You can use the Annotation property set select a subset of the objects for display in the legend.

```
[X,Y] = meshgrid(-2:.1:2);  
[Cm hC] = contour3(X.*exp(-X.^2-Y.^2));  
hA = get(hC, 'Annotation');  
hLL = get([hA{:}], 'LegendInformation');  
% Set the IconDisplayStyle property to display  
% the first, fifth, and ninth patch in the legend  
set([hLL{:}], {'IconDisplayStyle'}, ...  
    {'on', 'off', 'off', 'off', 'on', 'off', 'off', 'off', 'on'})
```

# Patch Properties

---

```
% Assign DisplayNames for the three patch  
that are displayed in the legend  
set(hC([1,5,9]),{'DisplayName'},{'bottom','middle','top'})  
legend show
```

BackFaceLighting  
unlit | lit | {reverselit}

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- unlit — Face not lit.
- lit — Face lit in normal way.
- reverselit — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

BusyAction  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the patch object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. You can also use a string that is a valid MATLAB expression or the name of a MATLAB file. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

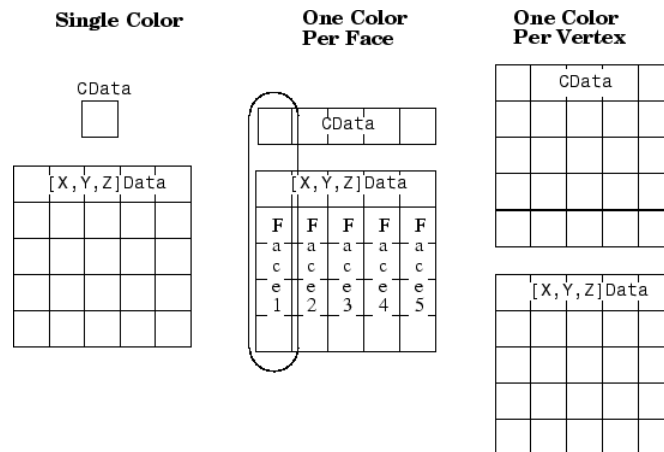

## `CData`

scalar | vector | matrix

# Patch Properties

*Patch colors.* Specifies the color of the patch. You can specify color for each vertex, each face, or a single color for the entire patch. The way MATLAB interprets CData depends on the type of data supplied. The data can be numeric values that are scaled to map linearly into the current colormap, integer values that are used directly as indices into the current colormap, or arrays of RGB values. RGB values are not mapped into the current colormap, but interpreted as the colors defined. On true color systems, MATLAB uses the actual colors defined by the RGB triples.

The following diagrams illustrate the dimensions of CData with respect to the coordinate data arrays, XData, YData, and ZData. The first diagram illustrates the use of indexed color.

The following diagram illustrates the use of true color. True color requires m-by-n-by-3 arrays to define red, green, and blue components for each color.

Note that if CData contains NaNs, MATLAB does not color the faces.

See the Faces, Vertices, and FaceVertexCData properties for an alternative method of patch definition.

CDataMapping  
 {scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the patch. If you use true color specification for CData or FaceVertexCData, this property has no effect.

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the `caxis` command for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. When not scaled, the data are usually integer values

# Patch Properties

---

ranging from 1 to `length(colormap)`. MATLAB maps values less than 1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

**Children**  
matrix of handles

Always the empty matrix; patch objects have no children.

**Clipping**  
{on} | off

*Clipping to axes rectangle.* When **Clipping** is on, MATLAB does not display any portion of the patch outside the axes rectangle.

**CreateFcn**  
string | function handle

*Callback routine executed during object creation.* Executes when MATLAB creates a patch object. You must define this property as a default value for patches or in a call to the patch function that creates a new object.

For example, the following statement creates a patch (assuming `x`, `y`, `z`, and `c` are defined), and executes the function referenced by the function handle `@myCreateFcn`.

```
patch(x,y,z,c,'CreateFcn',@myCreateFcn)
```

MATLAB executes the create function after setting all properties for the patch created. Setting this property on an existing patch object has no effect.

The handle of the object whose **CreateFcn** is being executed is accessible only through the root **CallbackObject** property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DeleteFcn**  
string | function handle

*Delete patch callback routine.* Executes when you delete the patch object (for example, when you issue a `delete` command or clear the axes (`cla`) or figure (`clf`) containing the patch). MATLAB executes the routine before deleting the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DiffuseStrength**  
scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the patch. Diffuse light comes from light objects in the axes.

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

**DisplayName**  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the patch object in the legend. The default is an empty string.

# Patch Properties

---

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EdgeAlpha

{scalar = 1} | flat | interp

*Transparency of the edges of patch faces.*

- `scalar` — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.
- `flat` — The alpha data (`FaceVertexAlphaData`) of each vertex controls the transparency of the edge that follows it.
- `interp` — Linear interpolation of the alpha data (`FaceVertexAlphaData`) at each vertex determines the transparency of the edge.

Note that you cannot specify `flat` or `interp` `EdgeAlpha` without first setting `FaceVertexAlphaData` to a matrix containing one alpha value per face (`flat`) or one alpha value per vertex (`interp`).

## EdgeColor

{ColorSpec} | none | flat | interp

*Color of the patch edge.* Determines how MATLAB colors the edges of the individual faces that make up the patch.

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is [0 0 0] (black). See the **ColorSpec** reference page for more information on specifying color.
- **none** — Edges not drawn.
- **flat** — The color of each vertex controls the color of the edge that follows it. This means **flat** edge coloring is dependent on the order in which you specify the vertices:

- **interp** — Linear interpolation of the **CData** or **FaceVertexCData** values at the vertices determines the edge color.

## EdgeLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on patch edges.

- **none** — Lights do not affect the edges of this object.
- **flat** — The effect of light objects is uniform across each edge of the patch.

# Patch Properties

---

- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase patch objects. Alternative erase modes are useful in creating animated sequences, where control of the way individual objects redraw is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the patch when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the patch by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the patch does not damage the color of the objects behind it. However, patch color depends on the color of the screen behind it and is correctly colored only when over the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.
- `background` — Erase the patch by drawing it in the axes background `Color`, or the figure background `Color` if the axes

Color is none. This damages objects that are behind the erased patch, but the patch is always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### FaceAlpha

{scalar = 1} | flat | interp

*Transparency of the patch face.*

- `scalar` — A single non-NaN value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).
- `flat` — The values of the alpha data (`FaceVertexAlphaData`) determine the transparency for each face. The alpha data at the first vertex determines the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`FaceVertexAlphaData`) at each vertex determines the transparency of each face.

Note that you cannot specify `flat` or `interp` `FaceAlpha` without first setting `FaceVertexAlphaData` to a matrix containing one alpha value per face (`flat`) or one alpha value per vertex (`interp`).

# Patch Properties

---

## FaceColor

{ColorSpec} | none | flat | interp

*Color of the patch face.*

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See the **ColorSpec** reference page for more information on specifying color.
- **none** — Do not draw faces. Note that edges are drawn independently of faces.
- **flat** — The **CData** or **FaceVertexCData** property must contain one value per face and determines the color for each face in the patch. The color data at the first vertex determines the color of the entire face.
- **interp** — Bilinear interpolation of the color at each vertex determines the coloring of each face. The **CData** or **FaceVertexCData** property must contain one value per vertex.

## FaceLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of **light** objects on patch faces.

- **none** — Lights do not affect the faces of this object.
- **flat** — The effect of light objects is uniform across the faces of the patch. Select this choice to view faceted objects.
- **gouraud** — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- **phong** — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to

view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## Faces

m-by-n matrix

*Vertex connection defining each face.* Specifies which vertices in the Vertices property are connected. The Faces matrix defines  $m$  faces with up to  $n$  vertices each. Each row designates the connections for a single face, and the number of elements in that row that are not NaN defines the number of vertices for that face.

The Faces and Vertices properties provide an alternative way to specify a patch that can be more efficient than using  $x$ ,  $y$ , and  $z$  coordinates in most cases. For example, consider the following patch. It is composed of eight triangular faces defined by nine vertices.

The corresponding Faces and Vertices properties are shown to the right of the patch. Note how some faces share vertices with other faces. For example, the fifth vertex (V5) is used six times, once each by faces one, two, and three and six, seven, and eight. Without sharing vertices, this same patch requires 24 vertex definitions.

# Patch Properties

---

FaceVertexAlphaData  
m-by-1 matrix

*Face and vertex transparency data.* Specifies the transparency of patches that have been defined by the `Faces` and `Vertices` properties. The interpretation of the values specified for `FaceVertexAlphaData` depends on the dimensions of the data.

`FaceVertexAlphaData` can be one of the following:

- A single value, which applies the same transparency to the entire patch. The `FaceAlpha` property must be set to `flat`.
- An m-by-1 matrix (where m is the number of rows in the `Faces` property), which specifies one transparency value per face. The `FaceAlpha` property must be set to `flat`.
- An m-by-1 matrix (where m is the number of rows in the `Vertices` property), which specifies one transparency value per vertex. The `FaceAlpha` property must be set to `interp`.

The `AlphaDataMapping` property determines how MATLAB interprets the `FaceVertexAlphaData` property values.

FaceVertexCData  
matrix

*Face and vertex colors.* Specifies the color of patches defined by the `Faces` and `Vertices` properties. You must also set the values of the `FaceColor`, `EdgeColor`, `MarkerFaceColor`, or `MarkerEdgeColor` appropriately. The interpretation of the values specified for `FaceVertexCData` depends on the dimensions of the data.

For indexed colors, `FaceVertexCData` can be:

- A single value, which applies a single color to the entire patch.
- An n-by-1 matrix, where n is the number of rows in the `Faces` property, which specifies one color per face.

- An  $n$ -by-1 matrix, where  $n$  is the number of rows in the Vertices property, which specifies one color per vertex.

For true colors, FaceVertexCData can be:

- A 1-by-3 matrix, which applies a single color to the entire patch.
- An  $n$ -by-3 matrix, where  $n$  is the number of rows in the Faces property, which specifies one color per face.
- An  $n$ -by-3 matrix, where  $n$  is the number of rows in the Vertices property, which specifies one color per vertex.

The following diagram illustrates the various forms of the FaceVertexCData property for a patch having eight faces and nine vertices. The CDataMapping property determines how MATLAB interprets the FaceVertexCData property when you specify indexed colors.

# Patch Properties

---

HandleVisibility  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the patch can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the patch. If `HitTest` is `off`, clicking the patch selects the object below it (which might be the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Patch Properties

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of the patch edges.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line

Specifier	Line Style
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

#### `LineWidth`

width in points

*Edge line width.* The width, in points, of the patch edges 1 point =  $\frac{1}{72}$  inch. The default value is 0.5 points.

#### `Marker`

character (see table)

*Marker symbol.* Specifies marks that locate vertices. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

#### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond

# Patch Properties

---

Specifier	Marker Type
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' 'h'	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto} | flat

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — Defines the color to use.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Sets MarkerEdgeColor to the same color as the EdgeColor property.
- flat — The color of each vertex controls the color of the marker that denotes it.

## MarkerFaceColor

ColorSpec | {none} | auto | flat

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — Defines the color to use.

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes color, or the figure color, if the axes `Color` property is `none`.
- `flat` — The color of each vertex controls the color of the marker that denotes it.

## MarkerSize

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

## NormalMode

{auto} | manual

*MATLAB generated or user-specified normal vectors.*

- `auto` — MATLAB calculates vertex normals based on the coordinate data
- `manual` — If you specify your own vertex normals, MATLAB sets this property to `manual` and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of axes, `hggroup`, or `hgtransform`

*Parent of patch object.* Contains the handle of the patch object's parent. The parent of a patch object is the axes, `hggroup`, or `hgtransform` object that contains it. See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

# Patch Properties

---

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays selection handles or a dashed box (depending on the number of faces) if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by:

- Drawing handles at each vertex for a single-faced patch
- Drawing a dashed bounding box for a multifaced patch

When `SelectionHighlight` is off, MATLAB does not draw the indicators.

## SpecularColorReflectance

scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

## SpecularExponent

scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

## SpecularStrength

scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the patch. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the patch object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, suppose you use patch objects to create borders for a group of `uicontrol` objects and want to change the color of the borders in a `uicontrol`'s callback routine. Specify a `Tag` with the patch definition:

```
patch(X,Y,'k','Tag','PatchBorder')
```

Then use `findobj` in the `uicontrol`'s callback routine to obtain the handle of the patch and set its `FaceColor` property.

```
set(findobj('Tag','PatchBorder'),'FaceColor','w')
```

Type

string (read-only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For patch objects, `Type` is always `'patch'`.

# Patch Properties

---

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the patch.* Assign this property the handle of a uicontextmenu object created in the same figure as the patch. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the patch.

## UserData

matrix

*User-specified data.* Data you want to associate with the patch object. The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## VertexNormals

matrix

*Surface normal vectors.* Contains the vertex normals for the patch. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. Use this property to produce interesting lighting effects.

## Vertices

matrix

*Vertex coordinates.* A matrix containing the  $x$ -,  $y$ -,  $z$ -coordinates for each vertex. See the Faces property for more information.

## Visible

{on} | off

*Patch object visibility.*

- on — All patches are visible.
- off — The patch is not visible, but still exists, and you can query and set its properties.

## XData

vector | matrix

*X-coordinates.* The  $x$ -coordinates of the patch vertices. If XData is a matrix, each column represents the  $x$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

## YData

vector | matrix

*Y-coordinates.* The  $y$ -coordinates of the patch vertices. If YData is a matrix, each column represents the  $y$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

## ZData

vector | matrix

*Z-coordinates.* The  $z$ -coordinates of the patch vertices. If ZData is a matrix, each column represents the  $z$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

patch

# path

---

<b>Purpose</b>	View or change search path
<b>Alternatives</b>	As an alternative to the <code>path</code> function, use the Set Path dialog box.
<b>Syntax</b>	<pre>path path('newpath') path(<b>path</b>, 'newpath') path('newpath', <b>path</b>) p = path</pre>
<b>Description</b>	<p><code>path</code> displays the MATLAB search path, which is stored in <code>pathdef.m</code>.</p> <p><code>path('newpath')</code> changes the search path to <code>newpath</code>, where <code>newpath</code> is a string array of folders.</p> <p><code>path(<b>path</b>, 'newpath')</code> adds the <code>newpath</code> folder to the end of the search path. If <code>newpath</code> is already on the search path, then <code>path(<b>path</b>, 'newpath')</code> moves <code>newpath</code> to the end of the search path.</p> <p><code>path('newpath', <b>path</b>)</code> adds the <code>newpath</code> folder to the top of the search path. If <code>newpath</code> is already on the search path, then <code>path('newpath', <b>path</b>)</code> moves <code>newpath</code> to the top of the search path. To add multiple folders in one statement, instead use <code>addpath</code>.</p> <p><code>p = path</code> returns the search path to string variable <code>p</code>.</p>
<b>Examples</b>	<p>Display the search path:</p> <pre>path</pre> <p>MATLAB returns, for example</p> <pre>MATLABPATH  H:\My Documents\MATLAB C:\Program Files\MATLAB\R200nn\toolbox\matlab\general C:\Program Files\MATLAB\R200nn\toolbox\matlab\ops C:\Program Files\MATLAB\R200nn\toolbox\matlab\lang C:\Program Files\MATLAB\R200nn\toolbox\matlab\elmat</pre>

```
C:\Program Files\MATLAB\R200nn\toolbox\matlab\elfun  
...
```

R200nn represents the folder for the MATLAB release, for example, R2009b.

Add a new folder to the search path on Microsoft Windows platforms:

```
path(path, 'c:/tools/goodstuff')
```

# path

---

Add a new folder to the search path on UNIX<sup>6</sup> platforms:

```
path(path, '/home/tools/goodstuff')
```

Temporarily add the folder `my_files` to the search path, run `my_function` in `my_files`, then restore the previous search path:

```
p = path
path(p, 'my_files')
my_function
path(p)
```

## How To

- “What Is the MATLAB Search Path?”
- “Files and Folders that MATLAB Accesses”

6. UNIX is a registered trademark of The Open Group in the United States and other countries.

**Purpose** Save current search path to pathdef.m file

**Syntax** path2rc

**Description** path2rc runs savepath. The savepath function is replacing path2rc. Use savepath instead of path2rc and replace instances of path2rc with savepath.

# pathsep

---

**Purpose** Search path separator for current platform

**Syntax** `c = pathsep`

**Description** `c = pathsep` returns the search path separator character for this platform. The search path separator is the character that separates path names in the `pathdef.m` file, as returned by the `path` function. The character is a semicolon (;). For versions of MATLAB software earlier than version 7.7 (R2008b), the character on UNIX<sup>7</sup> platforms was a colon (:). Use `pathsep` to work programmatically with the content of the search path file.

**See Also** `fileparts` | `filesep` | `fullfile` | `path`

**How To**

- “What Is the MATLAB Search Path?”

7. UNIX is a registered trademark of The Open Group in the United States and other countries.

<b>Purpose</b>	Open Set Path dialog box to view and change search path
<b>Syntax</b>	<code>pathtool</code>
<b>Description</b>	<code>pathtool</code> opens the Set Path dialog box, a graphical user interface you use to view and modify the MATLAB search path.

# pathool

## See Also

`addpath` | `cd` | `dir` | `genpath` | `matlabroot` | `path` | `pathsep` | `rehash`  
| `restoredefaultpath` | `rmpath` | `savepath` | `startup` | `what`

## How To

- “What Is the MATLAB Search Path?”

**Purpose** Halt execution temporarily

**Syntax**

```

pause
pause(n)
pause on
pause off
pause query
state = pause('query')
oldstate = pause(newstate)

```

**Description** `pause`, by itself, causes the currently executing function to stop and wait for you to press any key before continuing. Pausing must be enabled for this to take effect. (See `pause on`, below). `pause` without arguments also blocks execution of Simulink models, but not repainting of them.

`pause(n)` pauses execution for `n` seconds before continuing, where `n` is any nonnegative real number. Pausing must be enabled for this to take effect.

Typing `pause(inf)` puts you into an infinite loop. To return to the MATLAB prompt, type **Ctrl+C**.

`pause on` enables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. Pausing remains enabled until you enter `pause off` in your function or at the command line.

`pause off` disables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. This allows normally interactive scripts to run unattended. Pausing remains disabled until you enter `pause on` in your function or at the command line, or start a new MATLAB session.

`pause query` displays 'on' if pausing is currently enabled. Otherwise, it displays 'off'.

`state = pause('query')` returns 'on' in character array `state` if pausing is currently enabled. Otherwise, the value of `state` is 'off'.

`oldstate = pause(newstate)`, enables or disables pausing, depending on the 'on' or 'off' value in `newstate`, and returns the former setting (also either 'on' or 'off') in character array `oldstate`.

# pause

---

## Tips

The accuracy of `pause` is subject to the scheduling resolution of the operating system you are using, and also to other system activity. It cannot be guaranteed with 100% confidence. Asking for finer resolutions shows higher relative error.

While MATLAB is paused, the following continue to execute:

- Repainting of figure windows, Simulink block diagrams, and Java windows
- HG callbacks from figure windows
- Event handling from Java windows

## See Also

`keyboard` | `input` | `drawnow`

**Purpose** Set or query plot box aspect ratio

**Syntax**

```
pbaspect
pbaspect([aspect_ratio])
pbaspect('mode')
pbaspect('auto')
pbaspect('manual')
pbaspect(axes_handle,...)
```

**Description** The plot box aspect ratio determines the relative size of the *x*-, *y*-, and *z*-axes.

`pbaspect` with no arguments returns the plot box aspect ratio of the current axes.

`pbaspect([aspect_ratio])` sets the plot box aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the *x*-, *y*-, and *z*-axes size. For example, a value of `[1 1 1]` (the default) means the plot box is a cube (although with stretch-to-fill enabled, it may not appear as a cube). See [Tips](#).

`pbaspect('mode')` returns the current value of the plot box aspect ratio mode, which can be either `auto` (the default) or `manual`. See [Remarks](#).

`pbaspect('auto')` sets the plot box aspect ratio mode to `auto`.

`pbaspect('manual')` sets the plot box aspect ratio mode to `manual`.

`pbaspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. If you do not specify an axes handle, `pbaspect` operates on the current axes.

**Tips** `pbaspect` sets or queries values of the axes object `PlotBoxAspectRatio` and `PlotBoxAspectRatioMode` properties.

When the plot box aspect ratio mode is `auto`, the MATLAB software sets the ratio to `[1 1 1]`, but may change it to accommodate manual settings of the data aspect ratio, camera view angle, or axis limits. See the axes `DataAspectRatio` property for a table listing the interactions between various properties.

Setting a value for the plot box aspect ratio or setting the plot box aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the plot box aspect ratio to its current value,

```
pbaspect(pbaspect)
```

can cause a change in the way the graphs look. See the Remarks section of the `axes` reference description, “Axes Aspect Ratio Properties” in the 3-D Visualization manual, and “Setting Aspect Ratio” in the MATLAB Graphics manual for a discussion of stretch-to-fill.

## Examples

The following surface plot of the function  $z = xe^{-x^2 - y^2}$  is useful to illustrate the plot box aspect ratio. First plot the function over the range  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ ,

```
[x,y] = meshgrid([-2:.2:2]);  
z = x.*exp(-x.^2 - y.^2);  
surf(x,y,z)
```

Querying the plot box aspect ratio shows that the plot box is square.

```
pbaspect
ans =
    1    1    1
```

It is also interesting to look at the data aspect ratio selected by MATLAB.

```
daspect
ans =
    4    4    1
```

To illustrate the interaction between the plot box and data aspect ratios, set the data aspect ratio to [1 1 1] and again query the plot box aspect ratio.

```
daspect([1 1 1])
```

# pbaspect

---

```
pbaspect
ans =
     4     4     1
```

The plot box aspect ratio has changed to accommodate the specified data aspect ratio. Now suppose you want the plot box aspect ratio to be [1 1 1] as well.

```
pbaspect([1 1 1])
```

Notice how MATLAB changed the axes limits because of the constraints introduced by specifying both the plot box and data aspect ratios.

You can also use `pbaspect` to disable stretch-to-fill. For example, displaying two subplots in one figure can give surface plots a squashed appearance. Disabling stretch-to-fill,

```
upper_plot = subplot(211);
surf(x,y,z)
lower_plot = subplot(212);
surf(x,y,z)
pbaspect(upper_plot, 'manual')
```

## How To

- [Setting Aspect Ratio](#)
- [Axes Aspect Ratio Properties](#)

**Purpose**

Preconditioned conjugate gradients method

**Syntax**

```
x = pcg(A,b)
pcg(A,b,tol)
pcg(A,b,tol,maxit)
pcg(A,b,tol,maxit,M)
pcg(A,b,tol,maxit,M1,M2)
pcg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = pcg(A,b,...)
[x,flag,relres] = pcg(A,b,...)
[x,flag,relres,iter] = pcg(A,b,...)
[x,flag,relres,iter,resvec] = pcg(A,b,...)
```

**Description**

`x = pcg(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric and positive definite, and should also be large and sparse. The column vector  $b$  must have length  $n$ . You also can specify  $A$  to be a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `pcg` converges, a message to that effect is displayed. If `pcg` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`pcg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `pcg` uses the default,  $1e-6$ .

`pcg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `pcg` uses the default,  $\min(n,20)$ .

`pcg(A,b,tol,maxit,M)` and `pcg(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for  $x$ . If  $M$  is `[]`

then `pcg` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns  $M \backslash x$ .

`pcg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `pcg` uses the default, an all-zero vector.

`[x,flag] = pcg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>pcg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>pcg</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>pcg</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>pcg</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = pcg(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = pcg(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = pcg(A,b,...)` also returns a vector of the residual norms at each iteration including  $\text{norm}(b-A*x0)$ .

## Examples

### Using `pcg` with Large Matrices

This example shows how to use `pcg` with a matrix input and with a function handle.

```
n1 = 21;  
A = gallery('moler',n1);  
b1 = sum(A,2);
```

```

tol = 1e-6;
maxit = 15;
M1 = spdiags((1:n1)',0,n1,n1);
[x1,flag1,rr1,iter1,rv1] = pcg(A,b1,tol,maxit,M1);

```

Alternatively, you can use the following function in place of the matrix A:

```

function y = applyMoler(x)
y = x;
y(end-1:-1:1) = y(end-1:-1:1) - cumsum(y(end:-1:2));
y(2:end) = y(2:end) - cumsum(y(1:end-1));

```

By using this function, you can solve larger systems more efficiently as there is no need to store the entire matrix A:

```

n2 = 21;
b2 = applyMoler(ones(n2,1));
tol = 1e-6;
maxit = 15;
M2 = spdiags((1:n2)',0,n2,n2);
[x2,flag2,rr2,iter2,rv2] = pcg(@applyMoler,b2,tol,maxit,M2);

```

### Using pcg with a Preconditioner

This example demonstrates how to use a preconditioner matrix with pcg.

#### 1

Create an input matrix and try to solve the system with pcg:

```

A = delsq(numgrid('S',100));
b = ones(size(A,1),1);
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-8,100);

```

f10 is 1 because pcg does not converge to the requested tolerance of 1e-8 within the requested maximum 100 iterations. A preconditioner can make the system converge more quickly.

#### 2

Use `ichol` with only one input argument to construct an incomplete Cholesky factorization with zero fill:

```
L = ichol(A);  
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-8,100,L,L');
```

`f11` is 0 because `pcg` drives the relative residual to  $9.8e-09$  (the value of `rr1`) which is less than the requested tolerance of  $1e-8$  at the seventy-seventh iteration (the value of `it1`) when preconditioned by the zero-fill incomplete Cholesky factorization. `rv1(1) = norm(b)` and `rv1(78) = norm(b-A*x1)`.

The previous matrix represents the discretization of the Laplacian on a  $100 \times 100$  grid with Dirichlet boundary conditions. This means that a modified incomplete Cholesky preconditioner might perform even better.

### 3

Use the `michol` option to create a modified incomplete Cholesky preconditioner:

```
L = ichol(A,struct('michol','on'));  
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-8,100,L,L');
```

In this case you attain convergence in only forty-seven iterations.

### 4

You can see how the preconditioners affect the rate of convergence of `pcg` by plotting each of the residual histories starting from the initial estimate (iterate number 0):

```
figure;  
semilogy(0:it0,rv0/norm(b),'b.');
```

```
hold on;  
semilogy(0:it1,rv1/norm(b),'r.');
```

```
semilogy(0:it2,rv2/norm(b),'k.');
```

```
legend('No Preconditioner','IC(0)','MIC(0)');
```

```
xlabel('iteration number');
```

```
ylabel('relative residual');  
hold off;
```

# pchip

---

**Purpose** Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)

**Syntax**  
`yi = pchip(x,y,xi)`  
`pp = pchip(x,y)`

**Description** `yi = pchip(x,y,xi)` returns vector `yi` containing elements corresponding to the elements of `xi` and determined by piecewise cubic interpolation within vectors `x` and `y`. The vector `x` specifies the points at which the data `y` is given. If `y` is a matrix, then the interpolation is performed for each column of `y` and `yi` is `length(xi)-by-size(y,2)`.

`pp = pchip(x,y)` returns a piecewise polynomial structure for use by `ppval`. `x` can be a row or column vector. `y` is a row or column vector of the same length as `x`, or a matrix with `length(x)` columns.

`pchip` finds values of an underlying interpolating function  $P(x)$  at intermediate points, such that:

- On each subinterval  $x_k \leq x \leq x_{k+1}$ ,  $P(x)$  is the cubic Hermite interpolant to the given values and certain slopes at the two endpoints.
- $P(x)$  interpolates  $y$ , i.e.,  $P(x_j) = y_j$ , and the first derivative  $P'(x)$  is continuous.  $P''(x)$  is probably not continuous; there may be jumps at the  $x_j$ .
- The slopes at the  $x_j$  are chosen in such a way that  $P(x)$  preserves the shape of the data and respects monotonicity. This means that, on intervals where the data are monotonic, so is  $P(x)$ ; at points where the data has a local extremum, so does  $P(x)$ .

---

**Note** If  $y$  is a matrix,  $P(x)$  satisfies the above for each column of  $y$ .

---

**Tips**

`spline` constructs  $S(x)$  in almost the same way `pchip` constructs  $P(x)$ . However, `spline` chooses the slopes at the  $x_j$  differently, namely to make even  $S''(x)$  continuous. This has the following effects:

- `spline` produces a smoother result, i.e.  $S''(x)$  is continuous.
- `spline` produces a more accurate result if the data consists of values of a smooth function.
- `pchip` has no overshoots and less oscillation if the data are not smooth.
- `pchip` is less expensive to set up.
- The two are equally expensive to evaluate.

**Examples**

```
x = -3:3;
y = [-1 -1 -1 0 1 1 1];
t = -3:.01:3;
p = pchip(x,y,t);
s = spline(x,y,t);
plot(x,y,'o',t,p,'- ',t,s,'- .')
legend('data','pchip','spline',4)
```

<b>Purpose</b>	Create protected function file
<b>Syntax</b>	<pre>pcode(fun) pcode(fun1,...,funN) pcode(fun,'-inplace')</pre>
<b>Description</b>	<p><code>pcode(fun)</code> encrypts the code in <code>fun.m</code> and produces a file called <code>fun.p</code>, known as a P-file. If <code>fun</code> is a folder, then all the script or function files in that folder are encrypted in P-files. MATLAB creates the P-files in the current folder. The original <code>.m</code> file or folder can be anywhere on the search path.</p> <p><code>pcode(fun1,...,funN)</code> creates N P-files from the listed files. If any inputs are folders, then MATLAB creates a P-file for every <code>.m</code> file the folders contain.</p> <p><code>pcode(fun,'-inplace')</code> creates P-files in the same folder as the script or function files.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• The pcode algorithm was redesigned in MATLAB 7.5 (Release R2007b). You can run older P-files in any current version of MATLAB; however, upcoming releases will not run P-files created before version 7.5. Files generated in 7.5, or later versions, cannot run in MATLAB 7.4 or earlier.</li><li>• When encrypting all files in a folder, pcode does not encrypt any files within subfolders.</li><li>• A P-file takes precedence over the corresponding <code>.m</code> file for execution, even after modifications to the <code>.m</code> file.</li><li>• MATLAB does not display any of the help comments that might be in the original <code>.m</code> file.</li></ul>
<b>Input Arguments</b>	<p><b>fun</b></p> <p>MATLAB file or directory containing MATLAB files. If <code>fun</code> resides within a package and/or class folder, then pcode creates the same package and/or class structure to house the resulting P-files.</p>

An input argument with no file extension and that is not a folder must be a function in the MATLAB path or in the current folder.

When using wild cards \*, pcode ignores all files with extensions other than .m.

## Examples

### P-Coding Multiple Files

Convert selected files from the sparfun folder into P-files.

Create a temporary folder and define an existing path to .m files.

```
tmp = tempname;  
mkdir(tmp);  
cd(tmp);  
fun = fullfile(matlabroot, 'toolbox', 'matlab', 'sparfun', 'spr*.m');
```

Create the P-files.

```
pcode(fun)  
dir(tmp)
```

```
.          ..          sprand.p      sprandn.p      sprandsym.p  sprank.p
```

The temporary folder now contains encoded P-files.

### P-Coding Files That Belong to a Package and/or Class

Generate P-files from input files that are part of a package and/or class. This example uses an existing MATLAB example class.

Define funclass as an existing a class folder that contains .m files.

```
funclass = fullfile(docroot, 'techdoc', 'matlab_ooop', ...  
    'examples', '@BankAccount')  
dir(funclass)
```

```
funclass =
```

```
C:\Program Files\MATLAB\R2013a\help\techdoc\matlab_ooop\examples\@BankAcco
```

```
.          ..          BankAccount.m
```

Create a temporary folder. This folder has no package or class structure at this time.

```
tmp = tempname;
mkdir(tmp);
cd(tmp);
dir(tmp)
```

```
.          ..
```

Create a P-file for every .m file in the path `funclass`. Because the input files are part of a package and/or class, MATLAB creates a folder structure so that the output file belongs to the same package and/or class.

```
pcode(funclass)
dir(tmp)
```

```
.          ..          @BankAccount
```

You see that the P-file resides in the same folder structure.

```
dir('@BankAccount')
```

```
.          ..          BankAccount.p
```

### **P-Coding In Place**

Generate P-files in the same folder as the input files using the option `inplace`

Copy several MATLAB files to a temporary folder.

```
fun = fullfile(matlabroot,'toolbox','matlab','sparfun','spr*.m');
tmp = tempname;
mkdir(tmp);
```

# pcode

---

```
copyfile(fun,tmp)
dir(tmp)
```

```
.          ..          sprand.m      sprandn.m      sprandsym.m  sprank.m
```

Create P-files in the same folder as the original .m files.

```
pcode(tmp, '-inplace')
dir(tmp)
```

```
.          sprand.m      sprandn.m      sprandsym.m  sprank.m
..         sprand.p      sprandn.p      sprandsym.p  sprank.p
```

## See Also

## Concepts

- “Protect Your Source Code”

**Purpose** Pseudocolor (checkerboard) plot

**Syntax**

```
pcolor(C)
pcolor(X,Y,C)
pcolor(axes_handles,...)
h = pcolor(...)
```

**Description** A pseudocolor plot is a rectangular array of cells with colors determined by **C**. MATLAB creates a pseudocolor plot using each set of four adjacent points in **C** to define a surface rectangle (i.e., cell).

The default shading is `faceted`, which colors each cell with a single color. The last row and column of **C** are not used in this case. With shading `interp`, each cell is colored by bilinear interpolation of the colors at its four vertices, using all elements of **C**.

The minimum and maximum elements of **C** are assigned the first and last colors in the colormap. Colors for the remaining elements in **C** are determined by a linear mapping from value to colormap element.

`pcolor(C)` draws a pseudocolor plot. The elements of **C** are linearly mapped to an index into the current colormap. The mapping from **C** to the current colormap is defined by `colormap` and `caxis`.

`pcolor(X,Y,C)` draws a pseudocolor plot of the elements of **C** at the locations specified by **X** and **Y**. The plot is a logically rectangular, two-dimensional grid with vertices at the points  $[X(i,j), Y(i,j)]$ . **X** and **Y** are vectors or matrices that specify the spacing of the grid lines. If **X** and **Y** are vectors, **X** corresponds to the columns of **C** and **Y** corresponds to the rows. If **X** and **Y** are matrices, they must be the same size as **C**.

`pcolor(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = pcolor(...)` returns a handle to a surface graphics object.

## Tips

A pseudocolor plot is a flat surface plot viewed from above. `pcolor(X,Y,C)` is the same as viewing `surf(X,Y,zeros(size(X)),C)` using `view([0 90])`.

When you use `shading faceted` or `shading flat`, the constant color of each cell is the color associated with the corner having the smallest  $x$ - $y$  coordinates. Therefore, `C(i,j)` determines the color of the cell in the  $i$ th row and  $j$ th column. The last row and column of `C` are not used.

When you use `shading interp`, each cell's color results from a bilinear interpolation of the colors at its four vertices, and all elements of `C` are used.

## Examples

A Hadamard matrix has elements that are +1 and -1. A colormap with only two entries is appropriate when displaying a pseudocolor plot of this matrix.

```
pcolor(hadamard(20))
colormap(gray(2))
axis ij
axis square
```

A simple color wheel illustrates a polar coordinate system.

```
n = 6;  
r = (0:n)'/n;  
theta = pi*(-n:n)/n;  
X = r*cos(theta);  
Y = r*sin(theta);  
C = r*cos(2*theta);  
pcolor(X,Y,C)
```

axis equal tight

## Algorithms

The number of vertex colors for `pcolor(C)` is the same as the number of cells for `image(C)`. `pcolor` differs from `image` in that `pcolor(C)` specifies the colors of vertices, which are scaled to fit the colormap; changing the axes `clim` property changes this color mapping. `image(C)` specifies the colors of cells and directly indexes into the colormap without scaling. Additionally, `pcolor(X,Y,C)` can produce parametric grids, which is not possible with `image`.

# pdepe

---

## Purpose

Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D

## Syntax

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
[sol,tsol,sole,te,ie] = pdepe(m,pdefun,icfun,bcfun,xmesh,
    tspan,options)
```

## Arguments

m	A parameter corresponding to the symmetry of the problem. m can be slab = 0, cylindrical = 1, or spherical = 2.
pdefun	A handle to a function that defines the components of the PDE.
icfun	A handle to a function that defines the initial conditions.
bcfun	A handle to a function that defines the boundary conditions.
xmesh	A vector [x0, x1, ..., xn] specifying the points at which a numerical solution is requested for every value in tspan. The elements of xmesh must satisfy $x_0 < x_1 < \dots < x_n$ . The length of xmesh must be $\geq 3$ .
tspan	A vector [t0, t1, ..., tf] specifying the points at which a solution is requested for every value in xmesh. The elements of tspan must satisfy $t_0 < t_1 < \dots < t_f$ . The length of tspan must be $\geq 3$ .
options	Some options of the underlying ODE solver are available in pdepe: RelTol, AbsTol, NormControl, InitialStep, MaxStep, and Events. In most cases, default values for these options provide satisfactory solutions. See odeset for details.

**Description**

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)` solves initial-boundary value problems for systems of parabolic and elliptic PDEs in the one space variable  $x$  and time  $t$ . `pdefun`, `icfun`, and `bcfun` are function handles. See the `function_handle` reference page for more information. The ordinary differential equations (ODEs) resulting from discretization in space are integrated to obtain approximate solutions at times specified in `tspan`. The `pdepe` function returns values of the solution on a mesh provided in `xmesh`.

“Parameterizing Functions” explains how to provide additional parameters to the functions `pdefun`, `icfun`, or `bcfun`, if necessary.

`pdepe` solves PDEs of the form:

$$c\left(x,t,u,\frac{\partial u}{\partial x}\right)\frac{\partial u}{\partial t} = x^{-m}\frac{\partial}{\partial x}\left(x^m f\left(x,t,u,\frac{\partial u}{\partial x}\right)\right) + s\left(x,t,u,\frac{\partial u}{\partial x}\right) \quad (1-4)$$

The PDEs hold for  $t_0 \leq t \leq t_f$  and  $a \leq x \leq b$ . The interval  $[a,b]$  must be finite.  $m$  can be 0, 1, or 2, corresponding to slab, cylindrical, or spherical symmetry, respectively. If  $m > 0$ , then  $a$  must be  $\geq 0$ .

In Equation 1-4,  $f(x,t,u,\partial u/\partial x)$  is a flux term and  $s(x,t,u,\partial u/\partial x)$  is a source term. The coupling of the partial derivatives with respect to time is restricted to multiplication by a diagonal matrix  $c(x,t,u,\partial u/\partial x)$ . The diagonal elements of this matrix are either identically zero or positive. An element that is identically zero corresponds to an elliptic equation and otherwise to a parabolic equation. There must be at least one parabolic equation. An element of  $c$  that corresponds to a parabolic equation can vanish at isolated values of  $x$  if those values of  $x$  are mesh points. Discontinuities in  $c$  and/or  $s$  due to material interfaces are permitted provided that a mesh point is placed at each interface.

For  $t = t_0$  and all  $x$ , the solution components satisfy initial conditions of the form

$$u(x,t_0) = u_0(x) \quad (1-5)$$

For all  $t$  and either  $x = a$  or  $x = b$ , the solution components satisfy a boundary condition of the form

$$p(x,t,u) + q(x,t)f\left(x,t,u,\frac{\partial u}{\partial x}\right) = 0 \quad (1-6)$$

Elements of  $q$  are either identically zero or never zero. Note that the boundary conditions are expressed in terms of the flux  $f$  rather than  $\partial u/\partial x$ . Also, of the two coefficients, only  $p$  can depend on  $u$ .

In the call `sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)`:

- $m$  corresponds to  $m$ .
- `xmesh(1)` and `xmesh(end)` correspond to  $a$  and  $b$ .
- `tspan(1)` and `tspan(end)` correspond to  $t_0$  and  $t_f$ .
- `pdefun` computes the terms  $c$ ,  $f$ , and  $s$  (Equation 1-4). It has the form

$$[c,f,s] = \text{pdefun}(x,t,u,\text{dudx})$$

The input arguments are scalars  $x$  and  $t$  and vectors  $u$  and  $\text{dudx}$  that approximate the solution  $u$  and its partial derivative with respect to  $x$ , respectively.  $c$ ,  $f$ , and  $s$  are column vectors.  $c$  stores the diagonal elements of the matrix  $c$  (Equation 1-4).

- `icfun` evaluates the initial conditions. It has the form

$$u = \text{icfun}(x)$$

When called with an argument  $x$ , `icfun` evaluates and returns the initial values of the solution components at  $x$  in the column vector  $u$ .

- `bcfun` evaluates the terms  $p$  and  $q$  of the boundary conditions (Equation 1-6). It has the form

$$[p1,q1,pr,qr] = \text{bcfun}(x1,u1,xr,ur,t)$$

$u1$  is the approximate solution at the left boundary  $x1 = a$  and  $ur$  is the approximate solution at the right boundary  $xr = b$ .  $p1$  and  $q1$  are column vectors corresponding to  $p$  and  $q$  evaluated at  $x1$ , similarly  $pr$  and  $qr$  correspond to  $xr$ . When  $m > 0$  and  $a = 0$ , boundedness of the solution near  $x = 0$  requires that the flux  $f$  vanish at  $a = 0$ . `pdepe`

imposes this boundary condition automatically and it ignores values returned in `pl` and `ql`.

`pdepe` returns the solution as a multidimensional array `sol`.

$u_i = \text{ui} = \text{sol}(:, :, i)$  is an approximation to the  $i$ th component of the solution vector  $u$ . The element  $\text{ui}(j, k) = \text{sol}(j, k, i)$  approximates  $u_i$  at  $(t, x) = (\text{tspan}(j), \text{xmesh}(k))$ .

$\text{ui} = \text{sol}(j, :, i)$  approximates component  $i$  of the solution at time  $\text{tspan}(j)$  and mesh points  $\text{xmesh}(:)$ . Use `pdeval` to compute the approximation and its partial derivative  $\partial u_i / \partial x$  at points not included in `xmesh`. See `pdeval` for details.

`sol = pdepe(m, pdefun, icfun, bcfun, xmesh, tspan, options)` solves as above with default integration parameters replaced by values in `options`, an argument created with the `odeset` function. Only some of the options of the underlying ODE solver are available in `pdepe`: `RelTol`, `AbsTol`, `NormControl`, `InitialStep`, and `MaxStep`. The defaults obtained by leaving off the input argument `options` will generally be satisfactory. See `odeset` for details.

`[sol, tsol, sole, te, ie] = pdepe(m, pdefun, icfun, bcfun, xmesh, tspan, options)` with the 'Events' property in `options` set to a function handle `Events`, solves as above while also finding where event functions  $g(t, u(x, t))$  are zero. For each function you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Three column vectors are returned by `events`: `[value, isterminal, direction] = events(m, t, xmesh, umesh)`. `xmesh` contains the spatial mesh and `umesh` is the solution at the mesh points. Use `pdeval` to evaluate the solution between mesh points. For the  $I$ -th event function, `value(i)` is the value of the function, `ISTERMINAL(I) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise. `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing. Output `tsol` is a column vector of times specified in `tspan`, prior to first terminal event. `SOL(j, :, :)` is the solution at `T(j)`. `TE` is a vector of times at which events occur. `SOLE(j, :, :)` is the solution at `TE(j)` and indices in vector `IE` specify which event occurred.

If  $UI = SOL(j, :, i)$  approximates component  $i$  of the solution at time  $TSPAN(j)$  and mesh points  $XMESH$ , `pdeval` evaluates the approximation and its partial derivative  $\partial u_i / \partial x$  at the array of points  $XOUT$  and returns them in  $UOUT$  and  $DUOUTDX$ :  $[UOUT, DUOUTDX] = PDEVAL(M, XMESH, UI, XOUT)$

---

**Note** The partial derivative  $\partial u_i / \partial x$  is evaluated here rather than the flux. The flux is continuous, but at a material interface the partial derivative may have a jump.

---

## Tips

- The arrays `xmesh` and `tspan` play different roles in `pdepe`.
  - tspan** – The `pdepe` function performs the time integration with an ODE solver that selects both the time step and formula dynamically. The elements of `tspan` merely specify where you want answers and the cost depends weakly on the length of `tspan`.
  - xmesh** – Second order approximations to the solution are made on the mesh specified in `xmesh`. Generally, it is best to use closely spaced mesh points where the solution changes rapidly. `pdepe` does *not* select the mesh in  $x$  automatically. You must provide an appropriate fixed mesh in `xmesh`. The cost depends strongly on the length of `xmesh`. When  $m > 0$ , it is not necessary to use a fine mesh near  $x = 0$  to account for the coordinate singularity.
- The time integration is done with `ode15s`. `pdepe` exploits the capabilities of `ode15s` for solving the differential-algebraic equations that arise when Equation 1-4 contains elliptic equations, and for handling Jacobians with a specified sparsity pattern.
- After discretization, elliptic equations give rise to algebraic equations. If the elements of the initial conditions vector that correspond to elliptic equations are not "consistent" with the discretization, `pdepe` tries to adjust them before beginning the time integration. For this reason, the solution returned for the initial time may have a discretization error comparable to that at any other time. If the mesh is sufficiently fine, `pdepe` can find consistent initial conditions close

to the given ones. If `pdepe` displays a message that it has difficulty finding consistent initial conditions, try refining the mesh.

No adjustment is necessary for elements of the initial conditions vector that correspond to parabolic equations.

## Examples

**Example 1.** This example illustrates the straightforward formulation, computation, and plotting of the solution of a single PDE.

$$\pi^2 \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left( \frac{\partial u}{\partial x} \right)$$

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial condition

$$u(x, 0) = \sin \pi x$$

and boundary conditions

$$u(0, t) = 0$$

$$\pi e^{-t} + \frac{\partial u}{\partial x}(1, t) = 0$$

It is convenient to use local functions to place all the functions required by `pdepe` in a single function.

```
function pdex1

m = 0;
x = linspace(0,1,20);
t = linspace(0,2,5);

sol = pdepe(m,@pdex1pde,@pdex1ic,@pdex1bc,x,t);
% Extract the first solution component as u.
u = sol(:,:,1);

% A surface plot is often a good way to study a solution.
```

```
surf(x,t,u)
title('Numerical solution computed with 20 mesh points.')
xlabel('Distance x')
ylabel('Time t')

% A solution profile can also be illuminating.
figure
plot(x,u(end,:))
title('Solution at t = 2')
xlabel('Distance x')
ylabel('u(x,2)')
% -----
function [c,f,s] = pdex1pde(x,t,u,DuDx)
c = pi^2;
f = DuDx;
s = 0;
% -----
function u0 = pdex1ic(x)
u0 = sin(pi*x);
% -----
function [pl,ql,pr,qr] = pdex1bc(xl,ul,xr,ur,t)
pl = ul;
ql = 0;
pr = pi * exp(-t);
qr = 1;
```

In this example, the PDE, initial condition, and boundary conditions are coded in local functions `pdex1pde`, `pdex1ic`, and `pdex1bc`.

The surface plot shows the behavior of the solution.

The following plot shows the solution profile at the final value of  $t$  (i.e.,  $t = 2$ ).

**Example 2.** This example illustrates the solution of a system of PDEs. The problem has boundary layers at both ends of the interval. The solution changes rapidly for small  $t$ .

The PDEs are

$$\frac{\partial u_1}{\partial t} = 0.024 \frac{\partial^2 u_1}{\partial x^2} - F(u_1 - u_2)$$

$$\frac{\partial u_2}{\partial t} = 0.170 \frac{\partial^2 u_2}{\partial x^2} + F(u_1 - u_2)$$

where  $F(y) = \exp(5.73y) - \exp(-11.46y)$ .

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial conditions

$$u_1(x, 0) \equiv 1$$

$$u_2(x, 0) \equiv 0$$

and boundary conditions

$$\frac{\partial u_1}{\partial x}(0, t) \equiv 0$$

$$u_2(0, t) \equiv 0$$

$$u_1(1, t) \equiv 1$$

$$\frac{\partial u_2}{\partial x}(1, t) \equiv 0$$

In the form expected by pdepe, the equations are

$$\begin{bmatrix} 1 \\ 1 \end{bmatrix} \cdot * \frac{\partial}{\partial t} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \frac{\partial}{\partial x} \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} + \begin{bmatrix} -F(u_1 - u_2) \\ F(u_1 - u_2) \end{bmatrix}$$

The boundary conditions on the partial derivatives of  $u$  have to be written in terms of the flux. In the form expected by pdepe, the left boundary condition is

$$\begin{bmatrix} 0 \\ u_2 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

and the right boundary condition is

$$\begin{bmatrix} u_1 - 1 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The solution changes rapidly for small  $t$ . The program selects the step size in time to resolve this sharp change, but to see this behavior in the plots, the example must select the output times accordingly. There are boundary layers in the solution at both ends of  $[0, 1]$ , so the example places mesh points near 0 and 1 to resolve these sharp changes. Often

some experimentation is needed to select a mesh that reveals the behavior of the solution.

```
function pdex4
m = 0;
x = [0 0.005 0.01 0.05 0.1 0.2 0.5 0.7 0.9 0.95 0.99 0.995 1];
t = [0 0.005 0.01 0.05 0.1 0.5 1 1.5 2];

sol = pdepe(m,@pdex4pde,@pdex4ic,@pdex4bc,x,t);
u1 = sol(:,:,1);
u2 = sol(:,:,2);

figure
surf(x,t,u1)
title('u1(x,t)')
xlabel('Distance x')
ylabel('Time t')

figure
surf(x,t,u2)
title('u2(x,t)')
xlabel('Distance x')
ylabel('Time t')
% -----
function [c,f,s] = pdex4pde(x,t,u,DuDx)
c = [1; 1];
f = [0.024; 0.17] .* DuDx;
y = u(1) - u(2);
F = exp(5.73*y) - exp(-11.47*y);
s = [-F; F];
% -----
function u0 = pdex4ic(x);
u0 = [1; 0];
% -----
function [pl,ql,pr,qr] = pdex4bc(xl,ul,xr,ur,t)
pl = [0; ul(2)];
ql = [1; 0];
```

```
pr = [ur(1)-1; 0];  
qr = [0; 1];
```

In this example, the PDEs, initial conditions, and boundary conditions are coded in local functions `pdex4pde`, `pdex4ic`, and `pdex4bc`.

The surface plots show the behavior of the solution components.

**Purpose** Evaluate numerical solution of PDE using output of pdepe

**Syntax** `[uout,duoutdx] = pdeval(m,x,ui,xout)`

### Arguments

m	Symmetry of the problem: slab = 0, cylindrical = 1, spherical = 2. This is the first input argument used in the call to pdepe.
xmesh	A vector [x0, x1, ..., xn] specifying the points at which the elements of ui were computed. This is the same vector with which pdepe was called.
ui	A vector sol(j,:,i) that approximates component i of the solution at time $t_j$ and mesh points xmesh, where sol is the solution returned by pdepe.
xout	A vector of points from the interval [x0,xn] at which the interpolated solution is requested.

### Description

`[uout,duoutdx] = pdeval(m,x,ui,xout)` approximates the solution  $u_i$  and its partial derivative  $\partial u_i / \partial x$  at points from the interval [x0,xn]. The pdeval function returns the computed values in uout and duoutdx, respectively.

---

**Note** pdeval evaluates the partial derivative  $\partial u_i / \partial x$  rather than the flux  $f$ . Although the flux is continuous, the partial derivative may have a jump at a material interface.

pdepe

# peaks

---

## Purpose

Example function of two variables

## Syntax

```
Z = peaks;  
Z = peaks(n);  
Z = peaks(V);  
Z = peaks(X,Y);
```

```
peaks;  
peaks(N);  
peaks(V);  
peaks(X,Y);
```

```
[X,Y,Z] = peaks;  
[X,Y,Z] = peaks(n);  
[X,Y,Z] = peaks(V);
```

## Description

`peaks` is a function of two variables, obtained by translating and scaling Gaussian distributions, which is useful for demonstrating `mesh`, `surf`, `pcolor`, `contour`, and so on.

`Z = peaks;` returns a 49-by-49 matrix.

`Z = peaks(n);` returns an n-by-n matrix.

`Z = peaks(V);` returns an n-by-n matrix, where `n = length(V)`.

`Z = peaks(X,Y);` evaluates `peaks` at the given `X` and `Y` (which must be the same size) and returns a matrix the same size.

`peaks(...)` (with no output argument) plots the peaks function with `surf`.

`[X,Y,Z] = peaks(...)`; returns two additional matrices, `X` and `Y`, for parametric plots, for example, `surf(X,Y,Z,de12(Z))`. If not given as input, the underlying matrices `X` and `Y` are

```
[X,Y] = meshgrid(V,V)
```

where `V` is a given vector, or `V` is a vector of length `n` with elements equally spaced from `-3` to `3`. If no input argument is given, the default `n` is `49`.

## **Examples**

This example creates a 5-by-5 matrix of peaks and displays the image:

```
peaks(5);
```

# peaks

---

See Examples section from `surf` for a more elaborate use case.

**See Also** `meshgrid` | `surf`

**Purpose**

Call Perl script using appropriate operating system executable

**Syntax**

```
perl('perlfile')  
perl('perlfile',arg1,arg2,...)  
result = perl(...)  
[result, status] = perl(...)
```

**Description**

`perl('perlfile')` calls the Perl script `perlfile`, using the appropriate operating system Perl executable. Perl is included with the MATLAB software on Microsoft Windows systems, and thus MATLAB users can run user-created MATLAB functions containing the `perl` function. On Linux and Macintosh systems, MATLAB calls the Perl interpreter available with the operating system.

`perl('perlfile',arg1,arg2,...)` calls the Perl script `perlfile`, using the appropriate operating system Perl executable, and passes the arguments `arg1`, `arg2`, and so on, to `perlfile`.

`result = perl(...)` returns the results of attempted Perl call to `result`.

`[result, status] = perl(...)` returns the results of attempted Perl call to `result` and its exit status to `status`.

It is sometimes beneficial to use Perl scripts instead of MATLAB code. The `perl` function allows you to run those scripts from MATLAB. Specific examples where you might choose to use a Perl script include:

- Perl script already exists
- Perl script preprocesses data quickly, formatting it in a way more easily read by MATLAB
- Perl has features not supported by MATLAB

**Examples**

Given the Perl script, `hello.pl`:

```
$input = $ARGV[0];  
print "Hello $input.";
```

# perl

---

At the MATLAB command line, type:

```
perl('hello.pl','World')
```

MATLAB displays:

```
ans =  
Hello World.
```

```

## See Also

[nchoosek](#) | [permute](#) | [randperm](#)

**Purpose** Rearrange dimensions of N-D array

**Syntax** `B = permute(A,order)`

**Description** `B = permute(A,order)` rearranges the dimensions of `A` so that they are in the order specified by the vector `order`. `B` has the same values of `A` but the order of the subscripts needed to access any particular element is rearranged as specified by `order`. All the elements of `order` must be unique, real, positive, integer values.

**Tips** `permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

**Examples** Given any matrix `A`, the statement

```
permute(A,[2 1])
```

is the same as `A.'`

For example:

```
A = [1 2; 3 4]; permute(A,[2 1])
ans =
     1     3
     2     4
```

The following code permutes a three-dimensional array:

```
X = rand(12,13,14);
Y = permute(X,[2 3 1]);
size(Y)
ans =
    13    14    12
```

**See Also** `ipermute` | `circshift` | `fliplr` | `flipud` | `reshape` | `shiftdim`

# persistent

---

**Purpose** Define persistent variable

**Syntax** `persistent X Y Z`

**Description** `persistent X Y Z` defines X, Y, and Z as variables that are local to the function in which they are declared; yet their values are retained in memory between calls to the function. Persistent variables are similar to global variables because the MATLAB software creates permanent storage for both. They differ from global variables in that persistent variables are known only to the function in which they are declared. This prevents persistent variables from being changed by other functions or from the MATLAB command line.

Whenever you clear or modify a function that is in memory, MATLAB also clears all persistent variables declared by that function. To keep a function in memory until MATLAB quits, use `mlock`.

If the persistent variable does not exist the first time you issue the `persistent` statement, it is initialized to the empty matrix.

It is an error to declare a variable persistent if a variable with the same name exists in the current workspace. MATLAB also errors if you declare any of a function's input or output arguments as persistent within that same function. For example, the following persistent declaration is invalid:

```
function myfun(argA, argB, argC)
persistent argB
```

**Tips** There is no function form of the `persistent` command (i.e., you cannot use parentheses and quote the variable names).

**Examples** This function writes a large array to a spreadsheet file and then reads several rows from the same file. Because you only need to write the array to the spreadsheet one time, the program tests whether an array can be read from the file and, if so, does not waste time in repeating that task. By defining the `dblArray` variable as persistent, you can easily check whether the array has been read from the spreadsheet file.

Here is the arrayToXLS function:

```
function arrayToXLS(A, xlsfile, x1, x2)
persistent dblArray;

if isempty(dblArray)
    disp 'Writing spreadsheet file ...'
    xlswrite(xlsfile, A);
end

disp 'Reading array from spreadsheet ...'
dblArray = xlsread(xlsfile, 'Sheet1', [x1 ':' x2])
fprintf('\n');
```

Run the function three times and observe the time elapsed for each run. The second and third run take approximately one tenth the time of the first run in which the function must create the spreadsheet:

```
largeArray = rand(4000, 200);

tic, arrayToXLS(largeArray, 'myTest.xls','E254', 'J256'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
    0.0982    0.3783    0.1264    0.7880    0.1902    0.5811
    0.2251    0.2704    0.5682    0.7271    0.8028    0.2834
    0.6453    0.5568    0.8254    0.4961    0.9096    0.5402
```

Elapsed time is 8.990525 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls','E257', 'J258'), toc
Reading array from spreadsheet ...
dblArray =
    0.4620    0.3781    0.6386    0.5930    0.0946    0.4865
    0.1605    0.1251    0.8709    0.5188    0.6702    0.2138
```

Elapsed time is 0.912534 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls','E259', 'J262'), toc
Reading array from spreadsheet ...
dblArray =
    0.7015    0.6588    0.4023    0.0359    0.4512    0.6097
    0.1308    0.6441    0.0431    0.6396    0.7481    0.8688
    0.8278    0.2686    0.5475    0.8550    0.5896    0.1080
    0.9437    0.1671    0.0505    0.1203    0.2461    0.7306
```

Elapsed time is 0.928843 seconds.

Now clear the arrayToXLS function from memory and observe that running it takes much longer again:

```
clear functions
```

```
tic, arrayToXLS(largeArray, 'myTest.xls','E263', 'J264'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
    0.6292    0.7788    0.0732    0.6481    0.9299    0.8631
    0.7700    0.5181    0.9805    0.5092    0.8658    0.4070
```

Elapsed time is 7.603461 seconds.

## See Also

## Purpose

Pie chart

## Syntax

```
pie(X)
pie(X,explode)
pie(...,labels)
pie(axes_handle,...)
h = pie(...)
```

## Description

`pie(X)` draws a pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

- If  $\text{sum}(X) = 1$ , then the values in `X` directly specify the area of the pie slices. `pie` draws only a partial pie if  $\text{sum}(X) < 1$ .
- If the sum of the elements in `X` is greater than one, then `pie` normalizes the values by  $X/\text{sum}(X)$  to determine the area of each slice of the pie.

`pie(X,explode)` offsets a slice from the pie. `explode` is a vector or matrix of zeros and nonzeros that correspond to `X`. A nonzero value offsets the corresponding slice from the center of the pie chart, so that `X(i,j)` is offset from the center if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`.

`pie(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie(...)` returns a vector of handles to patch and text graphics objects.

## Examples

### Create Pie Chart

Create a pie chart of vector `x`.

```
x = [1,3,0.5,2.5,2];  
figure  
pie(x)
```

To offset the second and fourth pie slices, set the corresponding explode elements to 1.

```
explode = [0,1,0,1,0];  
figure  
pie(x,explode)
```

### Specify Text Labels for Pie Chart

Specify the text labels for a pie chart.

```
x = 1:3;  
labels = {'Taxes', 'Expenses', 'Profit'};
```

```
figure  
pie(x, labels)
```

### Remove Piece From Pie Chart

Since the sum of the elements in `x` is less than 1, then `pie` draws a partial pie.

```
x = [0.19,0.22,0.41];  
figure  
pie(x)
```

**See Also**

`pie3`

**How To**

- `“`
- `“`

**Purpose**

3-D pie chart

**Syntax**

```
pie3(X)
pie3(X,explode)
pie3(...,labels)
pie3(axes_handle,...)
h = pie3(...)
```

**Description**

`pie3(X)` draws a three-dimensional pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

- If  $\text{sum}(X) = 1$ , then the values in `X` directly specify the area of the pie slices. `pie3` draws only a partial pie if  $\text{sum}(X) < 1$ .
- If the sum of the elements in `X` is greater than one, then `pie3` normalizes the values by  $X/\text{sum}(X)$  to determine the area of each slice of the pie.

`pie3(X,explode)` specifies whether to offset a slice from the center of the pie chart. `X(i,j)` is offset from the center of the pie chart if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie3(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`.

`pie3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie3(...)` returns a vector of handles to patch, surface, and text graphics objects.

**Examples****Create 3-D Pie Chart**

Create a 3-D pie chart of vector `x`.

```
x = [1,3,0.5,2.5,2];
```

# pie3

---

```
figure  
pie3(x);
```

To offset the second pie slice, set the corresponding `explode` element to 1.

```
explode = [0,1,0,0,0];  
figure  
pie3(x,explode)
```

### Specify Text Labels for 3-D Pie Chart

Create a 3-D pie chart and specify the text labels.

```
x = 1:3;  
labels = {'Taxes', 'Expenses', 'Profit'};
```

```
figure  
pie3(x, labels)
```

**See Also** [pie](#)

<b>Purpose</b>	Moore-Penrose pseudoinverse of matrix
<b>Syntax</b>	$B = \text{pinv}(A)$ $B = \text{pinv}(A, \text{tol})$
<b>Definitions</b>	<p>The Moore-Penrose pseudoinverse is a matrix <math>B</math> of the same dimensions as <math>A'</math> satisfying four conditions:</p> $A*B*A = A$ $B*A*B = B$ $A*B \text{ is Hermitian}$ $B*A \text{ is Hermitian}$ <p>The computation is based on <math>\text{svd}(A)</math> and any singular values less than <math>\text{tol}</math> are treated as zero.</p>
<b>Description</b>	<p><math>B = \text{pinv}(A)</math> returns the Moore-Penrose pseudoinverse of <math>A</math>.</p> <p><math>B = \text{pinv}(A, \text{tol})</math> returns the Moore-Penrose pseudoinverse and overrides the default tolerance, <math>\max(\text{size}(A)) * \text{norm}(A) * \text{eps}</math>.</p>
<b>Examples</b>	<p>If <math>A</math> is square and not singular, then <math>\text{pinv}(A)</math> is an expensive way to compute <math>\text{inv}(A)</math>. If <math>A</math> is not square, or is square and singular, then <math>\text{inv}(A)</math> does not exist. In these cases, <math>\text{pinv}(A)</math> has some of, but not all, the properties of <math>\text{inv}(A)</math>.</p> <p>If <math>A</math> has more rows than columns and is not of full rank, then the overdetermined least squares problem</p> $\text{minimize } \text{norm}(A*x-b)$ <p>does not have a unique solution. Two of the infinitely many solutions are</p> $x = \text{pinv}(A)*b$ <p>and</p> $y = A \setminus b$

These two are distinguished by the facts that  $\text{norm}(x)$  is smaller than the norm of any other solution and that  $y$  has the fewest possible nonzero components.

For example, the matrix generated by

```
A = magic(8); A = A(:,1:6)
```

is an 8-by-6 matrix that happens to have  $\text{rank}(A) = 3$ .

```
A =
    64     2     3    61    60     6
     9    55    54    12    13    51
    17    47    46    20    21    43
    40    26    27    37    36    30
    32    34    35    29    28    38
    41    23    22    44    45    19
    49    15    14    52    53    11
     8    58    59     5     4    62
```

The right-hand side is  $b = 260 \cdot \text{ones}(8, 1)$ ,

```
b =
    260
    260
    260
    260
    260
    260
    260
    260
    260
```

The scale factor 260 is the 8-by-8 magic sum. With all eight columns, one solution to  $A \cdot x = b$  would be a vector of all 1's. With only six columns, the equations are still consistent, so a solution exists, but it is not all 1's. Since the matrix is rank deficient, there are infinitely many solutions. Two of them are

```
x = pinv(A)*b
```

which is

```
x =  
  1.1538  
  1.4615  
  1.3846  
  1.3846  
  1.4615  
  1.1538
```

and

```
y = A\b
```

which produces this result.

```
Warning: Rank deficient, rank = 3  tol =  1.8829e-013.
```

```
y =  
  4.0000  
  5.0000  
   0  
   0  
   0  
 -1.0000
```

Both of these are exact solutions in the sense that  $\text{norm}(A*x-b)$  and  $\text{norm}(A*y-b)$  are on the order of roundoff error. The solution  $x$  is special because

```
norm(x) = 3.2817
```

is smaller than the norm of any other solution, including

```
norm(y) = 6.4807
```

On the other hand, the solution  $y$  is special because it has only three nonzero components.

# planerot

---

**Purpose** Givens plane rotation

**Syntax** `[G,y] = planerot(x)`

**Description** `[G,y] = planerot(x)` where  $x$  is a 2-component column vector, returns a 2-by-2 orthogonal matrix  $G$  so that  $y = G*x$  has  $y(2) = 0$ .

**Examples**

```
x = [3 4];  
[G,y] = planerot(x')
```

```
G =  
    0.6000    0.8000  
   -0.8000    0.6000
```

```
y =  
    5  
    0
```

**See Also** `qrdelete` | `qrinsert`

**Purpose**

Play audio from audioplayer object

**Syntax**

```
play(playerObj)
play(playerObj,start)
play(playerObj,[start,stop])
```

**Description**

`play(playerObj)` plays the audio associated with audioplayer object `playerObj` from beginning to end.

`play(playerObj,start)` plays audio from the sample indicated by `start` to the end.

`play(playerObj,[start,stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

**Examples****Play with and without Blocking**

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y,chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y,gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

# audioplayer.play

---

## Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

play(playerObj,start);
```

## Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

play(playerObj,[start,stop]);
```

## See Also

## How To

- “Play Audio”

**Purpose** Play audio from audiorecorder object

**Syntax**

```
player = play(recObj)  
player = play(recObj, start)  
player = play(recObj, [start stop])
```

**Description**

*player* = play(*recObj*) plays the audio associated with audiorecorder object *recObj* from beginning to end, and returns an audioplayer object.

*player* = play(*recObj*, *start*) plays audio from the sample indicated by *start* to the end.

*player* = play(*recObj*, [*start stop*]) plays audio from the sample indicated by *start* to the sample indicated by *stop*.

**Examples** Record 5 seconds of your speech with a microphone, and play it back. Display the properties of the audioplayer object.

```
myVoice = audiorecorder;  
  
disp('Start speaking.');
```

---

```
recordblocking(myVoice, 5);  
disp('End of recording. Playing back ...');
```

```
playerObj = play(myVoice);  
  
disp('Properties of playerObj:');  
get(playerObj)
```

---

Play back only the first 3 seconds of the speech recorded in the previous example:

```
play(myVoice, [1 myVoice.SampleRate*3]);
```

**See Also** audioplayer | audiorecorder

# audioplayer.playblocking

---

**Purpose** Play audio from audioplayer object, holding control until playback completes

**Syntax**

```
playblocking(playerObj)
playblocking(playerObj,start)
playblocking(playerObj,[start,stop])
```

**Description**

`playblocking(playerObj)` plays the audio associated with audioplayer object `playerObj` from beginning to end. `playblocking` does not return control until playback completes.

`playblocking(playerObj,start)` plays audio from the sample indicated by `start` to the end.

`playblocking(playerObj,[start,stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

## **Examples**      **Play with and without Blocking**

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y,chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y,gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

## Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

playblocking(playerObj,start);
beep;
```

## Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

playblocking(playerObj,[start,stop]);
beep;
```

## How To

- “Play Audio”

# plot

---

**Purpose** 2-D line plot

**Syntax**

```
plot(X,Y)
plot(X,Y,LineStyle)
plot(X1,Y1,...,Xn,Yn)
plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)

plot(Y)
plot(Y,LineStyle)

plot(__,Name,Value)
plot(axes_handle, __)

h = plot(__)
```

**Description** `plot(X,Y)` creates a 2-D line plot of the data in `Y` versus the corresponding values in `X`.

- If `X` and `Y` are both vectors, then they must have equal length and MATLAB plots `Y` versus `X`.
- If `X` and `Y` are both matrices, then they must have equal size and MATLAB plots columns of `Y` versus columns of `X`.
- If one of `X` or `Y` is a vector and the other is a matrix, then the matrix must have dimensions such that one of its dimensions equals the vector length. If the number of matrix rows equals the vector length, then MATLAB plots each matrix column versus the vector. If the number of matrix columns equals the vector length, then MATLAB plots each matrix row versus the vector. If the matrix is square, then MATLAB plots each column versus the vector.
- If one of `X` or `Y` is a scalar and the other is a vector, then MATLAB plots the vector as discrete points at the scalar value.

`plot(X,Y,LineStyle)` sets the line style, marker symbol, and color.

`plot(X1,Y1,...,Xn,Yn)` plots multiple X, Y pairs using the same axes for all lines.

`plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)` sets the line style, marker type, and color for each line. You can mix X, Y, LineSpec triplets with X, Y pairs. For example, `plot(X1,Y1,X2,Y2,LineStyle2,X3,Y3)`.

`plot(Y)` creates a 2-D line plot of the data in Y versus the index of each value.

- If Y is a vector, then the x-axis scale ranges from 1 to `length(Y)`.
- If Y is a matrix, then MATLAB plots the columns of Y versus their row number. The x-axis scale ranges from 1 to the number of rows in Y.
- If Y is complex, then MATLAB plots the imaginary part of Y versus the real part of Y, such that `plot(Y)` is equivalent to `plot(real(Y),imag(Y))`.

`plot(Y,LineStyle)` sets the line style, marker symbol, and color.

`plot(___,Name,Value)` specifies line properties using one or more Name,Value pair arguments. Use this option with any of the input argument combinations in the previous syntaxes. Name,Value pair settings apply to all the lines plotted. You cannot specify different Name,Value pairs for each data set.

`plot(axes_handle,___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle` can precede any of the input combinations in the previous syntaxes.

`h = plot(___)` returns a column vector of handles to the line objects, where h contains one handle per line plotted. When multiple lines are present, you can make changes to properties of a specific line by specifying a particular handle.

## Input Arguments

### Y - Data values to plot

scalar | vector | matrix

Data values to plot, specified as a scalar, a vector, or a matrix. To plot against specific  $x$ -values you must also specify X.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

### X - Locations along the x-axis to plot data values in Y

scalar | vector | matrix

Locations along the  $x$ -axis to plot data values in Y, specified as a scalar, a vector, or a matrix. If you specify both X and Y input arguments, and if either X or Y is complex, then plot ignores the imaginary components.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### LineStyle - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. The elements of the string can appear in any order, and you can omit one or more options from the string specifier. If you omit the line style and specify the marker character, then the plot shows only the marker and no line.

If Y is a matrix and you specify a color with LineSpec, then all lines are plotted using the specified color. If you specify a marker type or line style and do not specify a color, then MATLAB cycles through the predefined color order.

**Example:** '- -or' is a red dashed line with circle markers

Specifier	Line Style
-	Solid line (default)
--	Dashed line
:	Dotted line
-.	Dash-dot line

Specifier	Marker
o	Circle
+	Plus sign
*	Asterisk
.	Point
x	Cross
s	Square
d	Diamond
^	Upward-pointing triangle
v	Downward-pointing triangle
>	Right-pointing triangle
<	Left-pointing triangle
p	Pentagram
h	Hexagram

Specifier	Color
y	yellow
m	magenta
c	cyan

Specifier	Color
r	red
g	green
b	blue
w	white
k	black

## **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Marker', 'o', 'MarkerFaceColor', 'red'`

## **'Color' - Color**

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'Color',[0 1 0]

Example: 'Color','green'

Example: 'Color','g'

### 'LineStyle' - Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as the comma-separated pair consisting of 'LineStyle' and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

**Example:** 'LineStyle','-.'

## 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the stem and marker edge.

**Example:** 'LineWidth',0.75

## 'Marker' - Marker symbol

'none' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle

Specifier	Marker Symbol
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'Marker', '+'

**Example:** 'Marker', 'diamond'

### 'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector  
| string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'

RGB Vector	Short Name	Long Name
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'MarkerEdgeColor',[1 .8 .1]

**'MarkerFaceColor' - Marker face color**

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

### 'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'MarkerSize',3.75

## Output Arguments

### h - Handles to line objects

scalar | vector

Handles to the line objects, returned as a scalar or a vector. These are unique identifiers, which you can use to query and modify properties of a specific line.

## Examples

### Create Line Plot

Define  $x$  as a vector of linearly spaced values between 0 and  $2\pi$ . Use an increment of  $\pi/100$  between the values. Define  $y$  as sine values of  $x$ .

```
x = 0:pi/100:2*pi;
y = sin(x);
```

Create a line plot of the data.

# plot

---

```
figure % opens new figure window
plot(x,y)
```

## Plot Multiple Lines

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y1$  and  $y2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data.

```
x = linspace(-2*pi,2*pi);
```

```
y1 = sin(x);  
y2 = cos(x);  
  
figure  
plot(x,y1,x,y2)
```

### Create Line Plot From Matrix

Define Y as the 4-by-4 matrix returned by the magic function.

# plot

---

```
Y = magic(4)
```

```
Y =
```

```
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Create a 2-D line plot of Y. MATLAB plots each matrix column as a separate line.

```
figure
plot(Y)
```

### Specify Line Style

Plot three sine curves with a small phase shift between each line. Use the default line style for the first line. Specify a dashed line style for the second line and a dotted line style for the third line.

```
x = 0:pi/100:2*pi;  
y1 = sin(x);  
y2 = sin(x-0.25);  
y3 = sin(x-0.5);
```

# plot

```
figure
plot(x,y1,x,y2,'--',x,y3,':')
```

MATLAB cycles the line color through the default color order.

## Specify Line Style, Color, and Marker

Plot three sine curves with a small phase shift between each line. Use a green line with no markers for the first sine curve. Use a blue dashed

line with circle markers for the second sine curve. Use only cyan star markers for the third sine curve.

```
x = 0:pi/10:2*pi;
y1 = sin(x);
y2 = sin(x-0.25);
y3 = sin(x-0.5);

figure
plot(x,y1,'g',x,y2,'b-o',x,y3,'c*')
```

# plot

## Specify Line Width, Marker Size, and Marker Color

Create a line plot and use the `LineStyle` option to specify a dashed green line with square markers. Use `Name, Value` pairs to specify the line width, marker size, and marker colors. Set the marker edge color to blue and set the marker face color using an RGB color value.

```
x = -pi:pi/10:pi;  
y = tan(sin(x)) - sin(tan(x));
```

```
figure
plot(x,y,'--gs',...
      'LineWidth',2,...
      'MarkerSize',10,...
      'MarkerEdgeColor','b',...
      'MarkerFaceColor',[0.5,0.5,0.5])
```

## Add Title and Axis Labels

Use the `linspace` function to define `x` as a vector of 150 values between 0 and 10. Define `y` as cosine values of `x`.

```
x = linspace(0,10,150);  
y = cos(5*x);
```

Create a 2-D line plot of the cosine curve. Change the line color to a shade of blue-green using an RGB color value. Add a title and axis labels to the graph using the `title`, `xlabel`, and `ylabel` functions.

```
figure  
plot(x,y,'Color',[0,0.7,0.9])  
  
title('2-D Line Plot')  
xlabel('x')  
ylabel('cos(5x)')
```

### Specify Axes for Line Plot

Create a figure with two subplots and return the handle to each subplot axes, `s(1)` and `s(2)`.

```
figure; % new figure  
s(1) = subplot(2,1,1); % top subplot  
s(2) = subplot(2,1,2); % bottom subplot
```

# plot

---

Create a 2-D line plot in each axes by referring to the axes handles.  
Add a title and *y*-axis label to each axes by passing the axes handles to the `title` and `ylabel` functions.

```
x = linspace(0,3);  
y1 = sin(5*x);  
y2 = sin(15*x);  
  
plot(s(1),x,y1)  
title(s(1),'Top Subplot')
```

```
ylabel(s(1), 'sin(5x)')  
  
plot(s(2), x, y2)  
title(s(2), 'Bottom Subplot')  
ylabel(s(2), 'sin(15x)')
```

## Change Line Properties Using Handles

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y1$  and  $y2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data and return the handles of the two lines in  $h$ .

```
x = linspace(-2*pi,2*pi);  
y1 = sin(x);  
y2 = cos(x);  
  
figure  
h = plot(x,y1,x,y2);
```

Use the handle of the first line, `h(1)`, to change the line width to 2.  
Use the handle of the second line, `h(2)`, to add star markers to the plotted line.

```
set(h(1), 'LineWidth', 2);  
set(h(2), 'Marker', '*');
```

# plot

## Tips

- `plot` automatically chooses colors and line styles in the order specified by the `ColorOrder` and `LineStyleOrder` properties of the current axes. `plot` cycles through the color order with the first line style. Then, `plot` cycles through it again with each additional line style.

To change the color and line style orders for the current axes, set the `ColorOrder` and `LineStyleOrder` axes properties. If you do not specify these properties, then `plot` uses the default values. For

---

example, to set the line style order for the current axes to a solid line with asterisk markers, a dotted line, and circle markers with no line, use this command:

```
set(gca, 'LineStyleOrder', '-*|:|o')
```

- Data can include NaN and inf values, which cause breaks in the lines drawn. For example, this code plots the first two elements, skips the third element, and draws another line using the last two elements:  
`plot([1,2,NaN,4,5]).`

`title` | `xlabel` | `ylabel` | `xlim` | `ylim` | `legend` | `hold` | `LineStyleOrder` | `gca`

# plot3

---

**Purpose** 3-D line plot

**Syntax**

```
plot3(X1,Y1,Z1,...)
plot3(X1,Y1,Z1,LineStyle,...)
plot3(...,'PropertyName',PropertyValue,...)
h = plot3(...)
```

**Description** The `plot3` function displays a three-dimensional plot of a set of data points.

`plot3(X1,Y1,Z1,...)`, where  $X1$ ,  $Y1$ ,  $Z1$  are vectors or matrices, plots one or more lines in three-dimensional space through the points whose coordinates are the elements of  $X1$ ,  $Y1$ , and  $Z1$ .

`plot3(X1,Y1,Z1,LineStyle,...)` creates and displays all lines defined by the  $Xn, Yn, Zn, LineSpec$  quads, where  $LineSpec$  is a line specification that determines line style, marker symbol, and color of the plotted lines.

`plot3(...,'PropertyName',PropertyValue,...)` sets properties to the specified property values for all line graphics objects created by `plot3`. See `lineseries` properties for a description of the properties you can set.

`h = plot3(...)` returns a column vector of handles to `lineseries` graphics objects, with one handle per object.

**Tips** If one or more of  $X1$ ,  $Y1$ ,  $Z1$  is a vector, the vectors are plotted versus the rows or columns of the matrix, depending whether the vectors' lengths equal the number of rows or the number of columns.

You can mix  $Xn, Yn, Zn$  triples with  $Xn, Yn, Zn, LineSpec$  quads, for example,

```
plot3(X1,Y1,Z1,X2,Y2,Z2,LineStyle,X3,Y3,Z3)
```

See `LineStyle` and `plot` for information on line types and markers.

**Examples**

Plot a three-dimensional helix.

```
t = 0:pi/50:10*pi;
plot3(sin(t),cos(t),t)
xlabel('sin(t)')
ylabel('cos(t)')
zlabel('t')
grid on
axis square
```

## See Also

[axis](#) | [bar3](#) | [grid](#) | [line](#) | [LineStyle](#) | [lineseries](#) properties | [loglog](#) | [plot](#) | [scatter3](#) | [semilogx](#) | [semilogy](#) | [subplot](#)

**Purpose** Show or hide figure **Plot Browser**

**Syntax**

```
plotbrowser('on')
plotbrowser('off')
plotbrowser
plotbrowser(figure_handle,...)
```

**Description**

`plotbrowser('on')` displays the Plot Browser on the current figure.

`plotbrowser('off')` hides the Plot Browser on the current figure.

`plotbrowser` toggles the visibility of the Plot Browser on the current figure. You can use `plotbrowser('toggle')` instead for the same functionality.

`plotbrowser(figure_handle,...)` shows or hides the Plot Browser on the figure specified by `figure_handle`.

**Tips**

If you call `plotbrowser` in a MATLAB program and subsequent lines depend on the Plot Browser being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Alternatives**

To collectively enable **Plotting Tools**, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the **Plotting Tools**, use the smaller icon . Open or close the **Plot Browser** tool from the figure's **View** menu.

**See Also** `plottools` | `figurepalette` | `propertyeditor`

# plottedit

---

**Purpose** Interactively edit and annotate plots

**Syntax**

```
plottedit on
plottedit off
plottedit
plottedit(h)
plottedit('state')
plottedit(h, 'state')
```

**Description** `plottedit on` starts plot edit mode for the current figure, allowing you to use a graphical interface to annotate and edit plots easily. In plot edit mode, you can label axes, change line styles, and add text, line, and arrow annotations.

`plottedit off` ends plot mode for the current figure.

`plottedit` toggles the plot edit mode for the current figure.

`plottedit(h)` toggles the plot edit mode for the figure specified by figure handle `h`.

`plottedit('state')` specifies the `plottedit` state for the current figure. Values for `state` can be as shown.

Value for state	Description
on	Starts plot edit mode
off	Ends plot edit mode
showtoolsmenu	Displays the <b>Tools</b> menu in the menu bar
hidetoolsmenu	Removes the <b>Tools</b> menu from the menu bar

---

**Note** `hidetoolsmenu` is intended for GUI developers who do not want the **Tools** menu to appear in applications that use the figure window.

---

`plottedit(h, 'state')` specifies the plottedit state for figure handle `h`.

## Tips

### Plot Editing Mode Graphical Interface Components

To start plot edit mode, click this button.

Use these toolbar buttons to add a legend, text, and arrows.

Use the Edit, Insert, and Tools menus to add objects or edit existing objects in a graph.

Double-click on an object to select it.

Position labels, legends, and other objects by clicking and dragging.

Access object-specific plot edit functions through context-sensitive pop-up menus.

## Examples

Start plot edit mode for figure 2.

```
plottedit(2)
```

End plot edit mode for figure 2.

```
plottedit(2, 'off')
```

Hide the **Tools** menu for the current figure:

# plotedit

---

```
plotedit('hidetoolsmenu')
```

## See Also

[axes](#) | [line](#) | [open](#) | [plot](#) | [print](#) | [saveas](#) | [text](#) | [propedit](#)

**Purpose**

scatter plot matrix

**Syntax**

```
plotmatrix(X,Y)
plotmatrix(X)
plotmatrix( ___,LineStyle)
```

```
[H,AX,BigAx,P,PAx] = plotmatrix( ___ )
```

**Description**

`plotmatrix(X,Y)` creates a matrix of subaxes containing scatter plots of the columns of  $X$  against the columns of  $Y$ . If  $X$  is  $p$ -by- $n$  and  $Y$  is  $p$ -by- $m$ , then `plotmatrix` produces an  $n$ -by- $m$  matrix of subaxes.

`plotmatrix(X)` is the same as `plotmatrix(X,X)` except that the subaxes along the diagonal are replaced with histogram plots of the data in the corresponding column of  $X$ . For example, the subaxes along the diagonal in the  $i$ th column is replaced by `hist(X(:,i))`.

`plotmatrix( ___,LineStyle)` specifies the line style, marker symbol, and color for the scatter plots. The option `LineStyle` can be preceded by any of the input argument combinations in the previous syntaxes.

`[H,AX,BigAx,P,PAx] = plotmatrix( ___ )` returns handles to the graphic objects created as follows:

- `H` – Matrix of handles to the line objects used to create the scatter plots
- `AX` – Matrix of handles to the individual subaxes
- `BigAx` – Handle to the big axes that frames the subaxes
- `P` – Vector of handles for the patch objects that create the histogram plots
- `PAx` – Vector of handles to the invisible histogram axes

`BigAx` is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command will center text with respect to the big axes.

## Input Arguments

### **X - Data to display**

matrix

Data to display, specified as a matrix.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Y - Data to plot against X**

matrix

Data to plot against X, specified as a matrix.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **LineStyle - Line style, marker symbol, and color for scatter plots**

string

Line style, marker symbol, and color for the scatter plots, specified as a string. For more information on line style, marker symbol, and color options see LineSpec.

**Example:** `':*r'`

#### **Data Types**

char

## Output Arguments

### **H - Line object handles**

matrix

Line object handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific line object. The line objects are used to create the scatter plots.

### **AX - Subaxes handles**

matrix

Subaxes handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific subaxes.

### **BigAx - Big axes handle**

scalar

Big axes handle, returned as a scalar. This is a unique identifier, which you can use to query and modify properties of the big axes. BigAx is left as the current axes (gca) so that a subsequent title, xlabel, or ylabel command will center text with respect to the big axes.

### **P - Patch object handles**

vector | []

Patch object handles, returned as a vector or []. If histogram plots are created, then P is returned as a vector of patch object handles for the histogram plots. These are unique identifiers, which you can use to query and modify the properties of a specific patch object. If no histogram plots are created, then P is returned as empty brackets.

### **PAX - Handle to invisible histogram axes**

vector | []

Handle to invisible histogram axes, returned as a vector or []. If histogram plots are created, then PAX is returned as a vector of histogram axes handles. These are unique identifiers, which you can use to query and modify the properties of a specific axes, such as the axes scale. If no histogram plots are created, then PAX is returned as empty brackets.

## **Examples**

### **Create Scatter Plot Matrix with Two Matrix Inputs**

Initialize the random-number generator to make the output of randn repeatable. Set up X as a matrix of normally distributed pseudorandom data and Y as a matrix of integer values.

```
rng(0, 'twister');  
X = randn(50,3);
```

# plotmatrix

---

```
Y = reshape(1:150,50,3);
```

Create a scatter plot matrix of the columns of X against the columns of Y.

```
figure  
plotmatrix(X,Y)
```

The subaxes in the  $i$ th row,  $j$ th column of the matrix is a scatter plot of the  $i$ th column of Y against the  $j$ th column of X.

### **Create Scatter Plot Matrix with One Matrix Input**

Initialize the random-number generator to make the output of `randn` repeatable and generate a matrix of normally distributed pseudorandom data

```
rng(0, 'twister');  
X = randn(50,3);
```

Create a scatter plot matrix.

```
figure  
plotmatrix(X)
```

# plotmatrix

---

The subaxes in the  $i$ th row,  $j$ th column of the matrix is a scatter plot of the  $i$ th column of  $X$  against the  $j$ th column of  $X$ . Along the diagonal, `plotmatrix` creates a histogram plot of each column of  $X$ .

## Specify Marker Type and Color

Initialize the random-number generator to make the output of `randn` repeatable. Generate a matrix of normally distributed pseudorandom data.

```
rng(0,'twister');
```

```
X = randn(50,3);
```

Create a scatter plot matrix and specify the marker type and the color for the scatter plots.

```
figure
plotmatrix(X, '*r')
```

LineStyle sets properties for the scatter plots. To set properties for the histogram plots, use the patch object handles.

## Set Figure Properties Using Handles

Initialize the random-number generator to make the output of `randn` repeatable. Generate a matrix of normally distributed pseudorandom data.

```
rng(0, 'twister');  
X = randn(50,3);
```

Create a scatter plot matrix and get the handles to the objects created and the axes.

```
figure  
[H,AX,BigAx,P,PAX] = plotmatrix(X);
```

To set properties for the scatter plot objects, use the handles in `H`. To set properties for the histogram patch objects, use the handles in `P`. To set axes properties, use the axes handles, `AX`, `BigAx`, and `PAX`.

Set the color and marker type for the scatter plot in the lower left corner.

```
set(H(3), 'Color', 'g', 'Marker', '*');
```

Set the color for the histogram plot in the lower right corner.

```
set(P(3), 'EdgeColor', 'k', 'FaceColor', 'g');
```

Use the `title` command to title the figure.

```
title(BigAx, 'A Comparison of Data Sets');
```

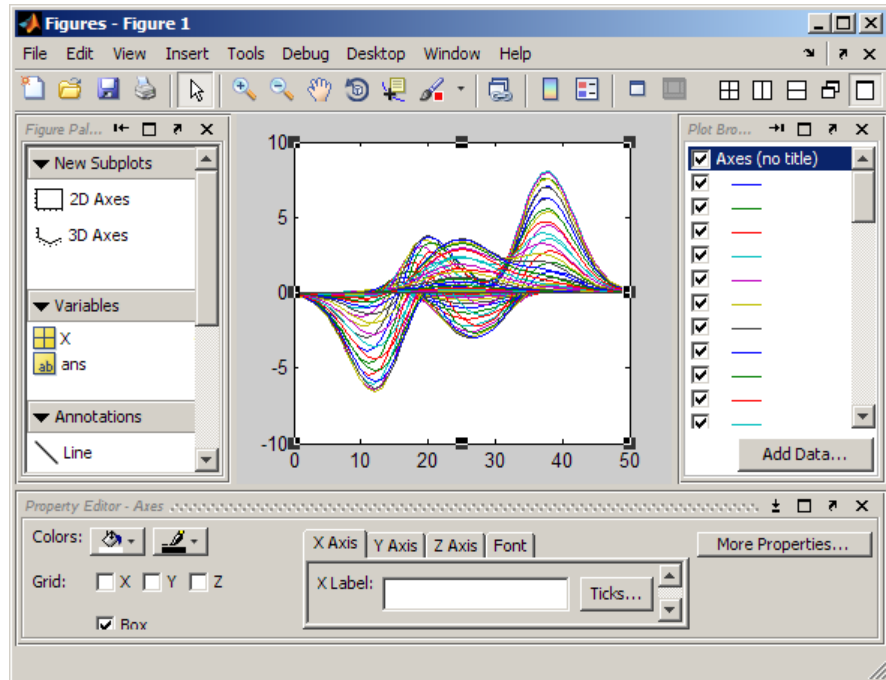

**See Also** [scatter](#) | [scatter3](#)

# plottools

## Purpose

Show or hide plot tools

## Syntax

```
plottools('on')  
plottools('off')  
plottools  
plottools(figure_handle,...)  
plottools(...,'tool')
```

## Description

`plottools('on')` displays the Figure Palette, Plot Browser, and Property Editor on the current figure, configured as you last used them.

`plottools('off')` hides the Figure Palette, Plot Browser, and Property Editor on the current figure.

`plottools` with no arguments, is the same as `plottools('on')`

`plottools(figure_handle,...)` displays or hides the plot tools on the specified figure instead of on the current figure.

`plottools(..., 'tool')` operates on the specified tool only. *tool* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

---

**Note** The first time you open the plotting tools, all three of them appear, grouped around the current figure as shown above. If you close, move, or undock any of the tools, MATLAB remembers the configuration you left them in and restores it when you invoke the tools for subsequent figures, both within and across MATLAB sessions.

---

## Alternatives

Click the larger **Plotting Tools** icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Plotting Tools — Interactive Plotting”.

## See Also

`figurepalette` | `plotbrowser` | `propertyeditor`

## Purpose

2-D line plots with y-axes on both left and right side

## Syntax

```
plotyy(X1,Y1,X2,Y2)
plotyy(X1,Y1,X2,Y2,function)
plotyy(X1,Y1,X2,Y2,'function1','function2')
[AX,H1,H2] = plotyy(...)
```

## Description

`plotyy(X1,Y1,X2,Y2)` plots `X1` versus `Y1` with y-axis labeling on the left and plots `X2` versus `Y2` with y-axis labeling on the right.

`plotyy(X1,Y1,X2,Y2,function)` uses the specified plotting function to produce the graph.

`function` can be either a function handle or a string specifying `plot`, `semilogx`, `semilogy`, `loglog`, `stem`, or any MATLAB function that accepts the syntax

```
h = function(x,y)
```

For example,

```
plotyy(x1,y1,x2,y2,@loglog) % function handle
plotyy(x1,y1,x2,y2,'loglog') % string
```

Function handles enable you to access user-defined local functions and can provide other advantages. See `@` for more information on using function handles.

`plotyy(X1,Y1,X2,Y2,'function1','function2')` uses `function1(X1,Y1)` to plot the data for the left axis and `function2(X2,Y2)` to plot the data for the right axis.

`[AX,H1,H2] = plotyy(...)` returns the handles of the two axes created in `AX` and the handles of the graphics objects from each plot in `H1` and `H2`. `AX(1)` is the left axes and `AX(2)` is the right axes.

## Examples

This example graphs two mathematical functions using `plot` as the plotting function. The two  $y$ -axes enable you to display both sets of data on one graph even though relative values of the data are quite different.

```
figure
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
[AX,H1,H2] = plotyy(x,y1,x,y2,'plot');
```

You can use the handles returned by `plotyy` to label the axes and set the line styles used for plotting. With the axes handles you can specify the `YLabel` properties of the left- and right-side  $y$ -axis:

```
set(get(AX(1),'Ylabel'),'String','Slow Decay')
set(get(AX(2),'Ylabel'),'String','Fast Decay')
```

Use the `xlabel` and `title` commands to label the  $x$ -axis and add a title:

```
xlabel('Time (\musec)')
title('Multiple Decay Rates')
```

Use the line handles to set the `LineStyle` properties of the left- and right-side plots:

```
set(H1,'LineStyle','--')
set(H2,'LineStyle',':')
```

## How To

- “Plotting with Two Y-Axes”
- “Using Multiple X- and Y-Axes”

**Purpose**

Summary of classes in MATLAB Plugins Interface

**Description**

Plugins customize a TestRunner object. The matlab.unittest.plugins package consists of the following customized MATLAB plugins.

matlab.unittest.plugins.DiagnosticsValidationPlugin validate diagnostic code

matlab.unittest.plugins.FailureDiagnosticsPlugin show diagnostics on failure

matlab.unittest.plugins.StopOnFailurePlugin debug test failures

matlab.unittest.plugins.TestSuiteProgressPlugin outputs progress information as text

**See Also**

“Customize Test Runner with Plugins”

# matlab.unittest.plugins.DiagnosticsValidationPlugin

---

<b>Purpose</b>	Plugin to help validate diagnostic code
<b>Description</b>	<p>The <code>DiagnosticsValidationPlugin</code> creates a plugin to help validate diagnostic code.</p> <p>The <code>DiagnosticsValidationPlugin</code> can be added to the <code>TestRunner</code> to confirm that user supplied diagnostics execute correctly. This is useful because most of the time tests should not encounter failure conditions. This results in diagnostic code which is not typically exercised. Therefore, if there is a programming error in this diagnostic code, it will not be evident until the test fails. However, at this point the diagnostics for that failure condition are lost due to the error in the diagnostic code.</p> <p>Using this plugin results in the unconditional evaluation of the diagnostics supplied by the test writer when running tests regardless of whether the test passes or fails. This helps a test author confirm that all of their diagnostic code is free from programming errors.</p> <p>The diagnostic analysis can reduce the test performance and can result in a very verbose text output when used. Be aware of these impacts before using this plugin for routine testing.</p>
<b>Construction</b>	<code>matlab.unittest.plugins.DiagnosticsValidationPlugin</code> creates a plugin to help validate diagnostic code.
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see <a href="#">Copying Objects</a> in the MATLAB documentation.
<b>Examples</b>	<b>Add Plugin to TestRunner</b> <pre>import matlab.unittest.TestRunner; import matlab.unittest.TestSuite; import matlab.unittest.plugins.DiagnosticsValidationPlugin;  % Create a TestSuite array suite = TestSuite.fromClass(?mypackage.MyTestClass); % Create a TestRunner with no plugins runner = TestRunner.withNoPlugins;</pre>

# matlab.unittest.plugins.DiagnosticsValidationPlugin

---

```
% Add a new plugin to the TestRunner
runner.addPlugin(DiagnosticsValidationPlugin);

% Run the suite to see all user supplied diagnostic output
result = runner.run(suite)
```

## Concepts

# matlab.unittest.plugins.FailureDiagnosticsPlugin

---

<b>Purpose</b>	Plugin to show diagnostics on failure
<b>Description</b>	The <code>FailureDiagnosticsPlugin</code> creates a plugin to show diagnostics on failure. It is added to the <code>TestRunner</code> to show diagnostics to the Command Window upon failure. This plugin is used by default when using <code>TestRunner.withTextOutput</code> .
<b>Construction</b>	<code>matlab.unittest.plugins.FailureDiagnosticsPlugin</code> creates a plugin to show diagnostics on failure.
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see <a href="#">Copying Objects in the MATLAB documentation</a> .
<b>Examples</b>	<b>Add Plugin to TestRunner</b> <pre>import matlab.unittest.TestRunner; import matlab.unittest.TestSuite; import matlab.unittest.plugins.FailureDiagnosticsPlugin;  % Create a TestSuite array suite = TestSuite.fromClass(?mypackage.MyTestClass); % Create a TestRunner with no plugins runner = TestRunner.withNoPlugins;  % Add a new plugin to the TestRunner runner.addPlugin(FailureDiagnosticsPlugin);  % Run the suite to see diagnostic output on failure result = runner.run(suite)</pre>
<b>See Also</b>	<code>matlab.unittest.diagnostics</code>   <code>matlab.unittest.plugins</code>
<b>Concepts</b>	

## Purpose

Plugin to debug test failures

## Description

The `StopOnFailuresPlugin` class provides a plugin to help debug test failures. The `StopOnFailuresPlugin` is added to the test runner to pause execution of a test and enter debug mode upon a qualification failure or uncaught error.

Upon encountering a qualification failure, the `StopOnFailuresPlugin` causes MATLAB to enter debug mode. At that point, MATLAB debugging commands such as `dbup`, `dbstep`, `dbcont`, and `dbquit` can be used to investigate the cause of the test failure.

The `StopOnFailuresPlugin` also causes MATLAB to enter debug mode upon encountering an uncaught error in a test. However, because the error disrupts the stack, it is not possible to use `dbup` to shift context to the source of the error.

## Construction

`matlab.unittest.plugins.StopOnFailuresPlugin` creates a plugin to debug test failures.

`matlab.unittest.plugins.StopOnFailuresPlugin('IncludingAssumptionFailures',tf)` indicates whether to react to assumption failures. By default, the `StopOnFailuresPlugin` only reacts to uncaught errors and verification, assertion, and fatal assertion qualification errors. However, when `'IncludingAssumptionFailures'` is set to `true`, the plugin also reacts to assumption failures.

## Input Arguments

### **tf - Indicator to react to assumption failures**

FALSE (default) | TRUE

Indicator to react to assumption failures, specified as logical `false` or `true`. When this value is `true`, the test runner reacts to assumption failures. When it is `false`, it ignores assumption failures.

# matlab.unittest.plugins.StopOnFailuresPlugin

---

## Properties

### IncludeAssumptionFailures

When this value is true, the instance reacts to assumption failures. When it is false, the instance ignores assumption failures. The `IncludeAssumptionFailures` property is false by default, but can be specified to be true by utilizing the `InlcudingAssumptionFailures` input during construction of the instance.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Add Plugin to TestRunner

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.StopOnFailuresPlugin;

% Create a TestSuite array
suite = TestSuite.fromClass(?mypackage.MyTestClass);
% Create a TestRunner with text output
runner = TestRunner.withTextOutput;

% Add a new plugin to the TestRunner
runner.addPlugin(StopOnFailuresPlugin(...
    'IncludingAssumptionFailures', true));

% Run the suite to enter debug mode upon failures
result = runner.run(suite)
```

## See Also

[dbup](#) | [dbstep](#) | [dbcont](#) | [dbquit](#) | [matlab.unittest.plugins](#)

## Concepts

# matlab.unittest.plugins.TestSuiteProgressPlugin

---

- Purpose** Plugin which outputs progress information as text
- Description** The `TestSuiteProgressPlugin` class creates a plugin to output progress information as text. The `TestSuiteProgressPlugin` can be added to the `TestRunner` to show progress of the test run to the Command Window when running test suites. This plugin is used by default when using `TestRunner.withTextOutput`.
- Construction** `matlab.unittest.plugins.TestSuiteProgressPlugin` creates a plugin to output progress information as text.
- Copy Semantics** Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Add Plugin to TestRunner

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.TestSuiteProgressPlugin;

% Create a TestSuite array
suite = TestSuite.fromClass(?mypackage.MyTestClass);
% Create a TestRunner with no plugins
runner = TestRunner.withNoPlugins;

% Add a new plugin to the TestRunner
runner.addPlugin(TestSuiteProgressPlugin);

% Run the suite to see progress of the test run as text output
result = runner.run(suite)
```

**See Also** `matlab.unittest.plugins`

## Concepts

# plus, +

---

## Purpose

Addition

## Syntax

$C = A + B$   
`C = plus(A,B)`

## Description

$C = A + B$  adds arrays A and B and returns the result in C.

$C = \text{plus}(A,B)$  is an alternate way to execute  $A + B$ , but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### B - Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Add Scalar to Array

Create an array, A, and add a scalar value to it.

```
A = [0 1; 1 0];  
C = A + 2
```

```
C =
```

```
     2     3  
     3     2
```

The scalar value is added to each entry of A.

### Add Two Arrays

Create two arrays, A and B, and add them together.

```
A = [1 0; 2 4];  
B = [5 9; 2 1];  
C = A + B
```

```
C =
```

```
     6     9  
     4     5
```

The elements of A are added to the corresponding elements of B.

# DelaunayTri.pointLocation

---

**Purpose** (Will be removed) Simplex containing specified location

---

**Note** `pointLocation(DelaunayTri)` will be removed in a future release. Use `pointLocation(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

**Syntax**

```
SI = pointLocation(DT,QX)
SI = pointLocation(DT,QX,QY)
SI = pointLocation(DT,QX,QY,QZ)
[SI, BC] = pointLocation(DT,...)
```

**Description** `SI = pointLocation(DT,QX)` returns the indices `SI` of the enclosing simplex (triangle/tetrahedron) for each query point location in `QX`. The enclosing simplex for point `QX(k,:)` is `SI(k)`. `pointLocation` returns `NaN` for all points outside the convex hull.

`SI = pointLocation(DT,QX,QY)` and `SI = pointLocation(DT,QX,QY,QZ)` allow the query point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`[SI, BC] = pointLocation(DT,...)` returns the barycentric coordinates `BC`.

**Input Arguments**

<code>DT</code>	Delaunay triangulation.
<code>QX</code>	Matrix of size <code>mpts-by-ndim</code> , <code>mpts</code> being the number of query points.

## Output Arguments

SI	Column vector of length <code>mpts</code> containing the indices of the enclosing simplex for each query point. <code>mpts</code> is the number of query points.
BC	BC is a <code>mpts-by-ndim</code> matrix, each row <code>BC(i,:)</code> represents the barycentric coordinates of <code>QX(i,:)</code> with respect to the enclosing simplex <code>SI(i)</code> .

## Examples

### Example 1

Create a 2-D Delaunay triangulation:

```
X = rand(10,2);  
dt = DelaunayTri(X);
```

Find the triangles that contain specified query points:

```
qrypts = [0.25 0.25; 0.5 0.5];  
triids = pointLocation(dt, qrypts)
```

### Example 2

Create a 3-D Delaunay triangulation:

```
x = rand(10,1);  
y = rand(10,1);  
z = rand(10,1);  
dt = DelaunayTri(x,y,z);
```

Find the triangles that contain specified query points and evaluate the barycentric coordinates:

```
qrypts = [0.25 0.25 0.25; 0.5 0.5 0.5];  
[tetids, bcs] = pointLocation(dt, qrypts)
```

# pol2cart

**Purpose** Transform polar or cylindrical coordinates to Cartesian

**Syntax**  
 $[X,Y] = \text{pol2cart}(\text{THETA},\text{RHO})$   
 $[X,Y,Z] = \text{pol2cart}(\text{THETA},\text{RHO},Z)$

**Description**  $[X,Y] = \text{pol2cart}(\text{THETA},\text{RHO})$  transforms the polar coordinate data stored in corresponding elements of THETA and RHO to two-dimensional Cartesian, or  $xy$ , coordinates. The arrays THETA and RHO must be the same size (or either can be scalar). The values in THETA must be in radians.

$[X,Y,Z] = \text{pol2cart}(\text{THETA},\text{RHO},Z)$  transforms the cylindrical coordinate data stored in corresponding elements of THETA, RHO, and Z to three-dimensional Cartesian, or  $xyz$  coordinates. The arrays THETA, RHO, and Z must be the same size (or any can be scalar). The values in THETA must be in radians.

**Algorithms** The mapping from polar and cylindrical coordinates to Cartesian coordinates is:

**Polar to Cartesian Mapping**

$$\begin{aligned}x &= \text{rho} * \cos(\text{theta}) \\y &= \text{rho} * \sin(\text{theta})\end{aligned}$$

**Polar to Cartesian Mapping**

$$\begin{aligned}x &= \text{rho} * \cos(\text{theta}) \\y &= \text{rho} * \sin(\text{theta}) \\z &= z\end{aligned}$$

**See Also**

[cart2pol](#) | [cart2sph](#) | [sph2cart](#)

# polar

---

## Purpose

Polar coordinate plot

## Syntax

```
polar(theta,rho)
polar(theta,rho,LineStyle)
polar(axes_handle,...)
h = polar(...)
```

## Description

The polar function accepts polar coordinates, plots them in a Cartesian plane, and draws the polar grid on the plane.

`polar(theta,rho)` creates a polar coordinate plot of the angle `theta` versus the radius `rho`. `theta` is the angle from the  $x$ -axis to the radius vector specified in radians; `rho` is the length of the radius vector specified in dataspace units.

`polar(theta,rho,LineStyle)` `LineStyle` specifies the line type, plot symbol, and color for the lines drawn in the polar plot.

`polar(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = polar(...)` returns the handle of a line object in `h`.

## Tips

Negative  $r$  values reflect through the origin, rotating by  $\pi$  (since  $(\theta,r)$  transforms to  $(r\cos(\theta), r\sin(\theta))$ ). If you want different behavior, you can manipulate  $r$  prior to plotting. For example, you can make  $r$  equal to  $\max(0,r)$  or  $\text{abs}(r)$ .

## Examples

### Simple Polar Plot

Create a simple polar plot using a dashed red line.

```
theta = 0:0.01:2*pi;
rho = sin(2*theta).*cos(2*theta);
```

```
figure  
polar(theta,rho,'--r')
```

**See Also**

# poly

---

**Purpose** Polynomial with specified roots

**Syntax**  
`p = poly(A)`  
`p = poly(r)`

**Description** `p = poly(A)` where  $A$  is an  $n$ -by- $n$  matrix returns an  $n+1$  element row vector whose elements are the coefficients of the characteristic polynomial,  $\det(\lambda I - A)$ . The coefficients are ordered in descending powers: if a vector  $c$  has  $n+1$  components, the polynomial it represents is  $c_1 s^n + \dots + c_n s + c_n + 1$

`p = poly(r)` where  $r$  is a vector returns a row vector whose elements are the coefficients of the polynomial whose roots are the elements of  $r$ .

**Tips** Note the relationship of this command to

`r = roots(p)`

which returns a column vector whose elements are the roots of the polynomial specified by the coefficients row vector  $p$ . For vectors, `roots` and `poly` are inverse functions of each other, up to ordering, scaling, and roundoff error.

**Examples** MATLAB displays polynomials as row vectors containing the coefficients ordered by descending powers. The characteristic equation of the matrix

$A =$

```
1   2   3
4   5   6
7   8   0
```

is returned in a row vector by `poly`:

`p = poly(A)`

`p =`  
1     -6     -72     -27

The roots of this polynomial (eigenvalues of matrix A) are returned in a column vector by `roots`:

```
r = roots(p)
```

```
r =
```

```
    12.1229
   -5.7345
   -0.3884
```

## Algorithms

The algorithms employed for `poly` and `roots` illustrate an interesting aspect of the modern approach to eigenvalue computation. `poly(A)` generates the characteristic polynomial of A, and `roots(poly(A))` finds the roots of that polynomial, which are the eigenvalues of A. But both `poly` and `roots` use `eig`, which is based on similarity transformations. The classical approach, which characterizes eigenvalues as roots of the characteristic polynomial, is actually reversed.

If A is an n-by-n matrix, `poly(A)` produces the coefficients `c(1)` through `c(n+1)`, with `c(1) = 1`, in

$$\det(\lambda I - A) = c_1 \lambda^n + \dots + c_n \lambda + c_{n+1}$$

The algorithm is

```
z = eig(A);
c = zeros(n+1,1); c(1) = 1;
for j = 1:n
    c(2:j+1) = c(2:j+1) - z(j)*c(1:j);
end
```

This recursion is easily derived by expanding the product.

$$(\lambda - \lambda_1)(\lambda - \lambda_2)\dots(\lambda - \lambda_n)$$

It is possible to prove that `poly(A)` produces the coefficients in the characteristic polynomial of a matrix within roundoff error of A. This is

true even if the eigenvalues of  $A$  are badly conditioned. The traditional algorithms for obtaining the characteristic polynomial, which do not use the eigenvalues, do not have such satisfactory numerical properties.

## See Also

`conv` | `polyval` | `residue` | `roots`

**Purpose**

Area of polygon

**Syntax**

```
A = polyarea(X,Y)
A = polyarea(X,Y,dim)
```

**Description**

`A = polyarea(X,Y)` returns the area of the polygon specified by the vertices in the vectors `X` and `Y`.

If `X` and `Y` are matrices of the same size, then `polyarea` returns the area of polygons defined by the columns `X` and `Y`.

If `X` and `Y` are multidimensional arrays, `polyarea` returns the area of the polygons in the first nonsingleton dimension of `X` and `Y`.

`A = polyarea(X,Y,dim)` operates along the dimension specified by scalar `dim`.

**Examples**

```
L = linspace(0,2.*pi,9); xv = 1.2*cos(L)';yv = 1.2*sin(L)';
xv = [xv ; xv(1)]; yv = [yv ; yv(1)];
A = polyarea(xv,yv);
plot(xv,yv); title(['Area = ' num2str(A)]); axis image
```

# polyarea

# polyeig

---

**Purpose** Polynomial eigenvalue problem

**Syntax**  
`[X,e] = polyeig(A0,A1,...,Ap)`  
`e = polyeig(A0,A1,...,Ap)`  
`[X, e, s] = polyeig(A0,A1,...,AP)`

**Description** `[X,e] = polyeig(A0,A1,...,Ap)` solves the polynomial eigenvalue problem of degree  $p$

$$\left(A_0 + \lambda A_1 + \dots + \lambda^p A_p\right)x = 0$$

where polynomial degree  $p$  is a non-negative integer, and  $A_0, A_1, \dots, A_p$  are input matrices of order  $n$ . The output consists of a matrix  $X$  of size  $n$ -by- $n \cdot p$  whose columns are the eigenvectors, and a vector  $e$  of length  $n \cdot p$  containing the eigenvalues.

If  $\lambda$  is the  $j$ th eigenvalue in  $e$ , and  $x$  is the  $j$ th column of eigenvectors in  $X$ , then  $(A_0 + \lambda A_1 + \dots + \lambda^p A_p) \cdot x$  is approximately 0.

`e = polyeig(A0,A1,...,Ap)` is a vector of length  $n \cdot p$  whose elements are the eigenvalues of the polynomial eigenvalue problem.

`[X, e, s] = polyeig(A0,A1,...,AP)` also returns a vector  $s$  of length  $p \cdot n$  containing condition numbers for the eigenvalues. At least one of  $A_0$  and  $A_p$  must be nonsingular. Large condition numbers imply that the problem is close to a problem with multiple eigenvalues.

**Tips** Based on the values of  $p$  and  $n$ , `polyeig` handles several special cases:

- $p = 0$ , or `polyeig(A)` is the standard eigenvalue problem: `eig(A)`.
- $p = 1$ , or `polyeig(A,B)` is the generalized eigenvalue problem: `eig(A,-B)`.
- $n = 1$ , or `polyeig(a0,a1,...,ap)` for scalars  $a_0, a_1, \dots, a_p$  is the standard polynomial problem: `roots([ap ... a1 a0])`.

If both  $A_0$  and  $A_p$  are singular the problem is potentially ill-posed. Theoretically, the solutions might not exist or might not be unique. Computationally, the computed solutions might be inaccurate. If one, but not both, of  $A_0$  and  $A_p$  is singular, the problem is well posed, but some of the eigenvalues might be zero or infinite.

Note that scaling  $A_0, A_1, \dots, A_p$  to have  $\text{norm}(A_i)$  roughly equal 1 may increase the accuracy of `polyeig`. In general, however, this cannot be achieved. (See Tisseur [3] for more detail.)

## Algorithms

The `polyeig` function uses the QZ factorization to find intermediate results in the computation of generalized eigenvalues. It uses these intermediate results to determine if the eigenvalues are well-determined. See the descriptions of `eig` and `qz` for more on this.

# polyfit

---

**Purpose** Polynomial curve fitting

**Syntax**  
`p = polyfit(x,y,n)`  
`[p,S] = polyfit(x,y,n)`  
`[p,S,mu] = polyfit(x,y,n)`

**Description** `p = polyfit(x,y,n)` finds the coefficients of a polynomial  $p(x)$  of degree  $n$  that fits the data,  $p(x(i))$  to  $y(i)$ , in a least squares sense. The result `p` is a row vector of length  $n+1$  containing the polynomial coefficients in descending powers:

$$p(x) = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}.$$

`[p,S] = polyfit(x,y,n)` returns the polynomial coefficients `p` and a structure `S` for use with `polyval` to obtain error estimates or predictions. Structure `S` contains fields `R`, `df`, and `normr`, for the triangular factor from a QR decomposition of the Vandermonde matrix of `x`, the degrees of freedom, and the norm of the residuals, respectively. If the data `y` are random, an estimate of the covariance matrix of `p` is  $(R_{\text{inv}} * R_{\text{inv}}') * \text{normr}^2 / \text{df}$ , where `Rinv` is the inverse of `R`. If the errors in the data `y` are independent normal with constant variance, `polyval` produces error bounds that contain at least 50% of the predictions.

`[p,S,mu] = polyfit(x,y,n)` finds the coefficients of a polynomial in

$$\hat{x} = \frac{x - \mu_1}{\mu_2}$$

where  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . `mu` is the two-element vector  $[\mu_1, \mu_2]$ . This centering and scaling transformation improves the numerical properties of both the polynomial and the fitting algorithm.

## Examples

This example involves fitting the error function, `erf(x)`, by a polynomial in `x`. This is a risky project because `erf(x)` is a bounded function, while polynomials are unbounded, so the fit might not be very good.

First generate a vector of  $x$  points, equally spaced in the interval  $[0, 2.5]$ ; then evaluate  $\text{erf}(x)$  at those points.

```
x = (0: 0.1: 2.5)';
y = erf(x);
```

The coefficients in the approximating polynomial of degree 6 are

```
p = polyfit(x,y,6)
```

```
p =
```

```
0.0084 -0.0983 0.4217 -0.7435 0.1471 1.1064 0.0004
```

There are seven coefficients, and the polynomial is

$$0.0084x^6 - 0.0983x^5 + 0.4217x^4 - 0.7435x^3 + 0.1471x^2 + 1.1064x + 0.0004$$

To see how good the fit is, evaluate the polynomial at the data points with:

```
f = polyval(p,x);
```

A table showing the data, fit, and error is

```
table = [x y f y-f]
```

```
table =
```

0	0	0.0004	-0.0004

2.5000	0.9996	0.9994	0.0002

# polyfit

On this interval, the interpolated values and the actual values agree fairly closely. Outside this interval, the extrapolated values quickly diverge from the actual data values, as the following plot demonstrates.

```
x = (0: 0.1: 5)';  
y = erf(x);  
f = polyval(p,x);  
plot(x,y,'o',x,f,'-')  
axis([0 5 0 2])
```

## Algorithms

The polyfit MATLAB file forms the Vandermonde matrix,  $V$ , whose elements are powers of  $x$ .  $v_{i,j} = x_i^{n-j}$

It then uses the backslash operator, `\`, to solve the least squares problem  $Vp \cong y$ .

See “Programmatic Fitting” for information about fitting different functions of  $x$ .

**See Also**

`poly` | `polyval` | `roots` | `lscov` | `cov`

# polyint

---

**Purpose** Integrate polynomial analytically

**Syntax** `polyint(p,k)`  
`polyint(p)`

**Description** `polyint(p,k)` returns a polynomial representing the integral of polynomial `p`, using a scalar constant of integration `k`. Specify `p` and `k` as type `double` or `single`.

`polyint(p)` assumes a constant of integration `k=0`.

**See Also** `polyder` | `polyval` | `polyvalm` | `polyfit`

**Purpose**

Polynomial evaluation

**Syntax**

```
y = polyval(p,x)
[y,delta] = polyval(p,x,S)
y = polyval(p,x,[],mu)
[y,delta] = polyval(p,x,S,mu)
```

**Description**

`y = polyval(p,x)` returns the value of a polynomial of degree  $n$  evaluated at  $x$ . The input argument  $p$  is a vector of length  $n+1$  whose elements are the coefficients in descending powers of the polynomial to be evaluated.

$$y = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}$$

$x$  can be a matrix or a vector. In either case, `polyval` evaluates  $p$  at each element of  $x$ .

`[y,delta] = polyval(p,x,S)` uses the optional output structure  $S$  generated by `polyfit` to generate error estimates `delta`. `delta` is an estimate of the standard deviation of the error in predicting a future observation at  $x$  by  $p(x)$ . If the coefficients in  $p$  are least squares estimates computed by `polyfit`, and the errors in the data input to `polyfit` are independent, normal, and have constant variance, then `y±delta` contains at least 50% of the predictions of future observations at  $x$ .

`y = polyval(p,x,[],mu)` or `[y,delta] = polyval(p,x,S,mu)` use  $\hat{x} = (x - \mu_1) / \mu_2$  in place of  $x$ . In this equation,  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . The centering and scaling parameters  $\text{mu} = [\mu_1, \mu_2]$  are optional output computed by `polyfit`.

**Tips**

The `polyvalm(p,x)` function, with  $x$  a matrix, evaluates the polynomial in a matrix sense. See `polyvalm` for more information.

# polyval

---

## Examples

The polynomial  $p(x) = 3x^2 + 2x + 1$  is evaluated at  $x = 5, 7,$  and  $9$  with

```
p = [3 2 1];  
polyval(p,[5 7 9])
```

which results in

```
ans =
```

```
86    162    262
```

For another example, see [polyfit](#).

## See Also

[polyfit](#) | [polyvalm](#) | [polyder](#) | [polyint](#)

**Purpose** Matrix polynomial evaluation

**Syntax** `Y = polyvalm(p,X)`

**Description** `Y = polyvalm(p,X)` evaluates a polynomial in a matrix sense. This is the same as substituting matrix `X` in the polynomial `p`.

Polynomial `p` is a vector whose elements are the coefficients of a polynomial in descending powers, and `X` must be a square matrix.

**Examples** The Pascal matrices are formed from Pascal's triangle of binomial coefficients. Here is the Pascal matrix of order 4.

```
X = pascal(4)
X =
     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    20
```

Its characteristic polynomial can be generated with the `poly` function.

```
p = poly(X)
p =
     1    -29     72    -29     1
```

This represents the polynomial  $x^4 - 29x^3 + 72x^2 - 29x + 1$ .

Pascal matrices have the curious property that the vector of coefficients of the characteristic polynomial is palindromic; it is the same forward and backward.

Evaluating this polynomial at each element is not very interesting.

```
polyval(p,X)
ans =
     16     16     16     16
     16     15    -140    -563
     16    -140   -2549  -12089
```

# polyvalm

---

```
16      -563  -12089  -43779
```

But evaluating it in a matrix sense is interesting.

```
polyvalm(p,X)
ans =
    0     0     0     0
    0     0     0     0
    0     0     0     0
    0     0     0     0
```

The result is the zero matrix. This is an instance of the Cayley-Hamilton theorem: a matrix satisfies its own characteristic equation.

**Purpose** Base 2 power and scale floating-point numbers

**Syntax**  
`X = pow2(Y)`  
`X = pow2(F,E)`

**Description** `X = pow2(Y)` returns an array `X` whose elements are 2 raised to the power `Y`.  
`X = pow2(F,E)` computes  $x = f * 2^e$  for corresponding elements of `F` and `E`. The result is computed quickly by simply adding `E` to the floating-point exponent of `F`. Arguments `F` and `E` are real and integer arrays, respectively.

**Tips** This function corresponds to the ANSI C function `ldexp()` and the IEEE floating-point standard function `scalbn()`.

**Examples** For IEEE arithmetic, the statement `X = pow2(F,E)` yields the values:

F	E	X
1/2	1	1
pi/4	2	pi
-3/4	2	-3
1/2	-51	eps
1-eps/2	1024	realmax
1/2	-1021	realmin

**See Also** `log2` | `exp` | `hex2num` | `realmax` | `realmin` | `power` | `mpower`

# power, .^

---

**Purpose** Element-wise power

**Syntax**  
`C = A.^B`  
`C = power(A,B)`

**Description** `C = A.^B` raises each element of `A` to the corresponding power in `B`.

`C = power(A,B)` is an alternate way to execute `A.^B`, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Base

scalar | vector | matrix | multidimensional array

Base, specified as a scalar, vector, matrix, or multidimensional array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### B - Exponent

scalar | vector | matrix | multidimensional array

Exponent, specified as a scalar, vector, matrix, or multidimensional array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Square Each Element of Vector

Create a vector, `A`, and square each element.

```
A = 1:5;
C = A.^2
```

```
C =
```

```
     1     4     9    16    25
```

### Find Inverse of Each Matrix Element

Create a matrix, A, and take the inverse of each element.

```
A = [1 2 3; 4 5 6; 7 8 9];
C = A.^-1
```

```
C =
```

```
    1.0000    0.5000    0.3333
    0.2500    0.2000    0.1667
    0.1429    0.1250    0.1111
```

An inversion of the elements is not equal to the inverse of the matrix, which is instead written  $A^{-1}$  or `inv(A)`.

### Find Roots of Number

Calculate the roots of -1 to the 1/3 power.

```
A = -1;
B = 1/3;
C = A.^B
```

```
C =
```

```
    0.5000 + 0.8660i
```

For negative base A and noninteger B, if `abs(B)` is less than 1, the power function returns the complex roots of A.

Use the `nthroot` function to obtain the real roots.

## power, .^

---

```
C = nthroot(A,3)
```

```
C =
```

```
-1
```

[realpowmpower](#) | [nthroot](#)

**Purpose** Evaluate piecewise polynomial

**Syntax** `v = ppval(pp,xx)`

**Description** `v = ppval(pp,xx)` returns the value of the piecewise polynomial  $f$ , contained in `pp`, at the entries of `xx`. You can construct `pp` using the functions `pchip`, `spline`, or the spline utility `mkpp`.

`v` is obtained by replacing each entry of `xx` by the value of  $f$  there. If  $f$  is scalar-valued, `v` is of the same size as `xx`. `xx` may be  $N$ -dimensional.

If `pp` was constructed by `pchip`, `spline`, or `mkpp` using the orientation of non-scalar function values specified for those functions, then:

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` is a vector of length  $N$ , then `V` has size  $[D1, \dots, Dr, N]$ , with `V(:,...,:,J)` the value of  $f$  at `xx(J)`.

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` has size  $[N1, \dots, Ns]$ , then `V` has size  $[D1, \dots, Dr, N1, \dots, Ns]$ , with `V(:,...,:, J1, ..., Js)` the value of  $f$  at `xx(J1, ..., Js)`.

## Examples

Compare the result of integrating  $\cos(x)$  between 0 and 10 to the result of integrating a piece-wise polynomial approximation of the same function.

```
a = 0; b = 10;
int1 = integral(@cos,a,b)
```

```
int1 =
    -0.5440
```

Create a piece-wise polynomial approximation of  $\cos(x)$  and integrate over the same interval.

```
x = a:b;
y = cos(x);
pp = spline(x,y);
int2 = integral(@(x)ppval(pp,x),a,b)
```

```
int2 =
```

# ppval

---

-0.5485

mkpp | spline | unmkpp

**Purpose**

Folder containing preferences, history, and layout files

**Syntax**

```
prefdir
folder = prefdir
folder = prefdir(1)
```

**Description**

prefdir returns the folder that contains

- Preferences for MATLAB and related products (`matlab.prf`)
- Command history file (`history.m`)
- MATLAB shortcuts (`shortcuts_2.xml`)
- MATLAB desktop layout files (`MATLABDesktop.xml` and `Your_Saved_LayoutMATLABLayout.xml`)
- Other related files

`folder = prefdir` assigns to `folder` the name of the folder containing preferences and related files.

`folder = prefdir(1)` creates a folder for preferences and related files if one does not exist. If the folder does exist, the name is assigned to `folder`.

**Tips**

- You must have write access to the preferences folder. Otherwise, MATLAB generates an error in the Command Window when you try to change preferences. This can happen if the folder is hidden, for example: `myname/.matlab/R2009a`.

**Examples**

View the location of the preferences folder:

```
prefdir
```

---

Make the preferences folder become the current folder:

```
cd(prefdir)
```

# prefdir

---

```
% Then, view the files for customizing MathWorks products:  
dir
```

On Windows platforms, go directly to the preferences folder in Microsoft Windows Explorer

```
winopen(prefdir)
```

## How To

- “Preferences Folder and Files MATLAB Uses When Multiple MATLAB Releases Are Installed”
- “Viewing Hidden Files and Folders”

**Purpose** Open Preferences dialog box

**Syntax** preferences

**Description** preferences displays the Preferences dialog box, from which you can make changes to options for MATLAB and related products.

**See Also** prefdir

**How To** • “Preferences”

# primes

---

**Purpose** Prime numbers less than or equal to input value

**Syntax** `p = primes(n)`

**Description** `p = primes(n)` returns a row vector containing all the prime numbers less than or equal to `n`. The data type of `p` is the same as that of `n`.

**Input Arguments**

**n - Input value**  
scalar, real integer value

Input value, specified as a scalar that is a real integer value.

**Example:** 10

**Example:** `int16(32)`

**Data Types**  
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Examples**

**Primes Less Than or Equal to 25**

```
p = primes(25)
```

```
p =
```

```
     2     3     5     7    11    13    17    19    23
```

**Primes Less Than or Equal to an Unsigned Integer**

```
n = uint16(12);
```

```
p = primes(n)
```

```
p =
```

```
     2     3     5     7    11
```

**See Also** `factor` | `isprime`

**Purpose** Print figure or save to file

**Contents**

Syntax

“Description” on page 1-4621

“Printer Drivers” on page 1-4623

“Graphics Format Files” on page 1-4627

“Printing Options” on page 1-4631

“Paper Sizes” on page 1-4634

“Printing Tips” on page 1-4636

“Examples” on page 1-4639

“Alternatives” on page 1-4641

**Syntax**

```
print
print('argument1', 'argument2', ...)
print(handle, 'filename')
print argument1 argument2 ... argumentn
```

**Description**

print sends the contents of the current figure, including bitmap representations of any user interface controls, to the printer using the device and system printing command defined by printopt.

print('argument1', 'argument2', ...) is the function form of print. It enables you to pass variables for any input arguments. This form is useful for passing file names and handles (for example, print(handle, 'filename')). See “Batch Processing” on page 1-4640 for an example. Also see “Specifying the Figure to Print” on page 1-4639 for further examples.

---

**Note** Print input only takes string variables and handles as inputs. Strings passed in as cell array or struct inputs are not accepted.

---

# print

---

`print argument1 argument2 ... argumentn` prints the figure using the specified arguments.

The following arguments apply to both the function and the command form:

Argument	Description
<code>handle</code>	Print the specified object.
<code>filename</code>	Direct the output to the PostScript file designated by <code>filename</code> . If <code>filename</code> does not include an extension, <code>print</code> appends an appropriate extension.
<code>-ddriver</code>	Print the figure using the specified printer <code>driver</code> , (such as color PostScript). If you omit <code>-ddriver</code> , <code>print</code> uses the default value stored in <code>printopt.m</code> . The table in “Printer Drivers” on page 1-4623 lists all supported device types.
<code>-dformat</code>	Copy the figure to the system Clipboard (Microsoft Windows platforms only). To be valid, the <code>format</code> for this operation must be either <code>-dmeta</code> (Windows Enhanced Metafile) or <code>-dbitmap</code> (Windows Bitmap).
<code>-dformat filename</code>	Export the figure to the specified file using the specified graphics <code>format</code> (such as TIFF). The table of “Graphics Format Files” on page 1-4627 lists all supported graphics file formats.
<code>-smodelname</code>	Print the current Simulink model <code>modelName</code> .
<code>-options</code>	Specify print options that modify the action of the <code>print</code> command. (For example, the <code>-noui</code> option suppresses printing of user interface controls.) “Printing Options” on page 1-4631 lists available options.

## Printer Drivers

The following table shows the more widely used printer drivers supported by MATLAB software. If you do not specify a driver, the default setting shown in the previous table is used. For a list of all supported printer drivers, type `print -d` at the MATLAB prompt. Some things to remember:

- As indicated in “Description” on page 1-4621 the `-d` switch specifies a printer driver or a graphics file format:
  - Specifying a printer driver without a file name or printer name (the `-P` option) sends the output formatted by the specified driver to your default printer, which may not be what you want to do.

---

**Note** On Windows systems, when you use the `-P` option to identify a printer to use, if you specify any driver other than `-dwin` or `-dwinc`, MATLAB writes the output to a file with an appropriate extension but does not send it to the printer. You can then copy that file to a printer.

---

- Specifying a `-dmeta` or a `-dbitmap` graphics format without a file name places the graphic on the system Clipboard, if possible (Windows platforms only).
- Specifying any other graphics format without a file name creates a file in the current folder with a name such as `figureN.fmt`, where `N` is 1, 2, 3, ... and `fmt` indicates the format type, for example, `eps` or `png`.
- Several drivers come from a product called Ghostscript, which is shipped with MATLAB software. The last column indicates when Ghostscript is used.
- Not all drivers are supported on all platforms. Non support is noted in the first column of the table.
- If you specify a particular printer with the `-P` option and do not specify a driver, a default driver for that printer is selected, either by the operating system or by MATLAB, depending on the platform:

- On Windows, the driver associated with this particular printing device is used.
- On Macintosh and UNIX platforms, the driver specified in `printopt.m` is used

See *Selecting the Printer* in the Graphics documentation for more information.

---

**Note** Support for some print options will be removed in a future release. The affected formats have an asterisk (\*) next to the option string in the following table. The asterisks provide a link to the Web site which supplies a form for users to give feedback about these changes.

<b>PostScript Level 2 color</b>	-dpsc2	No
<b>Windows color</b> (Windows only)	-dwinc	No
<b>Windows monochrome</b> (Windows only)	-dwin	No

---

**Tip** Generally, Level 2 PostScript files are smaller and are rendered more quickly when printing than Level 1 PostScript files. However, not all PostScript printers support Level 2, so determine the capabilities of your printer before using those drivers. Level 2 PostScript printing is the default for UNIX platforms. You can change this default by editing the `printopt.m` file. Likewise, if you want color PostScript printing to be the default instead of black-and-white PostScript printing, edit the line in the `printopt.m` file that reads `dev = '-dps2'`; to be `dev = '-dpsc2'`;

---

## Graphics Format Files

To save your figure as a graphics format file, specify a format switch and file name. To set the resolution of the output file for a built-in MATLAB format, use the `-r` switch. (For example, `-r300` sets the output resolution to 300 dots per inch.) The `-r` switch is also supported for Windows Enhanced Metafiles, JPEG, TIFF and PNG files, but is not supported for Ghostscript raster formats. For more information, see “Printing and Exporting without a Display” on page 1-4630 and “Resolution Considerations” on page 1-4633.

---

**Note** When you print to a file, the file name must have fewer than 128 characters, including path name. When you print to a file in your current folder, the filename must have fewer than 126 characters, because MATLAB places `./` or `.\` at the beginning of the filename when referring to it.

---

The following table shows the supported output formats for exporting from figures and the switch settings to use. In some cases, a format is available both as a MATLAB output filter and as a Ghostscript output filter. All formats except for EMF are supported on both Windows and UNIX platforms.

**Note** Support for some print options will be removed in a future release. The affected formats have an asterisk (\*) next to the option string in the following table. The asterisks provide a link to the Web site which supplies a form for users to give feedback about these changes.

<b>Graphics Format</b>	<b>Bitmap or Vector</b>	<b>Print Command Option String</b>	<b>MATLAB or Ghostscript</b>
<b>BMP</b> monochrome BMP	Bitmap	-dbmpmono	Ghostscript
<b>BMP</b> 24-bit BMP	Bitmap	-dbmp16m	Ghostscript
<b>BMP</b> 8-bit (256-color) BMP (this format uses a fixed colormap)	Bitmap	-dbmp256	Ghostscript
<b>BMP</b> 24-bit	Bitmap	-dbmp	MATLAB
<b>EMF</b>	Vector	-dmeta	MATLAB
<b>EPS</b> black and white	Vector	-deps	MATLAB
<b>EPS</b> color	Vector	-depsc	MATLAB
<b>EPS</b> Level 2 black and white	Vector	-deps2	MATLAB
<b>EPS</b> Level 2 color	Vector	-depsc2	MATLAB
<b>HDF</b> 24-bit	Bitmap	-dhdf	MATLAB
<b>ILL</b> (Adobe Illustrator)	Vector	-dill *	MATLAB
<b>JPEG</b> 24-bit	Bitmap	-djpeg	MATLAB
<b>PBM</b> (plain format) 1-bit	Bitmap	-dpbm	Ghostscript

<b>Graphics Format</b>	<b>Bitmap or Vector</b>	<b>Print Command Option String</b>	<b>MATLAB or Ghostscript</b>
<b>PBM</b> (raw format) 1-bit	Bitmap	-dpbmraw	Ghostscript
<b>PCX</b> 1-bit	Bitmap	-dpcxmono	Ghostscript
<b>PCX</b> 24-bit color PCX file format, three 8-bit planes	Bitmap	-dpcx24b	Ghostscript
<b>PCX</b> 8-bit newer color PCX file format (256-color)	Bitmap	-dpcx256	Ghostscript
<b>PCX</b> Older color PCX file format (EGA/VGA, 16-color)	Bitmap	-dpcx16	Ghostscript
<b>PDF</b> Color PDF file format	Vector	-dpdf	Ghostscript
<b>PGM</b> Portable Graymap (plain format)	Bitmap	-dpgm	Ghostscript
<b>PGM</b> Portable Graymap (raw format)	Bitmap	-dpgmraw	Ghostscript
<b>PNG</b> 24-bit	Bitmap	-dpng	MATLAB
<b>PPM</b> Portable Pixmap (plain format)	Bitmap	-dppm	Ghostscript
<b>PPM</b> Portable Pixmap (raw format)	Bitmap	-dppmraw	Ghostscript

<b>Graphics Format</b>	<b>Bitmap or Vector</b>	<b>Print Command Option String</b>	<b>MATLAB or Ghostscript</b>
SVG Scalable Vector Graphics (For Simulink Models Only)	Vector	-dsvg	MATLAB
TIFF 24-bit	Bitmap	-dtiff or -dtiffn	MATLAB
TIFF preview for EPS files	Bitmap	-tiff	

The TIFF image format is supported on all platforms by almost all word processors for importing images. The `-dtiffn` variant writes an uncompressed TIFF. JPEG is a lossy, highly compressed format that is supported on all platforms for image processing and for inclusion into HTML documents on the Web. To create these formats, MATLAB renders the figure using the Z-buffer rendering method and the resulting bitmap is then saved to the specified file.

## Printing and Exporting without a Display

On a UNIX platform (including Macintosh), where you can start in MATLAB `nodisplay` mode (`matlab -nodisplay`), you can print using most of the drivers you can use with a display and export to most of the same file formats. The PostScript and Ghostscript devices all function in `nodisplay` mode on UNIX platforms. The graphic devices `-djpeg`, `-dpng`, `-dtiff` (compressed TIFF bitmaps), and `-tiff` (EPS with TIFF preview) work as well, but under `nodisplay` they use Ghostscript to generate output instead of using the drivers built into MATLAB. However, Ghostscript ignores the `-r` option when generating `-djpeg`, `-dpng`, `-dtiff`, and `-tiff` image files. This means that you cannot vary the resolution of image files when running in `nodisplay` mode.

The same is true for the `-noFigureWindows` startup option which suppresses figures on all platforms. On Windows platforms the `-dwin`, `-dwinc`, and `-dsetup` options operate as usual under `-noFigureWindows`. However, the `printpreview` GUI does not function

in this mode. Naturally, the Windows only `-dwin` and `-dwinc` output formats cannot be used on UNIX or Mac platforms with or without a display.

The formats which you cannot generate in `nodisplay` mode on UNIX and Mac platforms are:

- `bitmap (-dbitmap)` — Windows bitmap file
- `bmp (-dbmp...)` — Monochrome and color bitmaps
- `hdf (-dhdf)` — Hierarchical Data Format
- `svg (-dsvg)` — Scalable Vector Graphics file
- `tifn (-dtifn)` — TIFF image file, no compression

In addition, `uicontrols` do not print or export in `nodisplay` mode.

## Printing Options

This table summarizes options that you can specify for `print`. The second column links to tutorials that provide operational details. Also see “Resolution Considerations” on page 1-4633 for information on controlling output resolution.

---

**Note** Support for some print options will be removed in a future release. The affected formats have an asterisk (\*) next to the option string in the following table. The asterisks provide a link to the Web site which supplies a form for users to give feedback about these changes.

---

Option	Description
<code>-adobecset *</code>	PostScript devices only. Use PostScript default character set encoding. See “Early PostScript 1 Printers”.
<code>-append</code>	PostScript devices only. Append figure to existing PostScript file. See “Settings That Are Driver Specific”.

Option	Description
-cmyk	PostScript devices only. Print with CMYK colors instead of RGB. See “Setting CMYK Color”.
-ddriver	Printing only. Printer driver to use. See “Printer Drivers” on page 1-4623 table.
-dformat	Exporting only. Graphics format to use. See “Graphics Format Files” table.
-dsetup *	Windows printing only. Display the (platform-specific) Print Setup dialog. Settings you make in it are saved, but nothing is printed.
-fhandle	Handle of figure to print. Note that you cannot specify both this option and the <i>-swindowtitle</i> option. See “Which Figure Is Printed”.
-loose	PostScript and Ghostscript printing only. Use loose bounding box for PostScript output. See “Producing Uncropped Figures”.
-noui	Suppress printing of user interface controls. See “Excluding User Interface Controls”.
-opengl	Render using the OpenGL algorithm. Note that you cannot specify this method in conjunction with <i>-zbuffer</i> or <i>-painters</i> . See “Selecting a Renderer”.
-painters	Render using the Painter’s algorithm. Note that you cannot specify this method in conjunction with <i>-zbuffer</i> or <i>-opengl</i> . See “Selecting a Renderer”.
-Pprinter	Specify name of printer to use. See “Selecting the Printer”.

Option	Description
<i>-rnumber</i>	PostScript and built-in raster formats, and Ghostscript vector format only. Specify resolution in dots per inch. Defaults to 90 for Simulink, 150 for figures in image formats and when printing in Z-buffer or OpenGL mode, screen resolution for metafiles, and 864 otherwise. Use <i>-r0</i> to specify screen resolution. For details, see “Resolution Considerations” on page 1-4633 and “Setting the Resolution”.
<i>-swindowtitle</i>	Specify name of Simulink system window to print. Note that you cannot specify both this option and the <i>-fhandle</i> option. See “Which Figure Is Printed”.
<i>-v</i>	Windows printing only. Display the Windows Print dialog box. The <i>v</i> stands for “verbose mode.”
<i>-zbuffer</i>	Render using the Z-buffer algorithm. Note that you cannot specify this method in conjunction with <i>-opengl</i> or <i>-painters</i> . See “Selecting a Renderer”.

### Resolution Considerations

Use *-rnumber* to specify the resolution of the generated output. In general, using a higher value will yield higher quality output but at the cost of larger output files. It affects the resolution and output size of all MATLAB built-in *raster* formats (which are identified in column four of the table in “Graphics Format Files” on page 1-4627).

---

**Note** Built-in graphics formats are generated directly from MATLAB without conversion through the Ghostscript library. Also, in headless (`nodisplay`) mode, writing to certain image formats is not done by built-in drivers, as it is when a display is being used. These formats are `-djpeg`, `-dtiff`, and `-dpng`. Furthermore, the `-dhdf` and `-dbmp` formats cannot be generated in headless mode (but you can substitute `-dbmp16m` for `-dbmp`). See “Printing and Exporting without a Display” on page 1-4630 for details on printing when not using a display.

---

Unlike the built-in MATLAB formats, graphic output generated via Ghostscript does not directly obey `-r` option settings. However, the intermediate PostScript file generated by MATLAB as input for the Ghostscript processor is affected by the `-r` setting and thus can indirectly influence the quality of the final Ghostscript generated output.

The effect of the `-r` option on output quality can be subtle at ordinary magnification when using the OpenGL or ZBuffer renderers and writing to one of the MATLAB built-in raster formats, or when generating vector output that contains an embedded raster image (for example, PostScript or PDF). The effect of specifying higher resolution is more apparent when viewing the output at higher magnification or when printed, since a larger `-r` setting provides more data to use when scaling the image.

When generating fully vectorized output (as when using the Painters renderer to output a vector format such as PostScript or PDF), the resolution setting affects the degree of detail of the output; setting resolution higher generates crisper output (but small changes in the resolution may have no observable effect). For example, the gap widths of lines that do not use a solid (‘-’) linestyle can be affected.

## Paper Sizes

MATLAB printing supports a number of standard paper sizes. You can select from the following list by setting the `PaperType` property of the figure or selecting a supported paper size from the Print dialog box.

<b>Property Value</b>	<b>Size (Width by Height)</b>
usletter	8.5 by 11 inches
uslegal	8.5 by 14 inches
tabloid	11 by 17 inches
A0	841 by 1189 mm
A1	594 by 841 mm
A2	420 by 594 mm
A3	297 by 420 mm
A4	210 by 297 mm
A5	148 by 210 mm
B0	1029 by 1456 mm
B1	728 by 1028 mm
B2	514 by 728 mm
B3	364 by 514 mm
B4	257 by 364 mm
B5	182 by 257 mm
arch-A	9 by 12 inches
arch-B	12 by 18 inches
arch-C	18 by 24 inches
arch-D	24 by 36 inches
arch-E	36 by 48 inches
A	8.5 by 11 inches
B	11 by 17 inches
C	17 by 22 inches

Property Value	Size (Width by Height)
D	22 by 34 inches
E	34 by 43 inches

## Printing Tips

### Setting Default Printer

You can edit the file `printopt.m` to set the default printer type and destination. If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see a printer which is already setup.

### Figures with Resize Functions

The `print` command produces a warning when you print a figure having a callback routine defined for the figure `ResizeFcn`. To avoid the warning, set the figure `PaperPositionMode` property to `auto` or select **Auto (Actual Size, Centered)** in the **File > Print Preview** dialog box.

### Troubleshooting Microsoft Windows Printing

If you encounter problems such as segmentation violations, general protection faults, or application errors, or the output does not appear as you expect when using Microsoft printer drivers, try the following:

- If your printer is PostScript compatible, print with one of the MATLAB built-in PostScript drivers. There are various PostScript device options that you can use with `print`, which all start with `-dps`.
- The behavior you are experiencing might occur only with certain versions of the print driver. Contact the print driver vendor for information on how to obtain and install a different driver.
- Try printing with one of the MATLAB built-in Ghostscript devices. These devices use Ghostscript to convert PostScript files into other formats, such as HP LaserJet, PCX, Canon BubbleJet, and so on.

- Copy the figure as a Windows Enhanced Metafile using the **Edit > Copy Figure** menu item on the figure window menu or the `print -dmeta` option at the command line. You can then import the file into another application for printing.

You can set copy options in the figure's **File > Preferences > Copying Options** dialog box. The Windows Enhanced Metafile Clipboard format produces a better quality image than Windows Bitmap.

### Printing MATLAB GUIs

You can generally obtain better results when printing a figure window that contains MATLAB `uicontrols` by setting these key properties:

- Set the figure `PaperPositionMode` property to `auto`. This ensures that the printed version is the same size as the on-screen version. With `PaperPositionMode` set to `auto` MATLAB does not resize the figure to fit the current value of the `PaperPosition`. This is particularly important if you have specified a figure `ResizeFcn`, because if MATLAB resizes the figure during the print operation, `ResizeFcn` is automatically called.

To set `PaperPositionMode` on the current figure, use the command:

```
set(gcf, 'PaperPositionMode', 'auto')
```

- Set the figure `InvertHardcopy` property to `off`. By default, MATLAB changes the figure background color of printed output to white, but does not change the color of `uicontrols`. If you have set the background color, for example, to match the gray of the GUI devices, you must set `InvertHardcopy` to `off` to preserve the color scheme.

To set `InvertHardcopy` on the current figure, use the command:

```
set(gcf, 'InvertHardcopy', 'off')
```

- Use a color device if you want lines and text that are in color on the screen to be written to the output file as colored objects. Black and

white devices convert colored lines and text to black or white to provide the best contrast with the background and to avoid dithering.

- Use the `print` command's `-loose` option to keep a bounding box from being too tightly wrapped around objects contained in the figure. This is important if you have intentionally used space between `uicontrols` or axes and the edge of the figure and you want to maintain this appearance in the printed output.

If you print or export in `nodisplay` mode, none of the `uicontrols` the figure has will be visible. If you run code that adds `uicontrols` to a figure when the figure is invisible, the controls will not print until the figure is made visible.

## Printing Interpolated Shading with PostScript Drivers

You can print MATLAB surface objects (such as graphs created with `surf` or `mesh`) using interpolated colors. However, only patch objects that are composed of triangular faces can be printed using interpolated shading.

Printed output is always interpolated in RGB space, not in the colormap colors. This means that if you are using indexed color and interpolated face coloring, the printed output can look different from what is displayed on screen.

PostScript files generated for interpolated shading contain the color information of the graphics object's vertices and require the printer to perform the interpolation calculations. This can take an excessive amount of time and in some cases, printers might time out before finishing the print job. One solution to this problem is to interpolate the data and generate a greater number of faces, which can then be flat shaded.

To ensure that the printed output matches what you see on the screen, print using the `-zbuffer` option. To obtain higher resolution (for example, to make text look better), use the `-r` option to increase the resolution. There is, however, a tradeoff between the resolution and the size of the created PostScript file, which can be quite large at higher resolutions. The default resolution of 150 dpi generally produces good

results. You can reduce the size of the output file by making the figure smaller before printing it and setting the figure `PaperPositionMode` to `auto`, or by just setting the `PaperPosition` property to a smaller size.

## Examples

### Specifying the Figure to Print

Pass a figure handle as a variable to the function form of `print`. For example:

```
h = figure;  
plot(1:4,5:8)  
print(h)
```

Save the figure with the handle `h` to a PostScript file named `Figure2`, which can be printed later:

```
print(h, '-dps', 'Figure2.ps')
```

Pass in a file name as a variable:

```
filename = 'mydata';  
print(h, '-dpSC', filename);
```

(Because a file name is specified, the figure will be printed to a file.)

### Specifying the Model to Print

Print a noncurrent Simulink model using the `-s` option with the title of the window (in this case, `f14`):

```
print('-sf14')
```

If the window title includes any spaces, you must call the function form rather than the command form of `print`. For example, this command saves the Simulink window title `Thruster Control`:

```
print('-sThruster Control')
```

To print the current system, use:

```
print('-s')
```

For information about issues specific to printing Simulink windows, see the Simulink documentation.

## Printing Figures at Screen Size

This example prints a surface plot with interpolated shading. Setting the current figure's (gcf) PaperPositionMode to auto enables you to resize the figure window and print it at the size you see on the screen. See “Printing Options” on page 1-4631 and “Printing Interpolated Shading with PostScript Drivers” on page 1-4638 for information on the -zbuffer and -r200 options.

```
surf(peaks)
shading interp
set(gcf, 'PaperPositionMode', 'auto')
print('-dpsc2', '-zbuffer', '-r200')
```

For additional details, see “Printing Images” in the MATLAB Graphics documentation.

## Batch Processing

You can use the function form of print to pass variables containing file names. For example, this for loop uses file names stored in a cell array to create a series of graphs and prints each one with a different file name:

```
fnames = {'file1', 'file2', 'file3'};
for k=1:length(fnames)
    surf(peaks)
    print('-dtiff', '-r200', fnames{k})
end
```

fnames is a cell of string arrays so each element is a string.

## Tiff Preview

The command

```
print('-depsc', '-tiff', '-r300', 'picture1')
```

saves the current figure at 300 dpi, in a color Encapsulated PostScript file named `picture1.eps`. The `-tiff` option creates a 72 dpi TIFF preview, which many word processor applications can display on screen after you import the EPS file. This enables you to view the picture on screen within your word processor and print the document to a PostScript printer using a resolution of 300 dpi.

### Alternatives

Select **File > Print** from the figure window to open the Print dialog box and **File > Print Preview** to open the Print Preview GUI. For details, see “How to Print or Export”.

### See Also

`figure` | `hgsave` | `imwrite` | `orient` | `printdlg` | `printopt` | `saveas`

# printopt

---

**Purpose** Configure printer defaults

**Syntax** [pcmd,dev] = printopt

**Description** [pcmd,dev] = printopt returns strings containing the current system-dependent printing command and output device. printopt is a file used by print to produce the hard-copy output. You can edit the file printopt.m to set your default printer type and destination.

pcmd and dev are platform-dependent strings. pcmd contains the command that print uses to send a file to the printer. dev contains the printer driver or graphics format option for the print command. Their defaults are platform dependent.

Platform	Print Command	Driver or Format
Mac and UNIX	lpr -r	-dps2
Windows	COPY /B %s LPT1:	-dwin

**See Also** printdlg | print

**Purpose** Print dialog box

**Syntax**

```
printdlg  
printdlg(fig)  
printdlg('-crossplatform',fig)  
printdlg('-setup',fig)
```

**Description** `printdlg` prints the current figure.

`printdlg(fig)` creates a modal dialog box from which you can print the figure window identified by the handle `fig`. Note that `uimenu`s do not print.

`printdlg('-crossplatform',fig)` displays the standard cross-platform MATLAB printing dialog rather than the built-in printing dialog box for Microsoft Windows computers. Insert this option before the `fig` argument.

`printdlg('-setup',fig)` forces the printing dialog to appear in a setup mode. This option is obsolete and will be removed in a future release.

---

**Note** If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see the printer which is already setup.

---

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

**See Also** `print` | `printopt` | `printpreview`

# printpreview

---

**Purpose** Preview figure to print

## **Contents**

“Description” on page 1-4644

“Right Pane Controls” on page 1-4645

“The Layout Tab” on page 1-4646

“The Lines/Text Tab” on page 1-4647

“The Color Tab” on page 1-4649

“The Advanced Tab” on page 1-4651

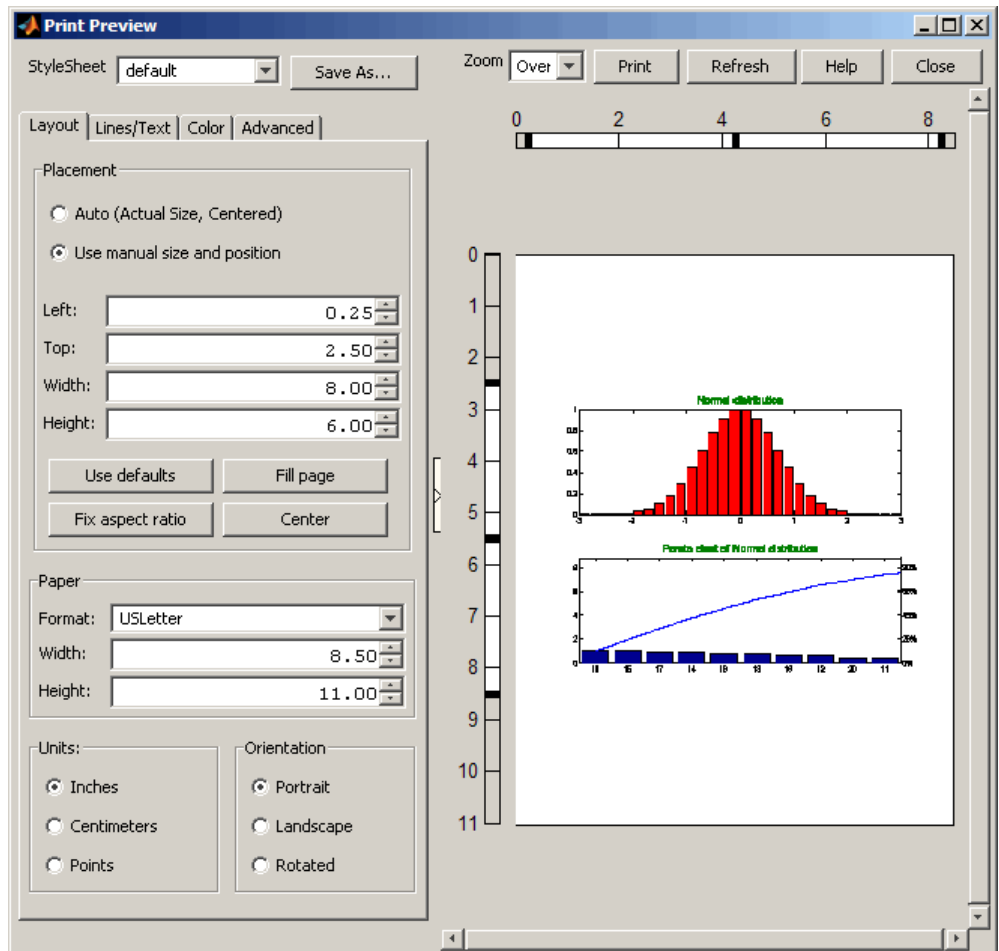

“Alternatives” on page 1-4652

**Syntax**  
`printpreview`  
`printpreview(f)`

**Description** `printpreview` displays a dialog box showing the figure in the currently active figure window as it will print. A scaled version of the figure displays in the right-hand pane of the GUI.

`printpreview(f)` displays a dialog box showing the figure having the handle `f` as it will print.

Use the Print Preview dialog box, shown below, to control the layout and appearance of figures before sending them to a printer or print file. Controls are grouped into four tabbed panes: **Layout**, **Lines/Text**, **Color**, and **Advanced**.

## Right Pane Controls

You can position and scale plots on the printed page using the rulers in the right-hand pane of the Print Preview dialog. Use the outer ruler handlebars to change margins. Moving them changes plot proportions. Use the center ruler handlebars to change the position of the plot on the page. Plot proportions do not change, but you can move portions of

the plot off the paper. The buttons on that pane let you refresh the plot, close the dialog (preserving all current settings), print the page immediately, or obtain context-sensitive help. Use the **Zoom** box and scroll bars to view and position page elements more precisely.

## The Layout Tab

Use the **Layout** tab, shown above, to control the paper format and placement of the plot on printed pages. The following table summarizes the **Layout** options:

Group	Option	Description
Placement	<b>Auto</b>	Let MATLAB decide placement of plot on page*
	<b>Use manual...</b>	Specify position parameters for plot on page*
	<b>Top, Left, Width, Height</b>	Standard position parameters in current units
	<b>Use defaults</b>	Revert to default position
	<b>Fill page</b>	Expand figure to fill printable area (see note below)
	<b>Fix aspect ratio</b>	Correct height/width ratio
	<b>Center</b>	Center plot on printed page
Paper	<b>Format</b>	U.S. and ISO® sheet size selector
	<b>Width, Height</b>	Sheet size in current units
Units	<b>Inches</b>	Use inches as units for dimensions and positions
	<b>Centimeters</b>	Use centimeters as units for dimensions and positions
	<b>Points</b>	Use points as units for dimensions and positions
Orientation	<b>Portrait</b>	Upright paper orientation

Group	Option	Description
	<b>Landscape</b>	Sideways paper orientation
	<b>Rotated</b>	Currently the same as <b>Landscape</b>

\* Selecting **Auto** in the Placement group sets the figure PaperPositionMode to 'auto' and disables the controls in that panel. Selecting **Use manual size and position** sets the figure PaperPositionMode to 'manual' and enables the controls. If you set PaperPositionMode programmatically, the print preview Placement controls respond accordingly.

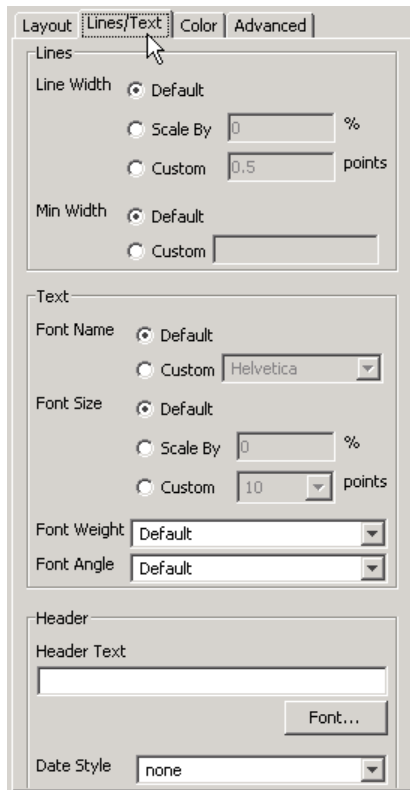

---

**Note** Selecting the **Fill page** option changes the PaperPosition property to fill the page, allowing objects in normalized units to expand to fill the space. If an object within the figure has an absolute size, for example a table, it can overflow the page when objects with normalized units expand. To avoid having objects fall off the page, do not use **Fill page** under such circumstances.

---

### The Lines/Text Tab

Use the **Lines/Text** tab, shown below, to control the line weights, font characteristics, and headers for printed pages. The following table summarizes the **Lines/Text** options:

Group	Option	Description
Lines	<b>Line Width</b>	Scale all lines by a percentage from 0 upward (100 being no change), print lines at a specified point size, or default line widths used on the plot
	<b>Min Width</b>	Smallest line width (in points) to use when printing; defaults to 0.5 point
Text	<b>Font Name</b>	Select a system font for all text on plot, or default to fonts currently used on the plot

Group	Option	Description
	<b>Font Size</b>	Scale all text by a percentage from 0 upward (100 being no change), print text at a specified point size, or default to this
	<b>Font Weight</b>	Select Normal ... Bold font styling for all text from drop-down menu or default to the font weights used on the plot
	<b>Font Angle</b>	Select Normal, Italic or Oblique font styling for all text from drop-down menu or default to the font angles used on the plot
Header	<b>Header Text</b>	Type the text to appear on the header at the upper left of printed pages, or leave blank for no header
	<b>Date Style</b>	Select a date format to have today's date appear at the upper left of printed pages, or none for no date

### The Color Tab

Use the **Color** tab, shown below, to control how colors are printed for lines and backgrounds. The following table summarizes the **Color** options:

Group	Option	Description
Color Scale	<b>Black and White</b>	Select to print lines and text in black and white, but use color for patches and other objects
	<b>Gray Scale</b>	Convert colors to shades of gray on printed pages

Group	Option	Description
	<b>Color</b>	Print everything in color, matching colors on plot; select RGB (default) or CMYK color model for printing
Background Color	<b>Same as figure</b>	Print the figure's background color as it is
	<b>Custom</b>	Select a color name, or type a colorspec for the background; white (default) implies no background color, even on colored paper.

### The Advanced Tab

Use the **Advanced** tab, shown below, to control finer details of printing, such as limits and ticks, renderer, resolution, and the printing of UIControls. The following table summarizes the **Advanced** options:

Group	Option	Description
Axes limits and ticks	<b>Recompute limits and ticks</b>	Redraw $x$ - and $y$ -axes ticks and limits based on printed plot size (default)
	<b>Keep limits and ticks</b>	Use the $x$ - and $y$ -axes ticks and limits shown on the plot when printing the previewed figure
Miscellaneous	<b>Renderer</b>	Select a rendering algorithm for printing: painters, zbuffer, opengl, or auto (default)
	<b>Resolution</b>	Select resolution to print at in dots per inch: 150, 300, 600, or auto (default), or type in any other positive value
	<b>Print UIControls</b>	Print all visible UIControls in the figure (default), or uncheck to exclude them from being printed

## Alternatives

Use **File > Print Preview** on the figure window menu to access the Print Preview dialog box, described below. For details, see “Using Print Preview”.

## How To

- How to Print or Export

**Purpose**

Product of array elements

**Syntax**

```
B = prod(A)
B = prod(A,dim)
B = prod( __ ,type)
```

**Description**

`B = prod(A)` returns the product of the array elements of `A`.

- If `A` is a vector, then `prod(A)` returns the product of the elements.
- If `A` is a nonempty matrix, then `prod(A)` treats the columns of `A` as vectors and returns a row vector of the products of each column.
- If `A` is an empty 0-by-0 matrix, `prod(A)` returns 1.
- If `A` is a multidimensional array, then `prod(A)` acts along the first nonsingleton dimension and returns an array of products. The size of this dimension reduces to 1 while the sizes of all other dimensions remain the same.

`prod` computes and returns `B` as `single` if the input, `A`, is `single`. For all other numeric and logical data types, `prod` computes and returns `B` as `double`.

`B = prod(A,dim)` returns the products along dimension `dim`. For example, if `A` is a matrix, `prod(A,2)` is a column vector containing the products of each row.

`B = prod( __ ,type)` multiplies in and returns an array in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be `'double'` or `'native'`.

**Input Arguments****A - Input array**

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

## dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension  $dim$  indicates the dimension whose length reduces to 1. The  $size(B, dim)$  is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array,  $A$ .

- If  $dim = 1$ , then  $prod(A, 1)$  returns a row vector containing the product of the elements in each column.
- If  $dim = 2$ , then  $prod(A, 2)$  returns a column vector containing the product of the elements in each row.

`prod` returns  $A$  if  $dim$  is greater than  $ndims(A)$ .

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**type - Output class**`'double' | 'native'`

Output class, specified as `'double'` or `'native'`, defines the data type that the operation is performed in and output in.

- If `type` is `'double'`, then `prod` computes and returns a double precision array, regardless of the input data type. For example, if `A` is `single`, then `prod` multiplies in and returns in `double`.
- If `type` is `'native'`, `prod` multiplies natively and returns an array with the same data type as the input array `A`. For example, if `A` is an 8-bit unsigned integer, `prod` multiplies natively and returns `B` with data type `uint8`.

**Data Types**`char`**Output Arguments****B - Product array**`scalar | vector | matrix | multidimensional array`

Product array, returned as a scalar, vector, matrix, or multidimensional array.

The class of `B` is as follows:

- If the `type` argument is not used and the input is not `single`, then the output is `double`.
- If the `type` argument is not used and the input is `single`, then the output is `single`.
- If the `type` argument specifies `'double'`, then the output is `double` regardless of the input data type.
- If the `type` argument specifies `'native'`, then the output is the same data type as the input.

**Definitions****First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If  $X$  is a 1-by- $n$  row vector, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

## Examples

### Product of Elements in Each Column

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

A =

```
     1     4     7
     2     5     8
     3     6     9
```

Find the product of the elements in each column.

```
B = prod(A)
```

B =

```
     6    120    504
```

The length of the first dimension is 1, and the length of the second dimension matches `size(A,2)`.

### Logical Input with Double Output

Create an array of logical values.

```
A = [true false; true true]
```

```
A =  
  
     1     0  
     1     1
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =  
  
     1     0
```

The output is double.

```
class(B)
```

```
ans =
```

```
double
```

### Product of Elements in Each Row

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

```
A =  
  
     1     4     7  
     2     5     8  
     3     6     9
```

Find the product of the elements in each row and reduce the length of the second dimension to 1.

```
dim = 2;  
B = prod(A,dim)
```

B =

```
28
80
162
```

The length of the first dimension matches `size(A,1)`, and the length of the second dimension is 1.

## Product of Elements in Each Plane

Create a 3-by-3-by-2 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9];
A(:,:,2)=[10:3:16;11:3:17;12:3:18]
```

A(:,:,1) =

```
1     4     7
2     5     8
3     6     9
```

A(:,:,2) =

```
10    13    16
11    14    17
12    15    18
```

Find the product of each element in the first plane with its corresponding element in the second plane.

```
dim = 3;
B = prod(A,dim)
```

B =

```
10    52    112
22    70    136
36    90    162
```

The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is 1.

### Single-Precision Input treated as Double

Create a 3-by-3 array of single-precision values.

```
A = single([1200 1500 1800; 1300 1600 1900; 1400 1700 2000])
```

A =

```
1200    1500    1800
1300    1600    1900
1400    1700    2000
```

Find the product of the elements in each row by performing the multiplication in double precision.

```
B = prod(A,2, 'double')
```

B =

```
1.0e+09 *
3.2400
3.9520
4.7600
```

The output is double precision.

```
class(B)
```

```
ans =
```

```
double
```

## Integer Data Type for Input and Output

Create a 3-by-3 array of 8-bit unsigned integers.

```
A = uint8([1:3:7;2:3:8;3:3:9])
```

```
A =
```

```
    1    4    7
    2    5    8
    3    6    9
```

Find the product of the elements in each column natively in `uint8`.

```
B = prod(A, 'native')
```

```
B =
```

```
    6   120   255
```

The result is an array of 8-bit unsigned integers.

```
class(B)
```

```
ans =
```

```
uint8
```

## See Also

cumprod | diff | sum | ndims
```

**Purpose**

Profile execution time for function

**Syntax**

```
profile on
profile -history
profile -nohistory
profile -history -historysize integer
profile -timer clock
profile -history -historysize integer -timer clock
profile off
profile resume
profile clear
profile viewer
S = profile('status')
stats = profile('info')
```

**Description**

The `profile` function helps you debug and optimize MATLAB code files by tracking their execution time. For each MATLAB function, MATLAB local function, or MEX-function in the file, `profile` records information about execution time, number of calls, parent functions, child functions, code line hit count, and code line execution time. Some people use `profile` simply to see the child functions; see also `depfun` for that purpose. To open the Profiler graphical user interface, use the `profile viewer` syntax. By default, Profiler time is CPU time. The total time reported by the Profiler is not the same as the time reported using the `tic` and `toc` functions or the time you would observe using a stopwatch.

---

**Note** If your system uses Intel multi-core chips, you may want to restrict the active number of CPUs to 1 for the most accurate and efficient profiling. See “Intel Multi-Core Processors — Setting for Most Accurate Profiling on Windows Systems” or “Intel Multi-Core Processors — Setting for Most Accurate Profiling on Linux Systems” for details on how to do this.

---

`profile on` starts the Profiler, clearing previously recorded profile statistics. Note the following:

- You can specify all, none, or a subset, of the `history`, `historysize` and `timer` options with the `profile on` syntax.
- You can specify options in any order, including before or after `on`.
- If the Profiler is currently on and you specify `profile` with one of the options, MATLAB software returns an error message and the option has no effect. For example, if you specify `profile timer real`, MATLAB returns the following error: The profiler has already been started. `TIMER` cannot be changed.
- To change options, first specify `profile off`, and then specify `profile on` or `profile resume` with new options.

`profile -history` records the exact sequence of function calls. The `profile` function records, by default, up to 1,000,000 function entry and exit events. For more than 1,000,000 events, `profile` continues to record other profile statistics, but not the sequence of calls. To change the number of function entry and exit events that the `profile` function records, use the `historysize` option. By default, the `history` option is not enabled.

`profile -nohistory` disables further recording of the history (exact sequence of function calls). Use the `-nohistory` option after having previously set the `-history` option. All other profiling statistics continue to be collected.

`profile -history -historysize integer` specifies the number of function entry and exit events to record. By default, `historysize` is set to 1,000,000.

`profile -timer clock` specifies the type of time to use. Valid values for `clock` are:

- `'cpu'` — The Profiler uses computer time (the default).
- `'real'` — The Profiler uses wall-clock time.

For example, `cpu` time for the `pause` function is typically small, but `real` time accounts for the actual time paused, and therefore would be larger.

`profile -history -historysize integer -timer clock` specifies all of the options. Any order is acceptable, as is a subset.

`profile off` stops the Profiler.

`profile resume` restarts the Profiler without clearing previously recorded statistics.

`profile clear` clears the statistics recorded by `profile`.

`profile viewer` stops the Profiler and displays the results in the Profiler window. For more information, see [Profiling for Improving Performance in the Desktop Tools and Development Environment documentation](#).

`S = profile('status')` returns a structure containing information about the current status of the Profiler. The table lists the fields in the order that they appear in the structure.

Field	Values	Default Value
ProfilerStatus	'on' or 'off'	off
DetailLevel	'mmex'	'mmex'
Timer	'cpu' or 'real'	'cpu'
HistoryTracking	'on' or 'off'	'off'
HistorySize	integer	1000000

`stats = profile('info')` displays a structure containing the results. Use this function to access the data generated by `profile`. The table lists the fields in the order that they appear in the structure.

Field	Description
FunctionTable	Structure array containing statistics about each function called
FunctionHistory	Array containing function call history

# profile

---

Field	Description
ClockPrecision	Precision of the profile function's time measurement
ClockSpeed	Estimated clock speed of the CPU
Name	Name of the profiler

The `FunctionTable` field is an array of structures, where each structure contains information about one of the functions or local functions called during execution. The following table lists these fields in the order that they appear in the structure.

Field	Description
CompleteName	Full path to <code>FunctionName</code> , including local functions
FunctionName	Function name; includes local functions
FileName	Full path to <code>FunctionName</code> , with file extension, excluding local functions
Type	MATLAB functions, MEX-functions, and many other types of functions including MATLAB local functions, nested functions, and anonymous functions
NumCalls	Number of times the function was called
TotalTime	Total time spent in the function and its child functions
TotalRecursiveTime	No longer used.
Children	<code>FunctionTable</code> indices to child functions
Parents	<code>FunctionTable</code> indices to parent functions

Field	Description
ExecutedLines	<p>Array containing line-by-line details for the function being profiled.</p> <p>Column 1: Number of the line that executed. If a line was not executed, it does not appear in this matrix.</p> <p>Column 2: Number of times the line was executed</p> <p>Column 3: Total time spent on that line. Note: The sum of Column 3 entries does not necessarily add up to the function's TotalTime.</p>
IsRecursive	BOOLEAN value: Logical 1 (true) if recursive, otherwise logical 0 (false)
PartialData	BOOLEAN value: Logical 1 (true) if function was modified during profiling, for example by being edited or cleared. In that event, data was collected only up until the point when the function was modified.

## Examples

### Profile, View Results, and Save Profile Data as HTML

This example profiles the MATLAB `magic` command and then displays the results in the Profiler window. The example then retrieves the profile data on which the HTML display is based and uses the `profsave` command to save the profile data in HTML form.

```
profile on
plot(magic(35))
profile viewer
p = profile('info');
profsave(p,'profile_results')
```

## Profile, Save Profile Data to a MAT-File, and View Results

Another way to save profile data is to store it in a MAT-file. This example stores the profile data in a MAT-file, clears the profile data from memory, and then loads the profile data from the MAT-file. This example also shows a way to bring the reloaded profile data into the Profiler graphical interface as live profile data, not as a static HTML page.

```
p = profile('info');
save myprofiledata p
clear p
load myprofiledata
profview(0,p)
```

## Profile and Show Results Including History

This example illustrates an effective way to view the results of profiling when the history option is enabled. The history data describes the sequence of functions entered and exited during execution. The `profile` command returns history data in the `FunctionHistory` field of the structure it returns. The history data is a 2-by-n array. The first row contains Boolean values, where 0 means entrance into a function and 1 means exit from a function. The second row identifies the function being entered or exited by its index in the `FunctionTable` field. This example reads the history data and displays it in the MATLAB Command Window.

```
profile on -history
plot(magic(4));
p = profile('info');

for n = 1:size(p.FunctionHistory,2)
    if p.FunctionHistory(1,n)==0
        str = 'entering function: ';
    else
        str = 'exiting function: ';
    end
    disp([str p.FunctionTable(p.FunctionHistory(2,n)).FunctionName])
end
```

end

## How To

- [Profiling for Improving Performance](#)
- [“Profiling Parallel Code”](#)

# profsave

---

**Purpose** Save profile report in HTML format

**Syntax** `profsave`  
`profsave(profinfo)`  
`profsave(profinfo,dirname)`

**Description** `profsave` executes the `profile('info')` function and saves the results in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of the structure returned by `profile`. By default, `profsave` stores the HTML files in a subfolder of the current folder named `profile_results`.

`profsave(profinfo)` saves the profiling results, `profinfo`, in HTML format. `profinfo` is a structure of profiling information returned by the `profile('info')` function.

`profsave(profinfo,dirname)` saves the profiling results, `profinfo`, in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of `profinfo` and stores them in the folder specified by `dirname`.

**Examples** Run profile and save the results.

```
profile on
plot(magic(5))
profile off
profsave(profile('info'),'myprofile_results')
```

**See Also** `profile`

**How To**

- [Profiling for Improving Performance](#)

**Purpose** Open Property Editor

**Syntax**  
`propedit`  
`propedit(handle_list)`

**Description** `propedit` starts the Property Editor, a graphical user interface to the properties of graphics objects. If no current figure exists, `propedit` will create one.

`propedit(handle_list)` edits the properties for the object (or objects) in `handle_list`.

Starting the Property Editor enables plot editing mode for the figure.

**See Also** `inspect` | `plottedit` | `propertyeditor`

# propedit (COM)

---

<b>Purpose</b>	Open built-in property page for control
<b>Syntax</b>	<code>h.propedit</code> <code>propedit(h)</code>
<b>Description</b>	<p><code>h.propedit</code> requests the control to display its built-in property page. Note that some controls do not have a built-in property page. For those controls, this command fails.</p> <p><code>propedit(h)</code> is an alternate syntax for the same operation.</p>
<b>Tips</b>	COM functions are available on Microsoft Windows systems only.
<b>See Also</b>	<code>inspect</code>   <code>get (COM)</code>

<b>Purpose</b>	Class property names
<b>Syntax</b>	<pre>properties('classname') properties(obj) p = properties(...)</pre>
<b>Description</b>	<p><code>properties('classname')</code> displays the names of the public properties for the MATLAB class named by <code>classname</code>. The <code>properties</code> function also displays inherited properties.</p> <p><code>properties(obj)</code> <code>obj</code> can be either a scalar object or an array of objects. When <code>obj</code> is scalar, <code>properties</code> also returns dynamic properties. See “Dynamic Properties — Adding Properties to an Instance” for information on using dynamic properties.</p> <p><code>p = properties(...)</code> returns the property names in a cell array of strings.</p>
<b>Definitions</b>	<p>A property is public when its <code>GetAccess</code> attribute value is <code>public</code> and its <code>Hidden</code> attribute value is <code>false</code> (default values for these attributes). See “Property Attributes” for a complete list of attributes.</p> <p><code>properties</code> is also a MATLAB class-definition keyword. See <code>classdef</code> for more information on class definition keywords.</p>
<b>Examples</b>	<p>Retrieve the names of the public properties of class <code>memmapfile</code> and store the result in a cell array of strings:</p> <pre>p = properties('memmapfile'); p ans =      'writable'     'offset'     'format'     'repeat'     'filename'</pre>

# properties

---

Construct an instance of the MException class and get its properties names:

```
me = MException('Msg:ID', 'MsgText');  
properties(me)  
Properties for class MException:
```

```
    identifier  
    message  
    cause  
    stack
```

## Tutorials

- “Properties”

**Purpose** Show or hide **Property Editor**

**Syntax**

```
propertyeditor('on')
propertyeditor('off')
propertyeditor
propertyeditor(figure_handle,...)
```

**Description** `propertyeditor('on')` displays the Property Editor tool on the current figure.

`propertyeditor('off')` hides the Property Editor on the current figure.

`propertyeditor` toggles the visibility of the Property Editor on the current figure. You can also use `propertyeditor('toggle')` instead for the same functionality.

`propertyeditor(figure_handle,...)` displays or hides the Property Editor on the figure specified by `figure_handle`.

**Tips** If you call `propertyeditor` in a MATLAB program and subsequent lines depend on the Property Editor being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Alternatives** To collectively enable **Plotting Tools**, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the **Plotting Tools**, use the smaller icon . Open or close the **Property Editor** tool from the figure's **View** menu. For details, see “The Property Editor”.

# propertyeditor

---

## **See Also**

**Purpose** Custom property list for object display

**Description** Use the PropertyGroup class to create custom property display lists for class derived from matlab.mixin.CustomDisplay.

**Construction** `P = matlab.mixin.util.PropertyGroup(propertyList)` constructs a property group with the supplied `propertyList`.

`P = matlab.mixin.util.PropertyGroup(propertyList,title)` displays `title` above the list of properties.

## Input Arguments

### **propertyList**

The `propertyList` is either a cell array of property names, or a scalar struct with property name-value pairs.

### **title**

Text to display above properties.

## Properties

### **NumProperties**

The number of properties in the `PropertyList`.

### **Attributes:**

Dependent	true
GetAccess	public
GetObservable	true
SetAccess	private
Transient	true

### **PropertyList**

The list of properties to display, stored as a scalar struct or a cell array of strings.

# matlab.mixin.util.PropertyGroup

---

## Attributes:

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

## Title

An optional Title for the PropertyGroup.

## Attributes:

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

**See Also** [matlab.mixin.CustomDisplay](#) |

**Purpose** Psi (polygamma) function

**Syntax**  
`Y = psi(X)`  
`Y = psi(k,X)`

**Description** `Y = psi(X)` evaluates the  $\psi$  function for each element of array `X`. `X` must be real and nonnegative. The  $\psi$  function, also known as the digamma function, is the logarithmic derivative of the gamma function

$$\begin{aligned}\psi(x) &= \text{digamma}(x) \\ &= \frac{d(\log(\Gamma(x)))}{dx} \\ &= \frac{d(\Gamma(x)) / dx}{\Gamma(x)}\end{aligned}$$

`Y = psi(k,X)` evaluates the  $k$ th derivative of  $\psi$  at the elements of `X`. `psi(0,X)` is the digamma function, `psi(1,X)` is the trigamma function, `psi(2,X)` is the tetragamma function, etc.

## Examples

### Example 1

Use the `psi` function to calculate Euler's constant,  $\gamma$ .

```
format long
-psi(1)
ans =
    0.57721566490153
```

```
-psi(0,1)
ans =
    0.57721566490153
```

### Example 2

The trigamma function of 2, `psi(1,2)`, is the same as  $(\pi^2/6) - 1$ .

```
format long
psi(1,2)
```

```
ans =  
    0.64493406684823
```

```
pi^2/6 - 1  
ans =  
    0.64493406684823
```

gamma | gammainc | gammaln

**Purpose**

Generate view of MATLAB file in specified format

**Syntax**

```
publish(file)
publish(file,format)

publish(file,Name,Value)
publish(file,options)

my_doc = publish(file, __ )
```

**Description**

`publish(file)` generates a view of a MATLAB file in HTML format for sharing your code. For example, `publish('myfile.m')` executes the code in `myfile.m` using the base workspace and saves the formatted code and results in `/html/myfile.html`. The `html` subfolder is relative to the `file` folder.

`publish(file,format)` generates a view of a MATLAB file in the specified file format. The resulting files save to the `html` subfolder for all file formats.

`publish(file,Name,Value)` generates a view of the MATLAB file, `file`, with options specified by one or more name-value pair arguments.

`publish(file,options)` uses the `options` structure to customize the output, which is useful when you want to preconfigure and save your options for repeated use. The `options` structure fields and values correspond to names and values of name-value pair arguments, respectively.

`my_doc = publish(file, __ )` generates a view of the MATLAB file `file`, and returns a string indicating the path of the resulting output file.

## Input Arguments

### **file - MATLAB file**

string

Full or partial path of the MATLAB file for which you want to generate a presentation view, specified as a string.

**Example:** 'myfile.m'

### **format - Output format of published file**

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml' | 'pdf'

Output format of published MATLAB file, specified as one of the following string values.

Output Format	String Value
Hypertext Markup Language	'html' (default)
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

**Example:** `publish('myfile.m','ppt');`

### **options - Options for published output**

MATLAB structure

Options for published output, specified as a structure. Use the options structure instead of name-value pair arguments when you want to reuse the same configuration for publishing multiple MATLAB code files.

The `options` structure field and values correspond to names and values of the name-value pair arguments, respectively.

For example, to specify the PDF output format and the output folder `C:\myPublishedOutput`, use:

```
options = struct('format','pdf','outputDir','C:\myPublishedOutput')
```

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'format','latex','showCode',false` specifies LaTeX output file format and excludes the code from the output.

### Output Options

#### 'format' - Published output file format

`'html'` (default) | `'doc'` | `'latex'` | `'ppt'` | `'xml'` | `'pdf'`

Published output file format, specified as the comma-separated pair consisting of `'format'` and one of the following string values.

Output Format	String Value
Hypertext Markup Language	'html' (default)
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

#### 'outputDir' - Output folder

`' '` (default) | full path

Output folder to which the published document is saved, specified as the comma-separated pair consisting of `'outputDir'` and the full path. You must specify the full path as a string, for example `'C:\myPublishedOutput'`.

The default value, `' '`, specifies the `html` subfolder of the current folder.

### **'stylesheet' - Extensible Stylesheet language (XSL) file**

`' '` (default) | full path to XSL file name

Extensible Stylesheet Language (XSL) file to use when publishing MATLAB code to HTML, XML, or LaTeX format, specified as the comma-separated pair consisting of `'stylesheet'` and the full path to the XSL file. The full path must be a string, for example, `'C:\myStylesheet\stylesheet.xml'`

The default value, `' '`, specifies the MATLAB default style sheet.

### **Figure Options**

#### **'createThumbnail' - Thumbnail image creation**

`true` (default) | `false`

Thumbnail image creation for the published document, specified as the comma-separated pair consisting of `'createThumbnail'` and either `true` or `false`. You can use this thumbnail to represent your file in HTML pages.

#### **'figureSnapMethod' - Published figure window appearance**

`'entireGUIWindow'` (default) | `'print'` | `'getframe'` | `'entireFigureWindow'`

Appearance of published figure windows, including window decorations and background color, specified as the comma-separated pair consisting of `'figureSnapMethod'` and one of the following string values.

String Value	Window Decorations		Background Color	
	GUIs	Figures	GUIs	Figures
<code>'entireGUIWindow'</code> (default)	Included	Excluded	Matches screen	White
<code>'print'</code>	Excluded	Excluded	White	White

**(Continued)**

'getframe'	Excluded	Excluded	Matches screen	Matches screen
'entireFigureWindow'	Included	Included	Matches screen	Matches screen

**'imageFormat' - Published image file format**

'png' | 'epsc2' | 'jpg' | ...

Published image file format, specified as the comma-separated pair consisting of 'imageFormat' and one of the following string values.

<b>'format' Value</b>	<b>Valid 'imageFormat' Value</b>	<b>Default 'imageFormat' Value</b>
'doc'	Any image format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'. If the 'figureSnapMethod' is 'print', then you can also specify 'eps', 'epsc', 'eps2', 'ill', 'meta', and 'pdf'.	'png'
'html'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'

## (Continued)

'latex'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'eps2', except when 'figureSnapMethod' is any one of the following: <ul style="list-style-type: none"><li>• 'getframe'</li><li>• 'entireFigureWindow'</li><li>• 'entireGUIWindow' and the snapped window is a GUI window</li></ul> In these cases the default is 'png'
'pdf'	'bmp' or 'jpg'.	'bmp'
'ppt'	Any format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'.	'png'
'xml'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'

### 'maxHeight' - Maximum height of published images

[] (default) | positive integer value

Maximum height of published images that the code generates, specified as the comma-separated pair consisting of `'maxHeight'` and one of the following values:

- `[]` (default)—Unrestricted height. This value is always used when the `'format'` value is `'pdf'`.
- Positive integer value that specifies the image height in pixels.

### **'maxWidth' - Maximum width of published images**

`[]` (default) | positive integer value

Maximum width of an image that the code generates, specified as the comma-separated pair consisting of `'maxWidth'` and one of the following values:

- `[]` (default)—Unrestricted width. This value is always used when the `'format'` value is `'pdf'`.
- Positive integer value that specifies the image width in pixels.

### **'useNewFigure' - Create new figure**

`true` (default) | `false`

A logical value that determines if MATLAB creates a new Figure window for figures that the code generates, specified as the comma-separated pair consisting of `'useNewFigure'` and one of the following:

- `true` (default)—If the code generates a figure, then MATLAB creates a Figure window with a white background, and at the default size before publishing.
- `false`—MATLAB does not create a figure window.

This value enables you to use a figure with different properties for publishing. For example, open a Figure window, change the size and background color, and then publish your code. Figures in your published document use the characteristics of the figure you opened before publishing.

## Code Options

### **'evalCode' - Option to run code**

true (default) | false

Option to evaluate code and include the MATLAB output in the published view, specified as a logical value.

### **'catchError' - Error handling during publishing**

true (default) | false

Error handling during publishing, specified as the comma-separated pair consisting of 'catchError' and one of the following logical values:

- true (default)—MATLAB continues publishing and includes the error in the published file.
- false—MATLAB displays the error at the command line and does not produce a published file.

### **'codeToEvaluate' - Additional code to evaluate during publishing**

string

Additional code to evaluate during publishing, specified as the comma-separated pair consisting of 'codeToEvaluate' and the string with the corresponding code. Use this option to specify code that does not appear in the MATLAB file, for example to set the value of an input argument for a function being published.

If this option is unspecified, MATLAB evaluates only the code in the MATLAB file you are publishing.

### **'maxOutputLines' - Maximum number of lines**

Inf (default) | Nonnegative integer value

Maximum number of lines in MATLAB output per cell evaluated during publishing, specified as the comma-separated pair consisting of 'maxOutputLines' and one of the following values:

- Inf (default)—MATLAB includes all output lines in the published output.

- Nonnegative integer—MATLAB truncates the number of lines in the output at the number of lines you specify.

**'showCode' - Option to include code in published file**

true (default) | false

Option to include code in published file, specified as the comma-separated pair consisting of 'maxOutputLines' and a logical value.

**Tips**

- If 'format' is 'html', MATLAB includes the code being published at the end of the published HTML file as comments, even when you set the 'showCode' option to false. Because MATLAB includes the code as comments, this code does not display in a Web browser. This enables you to use the grabcode function to extract the MATLAB code from an HTML file, even when the file does not display the code.
- MATLAB does not preserve syntax highlighting when you set 'format' to any of the following:
  - 'latex'
  - 'doc'
  - 'ppt'

**Definitions****Window Decorations**

Window decorations include window title bar, toolbar, menu bar, and window border.

**Syntax Highlighting**

Syntax highlighting colors various elements in code to help you identify these elements while reading or editing code. By default, keywords are blue, strings are purple, and unterminated strings are maroon.

**Examples****Generate HTML View of MATLAB Script**

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file, `fourier_demo2.m`, to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...  
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Generate an HTML view of the MATLAB file.

```
publish('fourier_demo2.m');
```

The `publish` command executes the code for each cell in `fourier_demo2.m`, and saves the file to `/html/fourier_demo2.html`.

View the HTML file.

```
web('html/fourier_demo2.html')
```

## **Generate View of MATLAB Script in Microsoft Word Format**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...  
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the file in Microsoft Word format.

```
publish('fourier_demo2.m','doc');
```

View the published output.

```
winopen('html/fourier_demo2.doc')
```

## **Publish MATLAB Script Using Name-Value Pairs to Customize the Output**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use name-value pair arguments to include window decorations in the published output.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...  
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the example MATLAB file to Microsoft Word format.

```
publish('fourier_demo2.m', 'figureSnapMethod', 'entireFigureWindow')
```

The 'figureSnapMethod','entireFigureWindow' name-value pair argument specifies to include the window decorations in the figures, and to match the figure background color to the screen color.

View the published output.

```
web('html/fourier_demo2.html')
```

### **Customize publish Output Using Options Structure**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use a structure to customize the published output.

Specifying options as a structure is useful when you want to preconfigure and save your options for repeated use.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...  
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Define options to customize the published output as a structure, `options_doc_nocode`.

```
options_doc_nocode.format = 'doc';  
options_doc_nocode.showCode = false;
```

Publish the file, specifying the options structure.

```
publish('fourier_demo2.m',options_doc_nocode);
```

## Save File Path of Published Script to Variable

Generate an HTML view of a MATLAB script, and save the path of the published HTML file to a variable.

This example assumes that the current folder is `C:\my_MATLAB_files`.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...  
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the MATLAB file, and save the path of the resulting published HTML file to an output variable.

```
mydoc = publish('fourier_demo2.m')
```

```
mydoc =
```

```
C:\my_MATLAB_files\html\fourier_demo2.html
```

## Concepts

- “Publishing MATLAB Code”
- “Publishing Markup”

## Purpose

Store character array in Automation server

## Syntax

### MATLAB Client

```
h.PutCharArray('varname', 'workspace', 'string')
PutCharArray(h, 'varname', 'workspace', 'string')
invoke(h, 'PutCharArray', 'varname', 'workspace', 'string')
```

### IDL Method Signature

```
PutCharArray([in] BSTR varname, [in] BSTR workspace,
[in] BSTR string)
```

### Microsoft Visual Basic Client

```
PutCharArray(varname As String, workspace As String,
string As String)
```

## Description

PutCharArray stores the character array in `string` in the specified workspace of the server attached to handle `h`, assigning to it the variable `varname`. The workspace argument can be either `base` or `global`.

## Tips

The character array specified in the `string` argument can have any dimensions. However, PutCharArray changes the dimensions to a 1-by-n column-wise representation, where n is the number of characters in the array. Executing the following commands in MATLAB illustrates this behavior:

```
h = actxserver('matlab.application');
chArr = ['abc'; 'def'; 'ghk']
chArr =
abc
def
ghk

h.PutCharArray('Foo', 'base', chArr)
tstArr = h.GetCharArray('Foo', 'base')
tstArr =
adgbehcfk
```

# PutCharArray

---

Server function names, like `PutCharArray`, are case sensitive when using the dot notation syntax shown in the Syntax section.

There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

## Examples

Store string `str` in the base workspace of the server using `PutCharArray`.

### MATLAB Client

```
h = actxserver('matlab.application');
h.PutCharArray('str', 'base', ...
    'He jests at scars that never felt a wound.')

S = h.GetCharArray('str', 'base')
S =
    He jests at scars that never felt a wound.
```

### Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab As Object
Try
    Matlab = GetObject(, "matlab.application")
Catch e As Exception
    Matlab = CreateObject("matlab.application")
End Try
MsgBox("MATLAB window created; now open it...")
```

Open the MATLAB window, then click **Ok**.

```
Matlab.PutCharArray("str", "base", _
    "He jests at scars that never felt a wound.")
MsgBox("In MATLAB, type" & vbCrLf _
    & "str")
```

In the MATLAB window type `str`; MATLAB displays:

```
str =  
He jests at scars that never felt a wound.
```

Click **Ok**.

```
MsgBox("closing MATLAB window...")
```

Click **Ok** to close and terminate MATLAB.

```
Matlab.Quit()
```

## See Also

[GetCharArray](#) | [PutWorkspaceData](#) | [GetWorkspaceData](#) | [Execute](#)

# PutFullMatrix

---

**Purpose** Matrix in Automation server workspace

**Syntax** **MATLAB Client**  
h.PutFullMatrix('varname', 'workspace', xreal, ximag)  
PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)

## IDL Method Signature

```
PutFullMatrix([in] BSTR varname, [in] BSTR workspace,  
[in] SAFEARRAY(double) xreal, [in] SAFEARRAY(double) ximag)
```

## Microsoft Visual Basic Client

```
PutFullMatrix([in] varname As String, [in] workspace As String,  
[in] xreal As Double, [in] ximag As Double)
```

**Description** h.PutFullMatrix('varname', 'workspace', xreal, ximag) stores a matrix in the specified workspace of the server attached to handle h and assigns it to variable varname. Use xreal and ximag for the real and imaginary parts of the matrix. The matrix cannot be a scalar, an empty array, or have more than two dimensions. The values for *workspace* are base or global.

PutFullMatrix(h, 'varname', 'workspace', xreal, ximag) is an alternate syntax.

For VBScript clients, use the GetWorkspaceData and PutWorkspaceData functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of safearray which is not supported by VBScript.

**Examples** This example uses a MATLAB client to write a matrix to the base workspace of the server:

```
h = actxserver('matlab.application');  
h.PutFullMatrix('M', 'base', rand(5), zeros(5))  
%Use one output for real values only  
xreal = h.GetFullMatrix('M', 'base', zeros(5), zeros(5))
```

This example uses a Visual Basic .NET client to write a matrix to the base workspace of the server:

```
Dim MatLab As Object
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim ZReal(4, 4) As Double
Dim ZImag(4, 4) As Double
Dim i, j As Integer

For i = 0 To 4
    For j = 0 To 4
        XReal(i, j) = Rnd() * 6
        XImag(i, j) = 0
    Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("M", "base", XReal, XImag)
MatLab.GetFullMatrix("M", "base", ZReal, ZImag)
```

Use a MATLAB client to write a matrix to the global workspace of the server:

```
h = actxserver('matlab.application');
h.PutFullMatrix('X', 'global', [1 3 5; 2 4 6], ...
    [1 1 1; 1 1 1])
h.invoke('Execute', 'whos global')
```

Use a Visual Basic .NET client to write a matrix to the global workspace of the server:

```
Dim MatLab As Object
```

# PutFullMatrix

---

```
Dim XReal(1,2) As Double
Dim XImag(1,2) As Double
Dim result As String
Dim i,j As Integer

For i = 0 To 1
  For j = 0 To 2
    XReal(i,j) = (j * 2 + 1) + i
    XImag(i,j) = 1
  Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("X","global",XReal,XImag)
result = Matlab.Execute("whos global")
MsgBox(result)
```

## How To

- “MATLAB COM Automation Server Interface”
- “Exchanging Data with the Server”

## Purpose

Data in Automation server workspace

## Syntax

### MATLAB Client

```
h.PutWorkspaceData('varname','workspace',data)
PutWorkspaceData(h,'varname','workspace',data)
```

### IDL Method Signature

```
PutWorkspaceData([in] BSTR varname, [in] BSTR workspace,
[in] VARIANT data)
```

### Microsoft Visual Basic Client

```
PutWorkspaceData(varname As String, workspace As String,
data As Object)
```

## Description

`h.PutWorkspaceData('varname','workspace',data)` stores data in the workspace of the server attached to handle `h` and assigns it to `varname`. The values for `workspace` are `base` or `global`.

`PutWorkspaceData(h,'varname','workspace',data)` is an alternate syntax.

Use `PutWorkspaceData` to pass numeric and character array data respectively to the server. Do *not* use `PutWorkspaceData` on sparse arrays, structures, or function handles. Use the `Execute` method for these data types.

The `GetWorkspaceData` and `PutWorkspaceData` functions pass numeric data as a variant data type. These functions are especially useful for VBScript clients as VBScript does not support the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`.

## Examples

Create an array in a MATLAB client and put it in the base workspace of the MATLAB Automation server:

```
h = actxserver('matlab.application');
for i = 0:6
    data(i+1) = i * 15;
end
```

# PutWorkspaceData

---

```
h.PutWorkspaceData('A','base',data)
```

---

Create an array in a Visual Basic .NET client and put it in the base workspace of the MATLAB Automation server:

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application:

```
Dim Matlab As Object
Dim data(6) As Double
Dim i As Integer
MatLab = CreateObject("matlab.application")
For i = 0 To 6
    data(i) = i * 15
Next i
MatLab.PutWorkspaceData("A","base",data)
MsgBox("In MATLAB, type" & vbCrLf & "A")
```

- 2 Open the MATLAB window and type A. MATLAB displays:

```
A =
     0     15     30     45     60     75     90
```

- 3 Click **Ok** to close and terminate MATLAB.

## How To

- “Executing Commands in the MATLAB Server”
- “Exchanging Data with the Server”

<b>Purpose</b>	Identify current folder
<b>Syntax</b>	<code>pwd</code> <code>currentFolder = pwd</code>
<b>Description</b>	<code>pwd</code> displays the MATLAB current folder. <code>currentFolder = pwd</code> returns the current folder as a string to <code>currentFolder</code> .
<b>Alternatives</b>	<ul style="list-style-type: none"><li>• Use the Current Folder toolbar.</li></ul>
<b>See Also</b>	<code>cd</code>   <code>dir</code>

**Purpose** Quasi-minimal residual method

**Syntax**

```
x = qmr(A,b)
qmr(A,b,tol)
qmr(A,b,tol,maxit)
qmr(A,b,tol,maxit,M)
qmr(A,b,tol,maxit,M1,M2)
qmr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = qmr(A,b,...)
[x,flag,relres] = qmr(A,b,...)
[x,flag,relres,iter] = qmr(A,b,...)
[x,flag,relres,iter,resvec] = qmr(A,b,...)
```

**Description** `x = qmr(A,b)` attempts to solve the system of linear equations  $A^*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A^*x$  and `afun(x, 'transp')` returns  $A' * x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `qmr` converges, a message to that effect is displayed. If `qmr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A^*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`qmr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `qmr` uses the default,  $1e-6$ .

`qmr(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `qmr` uses the default,  $\min(n,20)$ .

`qmr(A,b,tol,maxit,M)` and `qmr(A,b,tol,maxit,M1,M2)` use preconditioners  $M$  or  $M = M1 * M2$  and effectively solve the system  $\text{inv}(M) * A^*x = \text{inv}(M) * b$  for  $x$ . If  $M$  is `[]` then `qmr` applies no

preconditioner.  $M$  can be a function handle  $mfun$  such that  $mfun(x, 'notransp')$  returns  $M \setminus x$  and  $mfun(x, 'transp')$  returns  $M' \setminus x$ .

$qmr(A,b,tol,maxit,M1,M2,x0)$  specifies the initial guess. If  $x0$  is  $[]$ , then  $qmr$  uses the default, an all zero vector.

$[x,flag] = qmr(A,b,...)$  also returns a convergence flag.

Flag	Convergence
0	$qmr$ converged to the desired tolerance $tol$ within $maxit$ iterations.
1	$qmr$ iterated $maxit$ times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	The method stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during $qmr$ became too small or too large to continue computing.

Whenever  $flag$  is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the  $flag$  output is specified.

$[x,flag,relres] = qmr(A,b,...)$  also returns the relative residual norm  $\|b-A*x\|/\|b\|$ . If  $flag$  is 0,  $relres \leq tol$ .

$[x,flag,relres,iter] = qmr(A,b,...)$  also returns the iteration number at which  $x$  was computed, where  $0 \leq iter \leq maxit$ .

$[x,flag,relres,iter,resvec] = qmr(A,b,...)$  also returns a vector of the residual norms at each iteration, including  $\|b-A*x0\|$ .

## Examples

### Using $qmr$ with a Matrix Input

This example shows how to use  $qmr$  with a matrix input. The code:

```
n = 100;
on = ones(n,1);
```

```
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8; maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = qmr(A,b,tol,maxit,M1,M2);
```

displays the message:

```
qmr converged at iteration 9 to a solution...
with relative residual
5.6e-009
```

### Using qmr with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_qmr` that

- Calls `qmr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_qmr` are available to `afun`.

The following shows the code for `run_qmr`:

```
function x1 = run_qmr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = qmr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
    if strcmp(transp_flag,'transp')
        y = 4 * x;
    else
        y = A'*x;
    end
```

```

        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
        y(2:n) = y(2:n) - x(1:n-1);
    elseif strcmp(transp_flag,'notransp') % y = A*x
        y = 4 * x;
        y(2:n) = y(2:n) - 2 * x(1:n-1);
        y(1:n-1) = y(1:n-1) - x(2:n);
    end
end
end
end

```

When you enter

```
x1=run_qmr;
```

MATLAB software displays the message

```
qmr converged at iteration 9 to a solution with relative residual
5.6e-009
```

### Using a Preconditioner

This example demonstrates the use of a preconditioner.

#### 1

Load A = west0479, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

#### 2

Define b so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

#### 3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

## 4

Use `qmr` to find a solution at the requested tolerance and number of iterations:

```
[x0,f10,rr0,it0,rv0] = qmr(A,b,tol,maxit);
```

`f10` is 1 because `qmr` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

## 5

Plot the behavior of `qmr`:

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

## 6

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = qmr(A,b,tol,maxit,L,U);
```

f11 is 0 because qmr drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

## 8

You can follow the progress of qmr by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

| `function_handle` | `mldivide`

**Purpose** Orthogonal-triangular decomposition

**Syntax**

```
[Q,R] = qr(A)
[Q,R] = qr(A,0)
[Q,R,E] = qr(A)
[Q,R,E] = qr(A,'matrix')
[Q,R,e] = qr(A,'vector')
[Q,R,e] = qr(A,0)
X = qr(A)
X = qr(A,0)
R = qr(A)
R = qr(A,0)
[C,R] = qr(A,B)
[C,R,E] = qr(A,B)
[C,R,E] = qr(A,B,'matrix')
[C,R,e] = qr(A,B,'vector')
[C,R] = qr(A,B,0)
[C,R,e] = qr(A,B,0)
```

**Description**  $[Q,R] = qr(A)$ , where  $A$  is  $m$ -by- $n$ , produces an  $m$ -by- $n$  upper triangular matrix  $R$  and an  $m$ -by- $m$  unitary matrix  $Q$  so that  $A = Q \cdot R$ .

$[Q,R] = qr(A,0)$  produces the economy-size decomposition. If  $m > n$ , only the first  $n$  columns of  $Q$  and the first  $n$  rows of  $R$  are computed. If  $m \leq n$ , this is the same as  $[Q,R] = qr(A)$ .

If  $A$  is full:

$[Q,R,E] = qr(A)$  or  $[Q,R,E] = qr(A,'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A \cdot E = Q \cdot R$ . The column permutation  $E$  is chosen so that  $\text{abs}(\text{diag}(R))$  is decreasing.

$[Q,R,e] = qr(A,'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:,e) = Q \cdot R$ .

$[Q,R,e] = qr(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:,e) = Q \cdot R$ .

$X = \text{qr}(A)$  and  $X = \text{qr}(A,0)$  return a matrix  $X$  such that  $\text{triu}(X)$  is the upper triangular factor  $R$ .

If  $A$  is sparse:

$R = \text{qr}(A)$  computes a Q-less QR decomposition and returns the upper triangular factor  $R$ . Note that  $R = \text{chol}(A' * A)$ . Since  $Q$  is often nearly full, this is preferred to  $[Q,R] = \text{QR}(A)$ .

$R = \text{qr}(A,0)$  produces economy-size  $R$ . If  $m > n$ ,  $R$  has only  $n$  rows. If  $m \leq n$ , this is the same as  $R = \text{qr}(A)$ .

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A * E = Q * R$ . The column permutation  $E$  is chosen to reduce fill-in in  $R$ .

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:,e) = Q * R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:,e) = Q * R$ .

$[C,R] = \text{qr}(A,B)$ , where  $B$  has as many rows as  $A$ , returns  $C = Q' * B$ . The least-squares solution to  $A * X = B$  is  $X = R \setminus C$ .

$[C,R,E] = \text{qr}(A,B)$  or  $[C,R,E] = \text{qr}(A,B, 'matrix')$ , also returns a fill-reducing ordering. The least-squares solution to  $A * X = B$  is  $X = E * (R \setminus C)$ .

$[C,R,e] = \text{qr}(A,B, 'vector')$  returns the permutation information as a vector instead of a matrix. That is, the least-squares solution to  $A * X = B$  is  $X(e,:) = R \setminus C$ .

$[C,R] = \text{qr}(A,B,0)$  produces economy-size results. If  $m > n$ ,  $C$  and  $R$  have only  $n$  rows. If  $m \leq n$ , this is the same as  $[C,R] = \text{qr}(A,B)$ .

$[C,R,e] = \text{qr}(A,B,0)$  additionally produces a fill-reducing permutation vector  $e$ . In this case, the least-squares solution to  $A * X = B$  is  $X(e,:) = R \setminus C$ .

## Examples

Find the least squares approximate solution to  $A*x = b$  with the Q-less QR decomposition and one step of iterative refinement:

```
if issparse(A), R = qr(A);  
else R = triu(qr(A)); end  
x = R\ (R'\ (A'*b));  
r = b - A*x;  
err = R\ (R'\ (A'*r));  
x = x + err;
```

**Purpose** Remove column or row from QR factorization

**Syntax**

```
[Q1,R1] = qrdelete(Q,R,j)
[Q1,R1] = qrdelete(Q,R,j,'col')
[Q1,R1] = qrdelete(Q,R,j,'row')
```

**Description**

`[Q1,R1] = qrdelete(Q,R,j)` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the column `A(:,j)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

`[Q1,R1] = qrdelete(Q,R,j,'col')` is the same as `qrdelete(Q,R,j)`.

`[Q1,R1] = qrdelete(Q,R,j,'row')` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the row `A(j,:)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

**Examples**

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
[Q1,R1] = qrdelete(Q,R,j,'row');
```

```
Q1 =

## Algorithms

The `qrdelete` function uses a series of Givens rotations to zero out the appropriate elements of the factorization.

## See Also

`planerot` | `qr` | `qrinsert`

**Purpose** Insert column or row into QR factorization

**Syntax**

```
[Q1,R1] = qrinsert(Q,R,j,x)
[Q1,R1] = qrinsert(Q,R,j,x,'col')
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

**Description** [Q1,R1] = qrinsert(Q,R,j,x) returns the QR factorization of the matrix A1, where A1 is  $A = Q^*R$  with the column x inserted before  $A(:,j)$ . If A has n columns and  $j = n+1$ , then x is inserted after the last column of A.

[Q1,R1] = qrinsert(Q,R,j,x,'col') is the same as qrinsert(Q,R,j,x).

[Q1,R1] = qrinsert(Q,R,j,x,'row') returns the QR factorization of the matrix A1, where A1 is  $A = Q^*R$  with an extra row, x, inserted before  $A(j,:)$ .

## Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
x = 1:5;
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

## Algorithms

The `qrinsert` function inserts the values of `x` into the `j`th column (row) of `R`. It then uses a series of Givens rotations to zero out the nonzero elements of `R` on and below the diagonal in the `j`th column (row).

## See Also

`planerot` | `qr` | `qrdelete`

**Purpose** Rank 1 update to QR factorization

**Syntax** `[Q1,R1] = qrupdate(Q,R,u,v)`

**Description** `[Q1,R1] = qrupdate(Q,R,u,v)` when `[Q,R] = qr(A)` is the original QR factorization of A, returns the QR factorization of  $A + u \cdot v'$ , where u and v are column vectors of appropriate lengths.

**Tips** qrupdate works only for full matrices.

**Examples** The matrix

```
mu = sqrt(eps)
```

```
mu =
```

```
1.4901e-08
```

```
A = [ones(1,4); mu*eye(4)];
```

is a well-known example in least squares that indicates the dangers of forming  $A' \cdot A$ . Instead, we work with the QR factorization – orthonormal Q and upper triangular R.

```
[Q,R] = qr(A);
```

As we expect, R is upper triangular.

```
R =
```

```
-1.0000    -1.0000    -1.0000    -1.0000
         0     0.0000     0.0000     0.0000
         0         0     0.0000     0.0000
         0         0         0     0.0000
         0         0         0         0
```

# qrupdate

---

In this case, the upper triangular entries of R, excluding the first row, are on the order of  $\sqrt{\text{eps}}$ .

Consider the update vectors

$$u = [-1 \ 0 \ 0 \ 0 \ 0]'; \quad v = \text{ones}(4,1);$$

Instead of computing the rather trivial QR factorization of this rank one update to A from scratch with

$$[QT,RT] = \text{qr}(A + u*v')$$

QT =

$$\begin{bmatrix} 0 & 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 \end{bmatrix}$$

RT =

$$1.0\text{e-}007 * \begin{bmatrix} -0.1490 & 0 & 0 & 0 & 0 \\ 0 & -0.1490 & 0 & 0 & 0 \\ 0 & 0 & -0.1490 & 0 & 0 \\ 0 & 0 & 0 & 0 & -0.1490 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

we may use `qrupdate`.

$$[Q1,R1] = \text{qrupdate}(Q,R,u,v)$$

Q1 =

$$\begin{bmatrix} -0.0000 & -0.0000 & -0.0000 & -0.0000 & 1.0000 \\ 1.0000 & -0.0000 & -0.0000 & -0.0000 & 0.0000 \end{bmatrix}$$

```

    0.0000    1.0000   -0.0000   -0.0000    0.0000
    0.0000    0.0000    1.0000   -0.0000    0.0000
   -0.0000   -0.0000   -0.0000    1.0000    0.0000

```

R1 =

```

1.0e-007 *
0.1490    0.0000    0.0000    0.0000
      0    0.1490    0.0000    0.0000
      0      0    0.1490    0.0000
      0      0      0    0.1490
      0      0      0      0

```

Note that both factorizations are correct, even though they are different.

## Algorithms

qrupdate uses the algorithm in section 12.5.1 of the third edition of *Matrix Computations* by Golub and van Loan. qrupdate is useful since, if we take  $N = \max(m, n)$ , then computing the new QR factorization from scratch is roughly an  $O(N^3)$  algorithm, while simply updating the existing factors in this way is an  $O(N^2)$  algorithm.

cholupdate | qr

# quad

---

## Purpose

Numerically evaluate integral, adaptive Simpson quadrature  
quad will be removed in a future release. Use `integral` instead.

## Syntax

```
q = quad(fun,a,b)
q = quad(fun,a,b,tol)
q = quad(fun,a,b,tol,trace)
[q,fcnt] = quad(...)
```

## Description

*Quadrature* is a numerical method used to find the area under the graph of a function, that is, to compute a definite integral.

$$q = \int_a^b f(x) dx$$

`q = quad(fun,a,b)` tries to approximate the integral of function `fun` from `a` to `b` to within an error of  $1e-6$  using recursive adaptive Simpson quadrature. `fun` is a function handle. Limits `a` and `b` must be finite. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, the integrand evaluated at each element of `x`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quad(fun,a,b,tol)` uses an absolute error tolerance `tol` instead of the default which is  $1.0e-6$ . Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results. In MATLAB version 5.3 and earlier, the `quad` function used a less reliable algorithm and a default relative tolerance of  $1.0e-3$ .

`q = quad(fun,a,b,tol,trace)` with non-zero `trace` shows the values of [`fcnt` `a` `b-a` `Q`] during the recursion.

`[q,fcnt] = quad(...)` returns the number of function evaluations.

The function `quadl` may be more efficient with high accuracies and smooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

To compute the integral

$$\int_0^2 \frac{1}{x^3 - 2x - 5} dx,$$

write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

# quad

---

Then pass `@myfun`, a function handle to `myfun`, to `quad`, along with the limits of integration, 0 to 2:

```
Q = quad(@myfun,0,2)
```

```
Q =
```

```
-0.4605
```

Alternatively, you can pass the integrand to `quad` as an anonymous function handle `F`:

```
F = @(x)1./(x.^3-2*x-5);
```

```
Q = quad(F,0,2);
```

## Algorithms

`quad` implements a low order method using an adaptive recursive Simpson's rule.

## Diagnostics

`quad` may issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

**How To**

- “Anonymous Functions”

# quad2d

---

**Purpose** Numerically evaluate double integral, tiled method

**Syntax**  
`q = quad2d(fun,a,b,c,d)`  
`[q,errbnd] = quad2d(...)`  
`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)`

**Description** `q = quad2d(fun,a,b,c,d)` approximates the integral of `fun(x,y)` over the planar region  $a \leq x \leq b$  and  $c(x) \leq y \leq d(x)$ . `fun` is a function handle, `c` and `d` may each be a scalar or a function handle. All input functions must be vectorized. The function `Z=fun(X,Y)` must accept 2-D matrices `X` and `Y` of the same size and return a matrix `Z` of corresponding values. The functions `ymin=c(X)` and `ymax=d(X)` must accept matrices and return matrices of the same size with corresponding values.

`[q,errbnd] = quad2d(...)`. `errbnd` is an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)` performs the integration as above with specified values of optional parameters:

<code>AbsTol</code>	absolute error tolerance
<code>RelTol</code>	relative error tolerance

`quad2d` attempts to satisfy  $ERRBND \leq \max(AbsTol, RelTol * |Q|)$ . This is absolute error control when  $|Q|$  is sufficiently small and relative error control when  $|Q|$  is larger. A default tolerance value is used when a tolerance is not specified. The default value of `AbsTol` is  $1e-5$ . The default value of `RelTol` is  $100 * \text{eps}(\text{class}(Q))$ . This is also the minimum value of `RelTol`. Smaller `RelTol` values are automatically increased to the default value.

<code>MaxFunEvals</code>	Maximum allowed number of evaluations of <code>fun</code> reached.
--------------------------	--------------------------------------------------------------------

The `MaxFunEvals` parameter limits the number of vectorized calls to `fun`. The default is 2000.

<code>FailurePlot</code>	Generate a plot if <code>MaxFunEvals</code> is reached.
--------------------------	---------------------------------------------------------

Setting `FailurePlot` to `true` generates a graphical representation of the regions needing further refinement when `MaxFunEvals` is reached. No plot is generated if the integration succeeds before reaching `MaxFunEvals`. These (generally) 4-sided regions are mapped to rectangles internally. Clusters of small regions indicate the areas of difficulty. The default is `false`.

<code>Singular</code>	Problem may have boundary singularities
-----------------------	-----------------------------------------

With `Singular` set to `true`, `quad2d` will employ transformations to weaken boundary singularities for better performance. The default is `true`. Setting `Singular` to `false` will turn these transformations off, which may provide a performance benefit on some smooth problems.

## Examples

### Example 1

Integrate  $y\sin(x) + x\cos(y)$  over  $\pi \leq x \leq 2\pi$ ,  $0 \leq y \leq \pi$ . The true value of the integral is  $-\pi^2$ .

```
Q = quad2d(@(x,y) y.*sin(x)+x.*cos(y),pi,2*pi,0,pi)
```

### Example 2

Integrate  $[(x+y)^{1/2}(1+x+y)^2]^{-1}$  over the triangle  $0 \leq x \leq 1$  and  $0 \leq y \leq 1-x$ . The integrand is infinite at (0,0). The true value of the integral is  $\pi/4 - 1/2$ .

```
fun = @(x,y) 1./(sqrt(x + y) .* (1 + x + y).^2 )
```

In Cartesian coordinates:

```
ymax = @(x) 1 - x;
```

# quad2d

---

```
Q = quad2d(fun,0,1,0,ymax)
```

In polar coordinates:

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;  
rmax = @(theta) 1./(sin(theta) + cos(theta));  
Q = quad2d(polarfun,0,pi/2,0,rmax)
```

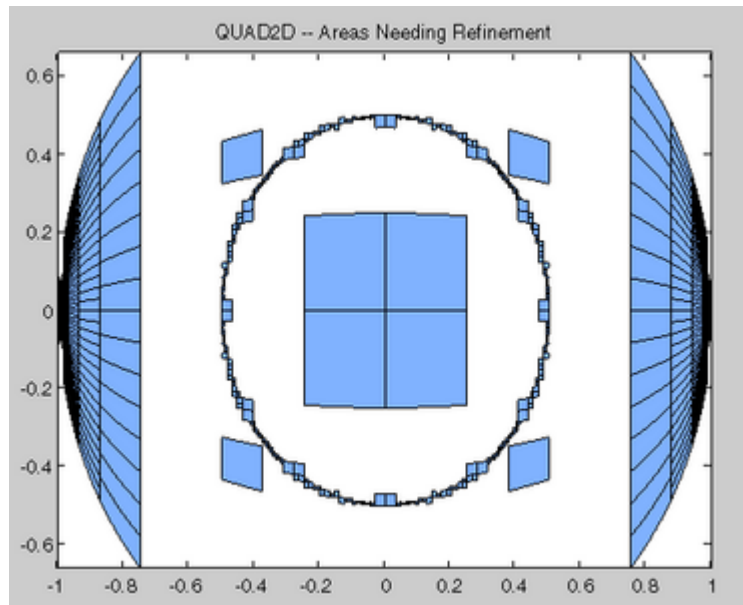

## Limitations

quad2d begins by mapping the region of integration to a rectangle. Consequently, it may have trouble integrating over a region that does not have four sides or has a side that cannot be mapped smoothly to a straight line. If the integration is unsuccessful, some helpful tactics are leaving `Singular` set to its default value of `true`, changing between Cartesian and polar coordinates, or breaking the region of integration into pieces and adding the results of integration over the pieces.

For example:

```
fun = @(x,y)abs(x.^2 + y.^2 - 0.25);  
c = @(x)-sqrt(1 - x.^2);  
d = @(x)sqrt(1 - x.^2);  
quad2d(fun,-1,1,c,d,'AbsTol',1e-8,...  
    'FailurePlot',true,'Singular',false)  
Warning: Reached the maximum number of function ...  
    evaluations (2000). The result fails the ...  
    global error test.
```

The failure plot shows two areas of difficulty, near the points  $(-1,0)$  and  $(1,0)$  and near the circle  $x^2 + y^2 = 0.25$ :

Changing the value of `Singular` to `true` will cope with the geometric singularities at  $(-1,0)$  and  $(1,0)$ . The larger shaded areas may need refinement but are probably not areas of difficulty.

```
Q = quad2d(fun,-1,1,c,d,'AbsTol',1e-8, ...
           'FailurePlot',true,'Singular',true)
```

```
Warning: Reached the maximum number of function ...
         evaluations (2000). The result passes the ...
         global error test.
```

# quad2d

From here you can take advantage of symmetry:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-8,...  
             'Singular',true, 'FailurePlot',true)
```

However, the code is still working very hard near the singularity. It may not be able to provide higher accuracy:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-10,...  
             'Singular',true,'FailurePlot',true)
```

```
Warning: Reached the maximum number of function ...  
evaluations (2000). The result passes the ...  
global error test.
```

At higher accuracy, a change in coordinates may work better.

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
Q = 4*quad2d(polarfun,0,pi/2,0,1,'AbsTol',1e-10)
```

It is best to put the singularity on the boundary by splitting the region of integration into two parts:

```
Q1 = 4*quad2d(polarfun,0,pi/2,0,0.5,'AbsTol',5e-11);
Q2 = 4*quad2d(polarfun,0,pi/2,0.5,1,'AbsTol',5e-11);
Q = Q1 + Q2
```

## How To

- “Anonymous Functions”

**Purpose** Numerically evaluate integral, adaptive Gauss-Kronrod quadrature

**Syntax**

```
q = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)
```

**Description** `q = quadgk(fun,a,b)` attempts to approximate the integral of a scalar-valued function `fun` from `a` to `b` using high-order global adaptive quadrature and default error tolerances. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, where `y` is the integrand evaluated at each element of `x`. `fun` must be a function handle. Limits `a` and `b` can be `-Inf` or `Inf`. If both are finite, they can be complex. If at least one is complex, the integral is approximated over a straight line path from `a` to `b` in the complex plane.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[q,errbnd] = quadgk(fun,a,b)` returns an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)` performs the integration with specified values of optional parameters. The available parameters are

Parameter	Description	
'AbsTol'	Absolute error tolerance.  The default value of 'AbsTol' is 1.e-10 (double), 1.e-5 (single).	quadgk attempts to satisfy $errbnd \leq \max(AbsTol, RelTol *  Q )$ . This is absolute error control when $ Q $ is sufficiently small and relative error control

Parameter	Description	
'RelTol'	Relative error tolerance. The default value of 'RelTol' is 1.e-6 (double), 1.e-4 (single).	when  Q  is larger. For pure absolute error control use 'AbsTol' > 0 and 'RelTol' = 0. For pure relative error control use 'AbsTol' = 0. Except when using pure absolute error control, the minimum relative tolerance is 'RelTol' >= 100*eps(class(Q)).
'Waypoints'	Vector of integration waypoints.	If fun(x) has discontinuities in the interval of integration, the locations should be supplied as a Waypoints vector. When a, b, and the waypoints are all real, only the waypoints between a and b are used, and they are used in sorted order. Note that waypoints are not intended for singularities in fun(x). Singular points should be handled by making them endpoints of separate integrations and adding the results.  If a, b, or any entry of the waypoints vector is complex, the integration is performed over a

Parameter	Description	
		sequence of straight line paths in the complex plane, from a to the first waypoint, from the first waypoint to the second, and so forth, and finally from the last waypoint to b.
'MaxIntervalCount'	Maximum number of intervals allowed. The default value is 650.	The 'MaxIntervalCount' parameter limits the number of intervals that quadgk uses at any one time after the first iteration. A warning is issued if quadgk returns early because of this limit. Routinely increasing this value is not recommended, but it may be appropriate when errbnd is small enough that the desired accuracy has nearly been achieved.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The quad function may be most efficient for low accuracies with nonsmooth integrands.
- The quadl function may be more efficient than quad at higher accuracies with smooth integrands.

- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

### Integrand with a singularity at an integration end point

Write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = exp(x).*log(x);
```

Then pass `@myfun`, a function handle to `myfun`, to `quadgk`, along with the limits of integration, 0 to 1:

```
q = quadgk(@myfun,0,1)
```

```
q =
```

```
-1.3179
```

Alternatively, you can pass the integrand to `quadgk` as an anonymous function handle `F`:

```
f = @(x)exp(x).*log(x);
q = quadgk(f,0,1);
```

### Oscillatory integrand on a semi-infinite interval

Integrate over a semi-infinite interval with specified tolerances, and return the approximate error bound:

```
f = @(x)x.^5.*exp(-x).*sin(x);
[q,errbnd] = quadgk(f,0,inf,'RelTol',1e-8,'AbsTol',1e-12)
```

```
q =
-15.0000
```

```
errbnd =
9.4386e-009
```

### Contour integration around a pole

Use Waypoints to integrate around a pole using a piecewise linear contour:

```
f = @(z)1./(2*z - 1);
q = quadgk(f,-1-i,-1-i,'Waypoints',[1-i,1+i,-1+i])
```

```
q =
0.0000 + 3.1416i
```

## Algorithms

quadgk implements adaptive quadrature based on a Gauss-Kronrod pair (15<sup>th</sup> and 7<sup>th</sup> order formulas).

## Diagnostics

quadgk may issue one of the following warnings:

'Minimum step size reached' indicates that interval subdivision has produced a subinterval whose length is on the order of roundoff

error in the length of the original interval. A nonintegrable singularity is possible.

'Reached the limit on the maximum number of intervals in use' indicates that the integration was terminated before meeting the tolerance requirements and that continuing the integration would require more than `MaxIntervalCount` subintervals. The integral may not exist, or it may be difficult to approximate numerically. Increasing `MaxIntervalCount` usually does not help unless the tolerance requirements were nearly met when the integration was previously terminated.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## How To

- “Anonymous Functions”

**Purpose**

Numerically evaluate integral, adaptive Lobatto quadrature  
quadl will be removed in a future release. Use `integral` instead.

**Syntax**

```
q = quadl(fun,a,b)
q = quadl(fun,a,b,tol)
quadl(fun,a,b,tol,trace)
[q,fcnt] = quadl(...)
```

**Description**

`q = quadl(fun,a,b)` approximates the integral of function `fun` from `a` to `b`, to within an error of  $10^{-6}$  using recursive adaptive Lobatto quadrature. `fun` is a function handle. It accepts a vector `x` and returns a vector `y`, the function `fun` evaluated at each element of `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quadl(fun,a,b,tol)` uses an absolute error tolerance of `tol` instead of the default, which is  $1.0e-6$ . Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results.

`quadl(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a q]` during the recursion.

`[q,fcnt] = quadl(...)` returns the number of function evaluations.

Use array operators `.*`, `./` and `.^` in the definition of `fun` so that it can be evaluated with a vector argument.

The function `quad` might be more efficient with low accuracies or nonsmooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.

# quadl

---

- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

Pass the function handle, `@myfun`, to `quadl`:

```
Q = quadl(@myfun,0,2);
```

where the function `myfun.m` is:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Pass anonymous function handle `F` to `quadl`:

```
F = @(x) 1./(x.^3-2*x-5);
Q = quadl(F,0,2);
```

## Algorithms

`quadl` implements a high order method using an adaptive Gauss/Lobatto quadrature rule.

## Diagnostics

quadl might issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## How To

- "Anonymous Functions"

# quadv

---

## Purpose

Vectorized quadrature

quadv will be removed in a future release. Use `integral` with the 'ArrayValued' option instead.

## Syntax

```
Q = quadv(fun,a,b)
Q = quadv(fun,a,b,tol)
Q = quadv(fun,a,b,tol,trace)
[Q,fcnt] = quadv(...)
```

## Description

`Q = quadv(fun,a,b)` approximates the integral of the complex array-valued function `fun` from `a` to `b` to within an error of  $1.e-6$  using recursive adaptive Simpson quadrature. `fun` is a function handle. The function `Y = fun(x)` should accept a scalar argument `x` and return an array result `Y`, whose components are the integrands evaluated at `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`Q = quadv(fun,a,b,tol)` uses the absolute error tolerance `tol` for all the integrals instead of the default, which is  $1.e-6$ .

---

**Note** The same tolerance is used for all components, so the results obtained with `quadv` are usually not the same as those obtained with `quad` on the individual components.

---

`Q = quadv(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q(1)]` during the recursion.

`[Q,fcnt] = quadv(...)` returns the number of function evaluations.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.

- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued fun.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of  $\text{fun}(x)$  to exist,  $\text{fun}(x)$  must decay as  $x$  approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if  $\text{fun}(x)$  decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint  $c$  like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

For the parameterized array-valued function `myarrayfun`, defined by

```
function Y = myarrayfun(x,n)
Y = 1./((1:n)+x);
```

the following command integrates `myarrayfun`, for the parameter value  $n = 10$  between  $a = 0$  and  $b = 1$ :

```
Qv = quadv(@(x)myarrayfun(x,10),0,1);
```

The resulting array `Qv` has 10 elements estimating  $Q(k) = \log((k+1)/(k))$ , for  $k = 1:10$ .

The entries in `Qv` are slightly different than if you compute the integrals using `quad` in a loop:

# quadv

---

```
for k = 1:10
    Qs(k) = quadv(@(x)myscalarfun(x,k),0,1);
end
```

where `myscalarfun` is:

```
function y = myscalarfun(x,k)
y = 1./(k+x);
```

## Purpose

Summary of classes in MATLAB Qualifications Interface

## Description

Qualifications are methods for testing values and responding to failures. Qualification failures might or might not correspond to a test failure, and they might or might not continue execution in the test when one is encountered. To determine which qualification to use, see “Select Qualifications”.

matlab.unittest.qualifications.AssertionFailedException Qualification to validate preconditions of a test

matlab.unittest.qualifications.AssumptionFailedException Qualification to filter test content

matlab.unittest.qualifications.FatalAssertionFailedException Qualification to abort test execution

matlab.unittest.qualifications.VerifiableQualification Qualification to produce soft-failure conditions

The package contains the following exception handling classes:

matlab.unittest.qualifications.AssertionFailedException Exception for assertion failures

matlab.unittest.qualifications.AssumptionFailedException Exception for assumption failures

matlab.unittest.qualifications.FatalAssertionFailedException Exception for fatal assertion failures

# matlab.unittest.qualifications.Assertable

---

**Purpose** Qualification to validate preconditions of a test

**Description** The `Assertable` class provides a qualification to validate preconditions of a test. Apart from actions performed for failures, the `Assertable` class works the same as other `matlab.unittest` qualifications.

Upon an assertion failure, the `Assertable` class throws an `AssertionFailedException` to inform the testing framework of the failure. This is most useful when a failure at the assertion point renders the rest of the current test method invalid, yet does not prevent proper execution of other test methods. Often, you use assertions to ensure that preconditions of the current test are not violated or that fixtures are set up correctly. Make sure the test content is “Exception Safe” on page 1-4744. If you cannot make the fixture teardown exception safe or if you cannot recover it after failure, use fatal assertions instead.

Use assertions to allow remaining test methods to receive coverage when preconditions are violated in a test and all fixture states are restorable. Assertions also reduce the noise level of failures by not performing later verifications that fail due the precondition failures. In the event of a failure, however, the test framework marks the full content of the test method that failed as incomplete. Therefore, if the failure does not affect the preconditions of the test or cause problems with fixture setup or teardown, use verifications, which give the added information for added information that the full test content was run.

## Methods

<code>assertClass</code>	Assert exact class of specified value
<code>assertEmpty</code>	Assert value is empty
<code>assertEqual</code>	Assert value is equal to specified value
<code>assertError</code>	Assert function throws specified exception

<code>assertFail</code>	Produce unconditional assertion failure
<code>assertFalse</code>	Assert value is false
<code>assertGreaterThan</code>	Assert value is greater than specified value
<code>assertGreaterThanOrEqual</code>	Assert value is greater than or equal to specified value
<code>assertInstanceOf</code>	Assert value is object of specified type
<code>assertLength</code>	Assert value has specified length
<code>assertLessThan</code>	Assert value is less than specified value
<code>assertLessThanOrEqual</code>	Assert value is less than or equal to specified value
<code>assertMatches</code>	Assert string matches specified regular expression
<code>assertNotEmpty</code>	Assert value is not empty
<code>assertNotEqual</code>	Assert value is not equal to specified value
<code>assertNotSameHandle</code>	Assert value is not handle to specified instance
<code>assertNumElements</code>	Assert value has specified element count
<code>assertReturnsTrue</code>	Assert function returns true when evaluated
<code>assertSameHandle</code>	Assert two values are handles to same instance
<code>assertSize</code>	Assert value has specified size

# matlab.unittest.qualifications.Assertable

---

<code>assertSubstring</code>	Assert string contains specified string
<code>assertThat</code>	Assert that value meets specified constraint
<code>assertTrue</code>	Assert value is true
<code>assertWarning</code>	Assert function issues specified warning
<code>assertWarningFree</code>	Assert function issues no warnings

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
close(f);
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.assertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assertEqual`.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
testCase.addTeardown(@close, f);
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Concepts

# matlab.unittest.qualifications.Assertable.assertClass

---

**Purpose** Assert exact class of specified value

**Syntax**

```
assertClass(assertable,actual,className)
assertClass(assertable,actual,metaClass)
assertClass(__,diagnostic)
```

**Description**

`assertClass(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertClass(assertable,actual,metaClass)` asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See `assertInstanceOf` to assert inclusion in a class hierarchy.

`assertClass(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
assertable.assertThat(actual, IsOfClass(className));
assertable.assertThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyClass`.

## **See Also**

`assertThat` | `assertInstanceOf` |

# matlab.unittest.qualifications.Assertable.assertEmpty

---

**Purpose** Assert value is empty

**Syntax** `assertEmpty(assertable,actual)`  
`assertEmpty(assertable,actual,diagnostic)`

**Description** `assertEmpty(assertable,actual)` asserts that `actual` is an empty MATLAB value.

`assertEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;  
assertable.assertThat(actual, IsEmpty());
```

This method is a convenience method. There exists more functionality when using the `IsEmpty` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

# matlab.unittest.qualifications.Assertable.assertEmpty

---

**Examples**      See examples for `verifyEmpty`.

**See Also**      `assertThat` | `assertNotEmpty` | `isempty`

# matlab.unittest.qualifications.Assertable.assertEqual

---

**Purpose** Assert value is equal to specified value

**Syntax** `assertEqual(actual,expected)`  
`assertEqual( __,Name,Value)`  
`assertEqual( __,diagnostic)`

**Description** `assertEqual(actual,expected)` asserts that `actual` is strictly equal to `expected`.

`assertEqual( __,Name,Value)` asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`assertEqual( __,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips** • This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

# matlab.unittest.qualifications.Assertable.assertEqual

---

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' ' ). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'AbsTol'**

**'RelTol'**

# matlab.unittest.qualifications.Assertable.assertEqual

---

**Examples**      See examples for `verifyEqual`.

**See Also**      `assertThat` | `assertNotEqual` |

# matlab.unittest.qualifications.Assertable.assertError

## Purpose

Assert function throws specified exception

## Syntax

```
assertError(assertable,actual,identifier)
assertError(assertable,actual,metaClass)
assertError( ____,diagnostic)
```

## Description

`assertError(assertable,actual,identifier)` asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assertError(assertable,actual,metaClass)` asserts that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assertError( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
assertable.assertThat(actual, Throws(identifier));
assertable.assertThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **identifier**

# matlab.unittest.qualifications.Assertable.assertError

---

Error identifier, specified as a string.

## **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyError`.

## **See Also**

`assertThat` | `assertWarning` | `MException` | `error`

# matlab.unittest.qualifications.Assertable.assertFail

---

<b>Purpose</b>	Produce unconditional assertion failure
<b>Syntax</b>	<code>assertFail(assertable)</code> <code>assertFail(assertable,diagnostic)</code>
<b>Description</b>	<code>assertFail(assertable)</code> produces an unconditional assertion failure when encountered. <code>assertFail(assertable,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.
<b>Input Arguments</b>	<p><b>assertable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assertion in conjunction with the test running framework.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul> <p>Diagnostic values can be nonscalar. For more information, see <code>matlab.unittest.diagnostics.Diagnostic</code>.</p>
<b>Examples</b>	See examples for <code>verifyFail</code> .

# matlab.unittest.qualifications.Assertable.assertFalse

---

## Purpose

Assert value is false

## Syntax

```
assertFalse(assertable,actual)
assertFalse(assertable,actual,diagnostic)
```

## Description

`assertFalse(assertable,actual)` asserts that `actual` is a scalar logical with the value of false.

`assertFalse(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
assertable.assertThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `assertThat`.

- Unlike `assertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assertTrue`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.Assertable.assertFalse

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** For examples, see `verifyFalse`.

**See Also** `assertThat` | `assertTrue` |

# matlab.unittest.qualifications.Assertable.assertGreaterThan

<b>Purpose</b>	Assert value is greater than specified value
<b>Syntax</b>	<pre>assertGreaterThan(assertable,actual,floor) assertGreaterThan(assertable,actual,floor,diagnostic)</pre>
<b>Description</b>	<p><code>assertGreaterThan(assertable,actual,floor)</code> asserts that all elements of <code>actual</code> are greater than all the elements of <code>floor</code>.</p> <p><code>assertGreaterThan(assertable,actual,floor,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• This method is functionally equivalent to: <pre>import matlab.unittest.constraints.IsGreaterThan; assertable.assertThat(actual, IsGreaterThan(floor));</pre></li></ul> <p>There exists more functionality when using the <code>IsGreaterThan</code> constraint directly via <code>assertThat</code>.</p>
<b>Input Arguments</b>	<p><b>assertable</b> The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assertion in conjunction with the test running framework.</p> <p><b>actual</b> The value to test. <code>actual</code> must be the same size as <code>floor</code> unless either one is scalar, at which point scalar expansion occurs.</p> <p><b>floor</b> Minimum value, exclusive.</p> <p><b>diagnostic</b> Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li></ul>

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThan`.

## See Also

`assertThat` | `assertGreaterThanOrEqual` | `assertLessThan` | `assertLessThanOrEqual` | `gt`

# matlab.unittest.qualifications.Assertable.assertGreaterThanOrEqualTo

## Purpose

Assert value is greater than or equal to specified value

## Syntax

```
assertGreaterThanOrEqualTo(assertable,actual,floor)
assertGreaterThanOrEqualTo(assertable,actual,floor,diagnostic)
```

## Description

`assertGreaterThanOrEqualTo(assertable,actual,floor)` asserts that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assertGreaterThanOrEqualTo(assertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
assertable.assertThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThanOrEqual`.

## See Also

# matlab.unittest.qualifications.Assertable.assertInstanceOf

## Purpose

Assert value is object of specified type

## Syntax

```
assertInstanceOf(assertable,actual,className)
assertInstanceOf(assertable,actual,metaClass)
assertInstanceOf(___,diagnostic)
```

## Description

`assertInstanceOf(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertInstanceOf(assertable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assertInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
assertable.assertThat(actual, IsInstanceOf(className));
assertable.assertThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyInstanceOf`.

# matlab.unittest.qualifications.Assertable.assertLessThan

**Purpose** Assert value is less than specified value

**Syntax** `assertLessThan(assertable,actual,ceiling)`  
`assertLessThan(assertable,actual,ceiling,diagnostic)`

**Description** `assertLessThan(assertable,actual,ceiling)` asserts that all elements of `actual` are less than all the elements of `ceiling`.  
`assertLessThan(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;  
assertable.assertThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertLessThan

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThan`.

## See Also

`assertThat` | `assertLessThanOrEqual` | `assertGreaterThan` | `assertGreaterThanOrEqual` | `lt`

# matlab.unittest.qualifications.Assertable.assertLessThanOrEqualTo

## Purpose

Assert value is less than or equal to specified value

## Syntax

```
assertLessThanOrEqualTo(assertable,actual,ceiling)
assertLessThanOrEqualTo(assertable,actual,ceiling,diagnostic)
```

## Description

`assertLessThanOrEqualTo(assertable,actual,ceiling)` asserts that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assertLessThanOrEqualTo(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
assertable.assertThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assertable.assertLessThanO

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThanOrEqual`.

## See Also

# matlab.unittest.qualifications.Assertable.assertNotEmpty

<b>Purpose</b>	Assert value is not empty
<b>Syntax</b>	<pre>assertNotEmpty(assertable,actual) assertNotEmpty(assertable,actual,diagnostic)</pre>
<b>Description</b>	<p><code>assertNotEmpty(assertable,actual)</code> asserts that <code>actual</code> is a non-empty MATLAB value.</p> <p><code>assertNotEmpty(assertable,actual,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• This method is functionally equivalent to: <pre>import matlab.unittest.constraints.IsEmpty; assertable.assertThat(actual, ~IsEmpty());</pre></li></ul> <p>There exists more functionality when using the <code>IsEmpty</code> constraint directly via <code>assertThat</code>.</p>
<b>Input Arguments</b>	<p><b>assertable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assertion in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul> <p>Diagnostic values can be nonscalar. For more information, see <code>matlab.unittest.diagnostics.Diagnostic</code>.</p>

# matlab.unittest.qualifications.Assertable.assertNotEmpty

---

**Examples**      See examples for `verifyNotEmpty`.

**See Also**      `assertThat` | `assertEmpty` | `isempty`

# matlab.unittest.qualifications.Assertable.assertNotEqual

## Purpose

Assert value is not equal to specified value

## Syntax

```
assertNotEqual(assertable, actual, notExpected)
assertNotEqual(assertable, actual, notExpected, diagnostic)
```

## Description

`assertNotEqual(assertable, actual, notExpected)` asserts that `actual` is not equal to `notExpected`.

`assertNotEqual(assertable, actual, notExpected, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpected**

Value to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Assertable.assertNotEqual

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyNotEqual`.

**See Also** `assertThat` | `assertEqual` |

# matlab.unittest.qualifications.Assertable.assertNotSameHandle

## Purpose

Assert value is not handle to specified instance

## Syntax

```
assertNotSameHandle(assertable, actual, notExpectedHandle)
assertNotSameHandle(assertable, actual, notExpectedHandle,
    diagnostic)
```

## Description

`assertNotSameHandle(assertable, actual, notExpectedHandle)` asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assertNotSameHandle(assertable, actual, notExpectedHandle, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assertable.assertThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assertable.assertNotSameHandle

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`.

## See Also

`assertThat` | `assertSameHandle` |

# matlab.unittest.qualifications.Assertable.assertNumElements

## Purpose

Assert value has specified element count

## Syntax

```
assertNumElements(assertable,actual,expectedElementCount)
assertNumElements(assertable,actual,expectedElementCount,
    diagnostic)
```

## Description

`assertNumElements(assertable,actual,expectedElementCount)` asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assertNumElements(assertable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
assertable.assertThat(actual, HasElementCount(expectedElementCount));
```

There exists more functionality when using the `HasElementCount` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedElementCount**

The expected number of elements in the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assertable.assertNumElements

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`.

## See Also

`assertThat` | `assertSize` | `assertLength` | `numel`

# matlab.unittest.qualifications.Assertable.assertReturnsTrue

**Purpose** Assert function returns true when evaluated

**Syntax** `assertReturnsTrue(assertable, actual)`  
`assertReturnsTrue(assertable, actual, diagnostic)`

**Description** `assertReturnsTrue(assertable, actual)` asserts that `actual` is a function handle that returns a scalar logical whose value is true.  
`assertReturnsTrue(assertable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assertTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;  
assertable.assertThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assertable.assertReturnsTrue

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`.

## See Also

`assertThat` | `assertTrue` |

# matlab.unittest.qualifications.Assertable.assertSameHandle

**Purpose** Assert two values are handles to same instance

**Syntax** `assertSameHandle(assertable,actual,expectedHandle)`  
`assertSameHandle(assertable,actual,expectedHandle,diagnostic)`

**Description** `assertSameHandle(assertable,actual,expectedHandle)` asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assertSameHandle(assertable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:  

```
import matlab.unittest.constraints.IsSameHandleAs;  
assertable.assertThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.

**Input Arguments**

**assertable**  
The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

**actual**  
The value to test.

**expectedHandle**  
The expected handle array.

**diagnostic**  
Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`.

## See Also

# matlab.unittest.qualifications.Assertable.assertSize

---

<b>Purpose</b>	Assert value has specified size
<b>Syntax</b>	<code>assertSize(assertable,actual,expectedSize)</code> <code>assertSize(assertable,actual,expectedSize,diagnostic)</code>
<b>Description</b>	<code>assertSize(assertable,actual,expectedSize)</code> asserts that <code>actual</code> is a MATLAB array whose size is <code>expectedSize</code> . <code>assertSize(assertable,actual,expectedSize,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.
<b>Tips</b>	<ul style="list-style-type: none"><li>This method is functionally equivalent to: <pre>import matlab.unittest.constraints.HasSize; assertable.assertThat(actual, HasSize(expectedSize));</pre> There exists more functionality when using the <code>HasSize</code> constraint directly via <code>assertThat</code>.</li></ul>
<b>Input Arguments</b>	<p><b>assertable</b> The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assertion in conjunction with the test running framework.</p> <p><b>actual</b> The value to test.</p> <p><b>expectedSize</b> The expected sizes of each dimension the array.</p> <p><b>diagnostic</b> Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>string</li><li>function handle</li><li><code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul>

# matlab.unittest.qualifications.Assertable.assertSize

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifySize`.

**See Also** `assertThat` | `assertLength` | `assertNumElements` | `size`

# matlab.unittest.qualifications.Assertable.assertSubstring

<b>Purpose</b>	Assert string contains specified string
<b>Syntax</b>	<code>assertSubstring(assertable,actual,substring)</code> <code>assertSubstring(assertable,actual,substring,diagnostic)</code>
<b>Description</b>	<code>assertSubstring(assertable,actual,substring)</code> asserts that <code>actual</code> is a string that contains <code>substring</code> . <code>assertSubstring(assertable,actual,substring,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.
<b>Tips</b>	<ul style="list-style-type: none"><li>This method is functionally equivalent to: <pre>import matlab.unittest.constraints.ContainsSubstring; assertable.assertThat(actual, ContainsSubstring(substring));</pre> There exists more functionality when using the <code>ContainsSubstring</code> constraint directly via <code>assertThat</code>.</li></ul>
<b>Input Arguments</b>	<p><b>assertable</b> The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assertion in conjunction with the test running framework.</p> <p><b>actual</b> The value to test.</p> <p><b>substring</b> The value to match, specified as a string.</p> <p><b>diagnostic</b> Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>string</li><li>function handle</li><li><code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul>

# matlab.unittest.qualifications.Assertable.assertSubstring

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifySubstring`.

**See Also** `assertThat` | `assertMatches` | `strfind`

# matlab.unittest.qualifications.Assertable.assertThat

---

**Purpose** Assert that value meets specified constraint

**Syntax** `assertThat(assertable,actual,constraint)`  
`assertThat(assertable,actual,constraint,diagnostic)`

**Description** `assertThat(assertable,actual,constraint)` asserts that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, an assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`assertThat(assertable,actual,constraint,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **constraint**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples**      See examples for `verifyThat`.

# matlab.unittest.qualifications.Assertable.assertTrue

---

## Purpose

Assert value is true

## Syntax

```
assertTrue(assertable,actual)
assertTrue(assertable,actual,diagnostic)
```

## Description

`assertTrue(assertable,actual)` asserts that `actual` is a scalar logical with the value of true.

`assertTrue(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and non-zero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
assertable.assertThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `assertThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `assertReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyTrue`.

## **See Also**

`assertThat` | `assertFalse` | `assertReturnsTrue` |

# matlab.unittest.qualifications.Assertable.assertWarning

## Purpose

Assert function issues specified warning

## Syntax

```
assertWarning(assertable,actual,warningID)
assertWarning(assertable,actual,warningID,diagnostic)
[output1,...,outputN] = assertWarning( ___ )
```

## Description

`assertWarning(assertable,actual,warningID)` asserts that `actual` issues a warning with the identifier `warningID`.

`assertWarning(assertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
assertable.assertThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.Assertable.assertWarning

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`.

## See Also

`assertThat` | `assertError` | `assertWarningFree` | `warning`

# matlab.unittest.qualifications.Assertable.assertWarningFree

## Purpose

Assert function issues no warnings

## Syntax

```
assertWarningFree(assertable,actual)
assertWarningFree(assertable,actual,diagnostic)
[output1,...,outputN] = assertWarningFree( ___ )
```

## Description

`assertWarningFree(assertable,actual)` asserts that `actual` is a function handle that issues no warnings.

`assertWarningFree(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
assertable.assertThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertWarningFree

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarningFree`.

## See Also

`assertThat` | `assertWarning` | `warning`

# matlab.unittest.qualifications.AssertionFailedException

---

**Purpose** Exception used for assertion failures

**Description** The `AssertionFailedException` class provides an exception used for assertion failures. This class is used exclusively by the `Assertable` qualification type.

**See Also** `Assertable` | `MException`

## Purpose

Qualification to filter test content

## Description

The `Assumable` class provides a qualification to filter test content. Apart from actions performed in the event of failures, the `Assumable` class works the same as other `matlab.unittest` qualifications.

Upon an assumption failure, the `Assumable` class informs the testing framework of the failure by throwing an `AssumptionFailedException`. The test framework then marks the test content as filtered and continues testing. Often, assumptions are used to ensure that the test is run only when certain preconditions are met. However, running the test without satisfying the preconditions does not produce a test failure. Ensure that the test content is “Exception Safe” on page 1-4799. If the failure condition is meant to produce a test failure, use assertions or verifications instead of assumptions.

The attributes specified in the `TestCase` method definition determine which tests are filtered. The following behavior occurs when the test framework encounters an assumption failure inside of a `TestCase` method:

- If you define the `TestCase` method using the `Test` attribute, the framework marks the entire method as filtered and runs subsequent test methods.
- If you define the `TestCase` method using the `TestMethodSetup` or `TestMethodTeardown` attributes, the test framework marks the method to run for that instance as filtered.
- If you define the `TestCase` method using the `TestClassSetup` or `TestClassTeardown` attributes, the test framework filters the entire `TestCase` class.

Filtering test content using assumptions does not produce test failures. Therefore, dead test code can result. Avoid this by monitoring filtered tests.

## Methods

<code>assumeClass</code>	Assume exact class of specified value
<code>assumeEmpty</code>	Assume value is empty
<code>assumeEqual</code>	Assume value is equal to specified value
<code>assumeError</code>	Assume function throws specified exception
<code>assumeFail</code>	Produce unconditional assumption failure
<code>assumeFalse</code>	Assume value is false
<code>assumeGreaterThan</code>	Assume value is greater than specified value
<code>assumeGreaterThanOrEqual</code>	Assume value is greater than or equal to specified value
<code>assumeInstanceOf</code>	Assume value is object of specified type
<code>assumeLength</code>	Assume value has specified length
<code>assumeLessThan</code>	Assume value is less than specified value
<code>assumeLessThanOrEqual</code>	Assume value is less than or equal to specified value
<code>assumeMatches</code>	Assume string matches specified regular expression
<code>assumeNotEmpty</code>	Assume value is not empty
<code>assumeNotEqual</code>	Assume value is not equal to specified value
<code>assumeNotSameHandle</code>	Assume value is not handle to specified instance

<code>assumeNumElements</code>	Assume value has specified element count
<code>assumeReturnsTrue</code>	Assume function returns true when evaluated
<code>assumeSameHandle</code>	Assume two values are handles to same instance
<code>assumeSize</code>	Assume value has specified size
<code>assumeSubstring</code>	Assume string contains specified string
<code>assumeThat</code>	Assume value meets specified constraint
<code>assumeTrue</code>	Assume value is true
<code>assumeWarning</code>	Assume function issues specified warning
<code>assumeWarningFree</code>	Assume function issues no warnings

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
close(f);
```

This code is exception safe because the test framework closes the figure in all cases.

# matlab.unittest.qualifications.Assumable

---

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.assertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assertEqual`.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
testCase.addTeardown(@close, f);
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Concepts

- “Filtered Tests”

# matlab.unittest.qualifications.Assumable.assumeClass

## Purpose

Assume exact class of specified value

## Syntax

```
assumeClass(assumable,actual,className)
assumeClass(assumable,actual,metaClass)
assumeClass( ____,diagnostic)
```

## Description

`assumeClass(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeClass(assumable,actual,metaClass)` assumes that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See `assumeInstanceOf` to assume inclusion in a class hierarchy.

`assumeClass( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
assumable.assumeThat(actual, IsOfClass(className));
assumable.assumeThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.Assumable.assumeClass

---

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyClass`.

## **See Also**

`assumeThat` | `assumeInstanceOf` |

# matlab.unittest.qualifications.Assumable.assumeEmpty

---

## Purpose

Assume value is empty

## Syntax

```
assumeEmpty(assumable,actual)
assumeEmpty(assumable,actual,diagnostic)
```

## Description

`assumeEmpty(assumable,actual)` assumes that `actual` is an empty MATLAB value.

`assumeEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assumable.assumeThat(actual, IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Assumable.assumeEmpty

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyEmpty`.

**See Also** `assumeThat` | `assumeNotEmpty` | `isempty`

# matlab.unittest.qualifications.Assumable.assumeEqual

## Purpose

Assume value is equal to specified value

## Syntax

```
assumeEqual(assumable,actual,expected)
assumeEqual( ____,Name,Value)
assumeEqual( ____,diagnostic)
```

## Description

`assumeEqual(assumable,actual,expected)` assumes that `actual` is strictly equal to `expected`.

`assumeEqual( ____,Name,Value)` assumes equality with additional options specified by one or more `Name,Value` pair arguments.

`assumeEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol))
```

# matlab.unittest.qualifications.Assumable.assumeEqual

---

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'AbsTol'**

**'RelTol'**

# matlab.unittest.qualifications.Assumable.assumeEqual

---

**Examples**      See examples for `verifyEqual`.

**See Also**      `assumeThat` | `assumeNotEqual` |

# matlab.unittest.qualifications.Assumable.assumeError

---

**Purpose** Assume function throws specified exception

**Syntax**  
`assumeError(assumable,actual,identifier)`  
`assumeError(assumable,actual,metaClass)`  
`assumeError( __,diagnostic)`

**Description** `assumeError(assumable,actual,identifier)` assumes that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assumeError(assumable,actual,metaClass)` assumes that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assumeError( __,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;  
assumable.assumeThat(actual, Throws(identifier));  
assumable.assumeThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **identifier**

# matlab.unittest.qualifications.Assumable.assumeError

---

Error identifier, specified as a string.

## **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyError`.

## **See Also**

`assumeThat` | `assumeWarning` | `MException` | `error`

# matlab.unittest.qualifications.Assumable.assumeFail

---

<b>Purpose</b>	Produce unconditional assumption failure
<b>Syntax</b>	<code>assumeFail(assumable)</code> <code>assumeFail(assumable,diagnostic)</code>
<b>Description</b>	<code>assumeFail(assumable)</code> produces an unconditional assumption failure when encountered.  <code>assumeFail(assumable,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.
<b>Input Arguments</b>	<p><b>assumable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assumption in conjunction with the test running framework.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul> <p>Diagnostic values can be nonscalar. For more information, see <code>matlab.unittest.diagnostics.Diagnostic</code>.</p>
<b>Examples</b>	See examples for <code>verifyFail</code> .

# matlab.unittest.qualifications.Assumable.assumeFalse

## Purpose

Assume value is false

## Syntax

```
assumeFalse(assumable,actual)
assumeFalse(assumable,actual,diagnostic)
```

## Description

`assumeFalse(assumable,actual)` assumes that `actual` is a scalar logical with the value of false.

`assumeFalse(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
assumable.assumeThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `assumeThat`.

- Unlike `assumeTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assumeTrue`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

# matlab.unittest.qualifications.Assumable.assumeFalse

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

For examples, see `verifyFalse`.

## See Also

`assumeThat` | `assumeTrue` |

# matlab.unittest.qualifications.Assumable.assumeGreaterThan

---

## Purpose

Assume value is greater than specified value

## Syntax

```
assumeGreaterThan(assumable,actual,floor)
assumeGreaterThan(assumable,actual,floor,diagnostic)
```

## Description

`assumeGreaterThan(assumable,actual,floor)` assumes that all elements of `actual` are greater than all the elements of `floor`.

`assumeGreaterThan(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThan;
assumable.assumeThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeGreaterThan

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThan`.

## See Also

`assumeThat` | `assumeGreaterThanOrEqual` | `assumeLessThanOrEqual`  
| `assumeLessThan` | `gt`

## Purpose

Assume value is greater than or equal to specified value

## Syntax

```
assumeGreaterThanOrEqual(assumable,actual,floor)
assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)
```

## Description

`assumeGreaterThanOrEqual(assumable,actual,floor)` assumes that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
assumable.assumeThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThanOrEqual`.

## See Also

`assumeThat` | `assumeGreaterThan` | `assumeLessThanOrEqual` | `assumeLessThan` | `ge`

# matlab.unittest.qualifications.Assumable.assumeInstanceOf

## Purpose

Assume value is object of specified type

## Syntax

```
assumeInstanceOf(assumable,actual,className)
assumeInstanceOf(assumable,actual,metaClass)
assumeInstanceOf(___,diagnostic)
```

## Description

`assumeInstanceOf(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeInstanceOf(assumable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assumeInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
assumable.assumeThat(actual, IsInstanceOf(className));
assumable.assumeThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.Assumable.assumeInstanceOf

---

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyInstanceOf`.

## **See Also**

`assumeThat` | `assumeClass` | `isa`

# matlab.unittest.qualifications.Assumable.assumeLength

---

## Purpose

Assume value has specified length

## Syntax

```
assumeLength(assumable,actual,expectedLength)
assumeLength(assumable,actual,expectedLength,diagnostic)
```

## Description

`assumeLength(assumable,actual,expectedLength)` assumes that `actual` is a MATLAB array whose length is `expectedLength`.

`assumeLength(assumable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
assumable.assumeThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeLength

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLength`.

## See Also

`assumeThat` | `assumeSize` | `assumeNumElements` | `length`

## Purpose

Assume value is less than specified value

## Syntax

```
assumeLessThan(assumable,actual,ceiling)
assumeLessThan(assumable,actual,ceiling,diagnostic)
```

## Description

`assumeLessThan(assumable,actual,ceiling)` assumes that all elements of `actual` are less than all the elements of `ceiling`.

`assumeLessThan(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
assumable.assumeThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeLessThan

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThan`.

## See Also

`assumeThat` | `assumeLessThanOrEqualTo` | `assumeGreaterThan` | `assumeGreaterThanEqualTo` | `lt`

## Purpose

Assume value is less than or equal to specified value

## Syntax

```
assumeLessThanOrEqualTo(assumable,actual,ceiling)
assumeLessThanOrEqualTo(assumable,actual,ceiling,diagnostic)
```

## Description

`assumeLessThanOrEqualTo(assumable,actual,ceiling)` assumes that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assumeLessThanOrEqualTo(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
assumable.assumeThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThanOrEqualTo`.

## See Also

`assumeThat` | `assumeLessThan` | `assumeGreaterThan` | `assumeGreaterThanOrEqual` | `le`

# matlab.unittest.qualifications.Assumable.assumeMatches

---

## Purpose

Assume string matches specified regular expression

## Syntax

```
assumeMatches(assumable,actual,expression)
assumeMatches(assumable,actual,expression,diagnostic)
```

## Description

`assumeMatches(assumable,actual,expression)` assumes that `actual` is a string that matches the regular expression defined by `expression`.

`assumeMatches(assumable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
assumable.assumeThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The string to test.

### **expression**

The value to match, specified as a regular expression.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeMatches

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyMatches`.

## See Also

`assumeThat` | `assumeSubstring` | `regexp`

# matlab.unittest.qualifications.Assumable.assumeNotEmpty

---

**Purpose** Assume value is not empty

**Syntax** `assumeNotEmpty(assumable,actual)`  
`assumeNotEmpty(assumable,actual,diagnostic)`

**Description** `assumeNotEmpty(assumable,actual)` assumes that `actual` is a non-empty MATLAB value.  
`assumeNotEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips** • This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;  
assumable.assumeThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Assumable.assumeNotEmpty

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyNotEmpty`.

**See Also** `assumeThat` | `assumeEmpty` | `isempty`

## Purpose

Assume value is not equal to specified value

## Syntax

```
assumeNotEqual(assumable,actual,notExpected)
assumeNotEqual(assumable,actual,notExpected,diagnostic)
```

## Description

`assumeNotEqual(assumable,actual,notExpected)` assumes that `actual` is not equal to `notExpected`.

`assumeNotEqual(assumable,actual,notExpected,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpected**

Value to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assumable.assumeNotEqual

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyNotEqual`.

**See Also** `assumeThat` | `assumeEqual` |

## Purpose

Assume value is not handle to specified instance

## Syntax

```
assumeNotSameHandle(assumable,actual,notExpectedHandle)
assumeNotSameHandle(assumable,actual,notExpectedHandle,
    diagnostic)
```

## Description

`assumeNotSameHandle(assumable,actual,notExpectedHandle)` assumes that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assumeNotSameHandle(assumable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assumable.assumeThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`.

## See Also

`assumeThat` | `assumeSameHandle` |

## Purpose

Assume value has specified element count

## Syntax

```
assumeNumElements(assumable,actual,expectedElementCount)
assumeNumElements(assumable,actual,expectedElementCount,
    diagnostic)
```

## Description

`assumeNumElements(assumable,actual,expectedElementCount)` assumes that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assumeNumElements(assumable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
assumable.assumeThat(actual, HasElementCount(expectedElementCount))
```

There exists more functionality when using the `HasElementCount` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedElementCount**

The expected number of elements in the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.Assumable.assumeNumElements

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`.

## See Also

`assumeThat` | `assumeSize` | `assumeLength` | `numel`

# matlab.unittest.qualifications.Assumable.assumeReturnsTrue

**Purpose** Assume function returns true when evaluated

**Syntax**  
`assumeReturnsTrue(assumable,actual)`  
`assumeReturnsTrue(assumable,actual,diagnostic)`

**Description**  
`assumeReturnsTrue(assumable,actual)` assumes that `actual` is a function handle that returns a scalar logical whose value is true.  
`assumeReturnsTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assumeTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assumeTrue`.

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;  
assumable.assumeThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.Assumable.assumeReturnsTrue

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`.

## See Also

`assumeThat` | `assumeTrue` |

## Purpose

Assume two values are handles to same instance

## Syntax

```
assumeSameHandle(assumable,actual,expectedHandle)
assumeSameHandle(assumable,actual,expectedHandle,diagnostic)
```

## Description

`assumeSameHandle(assumable,actual,expectedHandle)` assumes that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assumeSameHandle(assumable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assumable.assumeThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeSameHandle

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`.

## See Also

`assumeThat` | `assumeNotSameHandle` | `handle`

# matlab.unittest.qualifications.Assumable.assumeSize

## Purpose

Assume value has specified size

## Syntax

```
assumeSize(assumable,actual,expectedSize)
assumeSize(assumable,actual,expectedSize,diagnostic)
```

## Description

`assumeSize(assumable,actual,expectedSize)` assumes that `actual` is a MATLAB array whose size is `expectedSize`.

`assumeSize(assumable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
assumable.assumeThat(actual, HasSize(expectedSize));
```

There exists more functionality when using the `HasSize` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedSize**

The expected sizes of each dimension the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assumable.assumeSize

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySize`.

## See Also

`assumeThat` | `assumeLength` | `assumeNumElements` | `size`

**Purpose** Assume string contains specified string

**Syntax** `assumeSubstring(assumable,actual,substring)`  
`assumeSubstring(assumable,actual,substring,diagnostic)`

**Description** `assumeSubstring(assumable,actual,substring)` assumes that `actual` is a string that contains `substring`.  
`assumeSubstring(assumable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips** • This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;  
assumable.assumeThat(actual, ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **substring**

The value to match, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assumable.assumeSubstring

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySubstring`.

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples**      See examples for `verifyThat`.

# matlab.unittest.qualifications.Assumable.assumeTrue

## Purpose

Assume value is true

## Syntax

```
assumeTrue(assumable,actual)
assumeTrue(assumable,actual,diagnostic)
```

## Description

`assumeTrue(assumable,actual)` assumes that `actual` is a scalar logical with the value of true.

`assumeTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
assumable.assumeThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `assumeThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `assumeReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

# matlab.unittest.qualifications.Assumable.assumeTrue

---

## **actual**

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyTrue`.

## **See Also**

`assumeThat` | `assumeFalse` | `assumeReturnsTrue` |

# matlab.unittest.qualifications.Assumable.assumeWarning

## Purpose

Assume function issues specified warning

## Syntax

```
assumeWarning(assumable,actual,warningID)
assumeWarning(assumable,actual,warningID,diagnostic)
[output1,...,outputN] = assumeWarning( ___ )
```

## Description

`assumeWarning(assumable,actual,warningID)` assumes that `actual` issues a warning with the identifier `warningID`.

`assumeWarning(assumable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarning( ___ )` also return the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
assumable.assumeThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

# matlab.unittest.qualifications.Assumable.assumeWarning

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`.

## See Also

`assumeThat` | `assumeError` | `assumeWarningFree` | `warning`

# matlab.unittest.qualifications.Assumable.assumeWarning

## Purpose

Assume function issues no warnings

## Syntax

```
assumeWarningFree(assumable,actual)
assumeWarningFree(assumable,actual,diagnostic)
[output1,...,outputN] = assumeWarningFree( ___ )
```

## Description

`assumeWarningFree(assumable,actual)` assumes that `actual` is a function handle that issues no warnings.

`assumeWarningFree(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
assumable.assumeThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeWarningFree

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarningFree`.

# matlab.unittest.qualifications.AssumptionFailedException

---

**Purpose** Exception used for assumption failures

**Description** The AssumptionFailedException class provides an exception used for assumption failures. This class is used exclusively by the Assumable qualification type.

**See Also** Assumable | MException

# matlab.unittest.qualifications.FatalAssertable

---

**Purpose** Qualification to abort test execution

**Description** The `FatalAssertable` class provides a qualification to abort test execution. Apart from actions performed for failures, the `FatalAssertable` class works the same as `matlab.unittest` qualifications.

Upon a fatal assertion failure, the `FatalAssertable` class informs the testing framework of the failure by throwing a `FatalAssertionFailedException`. The test running framework then displays diagnostic information for the failure and aborts the entire test session. This is useful when the software under test contains so many errors that it does not make sense to continue the test session. Also, you can use fatal assertions in fixture teardown to guarantee the fixture state is restored correctly. If it is not restored, the full testing session will aborts and indicates to restart MATLAB before you resume testing. This allows later tests to run in a consistent MATLAB state. If you can recover the fixture teardown and make it “Exception Safe” on page 1-4854 for failures, use assertions instead.

Fatal assertions prevent false test failures due to the failure of a fundamental test. They also prevent false test failures when a prior test failed to restore test fixtures. If the test framework cannot properly tear down fixtures, restart MATLAB to ensure testing can resume in a clean state.

## Methods

<code>fatalAssertClass</code>	Fatally assert exact class of specified value
<code>fatalAssertEmpty</code>	Fatally assert value is empty
<code>fatalAssertEqual</code>	Fatally assert value is equal to specified value
<code>fatalAssertError</code>	Fatally assert function throws specified exception

<code>fatalAssertFail</code>	Produce unconditional fatal assertion failure
<code>fatalAssertFalse</code>	Fatally assert value is false
<code>fatalAssertGreaterThanOrEqual</code>	Fatally assert value is greater than or equal to specified value
<code>fatalAssertInstanceOf</code>	Fatally assert value is object of specified type
<code>fatalAssertLength</code>	Fatally assert value has specified length
<code>fatalAssertLessThan</code>	Fatally assert value is less than specified value
<code>fatalAssertLessThanOrEqual</code>	Fatally assert value is less than or equal to specified value
<code>fatalAssertMatches</code>	Fatally assert string matches specified regular expression
<code>fatalAssertNotEmpty</code>	Fatally assert value is not empty
<code>fatalAssertNotEqual</code>	Fatally assert value is not equal to specified value
<code>fatalAssertNotSameHandle</code>	Fatally assert value is not handle to specified instance
<code>fatalAssertNumElements</code>	Fatally assert value has specified element count
<code>fatalAssertReturnsTrue</code>	Fatally assert function returns true when evaluated
<code>fatalAssertSameHandle</code>	Fatally assert two values are handles to same instance
<code>fatalAssertSize</code>	Fatally assert value has specified size
<code>fatalAssertSubstring</code>	Fatally assert string contains specified string

<code>fatalAssertThat</code>	Fatally assert value meets specified constraint
<code>fatalAssertTrue</code>	Fatally assert value is true
<code>fatalAssertWarning</code>	Fatally assert function issues specified warning
<code>fatalAssertWarningFree</code>	Fatally assert function issues no warnings

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
close(f);
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.assertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assertEqual`.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
```

```
testCase.addTeardown(@close, f);
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Related Examples

- “Write Helper Function Using Fatal Assertions”

## Concepts

# matlab.unittest.qualifications.FatalAssertable.fatalAssertClass

## Purpose

Fatally assert exact class of specified value

## Syntax

```
fatalAssertClass(fatalAssertable,actual,className)
fatalAssertClass(fatalAssertable,actual,metaClass)
fatalAssertClass(___,diagnostic)
```

## Description

`fatalAssertClass(fatalAssertable,actual,className)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertClass(fatalAssertable,actual,metaClass)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertClass(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
fatalAssertable.fatalAssertThat(actual, IsOfClass(className));
fatalAssertable.fatalAssertThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyClass`.

**Examples** See examples for `verifyEmpty`.

**See Also** `fatalAssertThat` | `fatalAssertNotEmpty` | `isempty`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertEqual

**Purpose**                      Fatally assert value is equal to specified value

**Syntax**                      `fatalAssertEqual(fatalAssertable,actual,expected)`  
`fatalAssertEqual(___,Name,Value)`  
`fatalAssertEqual(___,diagnostic)`

**Description**                `fatalAssertEqual(fatalAssertable,actual,expected)` fatally asserts that `actual` is strictly equal to `expected` .

`fatalAssertEqual(___,Name,Value)` fatally asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`fatalAssertEqual(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**                         • This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'AbsTol'**

**'RelTol'**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertEqual

---

## Examples

See examples for `verifyEqual`.

## See Also

`fatalAssertThat` | `fatalAssertNotEqual` |

# matlab.unittest.qualifications.FatalAssertable.fatalAssertE

## Purpose

Fatally assert function throws specified exception

## Syntax

```
fatalAssertError(fatalAssertable,actual,identifier)
fatalAssertError(fatalAssertable,actual,metaClass)
fatalAssertError(___,diagnostic)
```

## Description

`fatalAssertError(fatalAssertable,actual,identifier)` fatally asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`fatalAssertError(fatalAssertable,actual,metaClass)` fatally asserts that `actual` is a function handle that throws an exception whose type is defined by the `metaClass` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class..

`fatalAssertError(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
fatalAssertable.fatalAssertThat(actual, Throws(identifier));
fatalAssertable.fatalAssertThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **identifier**

Error identifier, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertError

---

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyError`.

## **See Also**

`fatalAssertThat` | `fatalAssertWarning` | `MException` | `error`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertFail

---

## Purpose

Produce unconditional fatal assertion failure

## Syntax

```
fatalAssertFail(fatalAssertable)
fatalAssertFail(fatalAssertable,diagnostic)
```

## Description

`fatalAssertFail(fatalAssertable)` produces an unconditional fatal assertion failure when encountered.

`fatalAssertFail(fatalAssertable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyFail`.

# matlab.unittest.qualifications.FatalAssertable.fatalAssertFalse

## Purpose

Fatally assert value is false

## Syntax

```
fatalAssertFalse(fatalAssertable,actual)
fatalAssertFalse(fatalAssertable,actual,diagnostic)
```

## Description

`fatalAssertFalse(fatalAssertable,actual)` fatally asserts that `actual` is a scalar logical with the value of false.

`fatalAssertFalse(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
fatalAssertable.fatalAssertThat(actual, IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `fatalAssertThat`.

- Unlike `fatalAssertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `fatalAssertTrue`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertF

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyFalse`.

## See Also

# matlab.unittest.qualifications.FatalAssertable.fatalAssertGreater

## Purpose

Fatally assert value is greater than specified value

## Syntax

```
fatalAssertGreaterThan(fatalAssertable, actual, floor)
fatalAssertGreaterThan(fatalAssertable, actual, floor,
    diagnostic)
```

## Description

`fatalAssertGreaterThan(fatalAssertable, actual, floor)` fatally asserts that all elements of `actual` are greater than all the elements of `floor`.

`fatalAssertGreaterThan(fatalAssertable, actual, floor, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
matlab.unittest.constraints.IsGreaterThan;
fatalAssertable.fatalAssertThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

## Syntax

```
fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor)
fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor,
    diagnostic)
```

## Description

`fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor)` fatally asserts that all elements of `actual` are greater than or equal to all the elements of `floor`.

`fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
fatalAssertable.fatalAssertThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

# matlab.unittest.qualifications.FatalAssertable.fatalAssertInstance

## Purpose

Fatally assert value is object of specified type

## Syntax

```
fatalAssertInstanceOf(fatalAssertable,actual,className)  
fatalAssertInstanceOf(fatalAssertable,actual,metaClass)  
fatalAssertInstanceOf(___,diagnostic)
```

## Description

`fatalAssertInstanceOf(fatalAssertable,actual,className)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertInstanceOf(fatalAssertable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;  
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(className));  
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyInstanceOf`.

## **See Also**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertLength

## Purpose

Fatally assert value has specified length

## Syntax

```
fatalAssertLength(fatalAssertable,actual,expectedLength)
fatalAssertLength(fatalAssertable,actual,expectedLength,
    diagnostic)
```

## Description

`fatalAssertLength(fatalAssertable,actual,expectedLength)` fatally asserts that `actual` is a MATLAB array whose length is `expectedLength`.

`fatalAssertLength(fatalAssertable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
fatalAssertable.fatalAssertThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLength`.

## See Also

# matlab.unittest.qualifications.FatalAssertable.fatalAssertLessThan

## Purpose

Fatally assert value is less than specified value

## Syntax

```
fatalAssertLessThan(fatalAssertable,actual,ceiling)
fatalAssertLessThan(fatalAssertable,actual,ceiling,
    diagnostic)
```

## Description

`fatalAssertLessThan(fatalAssertable,actual,ceiling)` fatally asserts that all elements of `actual` are less than all the elements of `ceiling`.

`fatalAssertLessThan(fatalAssertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
assertable.assertThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `assertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThan`.

## Syntax

```
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling,
    diagnostic)
```

## Description

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)` fatally asserts that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
fatalAssertable.fatalAssertThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **actual**

The value to test.

### **ceiling**

Maximum value.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyLessThanOrEqual`.

## **See Also**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertMatches

## Purpose

Fatally assert string matches specified regular expression

## Syntax

```
fatalAssertMatches(fatalAssertable,actual,expression)
fatalAssertMatches(fatalAssertable,actual,expression,
    diagnostic)
```

## Description

`fatalAssertMatches(fatalAssertable,actual,expression)` fatally asserts that `actual` is a string that matches the regular expression defined by `expression`.

`fatalAssertMatches(fatalAssertable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
fatalAssertable.fatalAssertThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expression**

The value to match, specified as a regular expression.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.FatalAssertable.fatalAssertM

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyMatches`.

**Examples** See examples for `verifyNotEmpty`.

**See Also** `fatalAssertThat` | `fatalAssertEmpty` | `isempty`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertNotEqual

## Purpose

Fatally assert value is not equal to specified value

## Syntax

```
fatalAssertNotEqual(fatalAssertable, actual, notExpected)
fatalAssertNotEqual(fatalAssertable, actual, notExpected,
    diagnostic)
```

## Description

`fatalAssertNotEqual(fatalAssertable, actual, notExpected)` fatally asserts that `actual` is not equal to `notExpected`.

`fatalAssertNotEqual(fatalAssertable, actual, notExpected, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpected**

Value to compare.

## Examples

See examples for `verifyNotEqual`.

## See Also

`fatalAssertThat` | `fatalAssertEqual` |

# matlab.unittest.qualifications.FatalAssertable.fatalAssertNotSameHandle

## Purpose

Fatally assert value is not handle to specified instance

## Syntax

```
fatalAssertNotSameHandle(fatalAssertable,actual,  
    notExpectedHandle)  
fatalAssertNotSameHandle(fatalAssertable,actual,  
    notExpectedHandle,diagnostic)
```

## Description

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle)` fatally asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;  
fatalAssertable.fatalAssertThat(actual, ~IsSameHandleAs(notExpectedHandleArray))
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`.

## See Also

`fatalAssertThat` | `fatalAssertSameHandle` |

# matlab.unittest.qualifications.FatalAssertable.fatalAssertN

## Purpose

Fatally assert value has specified element count

## Syntax

```
fatalAssertNumElements(fatalAssertable,actual,  
    expectedElementCount)  
fatalAssertNumElements(fatalAssertable,actual,  
    expectedElementCount,diagnostic)
```

## Description

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount)` fatally asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;  
fatalAssertable.fatalAssertThat(actual, HasElementCount(expectedElementCount))
```

There exists more functionality when using the `HasElementCount` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedElementCount**

The expected number of elements in the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`.

## See Also

`fatalAssertThat` | `fatalAssertSize` | `fatalAssertLength` | `numel`

## Purpose

Fatally assert function returns true when evaluated

## Syntax

```
fatalAssertReturnsTrue(fatalAssertable,actual)  
fatalAssertReturnsTrue(fatalAssertable,actual,diagnostic)
```

## Description

`fatalAssertReturnsTrue(fatalAssertable,actual)` fatally asserts that `actual` is a function handle that returns a scalar logical whose value is true.

`fatalAssertReturnsTrue(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `fatalAssertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `fatalAssertTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;  
fatalAssertable.fatalAssertThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`.

## See Also

`fatalAssertThat` | `fatalAssertTrue` |

# matlab.unittest.qualifications.FatalAssertable.fatalAssertS

## Purpose

Fatally assert two values are handles to same instance

## Syntax

```
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle,
    diagnostic)
```

## Description

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)` fatally asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
fatalAssertable.fatalAssertThat(actual, IsSameHandleAs(expectedHandl
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.FatalAssertable.fatalAssertSame

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`.

## See Also

`fatalAssertThat` | `fatalAssertNotSameHandle` | `handle`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertS

## Purpose

Fatally assert value has specified size

## Syntax

```
fatalAssertSize(fatalAssertable, actual, expectedSize)
fatalAssertSize(fatalAssertable, actual, expectedSize,
    diagnostic)
```

## Description

`fatalAssertSize(fatalAssertable, actual, expectedSize)` fatally asserts that `actual` is a MATLAB array whose size is `expectedSize`. `fatalAssertSize(fatalAssertable, actual, expectedSize, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
fatalAssertable.fatalAssertThat(actual, HasSize(expectedSize));
```

There exists more functionality when using the `HasSize` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedSize**

The expected sizes of each dimension the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.FatalAssertable.fatalAssertSize

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySize`.

## See Also

`fatalAssertThat` | `fatalAssertLength` | `fatalAssertNumElements`  
| `size`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertS

## Purpose

Fatally assert string contains specified string

## Syntax

```
fatalAssertSubstring(fatalAssertable,actual,substring)
fatalAssertSubstring(fatalAssertable,actual,substring,
    diagnostic)
```

## Description

`fatalAssertSubstring(fatalAssertable,actual,substring)` fatally asserts that `actual` is a string that contains `substring`.

`fatalAssertSubstring(fatalAssertable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
fatalAssertable.fatalAssertThat(actual,...
    ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **substring**

The value to match, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySubstring`.

## See Also

`fatalAssertThat` | `fatalAssertMatches` | `strfind`

## Purpose

Fatally assert value meets specified constraint

## Syntax

```
fatalAssertThat(fatalAssertable, actual, constraint)
fatalAssertThat(fatalAssertable, actual, constraint, diagnostic)
```

## Description

`fatalAssertThat(fatalAssertable, actual, constraint)` fatally asserts that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, a fatal assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`fatalAssertThat(fatalAssertable, actual, constraint, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **constraint**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.FatalAssertable.fatalAssertThat

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyThat`.

# matlab.unittest.qualifications.FatalAssertable.fatalAssertT

## Purpose

Fatally assert value is true

## Syntax

```
fatalAssertTrue(fatalAssertable,actual)
fatalAssertTrue(fatalAssertable,actual,diagnostic)
```

## Description

`fatalAssertTrue(fatalAssertable,actual)` fatally asserts that `actual` is a scalar logical with the value of true.

`fatalAssertTrue(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
fatalAssertable.fatalAssertThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `fatalAssertThat`.

However, this method is optimized for performance and does not construct a new `IsTrue` constraint for each call. Sometimes such use can come at the expense of less diagnostic information. Use the `fatalAssertReturnsTrue` method for a similar approach which may provide better diagnostic information.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertTrue

---

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyTrue`.

## **See Also**

`fatalAssertThat` | `fatalAssertFalse` | `fatalAssertReturnsTrue` |

# matlab.unittest.qualifications.FatalAssertable.fatalAssertWarning

## Purpose

Fatally assert function issues specified warning

## Syntax

```
fatalAssertWarning(fatalAssertable,actual,warningID)
fatalAssertWarning(fatalAssertable,actual,warningID,
    diagnostic)
[output1,...,outputN] = fatalAssertWarning( ___ )
```

## Description

`fatalAssertWarning(fatalAssertable,actual,warningID)` fatally asserts that `actual` issues a warning with the identifier `warningID`.

`fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
fatalAssertable.fatalAssertThat(actual, IssuesWarnings({warningID}))
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertWarni

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`.

## See Also

`fatalAssertThat` | `fatalAssertError` | `fatalAssertWarningFree` | `warning`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertV

## Purpose

Fatally assert function issues no warnings

## Syntax

```
fatalAssertWarningFree(fatalAssertable,actual)
fatalAssertWarningFree(fatalAssertable,actual,diagnostic)
[output1,...,outputN] = fatalAssertWarningFree( __ )
```

## Description

`fatalAssertWarningFree(fatalAssertable,actual)` fatally asserts that `actual` is a function handle that issues no warnings.

`fatalAssertWarningFree(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarningFree( __ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
fatalAssertable.fatalAssertThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarningFree`.

## See Also

# matlab.unittest.qualifications.FatalAssertionFailedException

---

**Purpose** Exception used for fatal assertion failures

**Description** The FatalAssertionFailedException class provides an exception used for fatal assertion failures. This class is used exclusively by the FatalAssertable qualification type.

**See Also** FatalAssertable | MException

# matlab.unittest.qualifications.Verifiable

---

**Purpose** Qualification to produce soft-failure conditions

**Description** The `Verifiable` class provides a qualification to produce soft-failure conditions. Apart from actions performed for failures, the `Verifiable` class works the same as other `matlab.unittest` qualifications.

Upon a verification failure, the `Verifiable` class informs the testing framework of the failure, including all diagnostic information associated with the failure, but continues to execute the currently running test without throwing an `MException`. This is most useful when a failure at the verification point is not fatal to the remaining test content. Often, you use verifications as the primary verification of a Four-Phase Test. Use other qualification types, such as assertions, fatal assertions, and assumptions, to test for violation of preconditions or incorrect test setup.

Since verifications do not throw `MExceptions`, all test content runs to completion even when verification failures occur. This helps you understand how close a piece of software is to meeting the test suite requirements. Qualification types that throw exceptions do not provide this insight, since once an exception is thrown an arbitrary amount of code remains that is not reached or exercised. Verifications also provide more testing coverage in failure conditions. However, when you overuse verifications, they can produce excess noise for a single failure condition. If a failure condition will cause later qualification points to also fail, use assertions or fatal assertions instead.

## Methods

<code>verifyClass</code>	Verify exact class of specified value
<code>verifyEmpty</code>	Verify value is empty
<code>verifyEqual</code>	Verify value is equal to specified value
<code>verifyError</code>	Verify function throws specified exception

<code>verifyFail</code>	Produce unconditional verification failure
<code>verifyFalse</code>	Verify value is false
<code>verifyGreaterThan</code>	Verify value is greater than specified value
<code>verifyGreaterThanOrEqual</code>	Verify value is greater than or equal to specified value
<code>verifyInstanceOf</code>	Verify value is object of specified type
<code>verifyLength</code>	Verify value has specified length
<code>verifyLessThan</code>	Verify value is less than specified value
<code>verifyLessThanOrEqual</code>	Verify value is less than or equal to specified value
<code>verifyMatches</code>	Verify string matches specified regular expression
<code>verifyNotEmpty</code>	Verify value is not empty
<code>verifyNotEqual</code>	Verify value is not equal to specified value
<code>verifyNotSameHandle</code>	Verify value is not handle to specified instance
<code>verifyNumElements</code>	Verify value has specified element count
<code>verifyReturnsTrue</code>	Verify function returns true when evaluated
<code>verifySameHandle</code>	Verify two values are handles to same instance
<code>verifySize</code>	Verify value has specified size

# matlab.unittest.qualifications.Verifiable

---

<code>verifySubstring</code>	Verify string contains specified string
<code>verifyThat</code>	Verify value meets given constraint
<code>verifyTrue</code>	Verify value is true
<code>verifyWarning</code>	Verify function issues specified warning
<code>verifyWarningFree</code>	Verify function issues no warnings

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Related Examples

- “Write Test Methods Using Verifications”

## Concepts

## External Web Sites

- Four-Phase Test

# matlab.unittest.qualifications.Verifiable.verifyClass

## Purpose

Verify exact class of specified value

## Syntax

```
verifyClass(verifiable,actual,className)
verifyClass(verifiable,actual,metaClass)
verifyClass( ___,diagnostic)
```

## Description

`verifyClass(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyClass(verifiable,actual,metaClass)` verifies that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. Use `verifyInstanceOf` to verify inclusion in a class hierarchy.

`verifyClass( ___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- The method is functionally equivalent to the following methods:

```
import matlab.unittest.constraints.IsOfClass;
verifiable.verifyThat(actual, IsOfClass(className));
verifiable.verifyThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.Verifiable.verifyClass

---

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test a Class**

These interactive tests verify the class of the number, 5.

Create a `TestCase` object and the value to test.

```
testCase = matlab.unittest.TestCase;  
actvalue = 5;
```

Verify class of `actvalue` is `double`.

```
verifyClass(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify class of `actvalue` is `char`.

```
verifyClass(testCase, actvalue, 'char');
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyClass failed.  
--> The value's class is incorrect.
```

```
Actual Class:  
    double  
Expected Class:  
    char
```

```
Actual Value:  
    5
```

Test fails.

## Test a Function Handle

These interactive tests verify function handles, specified as a meta.class instance, ?function\_handle.

Create a TestCase object.

```
testCase = matlab.unittest.TestCase;
```

Create a function handle.

```
fh = @sin;  
verifyClass(testCase, fh, ?function_handle);
```

Interactive verification passed.

Test the function name.

```
fh = 'sin';  
verifyClass(testCase, fh, ?function_handle);
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

# matlab.unittest.qualifications.Verifiable.verifyClass

---

```
verifyClass failed.  
--> The value's class is incorrect.
```

```
Actual Class:  
    char  
Expected Class:  
    function_handle
```

```
Actual Value:  
    sin
```

Test fails.

## Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, BaseExample.

```
classdef BaseExample  
end
```

Create a derived class, DerivedExample.

```
classdef DerivedExample < BaseExample  
end
```

Verify the classes are not equal.

```
testCase = matlab.unittest.TestCase;  
verifyClass(testCase, DerivedExample(), ?BaseExample);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
verifyClass failed.  
--> The value's class is incorrect.
```

```
Actual Class:
    DerivedExample
Expected Class:
    BaseExample
```

```
Actual Value:
    DerivedExample with no properties.
```

Test fails.

## Test Class of Output Value

Use `verifyClass` to test the `add5` function returns a double value.

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.');
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double');
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@( )add5('0'),'add5:InputMustBeNumeric');
        end
    end
end
```

# matlab.unittest.qualifications.Verifiable.verifyClass

---

Create a test suite from the Add5Test class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');
```

```
result = run(suite);
```

```
Running Add5Test
```

```
..
```

```
Done Add5Test
```

---

# matlab.unittest.qualifications.Verifiable.verifyEmpty

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples **Test for Empty Strings**

Create a `TestCase` object.

```
testCase = matlab.unittest.TestCase;
verifyEmpty(testCase, '');
```

```
Interactive verification passed.
```

## **Test for Empty Arrays**

An array with any zero dimension is empty.

```
testCase = matlab.unittest.TestCase;
verifyEmpty(testCase, ones(2, 5, 0, 3));
```

```
Interactive verification passed.
```

```
verifyEmpty(testCase, [2 3], 'Array is not empty.');
```

```
Interactive verification failed.
```

```
-----
Test Diagnostic:
```

```
-----
Array is not empty.
```

```
-----
Framework Diagnostic:
```

```
-----
verifyEmpty failed.
```

```
--> The value must be empty.
```

```
--> The value has a size of [1 2].
```

```
Actual Value:
```

2 3

Test failed.

## Test for Empty Cell Arrays

Test empty cell array, {}.

```
testCase = matlab.unittest.TestCase;
verifyEmpty(testCase, {}, 'Cell array is not empty.');
```

Interactive verification passed.

A cell array of empty arrays is not empty.

```
verifyEmpty(testCase, {[], [], []}, 'Cell array is not empty.');
```

Interactive verification failed.

-----  
Test Diagnostic:

-----  
Cell array is not empty.

-----  
Framework Diagnostic:

-----  
verifyEmpty failed.  
--> The value must be empty.  
--> The value has a size of [1 3].

Actual Value:

```
    []    []    []
```

Test failed.

## Test for Empty Test Suite

Test for empty object, emptyTestSuite.

# matlab.unittest.qualifications.Verifiable.verifyEmpty

---

```
testCase = matlab.unittest.TestCase;  
emptyTestSuite = matlab.unittest.TestSuite.empty;  
verifyEmpty(testCase, emptyTestSuite);
```

Interactive verification passed.

## See Also

[verifyThat](#) | [verifyNotEmpty](#) | [isempty](#)

# matlab.unittest.qualifications.Verifiable.verifyEqual

## Purpose

Verify value is equal to specified value

## Syntax

```
verifyEqual(verifiable,actual,expected)
verifyEqual( ___,Name,Value)
verifyEqual( ___,diagnostic)
```

## Description

`verifyEqual(verifiable,actual,expected)` verifies that `actual` is strictly equal to `expected`.

`verifyEqual( ___,Name,Value)` verifies equality with additional options specified by one or more `Name,Value` pair arguments.

`verifyEqual( ___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

## Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
verifiable.verifyThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol))
```

# matlab.unittest.qualifications.Verifiable.verifyEqual

---

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'AbsTol'**

**'RelTol'**

## Examples

### Comparing Numeric Values

Numeric values are equivalent if they are of the same class with equivalent size, complexity, and sparsity.

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

A value is equal to itself.

```
verifyEqual(testCase, 5, 5);
```

```
Interactive verification passed.
```

Values must have equal sizes.

```
verifyEqual(testCase, [5 5], 5);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
verifyEqual failed.  
--> NumericComparator failed.  
    --> Sizes do not match.
```

```
Actual double size:  
      1      2  
Expected double size:  
      1      1
```

```
Actual Value:  
      5      5  
Expected Value:  
      5
```

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyEqual

---

## Test Classes

```
testCase = matlab.unittest.TestCase;  
verifyEqual(testCase, int8(5), int16(5));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

```
verifyEqual failed.  
--> NumericComparator failed.  
    --> Classes do not match.
```

```
    Actual Class:  
        int8  
    Expected Class:  
        int16
```

```
Actual Value:  
    5  
Expected Value:  
    5
```

Test failed.

## Test Cell Arrays

Each element of a cell array must be equal in value, class, and size.

```
testCase = matlab.unittest.TestCase;  
verifyEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});
```

Interactive verification passed.

## Test Numeric Tolerances

```
testCase = matlab.unittest.TestCase;  
verifyEqual(testCase, 4.95, 5);
```

# matlab.unittest.qualifications.Verifiable.verifyEqual

---

Interactive verification failed.

-----  
Test Diagnostic:  
-----

4.95 is not equal to 5

-----  
Framework Diagnostic:  
-----

verifyEqual failed.

--> NumericComparator failed.

--> The values are not equal using "isequaln".

Actual Value:

4.950000000000000

Expected Value:

5

Test failed.

verifyEqual(testCase, 1.5, 2, 'AbsTol', 1)

Interactive verification passed.

verifyEqual(testCase, 1.5, 2, 'RelTol', 0.1, ...

'Difference between actual and expected exceeds relative tolerance

Interactive verification failed.

-----  
Test Diagnostic:  
-----

Difference between actual and expected exceeds relative tolerance

-----

# matlab.unittest.qualifications.Verifiable.verifyEqual

---

```
Framework Diagnostic:
-----
verifyEqual failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> RelativeTolerance failed.
        --> The value was not within relative tolerance.

        Tolerance Definition:
            abs(expected - actual) <= tolerance .* abs(expected)
        Tolerance Value:
            0.1000000000000000

Actual Value:
    1.5000000000000000
Expected Value:
    2

Test failed.
```

## See Also

[verifyThat](#) | [verifyNotEqual](#) |

# matlab.unittest.qualifications.Verifiable.verifyError

## Purpose

Verify function throws specified exception

## Syntax

```
verifyError(verifiable,actual,identifier)  
verifyError(verifiable,actual,metaClass)  
verifyError( __ ,diagnostic)
```

## Description

`verifyError(verifiable,actual,identifier)` verifies that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`verifyError(verifiable,actual,metaClass)` verifies that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`verifyError( __ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;  
verifiable.verifyThat(actual, Throws(identifier));  
verifiable.verifyThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **identifier**

# matlab.unittest.qualifications.Verifiable.verifyError

---

Error identifier, specified as a string.

## **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test for Error IDs**

```
testCase = matlab.unittest.TestCase;

% Passing scenarios
%%
verifyError(testCase, @() error('SOME:error:id','Error!'), 'SOME:error:id');
verifyError(testCase, @testCase.assertFail, ...
    ?matlab.unittest.qualifications.AssertionFailedException);

% Failing scenarios
%%
verifyError(testCase, 5, 'some:id', '5 is not a function handle');
verifyError(testCase, @testCase.verifyFail, ...
    ?matlab.unittest.qualifications.AssertionFailedException, ...
    'Verifications dont throw exceptions. ');
verifyError(testCase, @() error('SOME:id'), 'OTHER:id', 'Wrong id');
verifyError(testCase, @() error('whoops'), ...
    ?matlab.unittest.qualifications.AssertionFailedException, ...
    'Wrong type of exception thrown');
```

## Test Error Condition

Create `testNonNumericInput` to test if function throws expected error message, `add5:InputMustBeNumeric`, for unexpected condition, input is char.

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.');
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double');
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric');
        end
    end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');
```

```
result = run(suite);
```

```
Running Add5Test
```

# matlab.unittest.qualifications.Verifiable.verifyError

---

```
..  
Done Add5Test
```

---

## See Also

[verifyThat](#) | [verifyWarning](#) | [MException](#) | [error matlab.unittest.constraints.Throws](#) | [matlab.unittest.diagnostics.Diagnostic](#) |

**Purpose** Produce unconditional verification failure

**Syntax** `verifyFail(verifiable)`  
`verifyFail(verifiable,diagnostic)`

**Description** `verifyFail(verifiable)` produces an unconditional verification failure when encountered.

`verifyFail(verifiable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### **Test for Failure Condition**

An example of where this method may be used is in a callback function that should not be executed in a given scenario. A test can confirm this does not occur by unconditionally performing a failure if the code path is reached.

Assume a handle class `MyHandle` with a `SomethingHappened` event.

# matlab.unittest.qualifications.Verifiable.verifyFail

---

```
classdef MyHandle < handle
    events
        SomethingHappened
    end
end
```

The following is a test method inside a TestCase class.

```
methods(Test)
    function testDisabledListeners(testCase)

        h = MyHandle;

        % Add a listener to a test helper method
        listener = h.addlistener('SomethingHappened', ...
            @testCase.shouldNotGetCalled);

        % Passing scenario (code path is not reached)
        %%%%%%%%%%%
        % Disabled listener should not invoke callbacks
        listener.Enabled = false;
        h.notify('SomethingHappened');

        % Failing scenario (code path is reached)
        %%%%%%%%%%%
        % Enabled listener invoke callback and fail
        listener.Enabled = true;
        h.notify('SomethingHappened');
    end
end
```

# matlab.unittest.qualifications.Verifiable.verifyFalse

---

## Purpose

Verify value is false

## Syntax

```
verifyFalse(verifiable,actual)  
verifyFalse(__,diagnostic)
```

## Description

`verifyFalse(verifiable,actual)` verifies that `actual` is a scalar logical with the value of false.

`verifyFalse(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;  
verifiable.verifyThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `verifyThat`.

- Unlike `verifyTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `verifyTrue`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

# matlab.unittest.qualifications.Verifiable.verifyFalse

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test MATLAB Logical Functions

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Test true.

```
verifyFalse(testCase, true);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyFalse failed.
```

```
--> The value must evaluate to "false".
```

```
Actual Value:
```

```
    1
```

Test failed.

Test false.

```
verifyFalse(testCase, false);
```

Interactive verification passed.

## Test the Value 0

The number 0 is a double value, not a logical value.

```
testCase = matlab.unittest.TestCase;
verifyFalse(testCase, 0);
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
verifyFalse failed.
--> The value must be logical. It is of type "double".
```

```
Actual Value:
             0
```

Test failed.

## Test Array of Logical Values

To be false, the value must be scalar.

```
testCase = matlab.unittest.TestCase;
verifyFalse(testCase, [false false false]);
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
verifyFalse failed.
--> The value must be scalar. It has a size of [1 3].
```

```
Actual Value:
             0     0     0
```

# matlab.unittest.qualifications.Verifiable.verifyFalse

---

Test failed.

Test an array of mixed logical values.

```
verifyFalse(testCase, [false true false], ...  
    'A mixed array of logicals is not the one false value');
```

Interactive verification failed.

-----

Test Diagnostic:

-----

A mixed array of logicals is not the one false value

-----

Framework Diagnostic:

-----

verifyFalse failed.

--> The value must be scalar. It has a size of [1 3].

Actual Value:

0 1 0

Test failed.

## See Also

[verifyThat](#) | [verifyTrue](#) |

**Purpose** Verify value is greater than specified value

**Syntax** `verifyGreaterThan(verifiable,actual,floor)`  
`verifyGreaterThan(__,diagnostic)`

**Description** `verifyGreaterThan(verifiable,actual,floor)` verifies that all elements of `actual` are greater than all the elements of `floor`.  
`verifyGreaterThan(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
matlab.unittest.constraints.IsGreaterThan;  
verifiable.verifyThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Verifiable.verifyGreaterThan

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 3 is greater than 2.

```
verifyGreaterThan(testCase, 3, 2);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
verifyGreaterThan(testCase, 5, 9);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyGreaterThan failed.
```

```
--> The value must be greater than the minimum value.
```

```
Actual Value:
```

```
5
```

```
Minimum Value (Exclusive):
```

```
9
```

```
Test failed.
```

## Compare an Array to a Scalar

Test if each element is greater than the FLOOR value, 2.

```
testCase = matlab.unittest.TestCase;  
verifyGreaterThan(testCase, [5 6 7], 2);
```

Interactive verification passed.

Test if value 5 is greater than each element in the FLOOR array, [1 2 3].

```
verifyGreaterThan(testCase, 5, [1 2 3]);
```

Interactive verification passed.

Test if each element in the matrix is greater than the FLOOR value, 4.

```
verifyGreaterThan(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

```
verifyGreaterThan failed.
```

```
--> Each element must be greater than the minimum value.
```

```
Failing Indices:
```

```
      1      2      3      5
```

```
Actual Value:
```

```
      1      2      3  
      4      5      6
```

```
Minimum Value (Exclusive):
```

```
      4
```

```
Test failed.
```

## Compare Arrays

Test if each element is greater than each corresponding element of the FLOOR array, [4 -9 0].

```
testCase = matlab.unittest.TestCase;  
verifyGreaterThan(testCase, [5 -3 2], [4 -9 0]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyGreaterThan(testCase, eye(2), eye(2));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

verifyGreaterThan failed.

--> Each element must be greater than each corresponding element of the m

Failing Indices:

1	2	3	4
---	---	---	---

Actual Value:

1	0
0	1

Minimum Value (Exclusive):

1	0
0	1

Test failed.

## See Also

| [verifyLessThan](#) | [gt](#)

## Purpose

Verify value is greater than or equal to specified value

## Syntax

```
verifyGreaterThanOrEqualTo(verifiable,actual,floor)  
verifyGreaterThanOrEqualTo( ____,diagnostic)
```

## Description

`verifyGreaterThanOrEqualTo(verifiable,actual,floor)` that all elements of `actual` are greater than or equal to all the elements of `floor`.

`verifyGreaterThanOrEqualTo( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;  
verifiable.verifyThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 3 is greater than 2.

```
verifyGreaterThanOrEqualTo(testCase, 3, 2);
```

```
Interactive verification passed.
```

Verify 3 is greater than or equal to 3.

```
verifyGreaterThanOrEqualTo(testCase, 3, 3);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
verifyGreaterThanOrEqualTo(testCase, 5, 9);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyGreaterThanOrEqualTo failed.
```

```
--> The value must be greater than or equal to the minimum value.
```

```
Actual Value:
```

```
5
```

```
Minimum Value (Inclusive):  
    9
```

Test failed.

## Compare an Array to a Scalar

Test if each element is greater than or equal to the FLOOR value, 2.

```
testCase = matlab.unittest.TestCase;  
verifyGreaterThanOrEqualTo(testCase, [5 2 7], 2);
```

Interactive verification passed.

Test if each element in the matrix is greater than or equal to the FLOOR value, 4.

```
verifyGreaterThanOrEqualTo(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

```

```
Failing Indices:
```

```
    1    3    5
```

```
Actual Value:
```

```
    1    2    3  
    4    5    6
```

```
Minimum Value (Inclusive):
```

```
    4
```

## Compare Arrays

Test if each element is greater than or equal to each corresponding element of the FLOOR array, [4 -3 0].

```
testCase = matlab.unittest.TestCase;  
verifyGreaterThanOrEqualTo(testCase, [5 -3 2], [4 -3 0]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyGreaterThanOrEqualTo(testCase, eye(2), eye(2));
```

Interactive verification passed.

## See Also

[verifyThat](#) | [verifyGreaterThan](#) | [verifyLessThan](#) | [verifyLessThanOrEqualTo](#) | [ge](#)

# matlab.unittest.qualifications.Verifiable.verifyInstanceOf

## Purpose

Verify value is object of specified type

## Syntax

```
verifyInstanceOf(verifiable,actual,className)
verifyInstanceOf(verifiable,actual,metaClass)
verifyInstanceOf(___,diagnostic)
```

## Description

`verifyInstanceOf(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyInstanceOf(verifiable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`verifyInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
verifiable.verifyThat(actual, IsInstanceOf(className));
verifiable.verifyThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.Verifiable.verifyInstanceOf

---

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test a Class**

These interactive tests verify the class of the number, 5.

Create a `TestCase` object and the value to test.

```
testCase = matlab.unittest.TestCase;  
actvalue = 5;
```

Verify `actvalue` is an instance of class `double`.

```
verifyInstanceOf(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify if `actvalue` is an instance of `char`.

```
verifyInstanceOf(testCase, 5, 'char');
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyInstanceOf failed.
```

--> The value must be an instance of the expected type.

```
Actual Class:
    double
Expected Type:
    char
```

```
Actual Value:
    5
```

Test failed.

## Test a Function Handle

These tests verify function handles, specified as a meta.class instance, ?function\_handle.

Create a function handle.

```
fh = @sin;
testCase = matlab.unittest.TestCase;
verifyInstanceOf(testCase, fh, ?function_handle);
```

Interactive verification passed.

Test the function name.

```
fh = 'sin';
verifyInstanceOf(testCase, fh, ?function_handle);
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
```

verifyInstanceOf failed.

```

```
Actual Value:
sin
```

Test failed.

## Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, BaseExample.

```
classdef BaseExample
end
```

Create a derived class, DerivedExample.

```
classdef DerivedExample < BaseExample
end
```

Verify DerivedExample is an instance of BaseExample.

```
testCase.verifyInstanceOf(DerivedExample(), ?BaseExample);
```

```
Interactive verification passed.
```

Verify BaseExample is not an instance of DerivedExample.

```
testCase.verifyInstanceOf(BaseExample(), ?DerivedExample);
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:

# matlab.unittest.qualifications.Verifiable.verifyLength

---

## Purpose

Verify value has specified length

## Syntax

```
verifyLength(verifiable,actual,expectedLength)  
verifyLength( ____,diagnostic)
```

## Description

`verifyLength(verifiable,actual,expectedLength)` verifies that `actual` is a MATLAB array whose length is `expectedLength`.

`verifyLength( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;  
verifiable.verifyThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Array Lengths

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify length of array is the expected value, 5.

```
verifyLength(testCase, ones(2, 5, 3), 5, 'User diagnostic');
```

```
Interactive verification passed.
```

Length of array is not the expected value, 3.

```
verifyLength(testCase, [2 3], 3);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----

# matlab.unittest.qualifications.Verifiable.verifyLessThan

---

**Purpose** Verify value is less than specified value

**Syntax** `verifyLessThan(verifiable,actual,ceiling)`  
`verifyLessThan( __ ,diagnostic)`

**Description** `verifyLessThan(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than all the elements of `ceiling`.  
`verifyLessThan( __ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;  
verifiable.verifyThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 2 is less than 3.

```
verifyLessThan(testCase, 2, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
verifyLessThan(testCase, 9, 5);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyLessThan failed.
```

```
--> The value must be less than the maximum value.
```

```
Actual Value:
```

```
    9
```

```
Maximum Value (Exclusive):
```

```
    5
```

```
Test failed.
```

## Compare an Array to a Scalar

Test if each element is less than the CEILING value, 9.

```
testCase = matlab.unittest.TestCase;  
verifyLessThan(testCase, [5 6 7], 9);
```

Interactive verification passed.

Test if each element in the matrix is less than the CEILING value, 4.

```
verifyLessThan(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

-----  
Framework Diagnostic:  
-----

verifyLessThan failed.

--> Each element must be less than the maximum value.

Failing Indices:

2 4 6

Actual Value:

1 2 3  
4 5 6

Maximum Value (Exclusive):

4

Test failed.

## Compare Arrays

Test if each element is less than each corresponding element of the CEILING array, [7 -1 8].

```
testCase = matlab.unittest.TestCase;  
verifyLessThan(testCase, [5 -3 2], [7 -1 8]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyLessThan(testCase, eye(2), eye(2));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

verifyLessThan failed.

--> Each element must be less than each corresponding element of the m

Failing Indices:

```
      1      2      3      4
```

Actual Value:

```
      1      0  
      0      1
```

Maximum Value (Exclusive):

```
      1      0  
      0      1
```

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyLessThanOrEqualTo

## Purpose

Verify value is less than or equal to specified value

## Syntax

```
verifyLessThanOrEqualTo(verifiable,actual,ceiling)  
verifyLessThanOrEqualTo(___,diagnostic)
```

## Description

`verifyLessThanOrEqualTo(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`verifyLessThanOrEqualTo(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;  
verifiable.verifyThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **ceiling**

Maximum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify 2 is less than 3.

```
verifyLessThanOrEqual(testCase, 2, 3);
```

```
Interactive verification passed.
```

Verify 3 is less than or equal to 3.

```
verifyLessThanOrEqual(testCase, 3, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
verifyLessThanOrEqual(testCase, 9, 5);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyLessThanOrEqual failed.
```

```
--> The value must be less than or equal to the maximum value.
```

```
Actual Value:
```

```
9
```

```
Maximum Value (Inclusive):  
    5
```

Test failed.

## Compare an Array to a Scalar

Test if each element is less than or equal to the ceiling value, 7.

```
testCase = matlab.unittest.TestCase;  
verifyLessThanOrEqualTo(testCase, [5 2 7], 7);
```

Interactive verification passed.

Test if each element in the matrix is less than or equal to the ceiling value, 4.

```
verifyLessThanOrEqualTo(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

```
verifyLessThanOrEqualTo failed.
```

```
--> Each element must be less than or equal to the maximum value.
```

```
Failing Indices:
```

```
    4    6
```

```
Actual Value:
```

```
    1    2    3  
    4    5    6
```

```
Maximum Value (Inclusive):
```

```
    4
```

Test failed.

## Compare Arrays

Test if each element is less than or equal to each corresponding element of the `ceiling` array, `[5 -3 8]`.

```
testCase = matlab.unittest.TestCase;  
verifyLessThanOrEqual(testCase, [5 -3 2], [5 -3 8]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyLessThanOrEqual(testCase, eye(2), eye(2));
```

Interactive verification passed.

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for String Matches

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Verify that strings matches a regular expression.

```
verifyMatches(testCase, 'Some String', 'Some [Ss]tring', ...  
    'My result should have matched the expression');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another string', '(Some |An)other');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another 3 strings', '^Another \d+ strings?$');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, '3 more strings', '\d+ strings?');
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyMatches failed.
```

```
--> The string did not match the regular expression.
```

```
Actual String:
```

```
    3 more strings
```

# matlab.unittest.qualifications.Verifiable.verifyMatches

---

Regular Expression:  
`\d+ strings?`

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyNotEmpty

---

## Purpose

Verify value is not empty

## Syntax

```
verifyNotEmpty(verifiable,actual)
verifyNotEmpty( ___,diagnostic)
```

## Description

`verifyNotEmpty(verifiable,actual)` verifies that `actual` is a non-empty MATLAB value.

`verifyNotEmpty( ___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
verifiable.verifyThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Verifiable.verifyNotEmpty

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Non-Empty Strings

Create a `TestCase` object.

```
testCase = matlab.unittest.TestCase;
```

```
verifyNotEmpty(testCase, '');
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyNotEmpty failed.  
--> The value must not be empty.  
--> The value has a size of [0 0].
```

```
Actual Value:  
    ''
```

Test failed.

### Test for Non-Empty Arrays

An array with any zero dimension is empty.

Test array [2 3].

```
testCase = matlab.unittest.TestCase;  
verifyNotEmpty(testCase, [2 3]);
```

```
Interactive verification passed.
```

Test array with a zero dimension.

```
verifyNotEmpty(testCase, ones(2, 5, 0, 3));
```

Interactive verification failed.

-----  
Framework Diagnostic:  
-----

verifyNotEmpty failed.  
--> The value must not be empty.  
--> The value has a size of [2 5 0 3].

Actual Value:  
Empty array: 2-by-5-by-0-by-3

Test failed.

## Test for Non-Empty Cell Arrays

A cell array of empty arrays is not empty.

```
testCase = matlab.unittest.TestCase;  
verifyNotEmpty(testCase, {[], [], []}, '');
```

Interactive verification passed.

## Test for Non-Empty Test Suite

Test an empty object, emptyTestSuite.

```
emptyTestSuite = matlab.unittest.TestSuite.empty;  
testCase = matlab.unittest.TestCase;  
verifyNotEmpty(testCase, emptyTestSuite);
```

Interactive verification failed.

-----  
Framework Diagnostic:  
-----

verifyNotEmpty failed.  
--> The value must not be empty.

# matlab.unittest.qualifications.Verifiable.verifyNotEmpty

---

```
--> The value has a size of [0 0].
```

```
Actual Value:
```

```
0x0 TestCase array with no properties.
```

```
Test failed.
```

# matlab.unittest.qualifications.Verifiable.verifyNotEqual

## Purpose

Verify value is not equal to specified value

## Syntax

```
verifyNotEqual(verifiable,actual,notExpected)
verifyNotEqual(___,diagnostic)
```

## Description

`verifyNotEqual(verifiable,actual,notExpected)` verifies that `actual` is not equal to `notExpected`.

`verifyNotEqual(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
verifiable.verifyThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpected**

Value to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Verifiable.verifyNotEqual

---

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Numeric Values

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Compare a value to itself.

```
verifyNotEqual(testCase, 5, 5);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
verifyNotEqual failed.  
--> NumericComparator passed.
```

```
Actual Value:
```

```
    5
```

```
Prohibited Value:
```

```
    5
```

```
Test failed.
```

Compare different number values.

```
verifyNotEqual(testCase, 4.95, 5, '4.95 should be different from 5');
```

```
Interactive verification passed.
```

```
Values 4.95 and 5 are not equal.
```

Compare values of different sizes.

```
verifyNotEqual(testCase, [5 5], 5, '[5 5] is not equal to 5');
```

```
Interactive verification passed.
```

Values are not equal.

## Compare Classes

```
testCase = matlab.unittest.TestCase;  
verifyNotEqual(testCase, int8(5), int16(5), 'Classes dont match');
```

```
Interactive verification passed.
```

## Compare Cell Arrays

Test a cell array by comparing each element.

```
testCase = matlab.unittest.TestCase;  
verifyNotEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyNotEqual failed.  
--> CellComparator passed.
```

```
Actual Value:  
      'cell'   [1x1 struct]   [5]  
Prohibited Value:  
      'cell'   [1x1 struct]   [5]
```

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyNotSameHandle

**Purpose** Verify value is not handle to specified instance

**Syntax** `verifyNotSameHandle(verifiable,actual,notExpectedHandle)`  
`verifyNotSameHandle( __ ,diagnostic)`

**Description** `verifyNotSameHandle(verifiable,actual,notExpectedHandle)` verifies that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`verifyNotSameHandle( __ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;  
verifiable.verifyThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle  
end
```

Create two handle variables.

```
h1 = ExampleHandle;  
h2 = ExampleHandle;
```

Handles point to different objects.

```
verifyNotSameHandle(testCase, h1, h2);
```

```
Interactive verification passed.
```

Show matching handle combinations.

```
verifyNotSameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyNotSameHandle failed.
```

# matlab.unittest.qualifications.Verifiable.verifyNotSameHandle

---

```
--> The two handles must not refer to the same handle, or should have  
different sizes.
```

```
Actual Value:  
    1x3 ExampleHandle array with no properties.  
Handle Object:  
    1x3 ExampleHandle array with no properties.
```

Test failed.

The order of the handle arguments matters.

```
verifyNotSameHandle(testCase, [h1 h2], [h2 h1]);
```

```
Interactive verification passed.
```

Test a handle with itself.

```
verifyNotSameHandle(testCase, h1, h1);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyNotSameHandle failed.  
--> The two handles must not refer to the same handle, or should have  
different sizes.
```

```
Actual Value:  
    ExampleHandle with no properties.  
Handle Object:  
    ExampleHandle with no properties.
```

Test failed.

Variables are not same size.

```
verifyNotSameHandle(testCase, h2, [h2 h2]);
```

```
Interactive verification passed.
```

```
Variables are the same size.
```

```

# matlab.unittest.qualifications.Verifiable.verifyNumElements

**Purpose** Verify value has specified element count

**Syntax** `verifyNumElements(verifiable,actual,expectedElementCount)`  
`verifyNumElements(___,diagnostic)`

**Description** `verifyNumElements(verifiable,actual,expectedElementCount)` verifies that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`verifyNumElements(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:  

```
import matlab.unittest.constraints.HasElementCount;  
verifiable.verifyThat(actual, HasElementCount(expectedElementCount));
```

There exists more functionality when using the `HasElementCount` constraint directly via `verifyThat`.

**Input Arguments**

**verifiable**  
The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

**actual**  
The value to test.

**expectedElementCount**  
The expected number of elements in the array.

**diagnostic**  
Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Matrices

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

```
n = 7;  
verifyNumElements(testCase, eye(n), n^2);
```

```
Interactive verification passed.
```

```
verifyNumElements(testCase, 3, 1);
```

```
Interactive verification passed.
```

```
verifyNumElements(testCase, [1 2 3; 4 5 6], 5);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
verifyNumElements failed.
```

```
--> The value did not have the correct number of elements.
```

```
Actual Number of Elements:

# matlab.unittest.qualifications.Verifiable.verifyReturnsTrue

**Purpose** Verify function returns true when evaluated

**Syntax** `verifyReturnsTrue(verifiable,actual)`  
`verifyReturnsTrue(___,diagnostic)`

**Description** `verifyReturnsTrue(verifiable,actual)` verifies that `actual` is a function handle that returns a scalar logical whose value is true.  
`verifyReturnsTrue(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `verifyTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `verifyTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;  
verifiable.verifyThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test if Condition is True

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;  
verifyReturnsTrue(testCase, @true);
```

```
Interactive verification passed.
```

Verify that it is true that two numbers are equal.

```
verifyReturnsTrue(testCase, @() isequal(1,1));
```

```
Interactive verification passed.
```

Verify that it is true that two letters are not the same.

```
verifyReturnsTrue(testCase, @() ~strcmp('a','b'));
```

```
Interactive verification passed.
```

Cause verification to fail by trying to verify that “false” evaluates to “true”.

```
verifyReturnsTrue(testCase, @false);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:
```

# matlab.unittest.qualifications.Verifiable.verifyReturnsTrue

---

```
-----  
verifyReturnsTrue failed.  
--> The function handle should have evaluated to "true".  
--> Returned value:  
      0
```

```
Actual Function Handle:  
      @false
```

Test failed.

Cause verification to fail by having the test specified in the function handle return a vector of logical values not a scalar logical value.

```
verifyReturnsTrue(testCase, @() strcmp('a',{ 'a','a'}));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----  
verifyReturnsTrue failed.  
--> The function handle should have returned a scalar. The return value h  
--> Returned value:  
      1      1
```

```
Actual Function Handle:  
      @()strcmp('a',{ 'a','a'})
```

Test failed.

Cause verification to fail by having the test specified in the function handle return a double not a logical.

```
verifyReturnsTrue(testCase, @() exist('exist'));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----  
verifyReturnsTrue failed.  
--> The function handle should have returned a logical value. It was c  
--> Returned value:  
    5
```

```
Actual Function Handle:  
    @()exist('exist')
```

Test failed.

## See Also

[verifyThat](#) | [verifyTrue](#) |

# matlab.unittest.qualifications.Verifiable.verifySameHandle

**Purpose** Verify two values are handles to same instance

**Syntax** `verifySameHandle(verifiable,actual,expectedHandle)`  
`verifySameHandle(__,diagnostic)`

**Description** `verifySameHandle(verifiable,actual,expectedHandle)` verifies that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`verifySameHandle(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;  
verifiable.verifyThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle  
end
```

Create two handle variables.

```
h1 = ExampleHandle;  
h2 = ExampleHandle;
```

Show matching handle combinations.

```
verifySameHandle(testCase, h1, h1);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h1], [h1 h1]);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification passed.
```

Handles must point to same object.

# matlab.unittest.qualifications.Verifiable.verifySameHandle

---

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Substrings

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Test that a substring is contained in a string.

```
verifySubstring(testCase, 'SomeLongString', 'Long');
```

```
Interactive verification passed.
```

Show that case matters.

```
verifySubstring(testCase, 'SomeLongString', 'lonG');
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
verifySubstring failed.  
--> The string must contain the substring.
```

```
Actual String:  
    SomeLongString  
Expected Substring:  
    lonG
```

Test failed.

Cause the verification to fail by testing a substring that isn't contained in the actual string.

# matlab.unittest.qualifications.Verifiable.verifySubstring

---

```
verifySubstring(testCase, 'SomeLongString', 'OtherString');
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:

# matlab.unittest.qualifications.Verifiable.verifyThat

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples      Test Conditions Using Constraints

```
% Passing scenarios
%%
import matlab.unittest.constraints.IsTrue;
verifyThat(testCase, true, IsTrue);

import matlab.unittest.constraints.IsEqualTo;
verifyThat(testCase, 5, IsEqualTo(5), '5 should be equal to 5');

import matlab.unittest.constraints.IsGreaterThan;
import matlab.unittest.constraints.HasNaN;
verifyThat(testCase, [5 NaN], IsGreaterThan(10) | HasNaN, ...
    'The value was not greater than 10 or NaN');

% Failing scenarios
%%
import matlab.unittest.constraints.AnyCellof;
import matlab.unittest.constraints.ContainsSubstring;
verifyThat(testCase, AnyCellof({'cell', 'of', 'strings'}), ...
    ContainsSubstring('char'), 'Test description');

import matlab.unittest.constraints.HasSize;
verifyThat(testCase, zeros(10,4,2), HasSize([10,5,2]), ...
    @() disp('A function handle diagnostic.));

import matlab.unittest.constraints.IsEmpty;
verifyThat(testCase, 5, IsEmpty);
```

# matlab.unittest.qualifications.Verifiable.verifyTrue

---

## Purpose

Verify value is true

## Syntax

```
verifyTrue(verifiable,actual)
verifyTrue(__,diagnostic)
```

## Description

`verifyTrue(verifiable,actual)` verifies that `actual` is a scalar logical with the value of true.

`verifyTrue(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
verifiable.verifyThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `verifyThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `verifyReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

## **actual**

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test MATLAB Logical Functions**

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Test true.

```
verifyTrue(testCase, true);
```

```
Interactive verification passed.
```

Test false.

```
verifyTrue(testCase, false);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
verifyTrue failed.
```

```
--> The value must evaluate to "true".
```

```
Actual Value:
```

```
    0
```

```
Test failed.
```

## Test the Value 1

```
The number 1 is a double value, not a logical value.
```

```
A double value of 1 is not true.
```

```
testCase = matlab.unittest.TestCase;  
verifyTrue(testCase, 1);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:
```

```
-----  
verifyTrue failed.
```

```
--> The value must be logical. It is of type "double".
```

```
Actual Value:
```

```
    1
```

```
Test failed.
```

## Test Array of Logical Values

```
To be true, the value must be scalar.
```

```
testCase = matlab.unittest.TestCase;  
verifyTrue(testCase, [true true true]);
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:
```

# matlab.unittest.qualifications.Verifiable.verifyTrue

---

```
-----  
verifyTrue failed.  
--> The value must be scalar. It has a size of [1 3].
```

```
Actual Value:  
      1      1      1
```

Test failed.

Optimized comparison that trades speed for less diagnostics.

```
verifyTrue(testCase, ~isempty(strfind('string', 'ring')), ...  
    'Could not find expected string');
```

In Verifiable>Verifiable.verifyWarning at 701
Interactive verification failed.
```

```
-----
Test Diagnostic:
-----
```

```
Did not issue specified warning
```

```
-----
Framework Diagnostic:
-----
```

```
verifyWarning failed.
```

```
--> The function handle did not issue a correct warning profile.
```

```
The expected warning profile ignores:
```

```
Set
```

```
Count
```

```
Order
```

```
--> The function handle did not issue the correct warnings.
```

```
Missing Warnings:
```

```
SOME:warning:id
```

```
Actual Warning Profile:
```

```
SOME:other:id
```

```
Expected Warning Profile:
```

```
SOME:warning:id
```

```
Evaluated Function:
```

```
@()warning('SOME:other:id','Warning message')
```

## Test a Function Without Warnings

Test the true function, which does not issue warnings.

# matlab.unittest.qualifications.Verifiable.verifyWarning

---

```
testCase = matlab.unittest.TestCase;
verifyWarning(testCase, @true, 'SOME:warning:id', ...
 '@true did not issue any warning');

Interactive verification failed.

-----
Test Diagnostic:
-----
@true did not issue any warning

-----
Framework Diagnostic:
-----
verifyWarning failed.
--> The function handle did not issue a correct warning profile.
    The expected warning profile ignores:
        Set
        Count
        Order
--> The function handle did not issue any warnings.

Expected Warning Profile:
    SOME:warning:id

Evaluated Function:
    @true

Test failed.
```

## Test Function With Output Arguments

Create a helper function that generates a warning and returns output.

```
function varargout = helper()
    warning('SOME:warning:id', 'Warning!');
    varargout = {123, 'abc'};
end
```

# matlab.unittest.qualifications.Verifiable.verifyWarning

---

Call helper.

```
testCase = matlab.unittest.TestCase;  
[actualOut1, actualOut2] = verifyWarning(testCase, @helper, ...  
    'SOME:warning:id');
```

Interactive verification passed.

## See Also

[verifyThat](#) | [verifyError](#) | [verifyWarningFree](#) | [warning](#)

# matlab.unittest.qualifications.Verifiable.verifyWarningFree

## Purpose

Verify function issues no warnings

## Syntax

```
verifyWarningFree(verifiable,actual)
verifyWarningFree(___,diagnostic)
output1,...,outputN = verifyWarningFree(___)
```

## Description

`verifyWarningFree(verifiable,actual)` verifies that `actual` is a function handle that issues no warnings.

`verifyWarningFree(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`output1,...,outputN = verifyWarningFree(___)` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
verifiable.verifyThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

### **Test for Warnings from MATLAB Functions**

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase;
```

Test the `why` function.

```
verifyWarningFree(testCase, @why);
```

```
The bald and not excessively bald and not excessively smart hamster of  
Interactive verification passed.
```

This is a randomly-generated message.

Test the `true` function.

```
verifyWarningFree(testCase, @true);
```

```
Interactive verification passed.
```

# questdlg

---

**Purpose** Create and open question dialog box

**Syntax**

```
button = questdlg('qstring')
button = questdlg('qstring','title')
button = questdlg('qstring','title',default)
button = questdlg('qstring','title','str1','str2',default)
button = questdlg('qstring','title','str1','str2','str3',
    default)
button = questdlg('qstring','title', ..., options)
```

**Description** `button = questdlg('qstring')` displays a modal dialog box presenting the question 'qstring'. The dialog has three default buttons, **Yes**, **No**, and **Cancel**. If the user presses one of these three buttons, `button` is set to the name of the button pressed. If the user presses the close button on the dialog without making a choice, `button` is set to the empty string. If the user presses the **Return** key, `button` is set to 'Yes'. 'qstring' is a cell array or a string that automatically wraps to fit within the dialog box.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`button = questdlg('qstring','title')` displays a question dialog with 'title' displayed in the dialog's title bar.

`button = questdlg('qstring','title',default)` specifies which push button is the default in the event that the **Return** key is pressed. '*default*' must be 'Yes', 'No', or 'Cancel'.

`button = questdlg('qstring','title','str1','str2',default)` creates a question dialog box with two push buttons labeled 'str1' and 'str2'. '*default*' specifies the default button selection and must be 'str1' or 'str2'.

`button = questdlg('qstring','title','str1','str2','str3',  
default)` creates a question dialog box with three push buttons labeled 'str1', 'str2', and 'str3'. *default* specifies the default button selection and must be 'str1', 'str2', or 'str3'.

When *default* is specified, but is not set to one of the button names, pressing the **Enter** key displays a warning and the dialog remains open.

`button = questdlg('qstring','title', ..., options)` replaces the string *default* with a structure, *options*. The structure specifies which button string is the default answer, and whether to use TeX to interpret the question string, *qstring*. Button strings and dialog titles cannot use TeX interpretation. The *options* structure must include the fields `Default` and `Interpreter`, both strings. It can include other fields, but `questdlg` does not use them. You can set `Interpreter` to 'none' or 'tex'. If the `Default` field does not contain a valid button name, a command window warning is issued and the dialog box does not respond to pressing the **Enter** key.

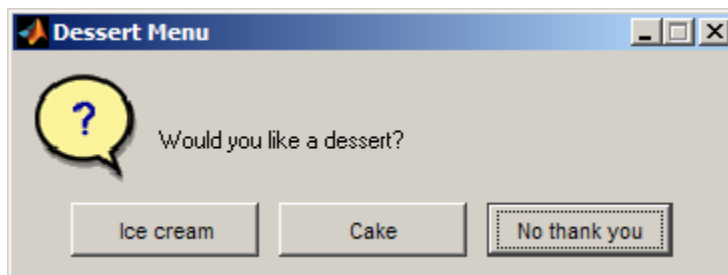

## Examples

### Example 1

Create a dialog that requests a dessert preference and encode the resulting choice as an integer.

```
% Construct a questdlg with three options
choice = questdlg('Would you like a dessert?', ...
    'Dessert Menu', ...
    'Ice cream','Cake','No thank you','No thank you');
% Handle response
switch choice
    case 'Ice cream'
        disp([choice ' coming right up.'])
        dessert = 1;
    case 'Cake'
        disp([choice ' coming right up.'])
        dessert = 2;
    case 'No thank you'
        disp('I'll bring you your check.')
        dessert = 0;
```

end

To access the return value assigned to `dessert`, save the example as a function, for example `choosedessert`, by inserting this line on top:

```
function dessert = choosedessert
```

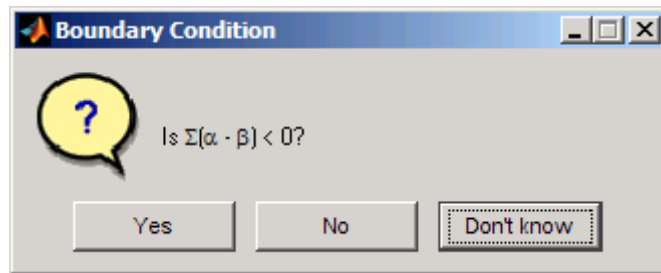

You can generalize the function by providing the cases as string or cell array calling arguments.

As the example shows, case statements can contain white space (but are case-sensitive).

## Example 2

Specify an options structure to use the TeX interpreter to format a question.

```
options.Interpreter = 'tex';  
% Include the desired Default answer  
options.Default = 'Don''t know';  
% Create a TeX string for the question  
qstring = 'Is  $\Sigma(\alpha - \beta) < 0$ ?';  
choice = questdlg(qstring, 'Boundary Condition', ...  
    'Yes', 'No', 'Don''t know', options)
```

# quit

---

<b>Purpose</b>	Terminate MATLAB program
<b>Alternatives</b>	As an alternative to the quit function, use the Close box in the MATLAB desktop.
<b>Syntax</b>	<pre>quit quit <b>cancel</b> quit <b>force</b></pre>
<b>Description</b>	<p>quit displays a confirmation dialog box if the confirm upon quitting preference is selected, and if confirmed or if the confirmation preference is not selected, terminates MATLAB after running <code>finish.m</code>, if <code>finish.m</code> exists. The workspace is not automatically saved by quit. To save the workspace or perform other actions when quitting, create a <code>finish.m</code> file to perform those actions. For example, you can display a custom dialog box to confirm quitting using a <code>finish.m</code> file—see the following examples for details. If an error occurs while <code>finish.m</code> is running, quit is canceled so that you can correct your <code>finish.m</code> file without losing your workspace.</p> <p>quit <b>cancel</b> is for use in <code>finish.m</code> and cancels quitting. It has no effect anywhere else.</p> <p>quit <b>force</b> bypasses <code>finish.m</code> and terminates MATLAB. Use this to override <code>finish.m</code>, for example, if an errant <code>finish.m</code> will not let you quit.</p>
<b>Tips</b>	<p>When using Handle Graphics objects in <code>finish.m</code>, use <code>uiwait</code>, <code>waitfor</code>, or <code>drawnow</code> so that figures are visible. See the reference pages for these functions for more information.</p> <p>If you want MATLAB to display the following confirmation dialog box after running quit, select <b>Preferences</b> in the <b>Environment</b> section on the <b>Home</b> tab. Then select the check box for Confirm before exiting MATLAB, and click <b>OK</b>.</p>

## Examples

Two sample `finish.m` files are included with MATLAB. Use them to help you create your own `finish.m`, or rename one of the files to `finish.m` to use it.

- `finishesav.m`—Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m`—Displays a dialog allowing you to cancel quitting; it uses `quit cancel` and contains the following code:

```
button = questdlg('Ready to quit?', ...
    'Exit Dialog', 'Yes', 'No', 'No');
switch button
    case 'Yes',
        disp('Exiting MATLAB');
        %Save variables to matlab.mat
        save
    case 'No',
        quit cancel;
end
```

## See Also

# Quit (COM)

---

**Purpose** Terminate MATLAB Automation server

**Syntax** **MATLAB Client**  
h.Quit  
Quit(h)  
invoke(h, 'Quit')

**IDL Method Signature**  
void Quit(void)

**Microsoft Visual Basic Client**  
Quit

**Description** Quit terminates the MATLAB server session attached to handle h.

**Tips** Server function names, like `Quit`, are case sensitive when using the first syntax shown.  
There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

**Purpose**

Quiver or velocity plot

**Syntax**

```
quiver(x,y,u,v)
quiver(u,v)
quiver(...,scale)
quiver(...,LineStyle)
quiver(...,LineStyle,'filled')
quiver(...,'PropertyName',PropertyValue,...)
quiver(axes_handle,...)
h = quiver(...)
```

**Description**

A quiver plot displays velocity vectors as arrows with components  $(u, v)$  at the points  $(x, y)$ .

For example, the first vector is defined by components  $u(1), v(1)$  and is displayed at the point  $x(1), y(1)$ .

`quiver(x,y,u,v)` plots vectors as arrows at the coordinates specified in each corresponding pair of elements in  $x$  and  $y$ . The matrices  $x$ ,  $y$ ,  $u$ , and  $v$  must all be the same size and contain corresponding position and velocity components. However,  $x$  and  $y$  can also be vectors, as explained in the next section. By default, the arrows are scaled to just not overlap, but you can scale them to be longer or shorter if you want.

`quiver(u,v)` draws vectors specified by  $u$  and  $v$  at equally spaced points in the  $x$ - $y$  plane.

`quiver(...,scale)` automatically scales the arrows to fit within the grid and then stretches them by the factor `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves the length. Use `scale = 0` to plot the velocity vectors without automatic scaling. You can also tune the length of arrows after they have been drawn by choosing the **Plot**

**Edit**  tool, selecting the quivergroup object, opening the Property Editor, and adjusting the **Length** slider.

`quiver(...,LineStyle)` specifies line style, marker symbol, and color using any valid `LineStyle`. `quiver` draws the markers at the origin of the vectors.

`quiver(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the quivergroup objects the function creates.

`quiver(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver(...)` returns the handle to the quivergroup object.

## Expanding x- and y-Coordinates

MATLAB expands `x` and `y` if they are not matrices. This expansion is equivalent to calling `meshgrid` to generate matrices from vectors:

```
[x,y] = meshgrid(x,y);  
quiver(x,y,u,v)
```

In this case, the following must be true:

`length(x) = n` and `length(y) = m`, where `[m,n] = size(u) = size(v)`.

The vector `x` corresponds to the columns of `u` and `v`, and vector `y` corresponds to the rows of `u` and `v`.

## Examples

### Plot Vector Velocities

Use `quiver` to display an arrow at each data point in `x` and `y` such that the arrow direction and length represent the corresponding values in `u` and `v`.

```
[x,y] = meshgrid(0:0.2:2,0:0.2:2);  
u = cos(x).*y;  
v = sin(x).*y;
```

figure

### Show Gradient with Quiver Plot

Plot the gradient of the function  $z = x e^{-x^2 - y^2}$ .

```
[X,Y] = meshgrid(-2:.2:2);  
Z = X.*exp(-X.^2 - Y.^2);  
[DX,DY] = gradient(Z,.2,.2);
```

# quiver

```
figure
contour(X,Y,Z)
hold on
quiver(X,Y,DX,DY)
hold off
```

## See Also

[contour](#) | [LineSpec](#) | [plot](#) | [quiver3](#)

## How To

- [Two-Dimensional Quiver Plots](#)

**Purpose** 3-D quiver or velocity plot

## Syntax

```
quiver3(x,y,z,u,v,w)
quiver3(z,u,v,w)
quiver3(...,scale)
quiver3(...,LineStyle)
quiver3(...,LineStyle,'filled')
quiver3(...,'PropertyName',PropertyValue,...)
quiver3(axes_handle,...)
h = quiver3(...)
```

## Description

A three-dimensional quiver plot displays vectors with components  $(u,v,w)$  at the points  $(x,y,z)$ , where  $u,v,w,x,y$ , and  $z$  all have real (non-complex) values.

`quiver3(x,y,z,u,v,w)` plots vectors with components  $(u,v,w)$  at the points  $(x,y,z)$ . The matrices  $x,y,z,u,v,w$  must all be the same size and contain the corresponding position and vector components.

`quiver3(z,u,v,w)` plots the vectors at the equally spaced surface points specified by matrix  $z$ . `quiver3` automatically scales the vectors based on the distance between them to prevent them from overlapping.

`quiver3(...,scale)` automatically scales the vectors to prevent them from overlapping, and then multiplies them by `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves them. Use `scale = 0` to plot the vectors without the automatic scaling.

`quiver3(...,LineStyle)` specifies line style, marker symbol, and color using any valid `LineStyle`. `quiver3` draws the markers at the origin of the vectors.

`quiver3(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver3(..., 'PropertyName', PropertyValue, ...)` specifies property name and property value pairs for the quivergroup object the function creates.

`quiver3(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver3(...)` returns a handle to the quivergroup object.

## Examples

### Plot Surface Normals

Plot the surface normals of the function  $z = xe^{-x^2-y^2}$ .

```
[X,Y] = meshgrid(-2:0.25:2, -1:0.2:1);  
Z = X.* exp(-X.^2 - Y.^2);  
[U,V,W] = surfnorm(X,Y,Z);
```

```
figure  
quiver3(X,Y,Z,U,V,W,0.5);
```

```
hold on  
surf(X,Y,Z);  
view(-35,45)  
axis ([-2 2 -1 1 -.6 .6])  
hold off
```

**See Also**

**How To**

- [Three-Dimensional Quiver Plots](#)

# Quivergroup Properties

---

**Purpose** Define quivergroup properties

**Modifying Properties** You can set and query graphics object properties using the set and get commands or the Property Editor (propertyeditor).

Note that you cannot define default properties for quivergroup objects. See Plot Objects for more information on quivergroup objects.

**Quivergroup Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation

hg.Annotation object (read-only)

*Control the display of quivergroup objects in legends.* Specifies whether this quivergroup object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the quivergroup object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the quivergroup object in a legend as one entry, but not its children objects
off	Do not include the quivergroup or its children in a legend (default)
children	Include only the children of the quivergroup as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### AutoScale

{on} | off

*Autoscale arrow length.* Based on average spacing in the  $x$  and  $y$  directions, `AutoScale` scales the arrow length to fit within the grid-defined coordinate data and keeps the arrows from overlapping. After autoscaling, `quiver` applies the `AutoScaleFactor` to the arrow length.

### AutoScaleFactor

scalar (default = 0.9)

*User-specified scale factor.* When `AutoScale` is on, the `quiver` function applies this user-specified autoscale factor to the arrow length. A value of 2 doubles the length of the arrows; 0.5 halves the length.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

# Quivergroup Properties

---

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## ButtonDownFcn

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the quivergroup object.* An array containing the handles of all line objects parented to this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

# Quivergroup Properties

---

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See `Function Handle Callbacks` for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcb0`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the quivergroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.

# Quivergroup Properties

---

- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object’s color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## `HandleVisibility`

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching

# Quivergroup Properties

---

the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and

the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the quiver plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`  
`on` | `{off}`

*Select the object by clicking lines or area of extent.* Select plot objects by:

- Clicking quiver arrows (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the quiver lines (excluding the baseline) to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the arrows).

`Interruptible`  
`off` | `{on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

# Quivergroup Properties

---

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the *gca* or *gcf* command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of quivergroup object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
'.'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

### LineWidth

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

### Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk

# Quivergroup Properties

---

Specifier	Marker Type
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MaxHeadSize`  
scalar (default = 0.2)

*Maximum size of arrowhead.* A value determining the maximum size of the arrowhead relative to the length of the arrow.

`Parent`  
handle of parent axes, `hggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hggroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

`Selected`  
on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the

# Quivergroup Properties

---

SelectionHighlight property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

SelectionHighlight  
{on} | off

*Object highlighted when selected.*

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

ShowArrowHead  
{on} | off

*Display arrowheads on vectors.* When this property is `on`, MATLAB draws arrowheads on the vectors displayed by `quiver`. When you set this property to `off`, `quiver` draws the vectors as lines without arrowheads.

Tag  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stem objects, `Type` is `'hggroup'`. This statement finds all the `hggroup` objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

# Quivergroup Properties

---

- **on** — Object and all children of the object are visible unless the child object's **Visible** property is **off**.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

## UData

matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors displayed as arrows in the quiver graph. For example, the first vector is defined by components UData(1),VData(1),WData(1).

## UDataSource

string (MATLAB variable)

*Link UData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the UData. The default value is an empty array.

```
set(h, 'UDataSource', 'Udatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's UDataSource does not change the object's UData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## VData

matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors displayed as arrows in the quiver graph. For example, the first vector is defined by components UData(1),VData(1),WData(1).

## VDataSource

MATLAB variable, as a string

*Link VData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the VData. The default value is an empty array.

```
set(h, 'VDataSource', 'Vdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's VDataSource does not change the object's VData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## WData

matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors

# Quivergroup Properties

---

displayed as arrows in the quiver graph. For example, the first vector is defined by components `UData(1),VData(1),WData(1)`.

## `WDataSource`

MATLAB variable, as a string

*Link WData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the `WData`. The default value is an empty array.

```
set(h, 'WDataSource', 'Wdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `WDataSource` does not change the object's `WData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## `XData`

vector | matrix

*X-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *x*-axis location in the `XData` array. `XData` can be either a matrix equal in size to all other data properties or for 2-D, a vector equal in length to the number of columns in `UData` or `VData`. That is, `length(XData) == size(UData,2)`.

If you do not specify `XData` (which is the input argument `X`), the `quiver` function uses the indices of `UData` to create the quiver graph. See the `XDataMode` property for related information.

`XDataMode`  
{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the input argument `X`), the `quiver` function sets this property to `manual`.

If you set `XDataMode` to `auto` after having specified `XData`, the `quiver` function resets the `x` tick-mark labels to the indices of the `U`, `V`, and `W` data, overwriting any previous values.

`XDataSource`  
MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# Quivergroup Properties

---

## YData

vector | matrix

*Y-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *y*-axis location in the `YData` array. `YData` can be either a matrix equal in size to all other data properties or for 2-D, a vector equal in length to the number of rows in `UData` or `VData`. That is, `length(YData) == size(UData,1)`.

If you do not specify `YData` (which is the input argument `Y`), the `quiver` function uses the indices of `VData` to create the quiver graph. See the `YDataMode` property for related information.

The input argument `Y` in the `quiver` function calling syntax assigns values to `YData`.

## YDataMode

{auto} | manual

*Use automatic or user-specified y-axis values.* If you specify `YData` (by setting the `YData` property or specifying the input argument `Y`), MATLAB sets this property to `manual`.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the *y* tick-mark labels to the indices of the `U`, `V`, and `W` data, overwriting any previous values.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's

`YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector | matrix

*Z-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *z*-axis location in the `ZData` array. `ZData` must be a matrix equal in size to `XData` and `YData`.

The input argument `Z` in the `quiver3` function calling syntax assigns values to `ZData`.

**Purpose** QZ factorization for generalized eigenvalues

**Syntax**  
 $[AA, BB, Q, Z] = \text{qz}(A, B)$   
 $[AA, BB, Q, Z, V, W] = \text{qz}(A, B)$   
 $\text{qz}(A, B, \text{flag})$

**Description** The `qz` function gives access to intermediate results in the computation of generalized eigenvalues.

$[AA, BB, Q, Z] = \text{qz}(A, B)$  for square matrices  $A$  and  $B$ , produces upper quasitriangular matrices  $AA$  and  $BB$ , and unitary matrices  $Q$  and  $Z$  such that  $Q^*A^*Z = AA$ , and  $Q^*B^*Z = BB$ . For complex matrices,  $AA$  and  $BB$  are triangular.

$[AA, BB, Q, Z, V, W] = \text{qz}(A, B)$  also produces matrices  $V$  and  $W$  whose columns are generalized eigenvectors.

$\text{qz}(A, B, \text{flag})$  for real matrices  $A$  and  $B$ , produces one of two decompositions depending on the value of `flag`:

'complex'	Produces a possibly complex decomposition with a triangular $AA$ . For compatibility with earlier versions, 'complex' is the default.
'real'	Produces a real decomposition with a quasitriangular $AA$ , containing 1-by-1 and 2-by-2 blocks on its diagonal.

If  $AA$  is triangular, the diagonal elements of  $AA$  and  $BB$ ,  $\alpha = \text{diag}(AA)$  and  $\beta = \text{diag}(BB)$ , are the generalized eigenvalues that satisfy

$$A * V * \beta = B * V * \alpha$$
$$\beta' * W' * A = \alpha' * W' * B$$

The eigenvalues produced by

$$\lambda = \text{eig}(A, B)$$

---

are the ratios of the  $\alpha$ s and  $\beta$ s.

$$\lambda = \alpha / \beta$$

If  $\mathbf{A}$  is not triangular, it is necessary to further reduce the 2-by-2 blocks to obtain the eigenvalues of the full system.

**See Also**

eig

# rand

---

**Purpose** Uniformly distributed pseudorandom numbers

**Syntax**

```
r = rand(n)
r = rand(m,n)
r = rand([m,n])
r = rand(m,n,p,...)
r = rand([m,n,p,...])
r = rand
r = rand(size(A))
r = rand(..., 'double')
r = rand(..., 'single')
```

**Description**

`r = rand(n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard uniform distribution on the open interval  $(0,1)$ .

`r = rand(m,n)` or `r = rand([m,n])` returns an  $m$ -by- $n$  matrix.

`r = rand(m,n,p,...)` or `r = rand([m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array.

`r = rand` returns a scalar.

`r = rand(size(A))` returns an array the same size as  $A$ .

`r = rand(..., 'double')` or `r = rand(..., 'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs  $m$ ,  $n$ ,  $p$ , ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `rand` is determined by the internal settings of the uniform random number generator that underlies `rand`, `randi`, and `randn`. You can control that shared random number generator using `rng`.

---

**Note** Use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”

---

## Examples

### Example 1

Generate values from the uniform distribution on the interval  $[a, b]$ :

```
r = a + (b-a).*rand(100,1);
```

### Example 2

Use the `randi` function, instead of `rand`, to generate integer values from the uniform distribution on the set 1:100:

```
r = randi(100,1,5);
```

### Example 3

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `rand` produces the same random numbers as if you restarted MATLAB:

```
rng('default')
rand(1,5)
ans =
    0.8147    0.9058    0.1270    0.9134    0.6324
```

### Example 4

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `rand`, restore the settings, and repeat those values:

```
s = rng;
u1 = rand(1,5)
u1 =
    0.0975    0.2785    0.5469    0.9575    0.9649
```

# rand

---

```
rng(s);  
u2 = rand(1,5)  
u2 =  
    0.0975    0.2785    0.5469    0.9575    0.9649
```

u2 contains exactly the same values as u1.

## Example 5

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `rand` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
rng('shuffle');  
rand(1,5);
```

## Related Examples

- “Random Numbers within a Specific Range”

**Purpose** Uniformly distributed random numbers

**Class** RandStream

**Syntax**

```
r = rand(s,n)
r = rand(s,m,n)
r = rand(s,[m,n])
r = rand(s,m,n,p,...)
r = rand(s,[m,n,p,...])
r = rand(s)
r = rand(s,size(A))
r = rand(..., 'double')
r = rand(..., 'single')
```

**Description**

`r = rand(s,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard uniform distribution on the open interval  $(0,1)$ . The values are drawn from the random stream `s`.

`r = rand(s,m,n)` or `r = rand(s,[m,n])` returns an  $m$ -by- $n$  matrix.

`r = rand(s,m,n,p,...)` or `r = rand(s,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array.

`r = rand(s)` returns a scalar.

`r = rand(s,size(A))` returns an array the same size as `A`.

`r = rand(..., 'double')` or `r = rand(..., 'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `rand` is determined by the internal state of the random number stream `s`. Resetting that stream to the same fixed state allows computations to be repeated. Setting

## rand (RandStream)

---

the stream to different states leads to unique computations, however, it does not improve any statistical properties.

### **See Also**

rand | @RandStream | randi (RandStream) | randn (RandStream) |  
randperm (RandStream)

**Purpose**

Uniformly distributed pseudorandom integers

**Syntax**

```
r = randi(imax,n)
r = randi(imax,m,n)
r = randi(imax,[m,n])
r = randi(imax,p1,...,pn)
r = randi(imax,[p1,...,pn])
r = randi(imax)
r = randi(imax,size(A))
r = randi([imin,imax],...)
r = randi(..., classname)
```

**Description**

`r = randi(imax,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom integer values drawn from the discrete uniform distribution on the interval  $[1,imax]$ .

`r = randi(imax,m,n)` and `r = randi(imax,[m,n])` return an  $m$ -by- $n$  matrix of numbers. Both  $m$  and  $n$  must be nonnegative integer values. If either  $m$  or  $n$  is negative, then it is treated as 0.

`r = randi(imax,p1,...,pn)` and `r = randi(imax,[p1,...,pn])` return an  $n$ -dimensional array.

`r = randi(imax)` returns a scalar value between 1 and  $imax$ . This is the same as `r = randi(imax,1)`

`r = randi(imax,size(A))` returns an array the same size as  $A$ .

`r = randi([imin,imax],...)` returns an array containing integer values drawn from the discrete uniform distribution on the interval  $[imin,imax]$ .

`r = randi(..., classname)` returns an array of integer values of class `classname`. `classname` does not support 64-bit integers.

Specify the size arguments,  $m$ ,  $n$  or  $p1, \dots, pn$ , as nonnegative integers. If you pass a negative size value, it will be treated as 0.

If you specify a distribution range using two numbers,  $[imin,imax]$ , both numbers must be integers that satisfy  $imin \leq imax$ . If you specify

the range using only the upper bound, `imax`, it must be a positive integer (greater than zero).

The sequence of numbers produced by `randi` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. `randi` uses one uniform random value to create each integer random value. You can control that shared random number generator using `rng`.

## Examples

### Example 1

Generate a 100-by-1 array of integer values from the uniform distribution on the set 1:10:

```
r = randi(10,100,1);
```

### Example 2

Generate a 100-by-1 array of integers drawn uniformly from 1:10:

```
r = randi(10,100,1,'uint32');
```

### Example 3

Generate a 100-by-1 array of integer values drawn uniformly from -10:10:

```
r = randi([-10 10],100,1);
```

### Example 4

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `randi` produces the same random numbers as if you restarted MATLAB:

```
rng('default');  
randi(10,1,5)
```

```
ans =  
     9     10     2     10     7
```

### Example 5

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `randi`, restore the settings, and repeat those values:

```
s = rng;
i1 = randi(10,1,5)
i1 =
     1     3     6    10    10
rng(s);
i2 = randi(10,1,5)
i2 =
     1     3     6    10    10
```

`i2` contains exactly the same values as `i1`.

### Example 6

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `randi` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session:

```
rng('shuffle');
randi(10,1,5);
```

- The arrays returned by `randi` might contain repeated integer values. This behavior is sometimes referred to as sampling with replacement. Use `randperm` if you require all unique values.

`rand` | `randn` | `rng` | `@RandStream` | `randi` (`RandStream`) | `randperm`

# randi (RandStream)

---

**Purpose** Uniformly distributed pseudorandom integers

**Class** RandStream

**Syntax**

```
r = randi(s,imax,n)
r = randi(s,imax,m,n)
r = randi(s,imax,[m,n])
r = randi(s,imax,m,n,p,...)
r = randi(s,imax,[m,n,p,...])
r = randi(s,imax)
r = randi(s,imax,size(A))
r = randi(s,[imin,imax],...)
r = randi(...,classname)
```

**Description**

`r = randi(s,imax,n)` returns an n-by-n matrix containing pseudorandom integer values drawn from the discrete uniform distribution on `1:imax`. `randi` draws those values from the random stream `s`.

`r = randi(s,imax,m,n)` or `r = randi(s,imax,[m,n])` returns an m-by-n matrix.

`r = randi(s,imax,m,n,p,...)` or `r = randi(s,imax,[m,n,p,...])` returns an m-by-n-by-p-by-... array.

`r = randi(s,imax)` returns a scalar.

`r = randi(s,imax,size(A))` returns an array the same size as `A`.

`r = randi(s,[imin,imax],...)` returns an array containing integer values drawn from the discrete uniform distribution on `imin:imax`.

`r = randi(...,classname)` returns an array of integer values of class `classname`. `classname` does not support 64-bit integers.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The arrays returned by `randi` might contain repeated integer values. This is sometimes referred to as sampling with replacement. To get unique integer values, sometimes referred to as sampling without replacement, use `randperm` (`RandStream`).

The sequence of numbers produced by `randi` is determined by the internal state of the random stream `s`. `randi` uses one uniform value from `s` to generate each integer value. Resetting `s` to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

### See Also

`randi` | `RandStream` | `rand` (`RandStream`) | `randn` (`RandStream`) | `randperm` (`RandStream`)

# randn

---

**Purpose** Normally distributed pseudorandom numbers

**Syntax**

```
r = randn(n)
r = randn(m,n)
r = randn([m,n])
r = randn(m,n,p,...)
r = randn([m,n,p,...])
r = randn
r = randn(size(A))
r = randn(...,'double')
r = randn(...,'single')
```

**Description**

`r = randn(n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard normal distribution.

`r = randn(m,n)` or `r = randn([m,n])` returns an  $m$ -by- $n$  matrix.

`r = randn(m,n,p,...)` or `r = randn([m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array.

`r = randn` returns a scalar.

`r = randn(size(A))` returns an array the same size as `A`.

`r = randn(...,'double')` or `r = randn(...,'single')` returns an array of normal values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `randn` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. `randn` uses one or more uniform random values to create each normal random value. You can control that shared random number generator using `rng`.

---

**Note** Use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”

---

## Examples

### Example 1

Generate values from a normal distribution with mean 1 and standard deviation 2:

```
r = 1 + 2.*randn(100,1);
```

### Example 2

Generate values from a bivariate normal distribution with specified mean vector and covariance matrix:

```
mu = [1 2];  
Sigma = [1 .5; .5 2]; R = chol(Sigma);  
z = repmat(mu,100,1) + randn(100,2)*R;
```

### Example 3

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `randn` produces the same random numbers as if you restarted MATLAB:

```
rng('default');  
randn(1,5)  
ans =  
    0.5377    1.8339   -2.2588    0.8622    0.3188
```

### Example 4

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `randn`, restore the settings, and repeat those values:

```
s = rng;
```

# randn

---

```
z1 = randn(1,5)
z1 =
    -1.3077    -0.4336     0.3426     3.5784     2.7694
rng(s);
z2 = randn(1,5)
z2 =
    -1.3077    -0.4336     0.3426     3.5784     2.7694
```

z2 contains exactly the same values as z1.

## Example 5

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `randn` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session:

```
rng('shuffle');
randn(1,5)
```

## See Also

## Related Examples

- “Random Numbers from a Normal Distribution with Specific Mean and Variance”

**Purpose** Normally distributed pseudorandom numbers

**Class** RandStream

**Syntax**

```
r = randn(s,m,n)
r = randn(s,[m,n])
r = randn(s,m,n,p,...)
r = randn(s,[m,n,p,...])
r = randn(s)
r = randn(s,size(A))
r = randn(...,'double')
r = randn(...,'single')
```

**Description**

`r = randn(s,n)` returns an n-by-n matrix containing pseudorandom values drawn from the standard normal distribution. `randn` draws those values from the random stream `s`.

`r = randn(s,m,n)` or `r = randn(s,[m,n])` returns an m-by-n matrix.

`r = randn(s,m,n,p,...)` or `r = randn(s,[m,n,p,...])` returns an m-by-n-by-p-by-... array.

`r = randn(s)` returns a scalar.

`r = randn(s,size(A))` returns an array the same size as `A`.

`r = randn(...,'double')` or `r = randn(...,'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `randn` is determined by the internal state of the random stream `s`. `randn` uses one or more uniform values from `s` to generate each normal value. Resetting that stream to the same fixed state allows computations to be repeated. Setting the

## randn (RandStream)

---

stream to different states leads to unique computations, however, it does not improve any statistical properties.

### **See Also**

[randn](#) | [RandStream](#) | [rand \(RandStream\)](#) | [randi \(RandStream\)](#)

**Purpose** Random permutation

**Syntax** `p = randperm(n)`  
`p = randperm(n,k)`

**Description** `p = randperm(n)` returns a row vector containing a random permutation of the integers from 1 to `n` inclusive.

`p = randperm(n,k)` returns a row vector containing `k` unique integers selected randomly from 1 to `n` inclusive.

**Tips** For `p = randperm(n,k)`, `p` contains `k` *unique* values. `randperm` performs `k`-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(n,1,k)`.

`randperm` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

**Examples** `randperm(6)`

might be the vector

```
[3 2 6 4 1 5]
```

or it might be some other permutation of the integers from 1 to 6, depending on the state of the random number generator. Two successive calls to `randperm` would in most cases return two different vectors:

```
randperm(6)
ans =
     5     2     6     4     1     3
```

```
randperm(6)
ans =
     4     1     6     2     3     5
```

---

# randperm

---

`randperm(6,3)`

might be the vector

`[4 2 5]`

or it might be some other permutation of any three integers from 1 to 6 inclusive, depending on the state of the random number generator.

## **See Also**

`permute` | `nchoosek` | `randi` | `randperm(RandStream)` | `perms` | `rng`

**Purpose** Random permutation

**Class** RandStream

**Syntax**  
`p = randperm(s,n)`  
`p = randperm(s,n,k)`

**Description** `p = randperm(s,n)` returns a row vector containing a random permutation of integers from 1 to *n* inclusive. `randperm(s,n)` uses random values drawn from the random stream *s*.

`p = randperm(s,n,k)` returns a row vector containing *k* unique integers selected randomly from 1 to *n* inclusive.

**Tips** For `p = randperm(s,n,k)`, *p* contains *k* *unique* values. `randperm` performs *k*-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(s,n,1,k)`.

**Examples** Create a random stream *s* and generate a random permutation of the integers from 1 to 6 based on *s*:

```
s = RandStream('mt19937ar','Seed',0);  
randperm(s,6)
```

MATLAB returns the vector

```
[6    3    5    1    2    4]
```

Use the random stream *s* to generate three integers between 1 and 10:

```
randperm(s,10,3)  
ans =  
     1     8     9
```

**See Also** `permute` | `randperm` | `nchoosek` | `perms` | `rand` | `randi` (RandStream)

# RandStream

---

**Purpose** Random number stream

**Constructor** RandStream

**Description** Pseudorandom numbers in MATLAB come from one or more random number streams. The simplest way to generate arrays of random numbers is to use `rand`, `randn`, or `randi`. These functions all rely on the same stream of uniform random numbers, known as the *global stream*. You can create other streams that act separately from the global stream, and you can use their `rand`, `randi`, or `randn` methods to generate arrays of random numbers. You can also create a random number stream and make it the global stream.

To create a single random number stream, use the `RandStream` constructor. To create multiple independent random number streams, use `RandStream.create`. The `rng` function provides a simple interface to create a new global stream.

`stream = RandStream.getGlobalStream` returns the global random number stream, that is, the one currently used by the `rand`, `randi`, and `randn` functions.

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream `stream` as the new global stream to be used by the `rand`, `randi`, and `randn` functions, and returns the previous global stream.

A random number stream `s` has properties that control its behavior. Access or assign to a property using `p = s.Property` or `s.Property = p`. The following table lists defined properties:

## Properties

Property	Description
Type	(Read-only) Generator algorithm used by the stream. The list of possible generators is given by <code>RandStream.list</code> .
Seed	(Read-only) Seed value used to create the stream.
NumStreams	(Read-only) Number of streams in the group in which the current stream was created.
StreamIndex	(Read-only) Index of the current stream from among the group of streams with which it was created.
State	<p>Internal state of the generator. You should not depend on the format of this property. The value you assign to <code>S.State</code> must be a value read from <code>S.State</code> previously. Use <code>reset</code> to return a stream to a predictable state without having previously read from the <code>State</code> property.</p> <p>The sequence of random numbers produced by a random number stream <code>s</code> is determined by the internal state of its random number generator. Saving and restoring the generator's internal state with the <code>State</code> property allows you to reproduce a sequence of random numbers.</p>

# RandStream

---

Property	Description
Substream	Index of the substream to which the stream is currently set. The default is 1. Multiple substreams are not supported by all generator types; the multiplicative lagged Fibonacci generator (mlfg6331_64) and combined multiple recursive generator (mrg32k3a) support substreams.
NormalTransform	Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values. Possible values are 'Ziggurat', 'Polar', or 'Inversion'.
RandnAlg	<p>RandnAlg has been removed. Use NormalTransform instead.</p> <p>Transformation algorithm that will be used by <code>randn(S, ...)</code> to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'.</p>
Antithetic	Logical value indicating whether S generates antithetic pseudorandom values, that is, the usual values subtracted from 1. The default is false.
FullPrecision	Logical value indicating whether S generates values using its full precision. Some generators can create pseudorandom values faster, but with fewer random bits, if FullPrecision is false. The default is true.

## Methods

Method	Description
<code>RandStream</code>	Create a random number stream.
<code>RandStream.create</code>	Create multiple independent random number streams.
<code>get</code>	Get the properties of a random stream object.
<code>list</code>	List available random number generator algorithms.
<code>set</code>	Set random stream property.
<code>RandStream.getGlobalStream</code>	Get the global random number stream.
<code>RandStream.getDefaultStream</code>	<code>RandStream.getDefaultStream</code> has been removed. Use <code>RandStream.getGlobalStream</code> instead. The shared random number stream used by <code>rand</code> , <code>randi</code> , and <code>randn</code> is now referred to as the global stream.  Default random number stream.
<code>RandStream.setGlobalStream</code>	Set global random number stream.
<code>RandStream.setDefaultStream</code>	<code>RandStream.setDefaultStream</code> has been removed. Use <code>RandStream.setGlobalStream</code> instead.  Set default random number stream property.
<code>reset</code>	Reset a stream to its initial internal state
<code>rand</code>	Pseudorandom numbers from a uniform distribution

# RandStream

---

Method	Description
randn	Pseudorandom numbers from a standard normal distribution
randi	Pseudorandom integers from a uniform discrete distribution
randperm	Random permutation of a set of values

## Examples

### Example 1

Create a single stream and designate it as the current global stream:

```
s = RandStream('mt19937ar', 'Seed', 1);  
RandStream.setGlobalStream(s);
```

### Example 2

Create three independent streams:

```
[s1,s2,s3] = RandStream.create('mrg32k3a', 'NumStreams', 3);  
r1 = rand(s1, 100000, 1);  
r2 = rand(s2, 100000, 1);  
r3 = rand(s3, 100000, 1);  
corrcoef([r1,r2,r3])
```

### Example 3

Create only one stream from a set of three independent streams, and designate it as the current global stream:

```
s2 = RandStream.create('mrg32k3a', 'NumStreams', 3, ...  
    'StreamIndices', 2);  
RandStream.setGlobalStream(s2);
```

### Example 4

Reset the global random number stream that underlies rand, randi, and randn back to its beginning, to reproduce previous results:

```
stream = RandStream.getGlobalStream;
```

```
reset(stream);
```

## Example 5

Save and restore the current global stream's state to reproduce the output of rand:

```
stream = RandStream.getGlobalStream;
savedState = stream.State;
u1 = rand(1,5)
u1 =
    0.8147    0.9058    0.1270    0.9134    0.6324

stream.State = savedState;
u2 = rand(1,5)
u2 =
    0.8147    0.9058    0.1270    0.9134    0.6324
```

u2 contains exactly the same values as u1.

## Example 6

Reset the global random number stream to its initial settings. This causes rand, randi, and randn to start over, as if in a new MATLAB session:

```
s = RandStream('mt19937ar','Seed',0);
RandStream.setGlobalStream(s);
```

## Example 7

Reinitialize the global random number stream using a seed based on the current time. This causes rand, randi, and randn to return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

# RandStream

---

## Example 8

Change the transformation algorithm that `randn` uses to create normal pseudorandom values from uniform values. This does not replace or reset the global stream.

```
stream = RandStream.getGlobalStream;  
stream.NormalTransform = 'inversion'
```

## See Also

[rand](#) | [rng](#) | [randn](#) | [randi](#)

**Purpose** Random number stream

**Class** RandStream

**Syntax**  
`s = RandStream('gentype')`  
`s = RandStream('gentype',Name,Value)`

**Description** `s = RandStream('gentype')` creates a random number stream that uses the uniform pseudorandom number generator algorithm specified by `gentype`. `RandStream.list` returns all possible values for `gentype`, or see “Choosing a Random Number Generator” for details on generator algorithms.

`s = RandStream('gentype',Name,Value)` allows you to specify one or more optional `Name,Value` pairs to control creation of the stream.

Once you have created a random, you can use `RandStream.setGlobalStream` to make it the global stream, so that the functions `rand`, `randi`, and `randn` draw values from it.

Parameters are for `RandStream` are:

Parameter	Description
Seed	Nonnegative scalar integer with which to initialize all streams. Seeds must be an integer between 0 and $2^{32} - 1$ or 'shuffle' to create a seed based on the current time. Default is 0.
NormalTransform	Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values. Possible values are 'Ziggurat', 'Polar', or 'Inversion'.
RandnAlg	<code>RandnAlg</code> has been removed. Use <code>NormalTransform</code> instead.

# RandStream constructor

---

Parameter	Description
	Transformation algorithm used by randn to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'.

## Examples

### Example 1

Create a random number stream, make it the global stream, and save and restore its state to reproduce the output of randn:

```
s = RandStream('mrg32k3a');
RandStream.setGlobalStream(s);
savedState = s.State;
z1 = randn(1,5)
z1 =
    -0.1894    -1.4426    -0.3592     0.8883    -0.4337
s.State = savedState;
z2 = randn(1,5)
z2 =
    -0.1894    -1.4426    -0.3592     0.8883    -0.4337
```

z2 contains exactly the same values as z1.

### Example 2

Return rand, randi, and randn to their default startup settings:

```
s = RandStream('mt19937ar','Seed',0)
RandStream.setGlobalStream(s);
```

### Example 3

Replace the current global random number stream with a stream whose seed is based on the current time, so rand, randi, and randn will return different values in different MATLAB sessions. It is usually not

desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');  
RandStream.setGlobalStream(s);
```

- Streams created using `RandStream` might not be independent from each other. Use `RandStream.create` to create multiple streams that are independent.

`RandStream.create`

# RandStream.getGlobalStream

---

**Purpose** Current global random number stream

**Class** @RandStream

**Syntax** `stream = RandStream.getGlobalStream`

**Description** `stream = RandStream.getGlobalStream` returns the current global random number stream.

`rand`, `randi`, and `randn` all rely on the same stream of uniform pseudorandom numbers, known as the *global stream*. `rand` draws one value from that stream to generate each uniform value it returns. `randi` draws one uniform value from that stream to generate each integer value it returns. And `randn` draws one or more uniform values to generate each normal value it returns. Note that there are also `rand`, `randi`, and `randn` methods for which you specify a specific random stream from which to draw values.

The `rng` function is a shorter alternative for many common uses of `RandStream.getGlobalStream`.

**See Also** `RandStream` | `rng` | `RandStream.setGlobalStream` | `rand` | `randi` | `randn`

**Purpose**

Set global random number stream

**Syntax**

```
prevstream = RandStream.setGlobalStream(stream)
```

**Description**

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream, specified as `stream`, to be the global stream that the `rand`, `randi`, and `randn` functions draw values from. It returns the previous global random number stream as `prevstream`.

`rand`, `randi`, and `randn` all rely on the same stream of uniform pseudorandom numbers, known as the *global stream*. `rand` draws one value from that stream to generate each uniform value it returns. `randi` draws one uniform value from that stream to generate each integer value it returns. And `randn` draws one or more uniform values to generate each normal value it returns. Note that there are also `rand`, `randi`, and `randn` methods for which you specify a specific random stream from which to draw values.

The `rng` function is a shorter alternative for many common uses of `RandStream.setGlobalStream`.

| [randn](#)

# rank

---

**Purpose** Rank of matrix

**Syntax**  
`k = rank(A)`  
`k = rank(A,tol)`

**Description** The rank function provides an estimate of the number of linearly independent rows or columns of a full matrix.

`k = rank(A)` returns the number of singular values of A that are larger than the default tolerance, `max(size(A))*eps(norm(A))`.

`k = rank(A,tol)` returns the number of singular values of A that are larger than `tol`.

**Tips** Use `sprank` to determine the structural rank of a sparse matrix.

**Algorithms** There are a number of ways to compute the rank of a matrix. MATLAB software uses the method based on the singular value decomposition, or SVD. The SVD algorithm is the most time consuming, but also the most reliable.

The rank algorithm is

```
s = svd(A);  
tol = max(size(A))*eps(max(s));  
r = sum(s > tol);
```

**See Also** `sprank`

**Purpose** Rational fraction approximation

**Syntax** `[N,D] = rat(X)`  
`[N,D] = rat(X,tol)`  
`rat(X)`

**Description** Even though all floating-point numbers are rational numbers, it is sometimes desirable to approximate them by simple rational numbers, which are fractions whose numerator and denominator are small integers. The `rat` function attempts to do this. Rational approximations are generated by truncating continued fraction expansions. The `rats` function calls `rat`, and returns strings.

`[N,D] = rat(X)` returns arrays `N` and `D` so that `N./D` approximates `X` to within the default tolerance, `1.e-6*norm(X(:),1)`.

`[N,D] = rat(X,tol)` returns `N./D` approximating `X` to within `tol`.  
`rat(X)`, with no output arguments, simply displays the continued fraction.

**Examples** Ordinarily, the statement

```
s = 1 - 1/2 + 1/3 - 1/4 + 1/5 - 1/6 + 1/7
```

produces

```
s =  
    0.7595
```

However, with

```
format rat
```

or with

```
rats(s)
```

the printed result is

```
s =  
    319/420
```

This is a simple rational number. Its denominator is 420, the least common multiple of the denominators of the terms involved in the original expression. Even though the quantity `s` is stored internally as a binary floating-point number, the desired rational form can be reconstructed.

To see how the rational approximation is generated, the statement `rat(s)` produces

```
1 + 1/(-4 + 1/(-6 + 1/(-3 + 1/(-5))))
```

And the statement

```
[n,d] = rat(s)
```

produces

```
n = 319, d = 420
```

The mathematical quantity  $\pi$  is not a rational number, but the MATLAB quantity `pi` that approximates it is a rational number. `pi` is the ratio of a large integer and  $2^{52}$ :

```
14148475504056880/4503599627370496
```

However, this is not a simple rational number. The value printed for `pi` with `format rat`, or with `rats(pi)`, is

```
355/113
```

This approximation was known in Euclid's time. Its decimal representation is

```
3.14159292035398
```

and so it agrees with `pi` to seven significant figures. The statement

```
rat(pi)
```

produces

```
3 + 1/(7 + 1/(16))
```

This shows how the 355/113 was obtained. The less accurate, but more familiar approximation 22/7 is obtained from the first two terms of this continued fraction.

## Algorithms

The `rat(X)` function approximates each element of `X` by a continued fraction of the form

$$\frac{n}{d} = d_1 + \frac{1}{d_2 + \frac{1}{\left(d_3 + \dots + \frac{1}{d_k}\right)}}$$

The  $d$ s are obtained by repeatedly picking off the integer part and then taking the reciprocal of the fractional part. The accuracy of the approximation increases exponentially with the number of terms and is worst when  $X = \text{sqrt}(2)$ . For  $x = \text{sqrt}(2)$ , the error with  $k$  terms is about  $2.68 * (.173)^k$ , so each additional term increases the accuracy by less than one decimal digit. It takes 21 terms to get full floating-point accuracy.

## See Also

`format` | `rats`

# rbbox

---

**Purpose** Create rubberband box for area selection

**Syntax**

```
rbbox
rbbox(initialRect)
rbbox(initialRect, fixedPoint)
rbbox(initialRect, fixedPoint, stepSize)
finalRect = rbbox(...)
```

**Description** `rbbox` initializes and tracks a rubberband box in the current figure. It sets the initial rectangular size of the box to 0, anchors the box at the figure's `CurrentPoint`, and begins tracking from this point.

`rbbox(initialRect)` specifies the initial location and size of the rubberband box as `[x y width height]`, where `x` and `y` define the lower left corner, and `width` and `height` define the size. `initialRect` is in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. The corner of the box closest to the pointer position follows the pointer until `rbbox` receives a button-up event.

`rbbox(initialRect, fixedPoint)` specifies the corner of the box that remains fixed. All arguments are in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. `fixedPoint` is a two-element vector, `[x y]`. The tracking point is the corner diametrically opposite the anchored corner defined by `fixedPoint`.

`rbbox(initialRect, fixedPoint, stepSize)` specifies how frequently the rubberband box is updated. When the tracking point exceeds `stepSize` figure units, `rbbox` redraws the rubberband box. The default stepsize is 1.

`finalRect = rbbox(...)` returns a four-element vector, `[x y width height]`, where `x` and `y` are the `x` and `y` components of the lower left corner of the box, and `width` and `height` are the dimensions of the box.

## Tips

rbbox is useful for defining and resizing a rectangular region:

- For box definition, `initialRect` is `[x y 0 0]`, where `(x,y)` is the figure's `CurrentPoint`.
- For box resizing, `initialRect` defines the rectangular region that you resize (e.g., a legend). `fixedPoint` is the corner diametrically opposite the tracking point.

rbbox returns immediately if a button is not currently pressed. Therefore, you use rbbox with `waitforbuttonpress` so that the mouse button is down when rbbox is called. rbbox returns when you release the mouse button.

## Examples

Assuming the current view is `view(2)`, use the current axes' `CurrentPoint` property to determine the extent of the rectangle in dataspace units:

```
k = waitforbuttonpress;
point1 = get(gca,'CurrentPoint');    % button down detected
finalRect = rbbox;                  % return figure units
point2 = get(gca,'CurrentPoint');    % button up detected
point1 = point1(1,1:2);              % extract x and y
point2 = point2(1,1:2);
p1 = min(point1,point2);             % calculate locations
offset = abs(point1-point2);         % and dimensions
x = [p1(1) p1(1)+offset(1) p1(1)+offset(1) p1(1) p1(1)];
y = [p1(2) p1(2) p1(2)+offset(2) p1(2)+offset(2) p1(2)];
hold on
axis manual
plot(x,y)                            % redraw in dataspace units
```

## See Also

`axis` | `dragrect` | `waitforbuttonpress`

# rcond

---

**Purpose** Matrix reciprocal condition number estimate

**Syntax** `c = rcond(A)`

**Description** `c = rcond(A)` returns an estimate for the reciprocal of the condition of  $A$  in 1-norm. If  $A$  is well conditioned, `rcond(A)` is near 1.0. If  $A$  is badly conditioned, `rcond(A)` is near 0.0. Compared to `cond`, `rcond` is a more efficient, but less reliable, method of estimating the condition of a matrix.

**See Also** `cond` | `condest` | `norm` | `normest` | `rank` | `svd`

<b>Purpose</b>	Right array division
<b>Syntax</b>	$x = A ./ B$ <code>x = rdivide(A,B)</code>
<b>Description</b>	<p><math>x = A ./ B</math> divides each element of <math>A</math> by the corresponding element of <math>B</math>. Inputs <math>A</math> and <math>B</math> must have the same size unless one is a scalar value. A scalar value is expanded into an array of the same size as the other input.</p> <p><code>x = rdivide(A,B)</code> is an alternative way to divide <math>A</math> by <math>B</math>, but is rarely used. It enables operator overloading for classes.</p>
<b>Input Arguments</b>	<p><b>A - Numerator</b> numeric array   sparse numeric array</p> <p>Numerator, specified as a full or sparse numeric array. If <math>B</math> is an integer data type, <math>A</math> must be the same integer type or a scalar double.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>Complex Number Support:</b> Yes</p> <p><b>B - Denominator</b> numeric array   sparse numeric array</p> <p>Denominator, specified as a full or sparse numeric array. If <math>A</math> is an integer data type, <math>B</math> must be the same integer type or a scalar double.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>Complex Number Support:</b> Yes</p>

# rdivide, ./

---

## Output Arguments

### x - Solution

numeric array | sparse numeric array

Solution, returned as a full or sparse numeric array. If either A or B is an integer data type, then x is that same integer data type.

## Examples

### Divide Two Numeric Arrays

Create two numeric arrays, A and B, and divide the second array, B, into the first, A.

```
A = [2 4 6 8; 3 5 7 9];  
B = 10*ones(2,4);  
x = A./B
```

x =

```
    0.2000    0.4000    0.6000    0.8000  
    0.3000    0.5000    0.7000    0.9000
```

### Integer Division

Divide an int16 scalar value by each element of an int16 vector.

```
a = int16(10);  
b = int16([3 4 6]);  
x = a./b
```

x =

```
     3     3     2
```

MATLAB rounds the results when dividing integer data types.

### Divide Scalar by Array

Create an array and divide it into a scalar.

```
C = 5;  
D = magic(3);
```

```
x = C./D
```

```
x =
```

```
    0.6250    5.0000    0.8333  
    1.6667    1.0000    0.7143  
    1.2500    0.5556    2.5000
```

When you specify a scalar value to be divided by an array, the scalar value expands into an array of the same size, then element-by-element division is performed.

## Tips

- When dividing integers, use `idivide` for more rounding options.
- MATLAB does not support complex integer division.

# VideoReader.read

---

**Purpose** Read video frame data from file

**Syntax**

```
video = read(obj)
video = read(obj,index)
video = read(__,'native')
```

**Description**

`video = read(obj)` reads in all video frames from the file associated with `obj`. The `read` method returns a H-by-W-by-B-by-F matrix, `video`, where H is the image frame height, W is the image frame width, B is the number of bands in the image (for example, 3 for RGB), and F is the number of frames read.

`video = read(obj,index)` reads only the specified frames. `index` can be a single number or a two-element array representing an index range of the video stream.

`video = read(__,'native')` returns data in the format specified by the `VideoFormat` property, and can include any of the input arguments in the previous syntaxes.

## Input Arguments

### **obj**

Name of multimedia object created with `VideoReader`.

### **index**

Frames to read, where the first frame number is 1. Use `Inf` to represent the last frame of the file.

For example:

```
video = read(obj, 1);           % first frame only
video = read(obj, [1 10]);      % first 10 frames
video = read(obj, Inf);         % last frame only
video = read(obj, [50 Inf]);    % frame 50 thru end
```

MATLAB cannot determine the number of frames in a variable frame rate file until you read the last frame. If the requested `index` extends beyond the end of the file, `read` returns either a

warning or an error. For more information, see “Read Variable Frame Rate Video”.

**Default:** [1 Inf]

## Output Arguments

### video

Array of data representing video frames, returned in a format dependent on the VideoFormat property of obj. For most files, the data type and dimensions of video are as follows. Note that when the VideoFormat property of obj is 'Indexed', the data type and dimensions of video depend on whether you call read with the 'native' argument.

Value of obj.VideoFormat	Data Type of video	Dimensions of video	Description
'RGB24'	uint8	H-by-W-by-3-by-F	RGB24 image
'Grayscale'	uint8	H-by-W-by-1-by-F	Grayscale image
'Indexed', without specifying 'native'	uint8	H-by-W-by-3-by-F	RGB24 image
'Indexed', specifying 'native'	struct	1-by-F	MATLAB movie, which is an array of frame structure arrays, each containing the fields cdata and colormap.

# VideoReader.read

---

H is the image frame height, W is the image frame width, and F is the number of frames read.

For Motion JPEG 2000 files, the data type and dimensions of video are as follows.

Value of obj.VideoFormat	Data Type of video	Dimensions of video	Description
'Mono8'	uint8	H-by-W-by-1-by-F	Mono image
'Mono8 Signed'	int8	H-by-W-by-1-by-F	Mono signed image
'Mono16'	uint16	H-by-W-by-1-by-F	Mono image
'Mono16 Signed'	int16	H-by-W-by-1-by-F	Mono signed image
'RGB24'	uint8	H-by-W-by-3-by-F	RGB24 image
'RGB24 Signed'	uint8	H-by-W-by-3-by-F	RGB24 signed image
'RGB48'	uint16	H-by-W-by-3-by-F	RGB48 image
'RGB48 Signed'	int16	H-by-W-by-3-by-F	RGB48 signed image

## Examples

Read and play back the movie file xylophone.mp4:

```
xyloObj = VideoReader('xylophone.mp4');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;

% Preallocate movie structure.
mov(1:nFrames) = ...
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...
          'colormap', []);
```

```
% Read one frame at a time.
for k = 1 : nFrames
    mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])

% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

## How To

- “Read Video Files”

# Tiff.read

---

**Purpose** Read entire image

**Syntax** `imageData = tiffobj.read()`  
`[Y,Cb,Cr] = tiffobj.read()`

**Description** `imageData = tiffobj.read()` reads the image data from the current image file directory (IFD) in the TIFF file associated with the `Tiff` object, `tiffobj`.

`[Y,Cb,Cr] = tiffobj.read()` reads the YCbCr component data from the current directory in the TIFF file. Depending upon the values of the `YCbCrSubSampling` tag, the size of the Cb and Cr channels might differ from the Y channel.

**Examples** Open a `Tiff` object and read data from the TIFF file:

```
t = Tiff('example.tif','r');
imageData = t.read();
t.close();
```

**See Also** `Tiff.write` | `imread`

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

<b>Purpose</b>	Read data asynchronously from device
<b>Syntax</b>	<code>readasync(obj)</code> <code>readasync(obj, size)</code>
<b>Description</b>	<p><code>readasync(obj)</code> initiates an asynchronous read operation on the serial port object, <code>obj</code>.</p> <p><code>readasync(obj, size)</code> asynchronously reads, at most, the number of bytes given by <code>size</code>. If <code>size</code> is greater than the difference between the <code>InputBufferSize</code> property value and the <code>BytesAvailable</code> property value, an error is returned.</p>
<b>Tips</b>	<p>Before you can read data, you must connect <code>obj</code> to the device with the <code>open</code> function. A connected serial port object has a <code>Status</code> property value of <code>open</code>. An error is returned if you attempt to perform a read operation while <code>obj</code> is not connected to the device.</p> <p>You should use <code>readasync</code> only when you configure the <code>ReadAsyncMode</code> property to <code>manual</code>. <code>readasync</code> is ignored if used when <code>ReadAsyncMode</code> is <code>continuous</code>.</p> <p>The <code>TransferStatus</code> property indicates if an asynchronous read or write operation is in progress. You can write data while an asynchronous read is in progress because serial ports have separate read and write pins. You can stop asynchronous read and write operations with the <code>stopasync</code> function.</p> <p>You can monitor the amount of data stored in the input buffer with the <code>BytesAvailable</code> property. Additionally, you can use the <code>BytesAvailableFcn</code> property to execute a callback function when the terminator or the specified amount of data is read.</p> <p><b>Rules for Completing an Asynchronous Read Operation</b></p> <p>An asynchronous read operation with <code>readasync</code> completes when one of these conditions is met:</p> <ul style="list-style-type: none"><li>• The terminator specified by the <code>Terminator</code> property is read.</li></ul>

# readasync

---

- The time specified by the `Timeout` property passes.
- The specified number of bytes is read.
- The input buffer is filled (if `size` is not specified).

Because `readasync` checks for the terminator, this function can be slow. To increase speed, you might want to configure `ReadAsyncMode` to `continuous` and continuously return data to the input buffer as soon as it is available from the device.

## Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to a Tektronix TDS 210 oscilloscope, configures `s` to read data asynchronously only if `readasync` is issued, and configures the instrument to return the peak-to-peak value of the signal on channel 1.

```
s = serial('COM1');
fopen(s)
s.ReadAsyncMode = 'manual';
fprintf(s, 'Measurement:Meas1:Source CH1')
fprintf(s, 'Measurement:Meas1:Type Pk2Pk')
fprintf(s, 'Measurement:Meas1:Value?')
```

Begin reading data asynchronously from the instrument using `readasync`. When the read operation is complete, return the data to the MATLAB workspace using `fscanf`.

```
readasync(s)
s.BytesAvailable
ans =
    15
out = fscanf(s)
out =
2.03999999619E0
fclose(s)
```

**Purpose**

Read data from specified strip

**Syntax**

```
stripData = tiffobj.readEncodedStrip(stripNumber)
[Y,Cb,Cr] = tiffobj.readEncodedStrip(stripNumber)
```

**Description**

`stripData = tiffobj.readEncodedStrip(stripNumber)` reads data from the strip specified by `stripNumber`. Strip numbers are one-based numbers.

`[Y,Cb,Cr] = tiffobj.readEncodedStrip(stripNumber)` reads YCbCr component data from the specified strip. The size of the chrominance components Cb and Cr might differ from the size of the luminance component Y depending on the value of the YCbCrSubSampling tag.

`readEncodeStrip` clips the last strip, if the strip extends past the `ImageLength` boundary.

**Examples****Read a Strip**

Read the first strip in the second image of a TIFF file.

Create a `Tiff` object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');
t.setDirectory(2);
```

Read the data in the first strip. Then, close the `Tiff` object.

```
data = t.readEncodedStrip(1);
t.close();
```

**References**

This method corresponds to the `TIFFReadEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# Tiff.readEncodedStrip

---

## **Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Read data from specified tile

**Syntax**  
`tiffData = tiffobj.readEncodedTile(tileNumber)`  
`[Y,Cb,Cr] = tiffobj.readEncodedTile(tileNumber)`

**Description**  
`tiffData = tiffobj.readEncodedTile(tileNumber)` reads data from the tile specified by `tileNumber`. Tile numbers are one-based numbers.  
`[Y,Cb,Cr] = tiffobj.readEncodedTile(tileNumber)` reads YCbCr component data from the specified tile. The size of the chrominance components Cb and Cr might differ from the size of the luminance component Y, depending on the value of the YCbCrSubSampling tag.  
`readEncodedTile` clips tiles on the last row or right-most column of an image if the tile extends past the `ImageLength` and `ImageLength` boundaries.

## Examples **Read a Tile**

Create a Tiff object associated with the example file, `example.tif`. Then, read the first tile of data.

```
t = Tiff('example.tif', 'r');  
data = t.readEncodedTile(1);  
t.close();
```

## References

This method corresponds to the `TIFFReadEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# Tiff.readRGBAImage

---

**Purpose** Read image using RGBA interface

**Syntax** `[RGB,alpha] = readRGBAImage()`

**Description** `[RGB,alpha] = readRGBAImage()` reads an entire image using the RGBA interface. `RGB` consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the tile, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).  
The pixel values may be transformed depending upon the values of the following tags:

PhotometricInterpretation

BitsPerSample

SamplesPerPixel

Orientation

ExtraSamples

ColorMap

**Examples** Return all image data as RGB, with associated alpha matting.

```
t = Tiff('example.tif','r');  
t.setDirectory(2);  
[RGB,A] = t.readRGBAImage();  
t.close();
```

**References** This method corresponds to the `TIFFReadRGBAImage` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

**See Also** `Tiff.readRGBAStrip` | `Tiff.readRGBATile` | `Tiff.read`

## **Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# Tiff.readRGBAStrip

---

**Purpose** Read strip data using RGBA interface

**Syntax** `[RGB,alpha] = readRGBAStrip(row)`

**Description** `[RGB,alpha] = readRGBAStrip(row)` reads a strip using the RGBA interface. `row` is a one-based number of any row contained by the strip. RGB consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the strip, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The strip is clipped if the strip boundary extends past the end of the image.

The pixel values may be transformed depending upon the values of the following tags:

PhotometricInterpretation

BitsPerSample

SamplesPerPixel

Orientation

ExtraSamples

ColorMap

**Examples** Open a Tiff object and read the strip of data that contains the first row, using the RGBA interface, from the example file, `example.tif`

```
t = Tiff('example.tif','r');
t.setDirectory(2);
[RGB,A] = t.readRGBAStrip(1);
t.close();
```

**References** This method corresponds to the `TIFFReadRGBAStrip` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

`Tiff.readRGBATile` | `Tiff.readRGBAImage`

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# Tiff.readRGBATile

---

**Purpose** Read tile data using RGBA interface

**Syntax** `[RGB,alpha] = readRGBATile(row,col)`

**Description** `[RGB,alpha] = readRGBATile(row,col)` reads a tile using the RGBA interface. `row` and `col` are the one-based row and column numbers of any pixel in the requested tile. `RGB` consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the tile, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The tile is clipped if the tile boundaries extend past the edges of the image.

The pixel values may be transformed depending upon the values of the following tags:

PhotometricInterpretation

BitsPerSample

SamplesPerPixel

Orientation

ExtraSamples

ColorMap

**Examples** Open a Tiff object and read the first tile using the RGBA interface.

```
t = Tiff('example.tif','r');
t.setDirectory(1);
[RGB,A] = t.readRGBATile(1,1);
t.close();
```

**References** This method corresponds to the `TIFFReadRGBATile` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

# Remove

---

**Purpose** Convenience function for static .NET System.Delegate Remove method

**Syntax** `result = Remove(combinedDelegate, removedDelegate)`

**Description** `result = Remove(combinedDelegate, removedDelegate)` removes last instance of the removedDelegate delegate from the combinedDelegate delegate.

**Input Arguments**

**combinedDelegate**  
.NET System.Delegate object. The combined delegate from which to remove the removedDelegate delegate.

**removedDelegate**  
.NET System.Delegate object. The delegate to remove from the combinedDelegate delegate.

**Output Arguments**

**result**  
.NET System.Delegate object. A new delegate which is the same as the combinedDelegate delegate except without the last instance of the removedDelegate delegate.

**Alternatives** Use the static Remove method of the System.Delegate class.

**See Also** RemoveAll | Combine

**How To**

# timeseries

---

**Purpose** Create `timeseries` object

**Description** Time series are data vectors sampled over time, in order, often at regular intervals. They are distinguished from randomly sampled data that form the basis of many other data analyses. Time series represent the time-evolution of a dynamic population or process. The linear ordering of time series gives them a distinctive place in data analysis, with a specialized set of techniques. Time series analysis is concerned with:

- Identifying patterns
- Modeling patterns
- Forecasting values

**Construction** `ts = timeseries` creates an empty time-series object.

`ts = timeseries(tsname)` creates an empty time-series object using the name, `tsname`, for the time-series object. This name can differ from the time-series variable name.

`ts = timeseries(data)` creates the time-series object using the specified data.

`ts = timeseries(data,time)` creates the time-series object using the specified data and time.

`ts = timeseries(data,time,quality)` specifies quality in terms of codes defined by `QualityInfo.Code`.

`ts = timeseries(data,'Name',tsname)` creates the time-series object using the specified data and the name, `tsname`.

`ts = timeseries(data,time,'Name',tsname)` creates the time-series object using the specified data, time, and the name, `tsname`.

`ts = timeseries(data,time,quality,'Name',tsname)` uses the specified quality and the name, `tsname`.

## Input Arguments

### **data**

The time-series data, which can be an array of samples

### **tsname**

Time-series name specified as a string

**Default:** ''

### **time**

The time vector.

When time values are date strings, you must specify `Time` as a cell array of date strings. When the time vector contains duplicate values:

- Duplicated values must occupy contiguous elements.
- Time values must not be decreasing.

Interpolating time-series data using methods like `resample` and `synchronize` can produce different results depending on whether the input `timeseries` contains duplicate times.

**Default:** A time vector that ranges from 0 to N-1 with a 1-second interval, where N is the number of samples.

### **quality**

An integer vector with values -128 to 127 that specifies the quality in terms of codes defined by `QualityInfo.Code`

When `Quality` is a vector:

- `Quality` must have the same length as the time vector.
- Each `Quality` value applies to the corresponding data sample.

When `Quality` is an array:

- `Quality` must have the same size as the data array.
- Each `Quality` value applies to the corresponding data value of the `ts.data` array.

## Properties

### Data

Time-series data, where each data sample corresponds to a specific time

The data can be a scalar, a vector, or a multidimensional array. Either the first or last dimension of the data must align with `Time`.

By default, NaNs represent missing or unspecified data. Set the `TreatNaNasMissing` property to determine how missing data is treated in calculations.

### Attributes:

Dependent	true
-----------	------

### DataInfo

Contains fields for storing contextual information about `Data`:

- `Unit` — String that specifies data units
- `Interpolation` — A `tsdata.interpolation` object that specifies the interpolation method for this `timeseries` object.  
Fields of the `tsdata.interpolation` object include:
  - `Fhandle` — Function handle to a user-defined interpolation function
  - `Name` — String that specifies the name of the interpolation method. Predefined methods include `'linear'` and `'zoh'` (zero-order hold). `'linear'` is the default.
- `UserData` — Any user-defined information entered as a string

## Events

An array of `tsdata.event` objects that stores event information for this `timeseries` object.

You add events by using the `addevent` method. Fields of the `tsdata.event` object include the following:

- `EventData` — Any user-defined information about the event
- `Name` — String that specifies the name of the event
- `Time` — Time value when this event occurs, specified as a real number or a date string
- `Units` — Time units
- `StartDate` — A reference date specified in MATLAB date-string format. `StartDate` is empty when you have a numerical (non-date-string) time vector.

## IsTimeFirst

Logical value (`true` or `false`) specifies whether the time vector is aligned with the first or last dimension of the `Data` array. The value is `false` for 3-D and higher dimensional data and `true` otherwise.

- `true` — The first dimension of the data array is aligned with the time vector. For example, `ts = timeseries(rand(3,3),1:3);`
- `false` — The last dimension of the data array is aligned with the time vector. For example: `ts = timeseries(rand(3,4,5),1:5);`

## Attributes:

<code>Dependent</code>	<code>true</code>
<code>SetAccess</code>	<code>'protected'</code>

## Length

Length of the time vector in the `timeseries` object

**Attributes:**

Dependent	true
SetAccess	'protected'

**Name**

The `timeseries` object name entered as a string, `tsname`.

This name can differ from the name of the `timeseries` variable in the MATLAB workspace.

**Quality**

An integer vector or array containing values -128 to 127 that specify the quality in terms of codes defined by `QualityInfo.Code`.

When `Quality` is a vector, it must have the same length as the time vector. In this case, each `Quality` value applies to a corresponding data sample.

When `Quality` is an array, it must have the same size as the data array. In this case, each `Quality` value applies to the corresponding value of the data array.

**Attributes:**

Dependent	true
-----------	------

**QualityInfo**

Provides a lookup table that converts numerical `Quality` codes to readable descriptions.

`QualityInfo` fields include the following:

- **Code** — Integer vector containing values -128 to 127 that define the “dictionary” of quality codes. You can assign one of these integer values to each `Data` value by using the `Quality` property.

- **Description** — Cell vector of strings, where each element provides a readable description of the associated quality Code.
- **UserData** — Stores any additional user-defined information.

Lengths of Code and Description must match.

### **Time**

Array of time values.

When `TimeInfo.StartDate` is empty, the numerical `Time` values are measured relative to 0 in specified units. When `TimeInfo.StartDate` is defined, the time values are date strings measured relative to the `StartDate` in specified units.

The length of `Time` must be the same as either the first or the last dimension of `Data`. When the data contains three or more dimensions, the length of `Time` matches the size of the last data dimension. Otherwise, the length of `Time` matches the size of the first data dimension.

#### **Attributes:**

Dependent	true
-----------	------

### **TimeInfo**

Uses the following fields for storing contextual information about `Time`:

- **Units** — Time units having any of following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', or 'nanoseconds'
- **Start** — Start time
- **End** — End time (read only)
- **Increment** — Interval between two subsequent time values
- **Length** — Length of the time vector (read only)

- **Format** — String defining the date string display format. See the MATLAB `datestr` function reference page for more information.
- **StartDate** — Date string defining the reference date. See the MATLAB `setabstime` function reference page for more information.
- **UserData** — Stores any additional user-defined information

## **TreatNaNasMissing**

Logical value that specifies how to treat NaN values in `Data`:

- **true** — (Default) Treats all NaN values as missing data except during statistical calculations.
- **false** — Includes NaN values in statistical calculations, in which case NaN values are propagated to the result.

## **UserData**

Generic field for data of any class that you want to add to the object.

**Default:** []

## **Methods**

### **Time-Series Methods**

- [Methods to Query and Set Object Properties and Plot the Data on page 5111](#)
- [Methods to Manipulate Data and Time on page 5111](#)
- [Event Methods on page 5112](#)
- [Methods to Arithmetically Combine `timeseries` Objects on page 5113](#)
- [Methods to Calculate Descriptive Statistics for a `timeseries` Object on page 5114](#)

## Methods to Query and Set Object Properties and Plot the Data

<code>get</code>	Query <code>timeseries</code> object property values.
<code>getdatasamplesize</code>	Return the size of each data sample in a <code>timeseries</code> object.
<code>getqualitydesc</code>	Return data quality descriptions based on the <code>Quality</code> property values assigned to a <code>timeseries</code> object.
<code>plot</code>	Plot the <code>timeseries</code> object.
<code>set</code>	Set <code>timeseries</code> property values.

## Methods to Manipulate Data and Time

<code>addsample</code>	Add a data sample to a <code>timeseries</code> object.
<code>append</code>	Concatenate <code>timeseries</code> objects in the time dimension.
<code>ctranspose</code>	Transpose a <code>timeseries</code> object.
<code>delsample</code>	Delete a sample from a <code>timeseries</code> object.
<code>detrend</code>	Subtract the mean or best-fit line and remove all NaNs from time-series data.
<code>filter</code>	Shape frequency content of time-series data using a 1-D digital filter.
<code>getabstime</code>	Extract a date-string time vector from a <code>timeseries</code> object into a cell array.
<code>getdatasamples</code>	Extract a subset of data samples from an existing <code>timeseries</code> object into an array using a subscripted indexed array.
<code>getsamples</code>	Extract a subset of data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object using a subscript indexed array.

## (Continued)

<code>getinterpmethod</code>	Get the interpolation method for a <code>timeseries</code> object.
<code>getsamplingsingtime</code>	Extract data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object based on specified start and end time values.
<code>idealfilter</code>	Apply an ideal pass or notch (noncausal) filter to a <code>timeseries</code> object.
<code>resample</code>	Select or interpolate data in a <code>timeseries</code> object using a new time vector.
<code>setabstime</code>	Set the time values in the time vector as date strings.
<code>setinterpmethod</code>	Set interpolation method for a <code>timeseries</code> object.
<code>setuniformtime</code>	Assign uniform time vector to <code>timeseries</code> object.
<code>synchronize</code>	Synchronize and resample two <code>timeseries</code> objects using a common time vector.
<code>transpose</code>	Transpose a <code>timeseries</code> object.

## Event Methods

To construct an event object, use the constructor `tsdata.event`. For an example of defining events for a time-series object, see “Defining Events”.

<code>addevent</code>	Add one or more events to a <code>timeseries</code> object.
<code>delevent</code>	Delete one or more events from a <code>timeseries</code> object.

## (Continued)

<code>gettsafteratevent</code>	Create a new <code>timeseries</code> object by extracting the samples from an existing time series that occur after or at a specified event.
<code>gettsafterevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur after a specified event from an existing time series.
<code>gettsatevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur at the same time as a specified event from an existing time series.
<code>gettsbeforeatevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur before or at a specified event from an existing time series.
<code>gettsbeforeevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur before a specified event from an existing time series.
<code>gettsbetweenevents</code>	Create a new <code>timeseries</code> object by extracting the samples that occur between two specified events from an existing time series.

## Methods to Arithmetically Combine `timeseries` Objects

<code>+</code>	Addition of the corresponding data values of <code>timeseries</code> objects.
<code>-</code>	Subtraction of the corresponding data values of <code>timeseries</code> objects.
<code>.*</code>	Element-by-element multiplication of <code>timeseries</code> data.

## (Continued)

*	Matrix-multiply <code>timeseries</code> data.
./	Right element-by-element division of <code>timeseries</code> data.
/	Right matrix division of <code>timeseries</code> data.
.\	Element-by-element left-array divide of <code>timeseries</code> data.
\	Left matrix division of <code>timeseries</code> data.

## Methods to Calculate Descriptive Statistics for a `timeseries` Object

<code>iqr</code>	Return the interquartile range of <code>timeseries</code> data.
<code>max</code>	Return the maximum value of <code>timeseries</code> data.
<code>mean</code>	Return the mean of <code>timeseries</code> data.
<code>median</code>	Return the median of <code>timeseries</code> data.
<code>min</code>	Return the minimum of <code>timeseries</code> data.
<code>std</code>	Return the standard deviation of <code>timeseries</code> data.
<code>sum</code>	Return the sum of <code>timeseries</code> data.
<code>var</code>	Return the variance of <code>timeseries</code> data.

## Definitions

### **timeseries**

The time-series object, called `timeseries`, is a MATLAB variable that contains time-indexed data and properties in a single, coherent structure. For example, in addition to data and time values, you can also use the time-series object to store events, descriptive information about data and time, data quality, and the interpolation method.

## Data Sample

A time-series *data sample* consists of one or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

For example, suppose that `ts.data` has the size 3-by-4-by-5 and the time vector has the length 5. Then, the number of samples is 5 and the total number of data values is  $3 \times 4 \times 5 = 60$ .

## Time Vector

A time vector of a `timeseries` object can be either numerical (double) values or valid MATLAB date strings.

When the `timeseries` `TimeInfo.StartDate` property is empty, the numerical time values are measured relative to 0 (or another numerical value) in specified units. In this case, the time vector is described as *relative* (that is, it contains time values that are not associated with a specific start date).

When `TimeInfo.StartDate` is nonempty, the time values are date strings measured relative to `StartDate` in specified units. In this case, the time vector is described as *absolute* (that is, it contains time values that are associated with a specific calendar date).

MATLAB supports the following date-string formats for time-series applications.

Date-String Format	Usage Example
dd-mmm-yyyy HH:MM:SS	01-Mar-2000 15:45:17
dd-mmm-yyyy	01-Mar-2000
mm/dd/yy	03/01/00
mm/dd	03/01
HH:MM:SS	15:45:17
HH:MM:SS PM	3:45:17 PM
HH:MM	15:45

# timeseries

---

Date-String Format	Usage Example
HH:MM PM	3:45 PM
mmm.dd,yyyy HH:MM:SS	Mar.01,2000 15:45:17
mmm.dd,yyyy	Mar.01,2000
mm/dd/yyyy	03/01/2000

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

Create a `timeseries` object called 'LaunchData' that contains four data sets, each stored as a column of length 5 and using the default time vector:

```
b = timeseries(rand(5, 4), 'Name', 'LaunchData')
```

---

Create a `timeseries` object containing a single data set of length 5 and a time vector starting at 1 and ending at 5:

```
b = timeseries(rand(5,1), [1 2 3 4 5])
```

---

Create a `timeseries` object called 'FinancialData' containing five data points at a single time point:

```
b = timeseries(rand(1,5), 1, 'Name', 'FinancialData')
```

## How To

- “MATLAB Objects”

## Purpose

Add data sample to timeseries object

## Syntax

```
ts1 = addsample(ts, s)
ts1 = addsample(ts, 'Data', data-value,
'Time',time-value,...,
    Name,Value)
```

## Description

`ts1 = addsample(ts, s)` adds one or more new data samples stored in a structure `s` to the timeseries object `ts`.

`ts1 = addsample(ts, 'Data', data-value, 'Time',time-value,..., Name,Value)` adds one or more data samples to the timeseries object `ts` along with additional options specified by one or more `Name,Value` pair arguments.

## Tips

- If `N` is the number of data samples, you can get the sample size of each time with `SampleSize = getsamplesize(ts)`.

When `ts.IsTimeFirst` is true, the size of the data is `N-by-SampleSize`. When `ts.IsTimeFirst` is false, the size of the data is `SampleSize-by-N`.

## Input Arguments

**s**

A structure that you must define before passing as an argument to `addsample`. It consists of the following optional fields:

- `s.data`
- `s.time`
- `s.quality`
- `s.overwriteflag`

### **data-value**

A numeric data value.

### **time-value**

# timeseries.addsample

---

A valid time vector.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Quality'**

Array of data quality codes.

**Default:** []

### **'OverwriteFlag'**

Logical value that controls whether to overwrite a data sample at the same time with the new sample you are adding to your `timeseries` object. When set to `true`, the new sample overwrites the old sample at the same time.

**Default:** `false`

## **Output Arguments**

**ts1**

The `timeseries` object that results when you add the specified samples to the original `timeseries` object.

## **Definitions**

### **data sample**

One or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

## **Examples**

Add a data value of 420 at time 3:

```
ts = ts.addsample('Time',3,'Data',420);
```

---

Add a data value of 420 at time 3 and specify quality code 1 for this data value. Set the `OverwriteFlag` to overwrite an existing value at time 3.

```
ts = ts.addsample('Data',3.2,'Quality',1,'OverwriteFlag',...  
                 true,'Time',3);
```

[timeseries](#) | [delsample](#) | [getdatasamples](#)

# timeseries.append

---

<b>Purpose</b>	Concatenate time series objects in time dimension
<b>Syntax</b>	<code>ts = append(ts1,ts2, ... tsn)</code>
<b>Description</b>	<code>ts = append(ts1,ts2, ... tsn)</code> creates a new <code>timeseries</code> object by concatenating <code>timeseries</code> <code>ts1</code> , <code>ts2</code> , and so on, along the time dimension.
<b>Tips</b>	<ul style="list-style-type: none"><li>• A single overlapping time between each input time series is valid, as long as the overlapping samples are identical.</li><li>• The time vectors must not overlap by a nonzero amount. That is, the last time in <code>ts1</code> must be earlier than or equal to the first time in <code>ts2</code>.</li><li>• The sample size of the time series must be the same.</li></ul>
<b>Input Arguments</b>	<p><b>ts1</b> The first <code>timeseries</code> object that you want to append.</p> <p><b>ts2</b> The second <code>timeseries</code> object that you want to append.</p> <p><b>tsn</b> The <code>n</code>th <code>timeseries</code> object that you want to append.</p>
<b>Output Arguments</b>	<p><b>ts</b> The <code>timeseries</code> object that results from appending the input <code>timeseries</code> objects.</p>
<b>Examples</b>	After creating <code>timeseries</code> objects, <code>ts1</code> and <code>ts2</code> , append them:  <pre>ts1 = timeseries(rand(5,1),[1 2 3 4 5]); ts2 = timeseries(rand(5,1),[6 7 8 9 10]); ts3 = append(ts1, ts2)</pre>
<b>See Also</b>	<code>timeseries</code>

**Purpose** Transpose timeseries object

**Syntax** `ts1 = ctranspose(ts)`

**Description** `ts1 = ctranspose(ts)` returns a new `timeseries` object `ts1` with the `IsTimeFirst` value set to opposite of what it is for `ts`. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector as a result of this operation.

## Tips

- The overloaded `ctranspose` method for `timeseries` objects does not transpose the data. Instead, this method changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, you must transpose the `Data` property of the `timeseries` object. For example, you can use the syntax `ctranspose(ts.Data)` or `(ts.Data)'`. The `Data` property value must be a 2-D array.
- Consider a `timeseries` object with 10 samples with the property `IsTimeFirst = True`. When you transpose this object, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

The following table summarizes the size for `Data` property of the `timeseries` object (up to three dimensions) before and after transposing.

### Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

# timeseries.ctranspose

---

## Input Arguments

**ts**

The timeseries object you want to transpose.

## Output Arguments

**ts1**

The transposed timeseries object.

## Examples

Suppose that a timeseries object `ts` has `ts.data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is set to `true`, which means that the first dimension of the data is aligned with the time vector. `ctranspose(ts)` modifies `ts`, such that the last dimension of the data is now aligned with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

`timeseries` | `transpose`

**Purpose** Remove sample from timeseries object

**Syntax** `ts1 = delsample(ts,Name,Value)`

**Description** `ts1 = delsample(ts,Name,Value)` deletes samples from the timeseries object `ts` based on the specified `Name,Value` pair arguments.

**Input Arguments**

**ts**  
A timeseries object.

**Name-Value Pair Arguments** Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Index**

The indices of the time vector that correspond to the samples you want to delete.

**Value**

The time values that correspond to the samples you want to delete.

**Output Arguments**

**ts1**  
The timeseries object that results from removing the specified samples.

**Examples** Create a timeseries object, and then remove samples:

```
ts = timeseries(rand(5,1),[10 20 30 40 50]);
```

```
% Remove data sample at time index 1
```

```
ts1 = delsample(ts,'Index', 1)
```

# timeseries.delsample

---

```
% Remove data sample at time value 20:  
ts2 = delsample(ts, 'Value', [20])  
set | timeseries
```

<b>Purpose</b>	Subtract mean or best-fit line and all NaNs from <code>timeseries</code> object
<b>Syntax</b>	<pre>ts1 = detrend(ts, method) ts1 = detrend(ts, method, index)</pre>
<b>Description</b>	<p><code>ts1 = detrend(ts, method)</code> subtracts either a mean or a best-fit line from time-series data, using the specified <code>method</code>. Usually for FFT processing.</p> <p><code>ts1 = detrend(ts, method, index)</code> uses the optional <code>index</code> to specify the columns or rows to detrend.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• You cannot apply <code>detrend</code> to <code>timeseries</code> data with more than two dimensions.</li></ul>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The <code>timeseries</code> object from which you want to subtract the mean or best-fit line and all NaNs.</p> <p><b>method</b></p> <p>A string that specifies one of the following <code>detrend</code> methods:</p> <ul style="list-style-type: none"><li>• 'constant' — Subtracts the mean.</li><li>• 'linear' — Subtracts the best-fit line.</li></ul> <p><b>index</b></p> <p>An integer array that specifies the columns or rows to detrend when <code>ts.IsTimeFirst</code> is true.</p>
<b>Output Arguments</b>	<p><b>ts1</b></p> <p>The <code>timeseries</code> object resulting from detrending the input <code>timeseries</code> object.</p>
<b>See Also</b>	<code>timeseries</code>

# timeseries.filter

---

**Purpose** Shape frequency content of time-series

**Syntax** `ts1 = filter(ts, numerator, denominator)`  
`ts1=filter(ts, numerator, denominator, index)`

**Description** `ts1 = filter(ts, numerator, denominator)` applies the transfer function filter  $b(z^{-1})/a(z^{-1})$  to the data in the timeseries object `ts`. `b` and `a` are the coefficient arrays of the transfer function numerator and denominator, respectively.

`ts1=filter(ts, numerator, denominator, index)` uses the optional `index` integer array to specify either the columns or rows to filter, depending on the value of `ts.IsTimeFirst`.

## Tips

- The time-series data must be uniformly sampled to use this filter.
- The following function

```
y = filter(b,a,x)
```

creates filtered data `y` by processing the data in vector `x` with the filter described by vectors `a` and `b`.

- The `filter` function is a general tapped delay-line filter, described by the difference equation:

$$a(1)y(n) = b(1)x(n) + b(2)x(n - 1) + \dots + b(nb)x(n - nb + 1) - a(2)y(n - 1) - \dots - a(N_a)y(n - N_b + 1).$$

Here,  $n$  is the index of the current sample,  $N_a$  is the order of the polynomial described by vector `a`, and  $N_b$  is the order of the polynomial described by vector `b`. The output  $y(n)$  is a linear combination of current and previous inputs,  $x(n) x(n - 1) \dots$ , and previous outputs,  $y(n - 1) y(n - 2) \dots$ .

- You use the discrete filter to shape the data by applying a transfer function to the input signal.

Depending on your objectives, the transfer function you choose might alter both the amplitude and the phase of the variations in the data at different frequencies to produce either a smoother or a rougher output.

- In digital signal processing (DSP), it is customary to write transfer functions as rational expressions in  $z^{-1}$  and to order the numerator and denominator terms in ascending powers of  $z^{-1}$ .

Taking the z-transform of the difference equation

$$a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \dots + b(nb)x(n-nb+1) - a(2)y(n-1) - \dots - a(na)y(na+1),$$

results in the transfer function

$$Y(z) = H(z^{-1})X(z) = \frac{b(1) + b(2)z^{-1} + \dots + b(nb)z^{-nb+1}}{a(1) + a(2)z^{-1} + \dots + a(na)z^{-na+1}} X(z),$$

where  $Y(z)$  is the z-transform of the filtered output  $y(n)$ . The coefficients  $b$  and  $a$  are unchanged by the z-transform.

## Input Arguments

### **ts**

The first `timeseries` object for which you want to shape the frequency content.

### **numerator**

The coefficient array of the transfer function numerator.

### **denominator**

The coefficient array of the transfer function denominator.

### **index**

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

# timeseries.filter

---

## Output Arguments

**ts1**

The timeseries object that results from filtering the input timeseries object.

## Examples

This example applies the following transfer function to the data in count.dat:

$$H(z^{-1}) = \frac{b(z^{-1})}{a(z^{-1})} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}$$

```
% Load the matrix count into the workspace:
```

```
load count.dat;
```

```
% Create a time-series object based on this matrix:
```

```
count1=timeseries(count(:,1),[1:24]);
```

```
% Enter the coefficients of the denominator ordered in  
% ascending powers of  $z^{-1}$  to  
% represent  $1 + 0.2z^{-1}$ :
```

```
a = [1 0.2];
```

```
% Enter the coefficients of the numerator to represent  $2 - 3z^{-1}$ :
```

```
b = [2 3];
```

```
% Call the filter method:
```

```
filter_count = filter(count1, b, a)
```

```
% Compare the original data and the shaped data with an  
% overlaid plot of the two curves:
```

```
plot(count1,'-.'), grid on, hold on
```

```
plot(filter_count, '- ')\nlegend('Original Data', 'Shaped Data', 2)
```

**See Also**

timeseries | idealfilter

# timeseries.get

---

**Purpose** Query `timeseries` object property values

**Syntax**  
`get(ts)`  
`value = get(ts, PropertyName)`

**Description** `get(ts)` displays all properties and values of the `timeseries` object, `ts`.  
`value = get(ts, PropertyName)` returns the property value for the specified `timeseries` object. The following syntax is equivalent:  
`value = ts.PropertyName`

**Input Arguments**  
**ts**  
A `timeseries` object.

**PropertyName**  
String specifying the name of a `timeseries` property. For a list of `timeseries` properties, see `timeseries`.

**Output Arguments**  
**value**  
String containing the value associated with the specified property.

**Examples** Create a `timeseries` object, and then get the name. This example gets the name three different ways:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5], 'Name', 'MyTimeseries');  
get(ts1)  
get(ts1, 'Name')  
value = ts1.Name
```

**See Also** `timeseries` | `set`

<b>Purpose</b>	Extract date-string time vector into cell array
<b>Syntax</b>	<code>getabstime(ts)</code>
<b>Description</b>	<code>getabstime(ts)</code> extracts the time vector from the <code>timeseries</code> object <code>ts</code> as a cell array of date strings.
<b>Tips</b>	<ul style="list-style-type: none"><li>To define the time vector relative to a calendar date, set the <code>TimeInfo.StartDate</code> property of the <code>timeseries</code> object. When the <code>TimeInfo.StartDate</code> format is a valid <code>datestr</code> format, the output strings from <code>getabstime</code> have the same format.</li></ul>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The <code>timeseries</code> object from which you want to extract the time vector.</p>
<b>Examples</b>	<p>The following example extracts a time vector as a cell array of date strings from a <code>timeseries</code> object.</p> <p>First, create a <code>timeseries</code> object.</p> <pre>ts = timeseries([3 6 8 0 10]);</pre> <p>The default time vector for <code>ts</code> is <code>[0 1 2 3 4]</code>, which starts at 0 and increases in 1-second increments. The length of the time vector is equal to the length of the data.</p> <p>Next, set the <code>StartDate</code> property.</p> <pre>ts.TimeInfo.StartDate = '10/27/2005 07:05:36';</pre> <p>Extract the time vector.</p> <pre>getabstime(ts)</pre> <p>MATLAB returns:</p> <pre>'27-Oct-2005 07:05:36'</pre>

# timeseries.getabstime

---

```
'27-Oct-2005 07:05:37'  
'27-Oct-2005 07:05:38'  
'27-Oct-2005 07:05:39'  
'27-Oct-2005 07:05:40'
```

Change the date-string format of the time vector, and then extract the time vector with the new date-string format:

```
ts.TimeInfo.Format = 'mm/dd/yy';  
getabstime(ts)
```

MATLAB returns:

```
'10/27/05'  
'10/27/05'  
'10/27/05'  
'10/27/05'  
'10/27/05'
```

## See Also

[timeseries](#) | [setabstime](#) | [datestr](#)

<b>Purpose</b>	Returns subset of time series samples using subscripted index array
<b>Syntax</b>	<code>datasamples = getdatasamples(ts, i)</code>
<b>Description</b>	<code>datasamples = getdatasamples(ts, i)</code> returns an array corresponding to the samples indicated by the array, <code>i</code> .
<b>Input Arguments</b>	<p><b>ts</b> The timeseries object from which you want to exact samples.</p> <p><b>i</b> An array of linear indices or logical values that specifies the time value or values for which you want to extract the corresponding samples.</p>
<b>Output Arguments</b>	<p><b>datasamples</b> The array that results from extracting the samples corresponding to the time value or values, <code>ts.time(i)</code>.</p>
<b>Examples</b>	<p>After creating a timeseries object, <code>ts</code>, extract the second and third data samples into an array:</p> <pre>ts = timeseries(rand(5,1),[1 2 3 4 5]); samples = getdatasamples(ts, [2 3])</pre>
<b>See Also</b>	<code>timeseries</code>   <code>getsamples</code>   <code>resample</code>

# timeseries.getdatasamplesize

---

**Purpose** Size of data sample in timeseries object

**Syntax** `getdatasamplesize(ts)`

**Description** `getdatasamplesize(ts)` returns the size of each data sample in a timeseries object.

**Input Arguments** **ts**  
String specifying the name of a timeseries object.

**Definitions** **data sample**  
One or more scalar values recorded at a specific time. The number of data samples is the same as the length of the time vector.

**Examples** After loading data and creating a timeseries object, get the size of a data sample:

```
% Load a 24-by-3 data array:  
load count.dat  
  
% Create a timeseries object with 24 time values:  
count_ts = timeseries(count,[1:24], 'Name', 'VehicleCount')  
  
% Get the size of the data sample for this timeseries object:  
getdatasamplesize(count_ts)
```

MATLAB returns the following, which indicates that the size of each data sample in `count_ts` is 1-by-3. In other words, MATLAB stores each data sample as a row with three values.

```
ans =  
  
     1     3
```

**See Also** `timeseries` | `set`

<b>Purpose</b>	Interpolation method for <code>timeseries</code> object
<b>Syntax</b>	<code>getinterpmethod(ts)</code>
<b>Description</b>	<code>getinterpmethod(ts)</code> returns the interpolation method that the <code>timeseries</code> object <code>ts</code> , uses as a string.
<b>Input Arguments</b>	<b>ts</b> The <code>timeseries</code> object from which you want to extract the interpolation method.
<b>Definitions</b>	<b>interpolation method</b> Predefined interpolation methods are zero-order hold, <code>zoh</code> , and linear interpolation, <code>linear</code> . Linear interpolation is the default.
<b>Examples</b>	Create a <code>timeseries</code> object, and then get its interpolation method:  <pre>ts = timeseries(rand(5)); getinterpmethod(ts)</pre> MATLAB returns:  <code>linear</code>
<b>See Also</b>	<code>timeseries</code>   <code>setinterpmethod</code>

# timeseries.getqualitydesc

---

**Purpose** Data quality descriptions

**Syntax** `getqualitydesc(ts)`

**Description** `getqualitydesc(ts)` returns a cell array of data quality descriptions based on the `Quality` values you assigned to a `timeseries` object, `ts`.

**Input Arguments**

**ts**  
A `timeseries` object.

**Examples** Create a `timeseries` object, and then get the data quality description strings for `ts`:

```
% Create a timeseries object, ts, with Data,
Time, and Quality
% values, respectively:

ts = timeseries([3; 4.2; 5; 6.1; 8], 1:5, [1; 0; 1; 0; 1]);

% Set the QualityInfo property, including Code and Description:

ts.QualityInfo.Code = [0 1];
ts.QualityInfo.Description = {'good' 'bad'};

% Get the data quality description strings for ts:
getqualitydesc(ts)

MATLAB returns:

ans =

    'bad'
    'good'
    'bad'
    'good'
    'bad'
```

**See Also** [timeseries](#)

# timeseries.getsamples

---

<b>Purpose</b>	Subset of time series samples using subscripted index array
<b>Syntax</b>	<code>ts1 = getsamples(ts, i)</code>
<b>Description</b>	<code>ts1 = getsamples(ts, i)</code> returns a new <code>timeseries</code> object by extracting samples from <code>timeseries</code> <code>ts</code> corresponding to the time or times indicated by the subscripted index array, <code>i</code> .
<b>Input Arguments</b>	<b>ts</b> The <code>timeseries</code> object from which you want to exact samples. <b>i</b> A subscripted index array that specifies the time value or values for which you want to extract the corresponding samples.
<b>Output Arguments</b>	<b>ts1</b> The <code>timeseries</code> object that results from extracting the samples corresponding to the time value or values <code>ts.time(i)</code> .
<b>Examples</b>	After creating a <code>timeseries</code> object, <code>ts</code> , extract the data samples at times 2 and 3 into a new <code>timeseries</code> object, <code>ts1</code> : <pre>ts = timeseries(rand(5,1),[1 2 3 4 5]); ts1 = getdatasamples(ts, ts.time([2 3]))</pre>
<b>See Also</b>	<code>timeseries</code>   <code>getdatasamples</code>   <code>resample</code>

<b>Purpose</b>	Extract data samples into new timeseries object
<b>Syntax</b>	<pre>ts1 = getsampleusingtime(ts, time) ts1 = getsampleusingtime(ts, starttime, endtime)</pre>
<b>Description</b>	<p><code>ts1 = getsampleusingtime(ts, time)</code> returns a new timeseries object, <code>ts1</code>, with a single sample corresponding to specified <code>time</code> in <code>ts</code>.</p> <p><code>ts1 = getsampleusingtime(ts, starttime, endtime)</code> returns a new timeseries object, <code>ts1</code>, with samples between the times <code>starttime</code> and <code>endtime</code> in <code>ts</code>.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• If the time vector in <code>ts</code> is not relative to a calendar date, then <code>starttime</code> and <code>endtime</code> must be numeric.</li><li>• If the time vector in <code>ts</code> is relative to a calendar date, then <code>starttime</code> and <code>endtime</code> values must be dates—either strings or <code>datenum</code> values.</li></ul>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The timeseries object from which you want to extract data samples.</p> <p><b>time</b></p> <p>The time corresponding to data sample you want to extract.</p> <p><b>starttime</b></p> <p>The time corresponding to the first data sample you want to extract.</p> <p><b>endtime</b></p> <p>The time corresponding to the last data sample you want to extract.</p>
<b>Output Arguments</b>	<p><b>ts1</b></p> <p>A timeseries object that contains the subset of data samples from the original timeseries object.</p>

# timeseries.getsampleusingtime

[timeseries](#)

## Purpose

Apply ideal (noncausal) filter to timeseries object

## Syntax

```
ts1 = idealfilter(ts, interval, filtertype)
ts1 = idealfilter(ts, interval, filtertype, index)
```

## Description

`ts1 = idealfilter(ts, interval, filtertype)` applies an ideal filter of `filtertype` to one or more frequency intervals that `interval` specifies for the `timeseries` object, `ts`.

`ts1 = idealfilter(ts, interval, filtertype, index)` applies an ideal filter and uses the optional `index` integer array to specify the columns or rows to filter.

## Tips

- Ideal filters require data to have a mean of zero and prepare the data by subtracting its mean. You can restore the filtered signal amplitude by adding the mean of the input data to the filter output values.
- Use the ideal *notch* filter when you want to remove variations in a specific frequency range. Alternatively, use the ideal *pass* filter to allow only the variations in a specific frequency range.
- If the time-series data is sampled nonuniformly, filtering resamples this data on a uniform time vector.
- All NaNs in the time series are interpolated before filtering, using the interpolation method you assigned to the `timeseries` object.

## Input Arguments

**ts**

The `timeseries` object to which you want to apply an ideal filter.

**interval**

The frequency interval (specified in cycles per time unit) at which you want the ideal filter applied. To specify several frequency intervals, use an `n`-by-2 array of start and end frequencies, where `n` represents the number of intervals.

**filtertype**

# timeseries.idealfilter

---

A string specifying the type of filter you want to apply, either pass or notch.

## index

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

## Output Arguments

### ts1

The `timeseries` object that results when you apply an ideal filter to the original `timeseries` object.

## Definitions

### ideal filter

Filters are *ideal* in the sense that they are *not realizable*. An ideal filter is noncausal and the ends of the filter amplitude are perfectly flat in the frequency domain.

## Examples

These examples first apply an ideal notch filter to the data in `count.dat`. Then, they apply a pass filter to the data:

```
% Load the count matrix into the workspace:
```

```
load count.dat;
```

```
% Create a timeseries object from column one of this matrix.
```

```
% Specify a time vector that ranges from 1 to 24 s in 1-s intervals.
```

```
count1=timeseries(count(:,1),1:24);
```

```
% Obtain the mean of the data:
```

```
countmean = mean(count1);
```

```
% Enter the frequency interval, in hertz, for filtering the data:
```

```
interval=[0.08 0.2];
```

```
% Invoke an ideal notch filter:
idealfilter_countn = idealfilter(count1,interval,'notch')

% Compare the original data and the shaped data on a line plot:

plot(count1,'-.'), grid on, hold on
plot(idealfilter_countn,'-')

% Restore the mean to the filtered data and show it on the line plot,
% adding a legend and a title:

countn_restored = idealfilter_countn + countmean;
plot(countn_restored,':m');
title('Notch Filter')
legend('Original Data','Shaped Data','Mean Restored',...
      'Location','NorthWest')
```

# timeseries.idealfilter

```
% Close the Figure window:
close
% Then, repeat the process using a pass rather than a notch filter:
figure
plot(count1,'-.'), grid on, hold on
idealfilter_countp = idealfilter(count1,interval,'pass');
plot(idealfilter_countp,'-')
countp_restored = idealfilter_countp + countmean;
plot(countp_restored,':m');
title('Pass Filter')
legend('Original Data','Shaped Data','Mean Restored',...
```

'Location', 'NorthWest')

## See Also

[timeseries | filter](#)

# timeseries.iqr

---

**Purpose** Interquartile range of timeseries data

**Syntax** `ts_iqr = iqr(ts)`  
`iqr(ts, Name, Value)`

**Description** `ts_iqr = iqr(ts)` returns the interquartile range of `ts.Data`.  
`iqr(ts, Name, Value)` reruns the interquartile range of `ts.Data` with the specified `Name, Value` pairs.

**Input Arguments** **ts**  
The timeseries object for which you want the interquartile range of timeseries data.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

### **'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

**Output Arguments** **ts\_iqr**  
The interquartile range of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_iqr` is the difference between the 75th and the 25th percentiles of the `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_iqr` is a row vector containing the interquartile range of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `iqr` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Create a time series with a missing value, represented by `NaN`, and then calculate the interquartile range of `ts.Data` after removing the missing value from the calculation:

```
ts = timeseries([3.0 NaN 5 6.1 8], 1:5);  
iqr(ts, 'MissingData', 'remove')
```

MATLAB returns:

```
3.0500
```

## See Also

[max](#) | [mean](#) | [median](#) | [min](#) | [std](#) | [sum](#) | [timeseries](#) | [var](#)

# timeseries.max

---

**Purpose** Maximum value of timeseries data

**Syntax**  
`ts_max = max(ts)`  
`ts_max = max(ts,Name,Value)`

**Description** `ts_max = max(ts)` returns the maximum value in the timeseries data.

`ts_max = max(ts,Name,Value)` returns the maximum value in the timeseries data with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

**ts**  
The timeseries object for which you want to determine the maximum data value.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**'MissingData'**

A string specifying one of two possible values, remove or interpolate, indicating how to treat missing data during the calculation.

**Default:** remove

**'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## Output Arguments

### ts\_max

The maximum data value in the specified timeseries object, as follows:

- When `ts.Data` is a vector, `ts_max` is the maximum value of `ts.Data` values.
- When `ts.Data` is a matrix, `IsTimeFirst` is true, and the first dimension of `ts` is aligned with time, then `ts_max` is a row vector containing the maximum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `max` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example illustrates how to find the maximum values in multivariate time-series data:

```
% Load a 24-by-3 data array:
load count.dat

% Create a timeseries object with 24 time values:
count_ts = timeseries(count,[1:24],'Name','CountPerSecond')

% Find the maximum in each data column for this timeseries object:

max(count_ts)
```

MATLAB returns:

```
114    145    257
```

## See Also

[iqr](#) | [mean](#) | [median](#) | [min](#) | [std](#) | [sum](#) | [timeseries](#) | [var](#)

# timeseries.mean

---

**Purpose** Mean value of timeseries data

**Syntax**  
`ts_mn = mean(ts)`  
`ts_mn = mean(ts,Name,Value)`

**Description** `ts_mn = mean(ts)` returns the mean value of `ts.Data`.  
`ts_mn = mean(ts,Name,Value)` returns the mean value of `ts.Data` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments** **ts**  
The timeseries object for which you want the mean value of data.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

### **'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

### **'Weighting'**

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

**ts\_mn**

The mean value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_mn` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true` and the first dimension of `ts` is aligned with time, then `ts_mn` is a row vector containing the mean value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `mean` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Find the mean values in multivariate time-series data:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond')
```

```
% Find the mean of each data column for this timeseries object:
```

```
mean(count_ts)
```

MATLAB returns:

```
32.0000    46.5417    65.5833
```

# timeseries.mean

---

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

# timeseries.median

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_med`

The median value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_med` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_med` is a row vector containing the median value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `median` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the median values in multivariate time-series data. MATLAB finds the median independently for each data column in the `timeseries` object:

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,[1:24],'Name','CountPerSecond');

% Find the median of each data column for this timeseries object:

median(count_ts)

MATLAB returns:

23.5000    36.0000    39.0000
```

## Algorithms

MATLAB determines weighting by:

- 1** Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2** Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3** Multiplying the data for each time by its normalized weighting.

# timeseries.min

---

**Purpose** Minimum value of timeseries data

**Syntax** `ts_min = min(ts)`  
`ts_min = method(ts,Name,Value)`

**Description** `ts_min = min(ts)` returns the minimum value in the timeseries data.  
`ts_min = method(ts,Name,Value)` uses additional options specified by one or more Name,Value pair arguments.

**Input Arguments** **ts**  
The timeseries object for which you want the minimum data value.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### **'MissingData'**

A string specifying one of two possible values, remove or interpolate, indicating how to treat missing data during the calculation.

**Default:** remove

### **'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## Output Arguments

### ts\_min

The minimum value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_min` is the minimum value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_min` is a row vector containing the minimum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `min` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the minimum values in multivariate time-series data. MATLAB finds the minimum independently for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24],'Name','CountPerSecond');
```

```
% Find the minimum in each data column for this timeseries object:
```

```
min(count_ts)
```

```
MATLAB returns:
```

```
7     9     7
```

## See Also

```
iqr | max | mean | median | std | sum | timeseries | var
```

# timeseries.plot

---

**Purpose** Plot time series

**Syntax**

```
plot(ts)
plot(tsc.tsname)
plot(ts,linespec)
plot(tsc.tsname,linespec)
plot(ts,Name, Value)
plot(tsc.tsname,Name, Value)
```

**Description** `plot(ts)` plots the timeseries data `ts` against time and interpolates values between samples by using either zero-order-hold ('zoh') or linear interpolation (the default). The plot displays in the current axes. MATLAB creates a title and axes, if none exists.

`plot(tsc.tsname)` plots the timeseries object, `tsname` that is part of the `tscollection`, `tsc`.

`plot(ts,linespec)` plots the timeseries data using a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(tsc.tsname,linespec)` plots the timeseries object that is part of a timeseries collection as a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(ts,Name, Value)` plots a line graph of the time series data using the values specified for `lineseries` properties.

`plot(tsc.tsname,Name, Value)` plots a line graph of the timeseries object that is part of the specified timeseries collection using the values specified for `lineseries` properties.

## Tips

- The `timeseries/plot` method generates titles and axis labels automatically. These labels are:
  - Plot Title — 'Time Series Plot: <name>'  
where <name> is the string assigned to `ts.Name`, or by default, 'unnamed'
  - X-Axis Label — 'Time (<units>)'

where `<units>` is the value of the `ts.TimeInfo.Units` field, which defaults to `'seconds'`

▪ Y-Axis Label — `'<name>'`

where `<name>` is the string assigned to `ts.Name`, or by default, `'unnamed'`

- You can place new time series data on a time series plot (by setting `hold on`, for example, and issuing another `timeseries/plot` command). When you add data to a plot, the title and axis labels become blank strings to avoid labeling confusion. You can add your own labels after plotting using the `title`, `xlabel`, and `ylabel` commands.
- Time series events, when defined, are marked in the plot with a circular marker with red fill. You can also specify markers for all data points using a `linespec` or `name/value` syntax in addition to any event markers your data defines. The event markers plot on top of the markers you define.
- The value assigned to `ts.DataInfo.Interpolation.Name` controls the type of interpolation the plot method uses when plotting and resampling time series data. Invoke the `timeseries` method `setinterpmethod` to change default linear interpolation to zero-order hold interpolation (staircase). This method creates a new `timeseries` object, with which you can overwrite the original one if you want. For example, to cause time series `ts` to use zero-order hold interpolation, type the following:

```
ts = ts.setinterpmethod('zoh');
```

## Input Arguments

**ts**  
A `timeseries` object.

**tsc**  
A `tscollection`.

**tsname**

The name of a timeseries object within the tscollection .

## Examples

### Plot Time Series Object with Specified Start Date

Create a time series object, set the start date, and then plot the time vector relative to the start date.

```
x = [2 5 8 2 11 3 6];  
ts1 = timeseries(x,1:7);  
ts1.Name = 'Daily Count';  
ts1.TimeInfo.Units = 'days';  
ts1.TimeInfo.StartDate='01-Jan-2011' % Set start date.  
ts1.TimeInfo.Format = 'mmm dd, yy' % Set format for display on x-axis.  
ts1.Time=ts1.Time-ts1.Time(1); % Express time relative to the start date.  
plot(ts1)
```

## Plot Two Time Series Objects on the Same Axes

Create two time series objects from traffic count data, and then plot them in sequence on the same axes. Add an event to one series, which is automatically displayed with a red marker.

```
load count.dat;
count1=timeseries(count(:,1),1:24);
count1.Name = 'Oak St. Traffic Count';
count1.TimeInfo.Units = 'hours';
plot(count1,':b'), grid on
```

```
% Obtain time of maximum value and add it as an event:
[~,index] = max(count1.Data);
max_event = tsdata.event('peak',count1.Time(index));
max_event.Units = 'hours';
% Add the event to the time series:
count1 = addevent(count1,max_event);
```

# timeseries.plot

```
% Replace plot with new one showing the event:  
plot(count1,'.-b'), grid on
```

```
% Make a new ts object from column 2 of the same data source:  
count2=timeseries(count(:,2),1:24);  
count2.Name = 'Maple St. Traffic Count';  
count2.TimeInfo.Units = 'Hours';  
% Turn hold on to add the new data to the plot:  
hold on  
% The plot method does not add labels to a held plot.  
% Use property/value pair to customize markers:  
plot(count2,'s-m','MarkerSize',6),
```

```
% Labels are erased, so generate them manually:  
title('Time Series: Oak Street and Maple Street')  
xlabel('Hour of day')  
ylabel('Vehicle count')  
% Add a legend in the upper left:  
legend('Oak St.', 'Maple St.', 'Location', 'northwest')
```

# timeseries.plot

## See Also

`timeseries` | `setinterpmethod` | `tscollection` | `tsdata.event`  
| `plot`

**Purpose** Select or interpolate timeseries data using new time vector

**Syntax**

```
ts1 = resample(ts, time)
ts1 = resample(ts, time, interp_method)
ts1 = resample(ts, time, interp_method, code)
```

**Description** `ts1 = resample(ts, time)` resamples the timeseries object, `ts`, using the new time vector. The `resample` method uses the default interpolation method, which you can view by using the `getinterpmethod(ts)` syntax.

`ts1 = resample(ts, time, interp_method)` resamples the timeseries object `ts` using the specified interpolation method, `interp_method`.

`ts1 = resample(ts, time, interp_method, code)` resamples the timeseries object `ts` using the interpolation method given by the string `interp_method`. MATLAB applies the `code` to all samples.

## Input Arguments

**ts**  
The timeseries object that you want to resample.

**time**  
The time vector you want to use to resample the timeseries object.

When `ts` uses date strings and `time` is numeric, then `time` is treated as specified relative to the `ts.TimeInfo.StartDate` property and in the same units that `ts` uses.

**interp\_method**  
A string specifying the interpolation method. Valid interpolation methods are `linear` and `zero-order hold, zoh`.

**Default:** `linear`

**code**

# timeseries.resample

---

An integer value that specifies the user-defined Quality code for resampling. MATLAB applies this Quality code to all samples.

## Output Arguments

**ts1**

The `timeseries` object that results when you interpolate the original `timeseries` object with a new time vector.

## Examples

This example shows how to resample a `timeseries` object.

Create a `timeseries` object.

```
ts1 = timeseries([1.1; 2.9; 3.7; 4.0; 3.0],1:5,'Name','speed');
```

View the time, data, and interpolation method.

```
ts1.time  
ts1.data  
ts1.getinterpmethod
```

Resample `ts1` using its default interpolation method.

```
res_ts=resample(ts1,[1 1.5 3.5 4.5 4.9]);
```

View the time, data, and interpolation method for the resampled object.

```
res_ts.time  
res_ts.data  
res_ts.getinterpmethod
```

<b>Purpose</b>	Set properties of <code>timeseries</code> object
<b>Syntax</b>	<pre>set(ts, PropertyName, Value) set(ts, PropertyName) set(ts)</pre>
<b>Description</b>	<p><code>set(ts, PropertyName, Value)</code> sets the named property, <code>Name</code>, of the <code>timeseries</code> object, <code>ts</code>, to the value, <code>Value</code>. The following syntax is equivalent:</p> <pre>ts.Property = Value</pre> <p><code>set(ts, PropertyName)</code> displays the value of the named property for the <code>timeseries</code> object, <code>ts</code>.</p> <p><code>set(ts)</code> displays all properties and values of the <code>timeseries</code> object <code>ts</code>.</p>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>A <code>timeseries</code> object.</p> <p><b>PropertyName</b></p> <p>A string specifying the name of a <code>timeseries</code> property. For a list of <code>timeseries</code> properties, see <code>timeseries</code>.</p> <p><b>Value</b></p> <p>The value to which you want to set the named property.</p>
<b>Examples</b>	<p>Create a <code>timeseries</code>, set its name to <code>mytimeseries</code>, and then view the <code>timeseries</code> properties:</p> <pre>ts1 = timeseries(rand(5,1),[1 2 3 4 5]); set(ts1, 'Name', 'mytimeseries') set(ts1)</pre>
<b>See Also</b>	<code>timeseries</code>   <code>get</code>

# timeseries.setabstime

---

**Purpose** Set times of timeseries object as date strings

**Syntax** `ts1=setabstime(ts, times)`  
`ts1=setabstime(ts, times, format)`

**Description** `ts1=setabstime(ts, times)` sets the times in `ts` to the date strings specified in `times`.

`ts1=setabstime(ts, times, format)` explicitly specifies the date-string format, `format`, used in `times`.

## Input Arguments

**ts**  
The timeseries object for which you want to set times as date strings.

**times**  
A cell array of strings or a char array containing valid date or time values in the same date format.

**format**  
The date-string format used for the time values.

## Output Arguments

**ts1**  
The timeseries object that results from setting times as date strings on the original timeseries object.

## Examples

Create a timeseries object, and then set the absolute time vector:

```
ts = timeseries(rand(3,1))
ts1 = setabstime(ts,{'12-DEC-2005 12:34:56',...
    '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
```

`% View each timeseries object in the Variable Editor to see the`  
`% differences in the time vectors for each.`

## See Also

`datestr` | `getabstime` | `timeseries`

## Purpose

Set default interpolation method for timeseries object

## Syntax

```
ts = setinterpmethod(ts, method)
ts = setinterpmethod(ts, fhandle)
ts = setinterpmethod(ts, interpobj)
```

## Description

`ts = setinterpmethod(ts, method)` sets the default interpolation method, `method`, for timeseries object, `ts`, and outputs it to `ts1`.

`ts = setinterpmethod(ts, fhandle)` sets the default interpolation method for timeseries object `ts`, where `fhandle` is a function handle to the interpolation method.

`ts = setinterpmethod(ts, interpobj)` sets the default interpolation method for timeseries object `ts`, where `interpobj` is a `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

## Tips

- This method is case sensitive.

## Input Arguments

### **ts**

The timeseries object for which you want to set the default interpolation method.

### **method**

A string specifying the interpolation method. Valid values are `linear` and `zero-order hold, zoh`.

**Default:** `linear`

### **fhandle**

A function handle to the interpolation method. The order of input arguments defining the function handle must be `new_time`, `time`, and `data`. The single output argument must be the interpolated data only.

### **interpobj**

# timeseries.setinterpmethod

---

A `tsdata.interpolation` object a `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

## Output Arguments

**ts1**

The `timeseries` object that results when you set the interpolation method for the original `timeseries` object.

## Examples

Set the default interpolation method for `timeseries` object `ts` to zero order hold:

```
ts = timeseries(rand(100,1),1:100);  
ts = setinterpmethod(ts,'zoh');  
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts`, where `fhandle` is a function handle to the interpolation method defined by function handle `myFuncHandle`:

```
ts = timeseries(rand(100,1),1:100);  
myFuncHandle = @(new_time, time, data)...  
    interp1(time, data, new_time,...  
            'linear','extrap');  
ts = setinterpmethod(ts, myFuncHandle);  
ts = resample(ts, [-5:0.1:10]);  
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts` to a `tsdata.interpolation` object:

```
ts = timeseries(rand(100,1),1:100);  
myFuncHandle = @(new_time, time, data)...  
    interp1(time, data, new_time,...  
            'linear','extrap');  
myInterpObj = tsdata.interpolation(myFuncHandle);  
ts = setinterpmethod(ts,myInterpObj);  
plot(ts);
```

**See Also** [timeseries](#) | [getinterpmethod](#)

# timeseries.setuniformtime

---

**Purpose** Modify uniform time vector of timeseries object

**Syntax**

```
ts2 = setuniformtime(ts1,'StartTime',StartTime)
ts2 = setuniformtime(ts1,'Interval',Interval)
ts2 = setuniformtime(ts1,'EndTime',EndTime)
ts2 = setuniformtime(ts1,'StartTime',StartTime,'Interval',
    Interval)
ts2 = setuniformtime(ts1,'StartTime',StartTime,'EndTime',
    EndTime)
ts2 = setuniformtime(ts1,'Interval',Interval,'EndTime',
    EndTime)
```

**Description**

`ts2 = setuniformtime(ts1,'StartTime',StartTime)` returns the time series with a modified uniform time vector, determined from the `StartTime` and `Interval`. `EndTime = StartTime + (length(ts1) - 1)`. The unit of time is unchanged.

`ts2 = setuniformtime(ts1,'Interval',Interval)` sets the `StartTime` to 0, and uses `EndTime = (length(ts1) - 1)*Interval`.

`ts2 = setuniformtime(ts1,'EndTime',EndTime)` sets the `StartTime` to 0, and uses `Interval = EndTime/(length(ts1) - 1)`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'Interval',Interval)` uses `EndTime = StartTime + (length(ts1) - 1) * Interval`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'EndTime',EndTime)` uses `Interval = (EndTime - StartTime)/(length(ts1) - 1)`.

`ts2 = setuniformtime(ts1,'Interval',Interval,'EndTime',EndTime)` uses `StartTime = EndTime - (length(ts1) - 1) * Interval`.

**Input Arguments**

**ts1** timeseries object to which you want to assign a uniform time vector.

## StartTime

Start time of uniform time vector, specified as a numeric value.

## Interval

Time interval of uniform time vector, specified as a numeric scalar value.

## EndTime

End time of uniform time vector specified as a numeric scalar value.

## Output Arguments

### ts2

Time series with uniform time vector, returned as a `timeseries` object.

## Examples

### Specify New Start Time

Modify the uniform time vector of time series data by specifying a new start time.

- 1 Load the sample data.

```
load count.dat;
```

- 2 Create a `timeseries` object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond')
```

- 3 Modify uniform time vector of `count_ts`.

```
count_ts = setuniformtime(count_ts,'StartTime',10);
```

The start time of the time vector is 10 seconds. `setuniformtime` uses a default time interval of 1 and computes the end time using:  $EndTime = StartTime + (length(count\_ts) - 1) * Interval$ .

# timeseries.setuniformtime

---

## Specify New Start and End Times

Modify the uniform time vector of time series data by specifying a new start time and end time.

- 1 Load sample data.

```
load count.dat;
```

- 2 Create timeseries object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
```

- 3 Assign a uniform time vector to count\_ts.

```
count_ts2 = setuniformtime(count_ts,'StartTime',10,'EndTime',20);
```

The start time of the time vector is now 10 seconds, and the end time is now 20 seconds. MATLAB computes the time interval using:

$$\text{Interval} = (\text{EndTime} - \text{StartTime}) / (\text{length}(\text{count\_ts}) - 1)$$

## See Also

[timeseries](#)

## Purpose

Synchronize and resample two `timeseries` objects using common time vector

## Syntax

```
[ts1 ts2] = synchronize(ts1,ts2, synchronizemethod)
[ts1 ts2] = synchronize(ts1,ts2, Name,Value)
```

## Description

`[ts1 ts2] = synchronize(ts1,ts2, synchronizemethod)` creates two new `timeseries` objects by synchronizing `ts1` and `ts2` using a common time vector and the specified method.

`[ts1 ts2] = synchronize(ts1,ts2, Name,Value)` creates the two new `timeseries` objects with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ts1**

One of the `timeseries` objects that you want to synchronize and resample.

### **ts2**

The other `timeseries` object that you want to synchronize and resample.

### **synchronizemethod**

A string that defines the method for synchronizing the `timeseries` object. It can be any one of the following:

- **Union** — Resample `timeseries` objects using a time vector that is a union of the time vectors of `ts1` and `ts2` on the time range where the two time vectors overlap.
- **Intersection** — Resample `timeseries` objects on a time vector that is the intersection of the time vectors of `ts1` and `ts2`.
- **Uniform** — Requires an additional argument as follows:

```
[ts1 ts2] = synchronize(ts1,ts2,'Uniform','Interval',value)
```

# timeseries.synchronize

---

This method resamples time series on a uniform time vector, where `value` specifies the time interval between two consecutive samples. The uniform time vector is the overlap of the time vectors of `ts1` and `ts2`. The interval units are the smaller units of `ts1` and `ts2`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'InterpMethod'**

Forces the specified interpolation method (over the default method) for this synchronize operation. Can be either a string, `linear` or `zoh`, or a `tsdata.interpolation` object that contains a user-defined interpolation method.

**Default:** `linear`

## **'QualityCode'**

Integer (between -128 and 127) used as the quality code for both time series after the synchronization.

## **'KeepOriginalTimes'**

Logical value (`true` or `false`) indicating whether the new time series should keep the original time values.

## **'tolerance'**

Real number used as the tolerance for differentiating two time values when comparing the `ts1` and `ts2` time vectors. The default tolerance is  $1e-10$ . For example, when the sixth time value in `ts1` is  $5+(1e-12)$  and the sixth time value in `ts2` is  $5-(1e-13)$ , both values are treated as 5 by default. To differentiate those

two times, you can set 'tolerance' to a smaller value such as 1e-15, for example.

## Output Arguments

**ts1**

One of the `timeseries` objects that you synchronized and resampled.

**ts2**

The other `timeseries` object that you synchronized and resampled.

## Examples

This example illustrates how the `KeepOriginalTime` property affects synchronization.

```
% Create two timeseries, such that ts1.timeinfo.StartDate  
% is one day after ts2.timeinfo.StartDate:
```

```
ts1 = timeseries([1 2],[datestr(now); datestr(now+1)]);  
ts2 = timeseries([1 2],[datestr(now-1); datestr(now)]);
```

```
% If you use this code, then ts1.timeinfo.StartDate  
% is changed to match ts2.TimeInfo.StartDate  
% and ts1.Time changes to 1:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union');
```

```
% But if you use this code, then ts1.timeinfo.StartDate  
% is unchanged and ts1.Time is still 0:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union','KeepOriginalTimes',true);
```

## See Also

[set](#) | [timeseries](#)

# timeseries.transpose

---

**Purpose** Transpose timeseries object

**Syntax** `ts1 = transpose(ts)`

**Description** `ts1 = transpose(ts)` returns a new timeseries object, `ts1`, with `IsTimeFirst` value set to the opposite of what it is for `ts`. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector.

- Tips**
- The transpose function that is overloaded for timeseries objects does not transpose the data. Instead, this function changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, transpose the `Data` property of the time series. For example, you can use the syntax `transpose(ts.Data)` or `(ts.Data)'`. The value of the `Data` property must be a 2-D array.
  - Consider a time series with 10 samples with the property `IsTimeFirst = True`. When you transpose this time series, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

The following table summarizes how the size for timeseries data (up to three dimensions) display before and after transposing.

### Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

### Input Arguments

**ts**  
The timeseries object that you want to transpose.

## Output Arguments

**ts1**

The `timeseries` object that is the result of transposing the original `timeseries` object.

## Examples

Suppose that a `timeseries` object, `ts`, has `ts.Data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is `true`, which means that the first dimension of the data aligns with the time vector. `transpose(ts)` modifies the `timeseries` object, such that the last dimension of the data now aligns with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

## See Also

`timeseries` | `transpose`

# timeseries.std

---

**Purpose** Standard deviation of timeseries data

**Syntax**  
`ts_std = std(ts)`  
`ts_std = std(ts,Name,Value)`

**Description** `ts_std = std(ts)` returns the standard deviation of the timeseries data.

`ts_std = std(ts,Name,Value)` specifies additional options specified with one or more `Name,Value` pair arguments.

## Input Arguments

**ts**  
The timeseries object for which you want the standard deviation of the data.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### 'MissingData'

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

#### 'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

#### 'Weighting'

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_std`

The standard deviation of `ts.Data` values as follows:

- When `ts.Data` is a vector, `ts_std` is the standard deviation of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_std` is the standard deviation of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `std` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the standard deviation for a `timeseries` object. MATLAB calculates the standard deviation for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the standard deviation of each data column for this  
% timeseries object:
```

```
std(count_ts)
```

```
MATLAB returns:
```

```
25.3703    41.4057    68.0281
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

<b>Purpose</b>	Sum of timeseries data
<b>Syntax</b>	<pre>ts_sm = sum(ts) ts_sm = sum(ts,Name,Value)</pre>
<b>Description</b>	<p><code>ts_sm = sum(ts)</code> returns the sum of the timeseries data.</p> <p><code>ts_sm = sum(ts,Name,Value)</code> specifies additional options with one or more Name,Value pair arguments.</p>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The timeseries object for which you want the sum of the data.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.</p> <p><b>'MissingData'</b></p> <p>A string specifying one of two possible values, <code>remove</code> or <code>interpolate</code>, indicating how to treat missing data during the calculation.</p> <p><b>Default:</b> <code>remove</code></p> <p><b>'Quality'</b></p> <p>A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).</p> <p><b>'Weighting'</b></p>

# timeseries.sum

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

**ts\_sm**

The sum of the `timeseries` data, as follows:

- When `ts.Data` is a vector, `ts_sm` is the sum of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_sm` is a row vector containing the sum of each column of `ts.Data`.

When `ts.Data` is a N-dimensional array, `sum` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Calculate the sum of each data column for a `timeseries` object:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the sum of each data column for this timeseries object:
```

```
sum(count_ts)
```

```
MATLAB returns:
```

```
768      1117      1574
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

# timeseries.var

---

**Purpose** Variance of timeseries data

**Syntax**  
`ts_var = var(ts)`  
`ts_var = var(ts,Name,Value)`

**Description** `ts_var = var(ts)` returns the variance of `ts.data`.  
`ts_var = var(ts,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments** **ts**  
The timeseries object for which you want the variance of the data.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

### **'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

### **'Weighting'**

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_var`

The variance of `ts.data`, as follows:

- When `ts.Data` is a vector, then `ts_var` is the variance of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with `time`, then `ts_var` is a row vector containing the variance of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `var` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example calculates the variance values of a multivariate `timeseries` object. MATLAB calculates the variance independently for each data column in the `timeseries` object.

Load a 24-by-3 data array. Then create a `timeseries` object with 24 time values.

```
load count.dat
count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond');
```

Calculate the variance of each data column.

```
var(count_ts)
```

MATLAB returns:

```
1.0e+03 *
    0.6437    1.7144    4.6278
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

## Purpose

Triangulation in 2-D or 3-D

## Description

Use triangulation to create an in-memory representation of any 2-D or 3-D triangulation data that is in matrix format, such as the matrix output from the `delaunay` function or other software tools. When your data is represented using `triangulation`, you can perform topological and geometric queries, which you can use to develop geometric algorithms. For example, you can find the triangles or tetrahedra attached to a vertex, those that share an edge, their circumcenters, and other features.

## Construction

`TR = triangulation(T,P)` creates a 2-D or 3-D triangulation representation using the triangulation connectivity list, `T`, and the points in matrix `P`.

`TR = triangulation(T,x,y)` creates a 2-D triangulation representation with the point coordinates specified as column vectors, `x` and `y`.

`TR = triangulation(T,x,y,z)` creates a 3-D triangulation representation with the point coordinates specified as column vectors, `x`, `y`, and `z`.

## Input Arguments

### T

Triangulation connectivity list, specified as an  $m$ -by- $n$  matrix, where  $m$  is the number of triangles or tetrahedra, and  $n$  is the number of vertices per triangle or tetrahedron. Each element in `T` is a “Vertex ID” on page 1-5191. Each row of `T` contains the vertex IDs that define a triangle or tetrahedron.

### P

Points, specified as a matrix whose columns are the `x`, `y`, (and possibly `z`) coordinates of the triangulation points. The row numbers of `P` are the vertex IDs in the triangulation.

### x

# triangulation

---

$x$ -coordinates vector, specified as a column vector containing the  $x$ -coordinates of the triangulation points.

## **y**

$y$ -coordinates vector, specified as a column vector containing the  $y$ -coordinates of the triangulation points.

## **z**

$z$ -coordinates vector, specified as a column vector containing the  $z$ -coordinates of the triangulation points.

## **Properties**

### **Points**

Points in the triangulation, represented as a matrix containing the following information:

- Each row in `TR.Points` contains the coordinates of a vertex.
- Each row number of `TR.Points` is a vertex ID.

### **ConnectivityList**

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each element in `TR.ConnectivityList` is a vertex ID.
- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `TR.ConnectivityList` is a “Triangle or Tetrahedron ID” on page 1-5191.

## **Methods**

<code>barycentricToCartesian</code>	Converts point coordinates from barycentric to Cartesian
<code>cartesianToBarycentric</code>	Converts point coordinates from Cartesian to barycentric

circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
neighbors	Neighbors to specified triangle or tetrahedron
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

# triangulation

---

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### 2-D Triangulation

Define the points in the triangulation.

```
P = [ 2.5    8.0  
      6.5    8.0  
      2.5    5.0  
      6.5    5.0  
      1.0    6.5  
      8.0    6.5];
```

Define the triangles. This is the triangulation connectivity list.

```
T = [5  3  1;  
     3  2  1;  
     3  4  2;  
     4  6  2];
```

Create the triangulation representation.

```
TR = triangulation(T,P)
```

```
TR =
```

```
    triangulation with properties:
```

```
          Points: [6x2 double]  
    ConnectivityList: [4x3 double]
```

Examine the coordinates of the vertices of the first triangle.

```
TR.Points(TR.ConnectivityList(1,:),:)
```

```
ans =
```

```
    1.0000    6.5000
```

```
2.5000 5.0000  
2.5000 8.0000
```

**See Also** `delaunayTriangulation` |

# triangulation.barycentricToCartesian

---

<b>Purpose</b>	Converts point coordinates from barycentric to Cartesian
<b>Syntax</b>	<code>PC = barycentricToCartesian(TR,ti,B)</code>
<b>Description</b>	<code>PC = barycentricToCartesian(TR,ti,B)</code> returns the Cartesian coordinates of the points in <code>B</code> . Each row, <code>B(j,:)</code> , contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, <code>ti(j)</code> . The point, <code>PC(j,:)</code> , is the <code>j</code> th point represented in Cartesian coordinates.
<b>Input Arguments</b>	<b>TR</b> Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code> . <b>ti</b> Triangle or tetrahedron IDs, specified as a column vector. <b>B</b> Barycentric coordinates, specified as a matrix. Each row, <code>B(j,:)</code> , contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, <code>ti(j)</code> .
<b>Output Arguments</b>	<b>PC</b> Cartesian coordinates, returned as a matrix. The point, <code>PC(j,:)</code> , is the <code>j</code> th point represented in Cartesian coordinates.
<b>Definitions</b>	<b>Triangle or Tetrahedron ID</b> A row number of the matrix, <code>TR.ConnectivityList</code> . Use this ID to refer a specific triangle or tetrahedron.
<b>Examples</b>	<b>Barycentric Coordinates Converted to Cartesian Coordinates</b> Create a triangulation from a set of points, <code>P</code> , and triangulation connectivity list, <code>T</code> .

```
P = [ 2.5    8.0  
      6.5    8.0  
      2.5    5.0  
      6.5    5.0  
      1.0    6.5  
      8.0    6.5];
```

```
T = [5  3  1;  
     3  2  1;  
     3  4  2;  
     4  6  2];
```

```
TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Specify the barycentric coordinates of the second point in the triangle.

```
B = [0 1 0];
```

Convert the point to Cartesian coordinates.

```
PC = barycentricToCartesian(TR,ti,B)
```

```
PC =
```

```
    2.5000    5.0000
```

## Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';  
y = [0 0 0 0 8 8 8 8]';  
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

# triangulation.barycentricToCartesian

---

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
axis equal;
```

Create a new triangulation which is a deformed version of DT .

```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

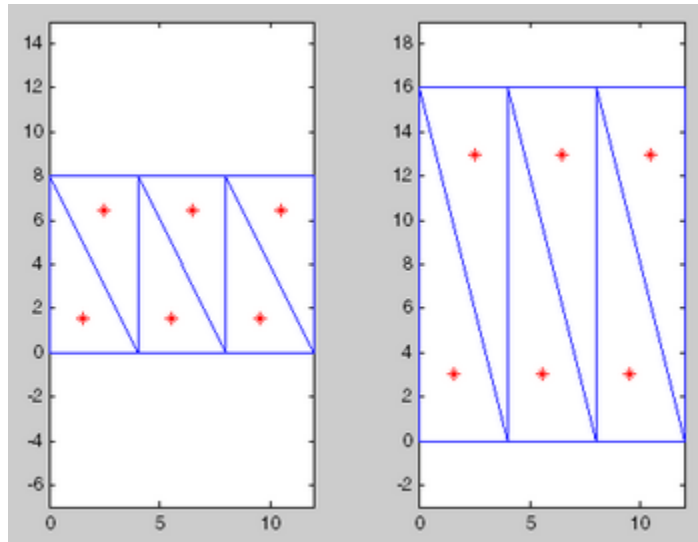

Compute the barycentric coordinates for the incenters of DT, and use them to compute the Cartesian coordinates of the analogous points in TR.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```

# triangulation.barycentricToCartesian

# triangulation.cartesianToBarycentric

---

<b>Purpose</b>	Converts point coordinates from Cartesian to barycentric
<b>Syntax</b>	<code>B = cartesianToBarycentric(TR,ti,PC)</code>
<b>Description</b>	<code>B = cartesianToBarycentric(TR,ti,PC)</code> returns the barycentric coordinates of the points in <code>PC</code> . Each row, <code>PC(j,:)</code> , contains the Cartesian coordinates of a point you want to convert. <code>B(j,:)</code> are the barycentric coordinates of the point, <code>PC(j,:)</code> , with respect to triangle or tetrahedron, <code>ti(j)</code> .
<b>Input Arguments</b>	<b>TR</b> Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code> . <b>ti</b> Triangle or tetrahedron IDs, specified as a column vector. <b>PC</b> Cartesian coordinates, specified as a matrix. Each row, <code>PC(j,:)</code> , contains the Cartesian coordinates of a point with respect to triangle or tetrahedron, <code>ti(j)</code> .
<b>Output Arguments</b>	<b>B</b> Barycentric coordinates, returned as a matrix. <code>B(j,:)</code> are the barycentric coordinates of <code>PC(j,:)</code> with respect to <code>ti(j)</code> .
<b>Definitions</b>	<b>Triangle or Tetrahedron ID</b> A row number of the matrix, <code>TR.ConnectivityList</code> . Use this ID to refer a specific triangle or tetrahedron.
<b>Examples</b>	<b>Cartesian Coordinates Coverted to Barycentric Coordinates</b> Create a triangulation from a set of points, <code>P</code> , and triangulation connectivity list, <code>T</code> .

```
P = [ 2.5    8.0  
      6.5    8.0  
      2.5    5.0  
      6.5    5.0  
      1.0    6.5  
      8.0    6.5];
```

```
T = [5  3  1;  
     3  2  1;  
     3  4  2;  
     4  6  2];
```

```
TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Get the coordinates of the third vertex in the first triangle.

```
PC = TR.Points(TR.ConnectivityList(1,3),:)
```

```
PC =
```

```
    2.5000    8.0000
```

Convert the point to barycentric coordinates.

```
B = cartesianToBarycentric(TR,ti,PC)
```

```
B =
```

```
    0    0    1
```

## Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';
```

# triangulation.cartesianToBarycentric

---

```
y = [0 0 0 0 8 8 8 8]';  
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure  
subplot(1,2,1);  
triplot(DT);  
hold on;  
plot(cc(:,1),cc(:,2),'*r');  
hold off;  
axis equal;
```

Create a new triangulation which is a deformed version of DT .

```
ti = DT.ConnectivityList;  
y = [0 0 0 0 16 16 16 16]';  
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of DT, and use them to compute the Cartesian coordinates of the analogous points in TR.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);  
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);  
triplot(TR);  
hold on;  
plot(xc(:,1),xc(:,2),'*r');  
hold off;  
axis equal;
```

**See Also** [barycentricToCartesian](#) | [delaunayTriangulation](#) |

# triangulation.circumcenter

---

**Purpose** Circumcenter of triangle or tetrahedron

**Syntax**  
`CC = circumcenter(TR,ti)`  
`[CC,r] = circumcenter(TR,ti)`  
`CC = circumcenter(TR)`  
`[CC,r] = circumcenter(TR)`

**Description** `CC = circumcenter(TR,ti)` returns the coordinates of the circumcenter of each triangle or tetrahedron specified in `ti`.  
`[CC,r] = circumcenter(TR,ti)` also returns the corresponding radii of the circumscribed circles or spheres.  
`CC = circumcenter(TR)` returns the circumcenters of all triangles or tetrahedra in the triangulation.  
`[CC,r] = circumcenter(TR)` also returns the corresponding radii of the circumscribed circles or spheres for the entire triangulation.

## Input Arguments

**TR**  
Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**  
Triangle or tetrahedron IDs, specified as a column vector.

## Output Arguments

**CC**  
Circumcenters, returned as a matrix. Each row, `CC(j,:)`, contains the coordinates of the circumcenter of `ti(j)`.

**r**  
Radii of the circumscribed circles or spheres, returned as a vector. The radius at `r(j)` corresponds to the circle or sphere circumscribing `ti(j)`.

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Circumcenters in 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Compute the circumcenters.

```
CC = circumcenter(TR);
triplot(TR)
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(CC(:,1),CC(:,2), '*r');
hold off;
```

# triangulation.circumcenter

The circumcenters represent points on the medial axis of the polygon.

## Circumcenters in 3-D Delaunay Triangulation

Create the Delaunay triangulation using a random set of points, P.

```
P = gallery('uniformdata',10,3,0);  
DT = delaunayTriangulation(P);
```

Calculate the circumcenters of the first five tetrahedra in DT.

```
CC = circumcenter(DT,[1:5]')
```

```
CC =
```

```
0.9626    0.3892    0.0928  
6.3458    0.2377    3.1814  
0.4820    0.9064    0.5176
```

```
-1.2993    1.8384   -1.2185  
-0.1595    1.0852   -0.2536
```

## See Also

[incenter](#) | [deLaunayTriangulation](#) |

# triangulation.edgeAttachments

---

**Purpose** Triangles or tetrahedra attached to specified edge

**Syntax** `ti = edgeAttachments(TR,vstart,vend)`  
`ti = edgeAttachments(TR,E)`

**Description** `ti = edgeAttachments(TR,vstart,vend)` returns the triangles or tetrahedra attached to the specified edges. To specify the edges, use the vectors, `vstart` and `vend`. These vectors contain the “Vertex ID” on page 1-5207 at the start and end of each edge.

`ti = edgeAttachments(TR,E)` specifies the starting and ending vertices of each edge in a 2-column matrix, `E`.

## Input Arguments

**TR**  
Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**vstart**  
IDs of starting vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the start of an edge.

**vend**  
IDs of ending vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the end of an edge.

**E**  
IDs of the edge vertices, specified as a 2-column matrix of vertex IDs. Each row of `E` corresponds to an edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of an edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

## Output Arguments

**ti**  
IDs of the triangles or tetrahedra attached to the edges, returned as an `m-by-1` cell array. Each cell in `ti` contains the IDs of the

attached triangles or tetrahedra. The attachments to the edge located between the vertices, `vstart(j)` and `vend(j)`, or `E(j, :)`, are returned in `ti{j}`. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each edge can vary.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Edge Attachments in 3-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load tetmesh
TR = triangulation(tet,X);
```

Define the starting and ending vertices of the edges.

```
vstart = [15; 21];
vend = [936; 716];
```

Find the edge attachments.

```
ti = edgeAttachments(TR,vstart,vend);
```

Examine the attachments to the first edge.

```
ti{1}
```

```
ans =
```

```
    927    2060    3438    3423    2583    4690
```

# triangulation.edgeAttachments

---

## Edge Attachments in 2-D Delaunay Triangulation

Create a Delaunay triangulation.

```
x = [0 1 1 0 0.5]';  
y = [0 0 1 1 0.5]';  
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to edge (1,5).

```
ti = edgeAttachments(DT,1,5);  
ti{:}
```

```
ans =
```

```
4      1
```

# triangulation.faceNormal

---

<b>Purpose</b>	Triangulation face normal
<b>Syntax</b>	<code>FN = faceNormal(TR,ti)</code> <code>FN = faceNormal(TR)</code>
<b>Description</b>	<code>FN = faceNormal(TR,ti)</code> returns the unit normal vector to each triangle specified by <code>ti</code> . The <code>faceNormal</code> function supports only 2-D triangulations. <code>FN = faceNormal(TR)</code> returns the unit normal vectors to all triangles.
<b>Input Arguments</b>	<b>TR</b> Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code> . <b>ti</b> Triangle IDs, specified as a column vector.
<b>Output Arguments</b>	<b>FN</b> Face normals, returned as a matrix. Each row, <code>FN(j,:)</code> , is the unit normal vector to triangle <code>ti(j)</code> . If you do not specify <code>ti</code> , then <code>faceNormal</code> returns the unit normal information for the entire triangulation. In this case, the normal associated with <code>TR.ConnectivityList(j,:)</code> is <code>FN(j,:)</code> .
<b>Definitions</b>	<b>Triangle ID</b> A row number of the matrix, <code>TR.ConnectivityList</code> . You use this ID to refer a specific triangle.
<b>Examples</b>	<b>Plot Unit Normals to Facets on a Spherical Surface</b> Create a set of random points on a spherical surface. <pre>theta = gallery('uniformdata',[100,1],0)*2*pi; phi = gallery('uniformdata',[100,1],1)*pi;</pre>

```
x = cos(theta).*sin(phi);  
y = sin(theta).*sin(phi);  
z = cos(phi);
```

Triangulate the points with `delaunayTriangulation`.

```
DT = delaunayTriangulation(x,y,z);
```

Find the free boundary facets and use them to create a triangulation representation for plotting.

```
[T,Xb] = freeBoundary(DT);  
TR = triangulation(T,Xb);
```

Plot the triangulation.

```
figure  
trisurf(T,Xb(:,1),Xb(:,2),Xb(:,3), ...  
        'FaceColor', 'cyan', 'faceAlpha', 0.8);  
axis equal;  
hold on;
```

Calculate the incenters and face normals.

```
P = incenter(TR);  
fn = faceNormal(TR);
```

Display the normal vectors on the surface.

```
quiver3(P(:,1),P(:,2),P(:,3), ...  
        fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');  
hold off;
```

# triangulation.faceNormal

---

**See Also**      `freeBoundary` | `deLaunayTriangulation` |

<b>Purpose</b>	Triangulation sharp edges
<b>Syntax</b>	<code>FE = featureEdges(TR,filterangle)</code>
<b>Description</b>	<p><code>FE = featureEdges(TR,filterangle)</code> returns the feature edges in a 2-D triangulation.</p> <p>Use this method to extract the sharp edges in the surface mesh for display purposes. A feature edge is an edge that has any of the following attributes:</p> <ul style="list-style-type: none"><li>• The edge is shared by only one triangle.</li><li>• The edge is shared by more than two triangles.</li><li>• The edge is shared by a pair of triangles with angular deviation greater than the <code>filterangle</code>.</li></ul>
<b>Input Arguments</b>	<p><b>TR</b></p> <p>Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code>.</p> <p><b>filterangle</b></p> <p>Filter angle, specified as a scalar value in the range <math>[0,\pi]</math>. <code>featureEdges</code> returns adjacent triangles that have a dihedral angle that deviates from <math>\pi</math> by an angle greater than <code>filterangle</code>.</p>
<b>Output Arguments</b>	<p><b>FE</b></p> <p>Feature edge vertex IDs, returned as a two-column matrix. Each row of <code>FE</code> corresponds to a feature edge and contains two IDs:</p> <ul style="list-style-type: none"><li>• <code>FE(j,1)</code> is the ID of the vertex at the start of the edge.</li><li>• <code>FE(j,2)</code> is the ID of the vertex at end of the edge.</li></ul>

# triangulation.featureEdges

---

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Feature Edges Shown on a Surface

Use `featureEdges` to find the feature edges of a surface and display them on a plot.

Create a surface triangulation.

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
DT = delaunayTriangulation(x,y);
T = DT(:,:);
```

Elevate the 2-D mesh to create a surface.

```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(T,x,y,z,'FaceColor','cyan');
axis equal;
```

Compute the feature edges using a filter angle of  $\pi/6$ .

```
TR = triangulation(T,x,y,z);
fe = featureEdges(TR,pi/6)';
subplot(1,2,2);
trisurf(TR,'FaceColor','cyan','EdgeColor',...
'none','FaceAlpha',0.8);
axis equal;
```

Add the feature edges to the plot.

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
```

## See Also

[edges](#) | [delaunayTriangulation](#) |

# triangulation.freeBoundary

---

**Purpose** Triangulation facets referenced by only one triangle or tetrahedron

**Syntax** `FBtri = freeBoundary(TR)`  
`[FBtri,FBpoints] = freeBoundary(TR)`

**Description** `FBtri = freeBoundary(TR)` returns the free boundary facets of `TR.ConnectivityList`. A facet in `TR` is on the free boundary if it is referenced by only one triangle or tetrahedron.

`[FBtri,FBpoints] = freeBoundary(TR)` also returns a matrix containing the vertices of the free boundary facets.

## Input Arguments

**TR**  
Triangulation representation, see `triangulation` or `delaunayTriangulation`.

## Output Arguments

**FBtri**  
Triangulation connectivity list, returned as a matrix that contains the following information:

- Each row in `FBtri` represents a facet on the free boundary.
- Each element is a “Vertex ID” on page 1-5219.

The vertex IDs in `FBtri` reference a specific matrix, depending on the syntax you choose:

- If you call `freeBoundary` with one output argument, then the elements of `FBtri` are row numbers of `TR.Points`.
- If you call `freeBoundary` with two output arguments, then the elements of `FBtri` are row numbers of `FBpoints`.

## FBpoints

Free boundary points, returned as a matrix containing the coordinates of the vertices of the free boundary facets. Each row of `FBpoints` contains coordinates of a vertex.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points` or `FBpoints`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Surface of 3-D Triangulation

Use `freeBoundary` to extract the facets of a 3-D triangulation that cover the surface of an object.

Load a 3-D triangulation.

```
load tetmesh;  
TR = triangulation(tet,X);
```

Compute the boundary triangulation.

```
[FBtri,FBpoints] = freeBoundary(TR);
```

Plot the boundary triangulation.

```
trisurf(FBtri,FBpoints(:,1),FBpoints(:,2),FBpoints(:,3), ...  
        'FaceColor','cyan','FaceAlpha', 0.8);
```

## Free Boundary of 2-D Delaunay Triangulation

Use `freeBoundary` when you want to highlight the outer edges of a 2-D Delaunay triangulation.

Create a triangulation from a random set of points.

```
x = gallery('uniformdata',[20,1],0);  
y = gallery('uniformdata',[20,1],1);  
DT = delaunayTriangulation(x,y);
```

Find the free boundary edges.

```
fe = freeBoundary(DT)';
```

Plot the mesh and highlight the free boundary edges in red.

```
triplot(DT);  
hold on;
```

```
plot(x(fe),y(fe),'-r','LineWidth',2) ;  
hold off;
```

## See Also

# triangulation.incenter

---

**Purpose** Incenter of triangle or tetrahedron

**Syntax** `IC = incenter(TR,ti)`  
`[IC,r] = incenter(TR,ti)`

**Description** `IC = incenter(TR,ti)` returns the coordinates of the incenter of each triangle or tetrahedron specified by `ti`.  
`[IC,r] = incenter(TR,ti)` also returns the radii of the inscribed circles or spheres.

**Input Arguments** **TR**  
Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**  
Triangle or tetrahedron IDs, specified as a column vector.

**Output Arguments** **IC**  
Incenters, returned as a matrix. Each row of `IC` contains the coordinates of an incenter. For example, `IC(j,:)` is the incenter of `ti(j)`.

**r**  
Radii of the inscribed circles or spheres, returned as a vector. `r(j)` is the radius of the inscribed circle or sphere whose center is `IC(j,:)`.

**Definitions** **Triangle or Tetrahedron ID**  
A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

**Examples** **Find Incenters in 3-D Triangulation**

Load a 3-D triangulation.

```
load tetmesh
```

Calculate the incenters of the first five tetrahedra.

```
TR = triangulation(tet,X);  
IC = incenter(TR,[1:5]')
```

```
IC =
```

```
-6.1083  -31.0234   8.1439  
-2.1439  -31.0283   5.8742  
-1.9555  -31.9463   7.4112  
-4.3019  -30.8460  10.5169  
-3.1596  -29.3642   6.1851
```

## Find Incenters in 2-D Delaunay Triangulation

Create the Delaunay triangulation.

```
x = [0 1 1 0 0.5]';  
y = [0 0 1 1 0.5]';  
DT = delaunayTriangulation(x,y);
```

Calculate incenters of the triangles

```
IC = incenter(DT)
```

```
IC =
```

```
0.2071    0.5000  
0.5000    0.7929  
0.7929    0.5000  
0.5000    0.2071
```

Plot the triangles and incenters.

```
triplot(DT);  
axis equal;
```

# triangulation.incenter

---

```
axis([-0.2 1.2 -0.2 1.2]);  
hold on;  
plot(IC(:,1),IC(:,2),'*r');  
hold off;
```

[circumcenter](#) | [delaunayTriangulation](#) |

**Purpose**

Test if two vertices are connected by edge

**Syntax**

```
tf = isConnected(TR,vstart,vend)
tf = isConnected(TR,E)
```

**Description**

`tf = isConnected(TR,vstart,vend)` returns a logical array of true or false values that indicate whether the specified pairs of vertices are connected by an edge. Element `tf(j)` is true when the vertices, `vstart(j)` and `vend(j)`, are connected by an edge.

`tf = isConnected(TR,E)` specifies the edge start and end indices in matrix `E`. Element `tf(j)` is true when the vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

**Input Arguments****TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**vstart**

IDs of start vertices, specified as a column vector. Each vertex ID refers to a vertex at the start of an edge.

**vend**

IDs of end vertices, specified as a column vector. Each vertex ID refers to a vertex at the end of an edge.

**E**

IDs of the edge vertices, specified as a two-column matrix. Each row of `E` corresponds to a candidate edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of a candidate edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

# triangulation.isConnected

---

## Output Arguments

**tf**

Logical values, returned as a column vector. Element `tf(j)` is true when either of the following are true:

- The vertices, `vstart(j)` and `vend(j)`, are connected by an edge.
- The vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

Otherwise, `tf(j)` is false.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Determine Whether Vertices are connected by an Edge in 2-D

Load a 2-D triangulation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Determine whether vertices 3 and 117 are connected by an edge.

```
isConnected(TR,3,117)
```

```
ans =
```

```
1
```

The vertices are connected by an edge.

Determine whether vertices 3 and 164 are connected by an edge.

```
isConnected(TR,3,164)
```

```
ans =
```

0

The vertices are not connected by an edge.

## Determine Whether Vertices are connected by an Edge in 3-D

```
X = gallery('uniformdata',[10,3],0);  
DT = delaunayTriangulation(X);
```

Determine whether vertices 2 and 7 are connected by an edge.

```
E = [2 7];  
isConnected(DT,E)
```

```
ans =
```

1

The vertices are connected by an edge.

# triangulation.neighbors

---

**Purpose** Neighbors to specified triangle or tetrahedron

**Syntax** `N = neighbors(TR,ti)`  
`N = neighbors(TR)`

**Description** `N = neighbors(TR,ti)` returns the neighbors of the triangles or tetrahedra specified in `ti`.  
`N = neighbors(TR)` returns the neighbors of all the triangles or tetrahedra.

**Input Arguments** **TR**  
Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**  
Triangle or tetrahedron IDs, specified as a column vector.

**Output Arguments** **TN**  
IDs of the neighboring triangles or tetrahedra, returned as a matrix. The elements in `TN(i,:)` are the neighbors associated with `ti(i)`.  
By convention, `TN(i,j)` is the neighbor opposite the `j`th vertex of `ti(i)`. If a triangle or tetrahedron has one or more boundary facets, the nonexistent neighbors are represented as NaN values in `TN`.

**Definitions** **Triangle or Tetrahedron ID**

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

**Vertex ID**

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Query Neighbors in 2-D Delaunay Triangulation

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);  
y = gallery('uniformdata',[10,1],1);  
DT = delaunayTriangulation(x,y);
```

Find the neighbors of the first triangle.

```
TN = neighbors(DT,1)
```

```
TN =
```

```
NaN    4    5
```

The first triangle has a boundary edge and two neighbors.

Examine the vertex IDs of the first neighbor, TN(2).

```
DT.ConnectivityList(TN(2),:)
```

```
ans =
```

```
2    4    7
```

### Query Neighbors in 3-D Triangulation

Create the Delaunay triangulation.

```
load tetmesh  
TR = triangulation(tet,X);
```

Find the neighbors to each triangle in the triangulation.

```
TN = neighbors(TR);
```

Find the neighbors of the fifth tetrahedron.

```
TN(5,:)
```

# triangulation.neighbors

---

```
ans =  
      2360      1539         2      1851
```

Examine the vertex IDs of the first neighbor, `TN(1)`.

```
TR.ConnectivityList(TN(1),:)
```

```
ans =  
      1093      891      893      858
```

## See Also

[edgeAttachments](#) | [delaunayTriangulation](#) |

<b>Purpose</b>	Size of triangulation connectivity list
<b>Syntax</b>	<code>sz = size(TR)</code>
<b>Description</b>	<code>sz = size(TR)</code> returns the size the triangulation connectivity list.
<b>Input Arguments</b>	<b>TR</b> Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code> .
<b>Output Arguments</b>	<b>sz</b> Size of connectivity list, returned as a two-element row vector. The first element, <code>sz(1)</code> is the number of triangles or tetrahedra in the triangulation, and <code>sz(2)</code> is the number of vertices per triangle or tetrahedron.

## Examples **Size of 2-D Triangulation**

Create a triangulation.

```
P = [ 2.5    8.0  
      6.5    8.0  
      2.5    5.0  
      6.5    5.0  
      1.0    6.5  
      8.0    6.5];
```

```
T = [5  3  1;  
     3  2  1;  
     3  4  2;  
     4  6  2];
```

```
TR = triangulation(T,P);
```

Get the size of the connectivity list.

# triangulation.size

---

```
size(TR)
```

```
ans =
```

```
     4     3
```

The triangulation has 4 triangles, and each triangle has 3 vertices.

## See Also

[sizedelaunayTriangulation](#) |

<b>Purpose</b>	Triangles or tetrahedra attached to specified vertex
<b>Syntax</b>	<pre>ti = vertexAttachments(TR,vi) ti = vertexAttachments(TR)</pre>
<b>Description</b>	<p><code>ti = vertexAttachments(TR,vi)</code> returns the triangles or tetrahedra attached to the specified vertices, <code>vi</code>.</p> <p><code>ti = vertexAttachments(TR)</code> returns the triangles or tetrahedra attached to every vertex in the triangulation.</p>
<b>Input Arguments</b>	<p><b>TR</b></p> <p>Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code>.</p> <p><b>vi</b></p> <p>Query vertices, specified as a column vector of vertex IDs.</p>
<b>Output Arguments</b>	<p><b>ti</b></p> <p>IDs of the triangles or tetrahedra attached to the vertices, returned as an <code>m</code>-by-1 cell array. Each cell in <code>ti</code> contains the IDs of the attached triangles or tetrahedra. <code>ti{j}</code> contains the attachments to the vertex, <code>vi(j)</code>. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each vertex can vary.</p>
<b>Definitions</b>	<p><b>Triangle or Tetrahedron ID</b></p> <p>A row number of the matrix, <code>TR.ConnectivityList</code>. Use this ID to refer a specific triangle or tetrahedron.</p> <p><b>Vertex ID</b></p> <p>A row number of the matrix, <code>TR.Points</code>. Use this ID to refer a specific vertex in the triangulation.</p>

# triangulation.vertexAttachments

---

## Examples

### Attachments to Specific Vertex in 2-D Delaunay Triangulation

Locate and plot the attachments to a specific vertex.

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20,1],0);  
y = gallery('uniformdata',[20,1],1);  
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to the fifth vertex.

```
ti = vertexAttachments(DT,5);  
ti{:}
```

```
ans =
```

```
    18    23    21    22
```

Plot the triangulation.

```
triplot(DT);  
hold on;
```

Plot the triangles attached to vertex 5 (in red).

```
triplot(DT(ti{:},:),x,y,'Color','r');  
hold off;
```

**See Also**

[edgeAttachments](#) | [delaunayTriangulation](#) |

# triangulation.vertexNormal

---

**Purpose** Triangulation vertex normal

**Syntax** VN = vertexNormal(TR,vi)  
VN = vertexNormal(TR)

**Description** VN = vertexNormal(TR,vi) returns the unit normal vector to each of the specified vertices in vi.  
VN = vertexNormal(TR) returns the normal information for all vertices in the triangulation.

**Input Arguments** **TR**  
Triangulation representation, see triangulation or delaunayTriangulation.

**vi**  
IDs of vertices to query, specified as a column vector. Each element in vi is a “Vertex ID” on page 1-5236.

**Output Arguments** **VN**  
Vertex normals, returned a matrix. Each row, VN(j,:), is the unit normal vector at the vertex vi(j). The vector at VN(j,:) is the average unit normal of the faces attached to vertex vi(j).  
If you do not specify vi, then vertexNormal returns the unit normal information for all vertices in the triangulation. In this case, the normal associated with TR.Points(j,:) is VN(j,:).

**Definitions** **Vertex ID**  
A row number of the matrix, TR.Points. Use this ID to refer a specific vertex in the triangulation.

**Examples** **Unit Normal Vectors to the Surface of a Cube**

Create a 3-D triangulation representing the volume of a cube.

```
[X,Y,Z] = meshgrid(1:4);  
X = X(:);  
Y = Y(:);  
Z = Z(:);  
dt = delaunayTriangulation(X,Y,Z);
```

Find the surfaces of the cube and isolate them in a 2-D triangulation.

```
[Tfb,Xfb] = freeBoundary(dt);  
TR = triangulation(Tfb,Xfb);
```

Find the unit normal vectors to the triangles on the surface of the cube.

```
vn = vertexNormal(TR);
```

Plot the results.

```
trisurf(TR,'FaceColor',[0.8 0.8 1.0]);  
axis equal  
hold on  
quiver3(Xfb(:,1),Xfb(:,2),Xfb(:,3),...  
        vn(:,1),vn(:,2),vn(:,3),0.5,'color','b');  
hold off
```

# triangulation.vertexNormal

---

**See Also**

`freeBoundary` | `deLaunayTriangulation` |

**Purpose**

Create table from file

**Syntax**

```
T = readtable(filename)
T = readtable(filename,Name,Value)
```

**Description**

`T = readtable(filename)` creates a table by reading column oriented data from a file.

`readtable` determines the file format from the file name's extension:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls` or `.xlsx` for Excel spreadsheet files

`readtable` creates one variable in `T` for each column in the file and reads variable names from the first row of the file. By default, the variables created are `double` if the entire column is numeric, or cell arrays of strings if any element in a column is not numeric.

`T = readtable(filename,Name,Value)` creates a table from a file with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify not to read the first row of the file as variable names.

**Input Arguments****filename - Name of file to read**

string

Name of the file to read, specified as a string. If `filename` includes the file extension, then `readtable` determines the file format from the extension. Otherwise, you must specify the 'FileType' name-value pair arguments to indicate the type of file.

For a delimited text file, `readtable` converts empty fields in the file to either `NaN` (for a numeric variable) or the empty string (for a string-valued variable). All lines in the text file must have the same number of delimiters. `readtable` ignores insignificant white space in the file.

**Example:** `'myFile.xlsx'`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'ReadVariableNames'`, `false` indicates that the first row of the file does not correspond to variable names.

## **'FileType' - Type of file**

`'text'` | `'spreadsheet'`

Type of file, specified as the comma-separated pair consisting of `'FileType'` and the string `'text'` or `'spreadsheet'`.

You must specify the `'FileType'` name-value pair argument if the `filename` input argument does not include the file extension or if the extension is other than one of the following.

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls` or `.xlsx` for spreadsheet files

**Example:** `'FileType', 'text'`

## **'ReadVariableNames' - Indicator for reading first row as variable names**

`true` (default) | `false` | `1` | `0`

Indicator for reading the first row as variable names, specified as the comma-separated pair consisting of `'ReadVariableNames'` and either `true`, `false`, `1`, or `0`.

<code>true</code>	<code>readtable</code> reads the first row of the file as variable names for the table. This is the default behavior.  If both the <code>'ReadVariablesNames'</code> and <code>'ReadRowNames'</code> logical indicators are <code>true</code> , then <code>readtable</code> saves the name in the first column of the first row of the file as the first dimension name in the property, <code>T.Properties.DimensionNames</code> .
<code>false</code>	<code>readtable</code> creates default variable names of the form <code>'Var1', ..., 'VarN'</code> , where <code>N</code> is the number of variables. The first row of the file becomes the first row in the table.

### **'ReadRowNames' - Indicator for reading the first column as row names**

`false` (default) | `true` | 0 | 1

Indicator for reading first column as row names, specified as the comma-separated pair consisting of `'ReadRowNames'` and either `false`, `true`, 0, or 1.

<code>false</code>	<code>readtable</code> does not read the first column of the file as row names. The first column of the file becomes the first variable in the table. This is the default behavior.
<code>true</code>	<code>readtable</code> reads the first column of the file as row names for the table.  If both the <code>'ReadVariablesNames'</code> and <code>'ReadRowNames'</code> logical indicators are <code>true</code> , then <code>readtable</code> saves the name in the first column of the first row of the file as the first dimension name in the property, <code>T.Properties.DimensionNames</code> .

### **'TreatAsEmpty' - Strings to treat as empty value**

string | cell array of strings

# readtable

---

Strings to treat as empty value, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a string or a cell array of strings. Table elements corresponding to these are set to NaN.

'TreatAsEmpty' only applies to numeric columns in the file, and readtable does not accept numeric literals, such as '-99'.

**Example:** 'TreatAsEmpty', 'N/A' sets N/A within numeric columns to NaN.

**Example:** 'TreatAsEmpty', {'.', 'NA', 'N/A'} sets ., NA and N/A within numeric columns to NaN.

## 'Delimiter' - Field delimiter character

string

Field delimiter character, specified as the comma-separated pair consisting of 'Delimiter' and one of the following strings:

' , '	Comma. This is the default behavior.
' comma '	
' ' '	Space
' space '	
' \t '	Tab
' tab '	
' ; '	Semicolon
' semi '	
'   '	Vertical bar
' bar '	

You can use the 'Delimiter' name-value pair only with delimited text files.

**Example:** 'Delimiter', 'space'

**'HeaderLines' - Number of lines to skip at beginning of file**

0 (default) | positive integer

Number of lines to skip at beginning of file, specified as the comma-separated pair consisting of 'HeaderLines' and a positive integer.

You can use the 'HeaderLines' name-value pair only with delimited text files.

**Data Types**

single | double

**'Format' - Format of columns in file**

string of one or more conversion specifiers

Format of the columns in the file, specified as the comma-separated pair consisting of 'Format' and a string of one or more conversion specifiers.

By default, the variables created are either `double`, if the entire column is numeric, or cell arrays of strings, if any element in a column is not numeric.

The conversion specifiers are the same as those accepted by the `textscan` function. If you specify the 'Format' name-value pair argument, you can specify any of the name-value pair arguments accepted by the `textscan` function.

Specifying the format can significantly improve speed for some large files.

You can use the 'Format' name-value pair only with delimited text files.

**'Sheet' - Worksheet to read**

1 (default) | positive integer indicating worksheet index | string containing worksheet name

Worksheet to read, specified as the comma-separated pair consisting of 'Sheet' and a positive integer indicating the worksheet index or a string containing the worksheet name. The worksheet name string

# readtable

---

cannot contain a colon (:). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsfinfo(filename)`.

You can use the 'Sheet' name-value pair only with spreadsheet files.

**Example:** 'Sheet',2

## 'Range' - Rectangular portion of worksheet to read

string

Rectangular portion of the worksheet to read, specified as the comma-separated pair consisting of 'Range' and a string.

Specify the range using the syntax '*Corner1:Corner2*', where *Corner1* and *Corner2* are two opposing corners that define the region to read. For example, 'D2:H4' represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The 'Range' name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help).

If the spreadsheet contains figures or other nontablular information, use the 'Range' name-value pair argument to read only the tabular data. By default, `readtable` reads data from a spreadsheet contiguously out to the right-most column that contains data, including any empty columns that precede it.

You can use the 'Range' name-value pair only with spreadsheet files.

**Example:** 'Range', 'D2:H4'

## Output Arguments

### T - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

**Examples****Create Table from Text File**

Create a file, `myCsvTable.dat`, that contains the following comma-separated column oriented data.

```
LastName,Gender,Age,Height,Weight,Smoker
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file.

```
T = readtable('myCsvTable.dat')
```

```
T =
```

LastName	Gender	Age	Height	Weight	Smoker
'Smith'	'M'	38	71	176	1
'Johnson'	'M'	43	69	163	0
'Williams'	'F'	38	64	131	0
'Jones'	'F'	40	67	133	0
'Brown'	'F'	49	64	119	0

T contains one variable for each column in the file and `readtable` the entries in first line of the file as variable names.

**Create Table from Text File without Column Headings**

Create a file, `mySpaceDelimTable.txt`, that contains the following space delimited, column oriented data.

```
M 45 45 NY true
F 41 32 CA false
M 40 34 MA false
```

# readtable

---

Create a table from the space delimited text file that does not contain variable names as column headings.

```
T = readtable('mySpaceDelimTable.txt',...
    'Delimiter',' ','ReadVariableNames',false)
```

T =

Var1	Var2	Var3	Var4	Var5
'M'	45	45	'NY'	'true'
'F'	41	32	'CA'	'false'
'M'	40	34	'MA'	'false'

T contains default variable names.

## Create and Format Table from Text File

Create a file, myCsvTable.dat, that contains the following comma-separated column oriented data.

```
LastName,Gender,Age,Height,Weight,Smoker
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file. Format the first two variables as strings, the third variable as uint32, and the next two variables as double-precision, floating-point numbers. Format the last variable as a string.

```
T = readtable('myCsvTable.dat','Format','%s%s%u%f%f%s')
```

T =

LastName	Gender	Age	Height	Weight	Smoker
----------	--------	-----	--------	--------	--------

'Smith'	'M'	38	71	176	'1'
'Johnson'	'M'	43	69	163	'0'
'Williams'	'F'	38	64	131	'0'
'Jones'	'F'	40	67	133	'0'
'Brown'	'F'	49	64	119	'0'

The conversion specifiers are %s for a cell array of strings, %f for double, and %u for uint32.

### Create Table from Spreadsheet Including Row Names

Create a table from a spreadsheet that contains variable names in the first row and row names in the first column.

```
T = readtable('patients.xls','ReadRowNames',true);
```

Display the first five rows and first four variables of the table.

```
T(1:5,1:4)
```

```
ans =
```

	Gender	Age	Location	Height
Smith	'Male'	38	'County General Hospital'	71
Johnson	'Male'	43	'VA Hospital'	69
Williams	'Female'	38	'St. Mary's Medical Center'	64
Jones	'Female'	40	'VA Hospital'	67
Brown	'Female'	49	'County General Hospital'	64

View the DimensionNames property of the table.

```
T.Properties.DimensionNames
```

```
ans =
```

# readtable

---

```
'LastName' 'Variable'
```

'LastName' is the name in the first column of the first row of the spreadsheet.

## Read Specific Range of Data from Spreadsheet

Create a table from the 5-by-3 rectangular region between the two corners C2 and E6 on the spreadsheet `patients.xls`. Do not use the first row of this region as variable names.

```
T = readtable('patients.xls',...  
            'Range','C2:E6',...  
            'ReadVariableNames',false)
```

T =

Var1	Var2	Var3
38	'County General Hospital'	71
43	'VA Hospital'	69
38	'St. Mary's Medical Center'	64
40	'VA Hospital'	67
49	'County General Hospital'	64

T contains default variable names.

    1.6094    2.3979    2.3026    2.0794
    2.1972    1.9459    1.7918    2.4849
    1.3863    2.6391    2.7081         0
```

**See Also** `log` | `realpow` | `realsqrt`

**Purpose** Largest positive floating-point number

**Syntax** `n = realmax`

**Description** `n = realmax` returns the largest finite floating-point number in IEEE double precision.

`realmax('double')` is the same as `realmax` with no arguments.

`realmax('single')` returns the largest finite floating-point number in IEEE single precision.

**Examples** Find the value of the constant `realmax`:

```
ndouble = realmax
nsingle = realmax('single')
```

```
ndouble =
```

```
1.7977e+308
```

```
nsingle =
```

```
3.4028e+38
```

**See Also** `eps` | `realmin` | `intmax`

**Tutorials** • “Floating-Point Numbers”

# realmin

---

**Purpose** Smallest positive normalized floating-point number

**Syntax**

```
n = realmin
realmin('double')
realmin('single')
```

**Description** `n = realmin` returns the smallest positive normalized floating-point number in IEEE double precision.

`realmin('double')` is the same as `realmin` with no arguments.

`realmin('single')` returns the smallest positive normalized floating-point number in IEEE single precision.

**Examples** Find the value of the constant `realmin`:

```
ndouble = realmin
nsingle = realmin('single')
```

```
ndouble =
    2.2251e-308
```

```
nsingle =
    1.1755e-38
```

**See Also** `eps` | `realmax` | `intmin`

**Tutorials**

- “Floating-Point Numbers”

**Purpose** Array power for real-only output

**Syntax** `Z = realpow(X,Y)`

**Description** `Z = realpow(X,Y)` raises each element of array `X` to the power of its corresponding element in array `Y`. Arrays `X` and `Y` must be the same size. The range of `realpow` is the set of all real numbers, i.e., all elements of the output array `Z` must be real.

**Examples**

```
X = -2*ones(3,3)

X =
    -2    -2    -2
    -2    -2    -2
    -2    -2    -2
```

```
Y = pascal(3)
```

```
ans =
     1     1     1
     1     2     3
     1     3     6
```

```
realpow(X,Y)
```

```
ans =
    -2    -2    -2
    -2     4    -8
    -2    -8   64
```

**See Also** `reallog` | `realsqrt` | `power` | `mpower`

# realsqrt

---

**Purpose** Square root for nonnegative real arrays

**Syntax** `Y = realsqrt(X)`

**Description** `Y = realsqrt(X)` returns the square root of each element of array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

**Examples**

```
M = magic(4)

M =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

```
realsqrt(M)
```

```
ans =
    4.0000    1.4142    1.7321    3.6056
    2.2361    3.3166    3.1623    2.8284
    3.0000    2.6458    2.4495    3.4641
    2.0000    3.7417    3.8730    1.0000
```

**See Also** `reallog` | `realpow` | `sqrt` | `sqrtm`

---

<b>Purpose</b>	Record data and event information to file
<b>Syntax</b>	<pre>record(obj) record(obj, 'switch')</pre>
<b>Description</b>	<p><code>record(obj)</code> toggles the recording state for the serial port object, <code>obj</code>. <code>record(obj, 'switch')</code> initiates or terminates recording for <code>obj</code>. <code>switch</code> can be <code>on</code> or <code>off</code>. If <code>switch</code> is <code>on</code>, recording is initiated. If <code>switch</code> is <code>off</code>, recording is terminated.</p>
<b>Tips</b>	<p>Before you can record information to disk, <code>obj</code> must be connected to the device with the <code>fopen</code> function. A connected serial port object has a <code>Status</code> property value of <code>open</code>. An error is returned if you attempt to record information while <code>obj</code> is not connected to the device. Each serial port object must record information to a separate file. Recording is automatically terminated when <code>obj</code> is disconnected from the device with <code>fclose</code>.</p> <p>The <code>RecordName</code> and <code>RecordMode</code> properties are read-only while <code>obj</code> is recording, and must be configured before using <code>record</code>.</p> <p>For a detailed description of the record file format and the properties associated with recording data and event information to a file, refer to <a href="#">Debugging: Recording Information to Disk</a>.</p>
<b>Examples</b>	<p>This example creates the serial port object <code>s</code> on a Windows platform. It connects <code>s</code> to the device, configures <code>s</code> to record information to a file, writes and reads text data, and then disconnects <code>s</code> from the device.</p> <pre>s = serial('COM1'); fopen(s) s.RecordDetail = 'verbose'; s.RecordName = 'MySerialFile.txt'; record(s, 'on') fprintf(s, '*IDN?') out = fscanf(s); record(s, 'off')</pre>

# record

---

`fclose(s)`

## **See Also**

`fclose` | `fopen` | `RecordDetail` | `RecordMode` | `RecordName` | `RecordStatus` | `Status`

**Purpose** Record audio to audiorecorder object

**Syntax** `record(recorderObj)`  
`record(recorderObj, length)`

**Description** `record(recorderObj)` records audio from an input device, such as a microphone connected to your system. `recorderObj` is an audiorecorder object that defines the sample rate, bit depth, and other properties of the recording.

`record(recorderObj, length)` records for the number of seconds specified by `length`.

**Examples** Record 5 seconds of your speech with a microphone:

```
myVoice = audiorecorder;

% Define callbacks to show when
% recording starts and completes.
myVoice.StartFcn = 'disp(''Start speaking.'')';
myVoice.StopFcn = 'disp(''End of recording.'')';

record(myVoice, 5);
```

To listen to the recording, call the `play` method:

```
play(myVoice);
```

**See Also** `audiorecorder` | `getaudiodata` | `recordblocking`

**How To**

- “Record Audio”
- “Recording or Playing Audio within a Function”

# audiorecorder.recordblocking

---

<b>Purpose</b>	Record audio to <code>audiorecorder</code> object, holding control until recording completes
<b>Syntax</b>	<code>recordblocking(recorderObj, length)</code>
<b>Description</b>	<code>recordblocking(recorderObj, length)</code> records audio from an input device, such as a microphone connected to your system, for the number of seconds specified by <i>length</i> . The <code>recordblocking</code> method does not return control until recording completes. <i>recorderObj</i> is an <code>audiorecorder</code> object that defines the sample rate, bit depth, and other properties of the recording.
<b>Examples</b>	Record 5 seconds of your speech with a microphone, and play it back: <pre>myVoice = audiorecorder;  disp('Start speaking.');</pre> <code>recordblocking(myVoice, 5);</code> <pre>disp('End of recording. Playing back ...');</pre> <code>play(myVoice);</code>
<b>See Also</b>	<code>audiorecorder</code>   <code>getaudiodata</code>   <code>record</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Record Audio”</li></ul>

**Purpose** Create 2-D rectangle object

**Syntax**

```
rectangle  
rectangle('Position',[x,y,w,h])  
rectangle('Curvature',[x,y])  
rectangle('PropertyName',propertyvalue,...)  
h = rectangle(...)
```

**Properties** For a list of properties, see Rectangle Properties.

**Description** `rectangle` draws a rectangle with Position `[0,0,1,1]` and Curvature `[0,0]` (i.e., no curvature).

`rectangle('Position',[x,y,w,h])` draws the rectangle from the point `x,y` and having a width of `w` and a height of `h`. Specify values in axes data units.

Note that, to display a rectangle in the specified proportions, you need to set the axes data aspect ratio so that one unit is of equal length along both the `x` and `y` axes. You can do this with the command `axis equal` or `daspect([1,1,1])`.

`rectangle('Curvature',[x,y])` specifies the curvature of the rectangle sides, enabling it to vary from a rectangle to an ellipse. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from 0 (no curvature) to 1 (maximum curvature). A value of `[0,0]` creates a rectangle with square sides. A value of `[1,1]` creates an ellipse. If you specify only one value for Curvature, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

`rectangle('PropertyName',propertyvalue,...)` draws the rectangle using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Rectangle Properties.

# rectangle

---

`h = rectangle(...)` returns the handle of the rectangle object created.

## Tips

Rectangle objects are 2-D and can be drawn in an axes only if the view is `[0 90]` (i.e., `view(2)`). Rectangles are children of axes and are defined in coordinates of the axes data.

## Examples

This example sets the data aspect ratio to `[1,1,1]` so that the rectangle is displayed in the specified proportions (`daspect`). Note that the horizontal and vertical curvature can be different. Also, note the effects of using a single value for `Curvature`.

```
rectangle('Position',[0.59,0.35,3.75,1.37],...  
          'Curvature',[0.8,0.4],...  
          'LineWidth',2,'LineStyle','--')  
daspect([1,1,1])
```

Specifying a single value of `[0.4]` for `Curvature` produces

A Curvature of [1] produces a rectangle with the shortest side completely round:

This example creates an ellipse and colors the face red.

```
rectangle('Position',[1,2,5,10],'Curvature',[1,1],...  
         'FaceColor','r')  
daspect([1,1,1])  
xlim([0,7])
```

# rectangle

---

## Setting Default Properties

You can set default rectangle properties on the axes, figure, and root object levels:

```
set(0, 'DefaultRectangleProperty', PropertyValue...)  
set(gcf, 'DefaultRectangleProperty', PropertyValue...)  
set(gca, 'DefaultRectangleProperty', PropertyValue...)
```

where *Property* is the name of the rectangle property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the surface properties.

**See Also**    [line](#) | [patch](#) | [annotation](#) | [Rectangle Properties](#)

# Rectangle Properties

---

## Purpose

Define rectangle properties

## Creating Rectangle Objects

Use `rectangle` to create rectangle objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Rectangle Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this rectangle object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the rectangle object is displayed in a figure legend:

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Represent this rectangle object in a legend (default)
off	Do not include this rectangle object in a legend
children	Same as on because rectangle objects do not have children

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to on when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

# Rectangle Properties

---

BusyAction  
cancel | {queue}

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

ButtonDownFcn  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the rectangle object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src,evt)
% src - the object that is the source of the event
% evt - empty for this property
    sel_typ = get(gcf,'SelectionType')
    switch sel_typ
        case 'normal'
            disp('User clicked left-mouse button')
            set(src,'Selected','on')
        case 'extend'
            disp('User did a shift-click')
            set(src,'Selected','on')
        case 'alt'
            disp('User did a control-click')
            set(src,'Selected','on')
            set(src,'SelectionHighlight','off')
    end
end
```

Suppose `h` is the handle of a rectangle object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

vector of handles

The empty matrix; rectangle objects have no children.

## Clipping

{on} | off

# Rectangle Properties

---

*Clipping mode.* MATLAB clips rectangles to the axes plot box by default. If you set `Clipping` to `off`, rectangles are displayed outside the axes plot box. This can occur if you create a rectangle, set `hold` to `on`, freeze axis scaling (axis set to manual), and then create a larger rectangle.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a rectangle object. You must define this property as a default value for rectangles or in a call to the `rectangle` function to create a new rectangle object. For example, the statement:

```
set(0,'DefaultRectangleCreateFcn',@rect_create)
```

defines a default value for the rectangle `CreateFcn` property on the root level that sets the axes `DataAspectRatio` whenever you create a rectangle object. The callback function must be on your MATLAB path when you execute the above statement.

```
function rect_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    axh = get(src,'Parent');
    set(axh,'DataAspectRatio',[1,1,1])
end
```

MATLAB executes this function after setting all rectangle properties. Setting this property on an existing rectangle object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function

and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Curvature

one- or two-element vector `[x,y]`

*Amount of horizontal and vertical curvature.* Specifies the curvature of the rectangle sides, which enables the shape of the rectangle to vary from rectangular to ellipsoidal. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from 0 (no curvature) to 1 (maximum curvature). A value of `[0,0]` creates a rectangle with square sides. A value of `[1,1]` creates an ellipse. If you specify only one value for `Curvature`, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete rectangle callback function.* Executes when you delete the rectangle object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
```

# Rectangle Properties

---

```
obj_tp = get(src,'Type');
disp([obj_tp, ' object deleted'])
disp('Its user data is:')
disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the rectangle object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EdgeColor`  
{`ColorSpec`} | `none`

*Color of the rectangle edges.* Specifies the color of the rectangle edges as a color or specifies that no edges be drawn.

`EraseMode`  
{`normal`} | `none` | `xor` | `background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase rectangle objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the rectangle when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the rectangle by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath the rectangle.

# Rectangle Properties

---

However, the rectangle's color depends on the color of whatever is beneath it on the display.

- **background** — Erase the rectangle by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is none. This damages objects that are behind the erased rectangle, but rectangles are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### FaceColor

`ColorSpec` | `{none}`

*Color of rectangle face.* Specifies the color of the rectangle face, which is not colored by default.

### HandleVisibility

`{on}` | `callback` | `off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.

- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the Root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines if the rectangle can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the

# Rectangle Properties

---

rectangle. If `HitTest` is off, clicking the rectangle selects the object below it (which might be the axes containing it).

`Interruptible`  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of rectangle edge.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Width of the rectangle edge line.* Specify this value in points. 1 point =  $\frac{1}{72}$  inch. The default value is 0.5 points.

# Rectangle Properties

---

## Parent

handle of axes, hgroup, or hgtransform

*Parent of rectangle object.* Contains the handle of the rectangle object's parent. The parent of a rectangle object is the axes, hgroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Position

four-element vector [x,y,width,height]

*Location and size of rectangle.* Specifies the location and size of the rectangle in the data units of the axes. The point defined by x, y specifies one corner of the rectangle, and width and height define the size in units along the x- and y-axes respectively.

## Selected

on | off

*Is object selected?* When this property is on MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing handles at each vertex. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

## Type

string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For rectangle objects, `Type` is always `'rectangle'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the rectangle.* Assign this property the handle of a `uicontextmenu` object created in the same figure as the rectangle. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the rectangle.

## UserData

matrix

*User-specified data.* Data you want to associate with the rectangle object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Rectangle visibility.* By default, all rectangles are visible. When set to `off`, the rectangle is not visible, but still exists, and you can `get` and `set` its properties.

`rectangle`

# rectint

---

**Purpose** Rectangle intersection area

**Syntax** `area = rectint(A,B)`

**Description** `area = rectint(A,B)` returns the area of intersection of the rectangles specified by position vectors `A` and `B`.

If `A` and `B` each specify one rectangle, the output `area` is a scalar.

`A` and `B` can also be matrices, where each row is a position vector. `area` is then a matrix giving the intersection of all rectangles specified by `A` with all the rectangles specified by `B`. That is, if `A` is `n`-by-4 and `B` is `m`-by-4, then `area` is an `n`-by-`m` matrix where `area(i, j)` is the intersection area of the rectangles specified by the `i`th row of `A` and the `j`th row of `B`.

---

**Note** A position vector is a four-element vector `[x,y,width,height]`, where the point defined by `x` and `y` specifies one corner of the rectangle, and `width` and `height` define the size in units along the `x` and `y` axes respectively.

---

<b>Purpose</b>	Set option to move deleted files to recycle folder
<b>Syntax</b>	<pre>recycle stat = recycle previousStat = recycle state previousStat = recycle('state')</pre>
<b>Description</b>	<p><code>recycle</code> displays the current state, on or off, for recycling files you remove using the <code>delete</code> function. When the value is on, deleted files move to a different location. The location varies by platform—see “Deleting Files and Folders Using Functions”. When the value is off, the <code>delete</code> function permanently removes the files. For details, see the Tips section.</p> <p><code>stat = recycle</code> returns the current state for recycling files to the character array <code>stat</code>.</p> <p><code>previousStat = recycle state</code> sets the recycle option for MATLAB to the specified state, either on or off. The <code>previousStat</code> value is the recycle state before running the statement.</p> <p><code>previousStat = recycle('state')</code> is the function form of the syntax.</p>
<b>Tips</b>	<p>The preference for <b>Deleting files</b> sets the state of the <code>recycle</code> function at startup. When you change the preference, it changes the state of <code>recycle</code>. When you change the state of <code>recycle</code>, it does not change the preference. Use <code>recycle</code> to override the behavior of the preference. For example, regardless of the setting for the <b>Deleting files</b> preference, to remove <code>thisfile.m</code> permanently, run:</p> <pre>recycle('off') delete('thisfile.m')</pre> <p>After setting the <code>recycle</code> state to off, all files you delete using the <code>delete</code> function are deleted permanently until you do one of the following:</p> <ul style="list-style-type: none"><li>• Run <code>recycle('on')</code></li></ul>

# recycle

---

- Restart MATLAB. Upon startup, MATLAB sets the state for `recycle` to match the **Deleting files** preference.

## Examples

Start from a state where file recycling is off. Verify the current recycle state:

```
recycle
ans =
    off
```

Turn file recycling on. Delete a file and move it to the recycle bin or temporary folder:

```
recycle on;
delete myfile.txt
```

## How To

- “General Preferences”

**Purpose** Reduce number of patch faces

**Syntax**

```
reducepatch(p,r)
nfv = reducepatch(p,r)
nfv = reducepatch(fv,r)
nfv = reducepatch(p)
nfv = reducepatch(fv)
reducepatch(...,'fast')
reducepatch(...,'verbose')
nfv = reducepatch(f,v,r)
[nf,nv] = reducepatch(...)
```

**Description** `reducepatch(p,r)` reduces the number of faces of the patch identified by handle `p`, while attempting to preserve the overall shape of the original object. The MATLAB software interprets the reduction factor `r` in one of two ways depending on its value:

- If `r` is less than 1, `r` is interpreted as a fraction of the original number of faces. For example, if you specify `r` as 0.2, then the number of faces is reduced to 20% of the number in the original patch.
- If `r` is greater than or equal to 1, then `r` is the target number of faces. For example, if you specify `r` as 400, then the number of faces is reduced until there are 400 faces remaining.

`nfv = reducepatch(p,r)` returns the reduced set of faces and vertices but does not set the `Faces` and `Vertices` properties of patch `p`. The struct `nfv` contains the faces and vertices after reduction.

`nfv = reducepatch(fv,r)` performs the reduction on the faces and vertices in the struct `fv`.

`nfv = reducepatch(p)` and `nfv = reducepatch(fv)` uses a reduction value of 0.5.

`reducepatch(...,'fast')` assumes the vertices are unique and does not compute shared vertices.

`reducepatch(...,'verbose')` prints progress messages to the command window as the computation progresses.

# reducepatch

---

`nfv = reducepatch(f,v,r)` performs the reduction on the faces in `f` and the vertices in `v`.

`[nf,nv] = reducepatch(...)` returns the faces and vertices in the arrays `nf` and `nv`.

## Tips

If the patch contains nonshared vertices, MATLAB computes shared vertices before reducing the number of faces. If the faces of the patch are not triangles, MATLAB triangulates the faces before reduction. The faces returned are always defined as triangles.

The number of output triangles may not be exactly the number specified with the reduction factor argument (`r`), particularly if the faces of the original patch are not triangles.

## Examples

This example illustrates the effect of reducing the number of faces to only 15% of the original value.

```
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
set(p,'facecolor','w','EdgeColor','b');
daspect([1,1,1])
view(3)
figure;
h = axes;
p2 = copyobj(p,h);
reducepatch(p2,0.15)
daspect([1,1,1])
view(3)
```

Before Reduction

# reducepatch

---

After Reduction to 15% of Original Number of Faces

## How To

- [Vector Field Displayed with Cone Plots](#)

## Purpose

Reduce number of elements in volume data set

## Syntax

```
[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])
[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])
nv = reducevolume(...)
```

## Description

`[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])` reduces the number of elements in the volume by retaining every  $R_x^{\text{th}}$  element in the  $x$  direction, every  $R_y^{\text{th}}$  element in the  $y$  direction, and every  $R_z^{\text{th}}$  element in the  $z$  direction. If a scalar  $R$  is used to indicate the amount of reduction instead of a three-element vector, the MATLAB software assumes the reduction to be `[R R R]`.

The arrays  $X$ ,  $Y$ , and  $Z$  define the coordinates for the volume  $V$ . The reduced volume is returned in  $nv$ , and the coordinates of the reduced volume are returned in  $nx$ ,  $ny$ , and  $nz$ .

`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])` assumes the arrays  $X$ ,  $Y$ , and  $Z$  are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(V)`.

`nv = reducevolume(...)` returns only the reduced volume.

## Examples

This example uses a data set that is a collection of MRI slices of a human skull. This data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then reduced (`reducevolume`) so that what remains is every fourth element in the  $x$  and  $y$  directions and every element in the  $z$  direction.
- The reduced data is smoothed (`smooth3`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with an interpolated face color draws the end caps (`FaceColor`) `isocaps`.
- The view of the object is set (`view`, `axis`, `daspect`).

# reducevolume

---

- A 100-element grayscale colormap provides coloring for the end caps (colormap).
- Adding a light to the right of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = reducevolume(D,[4,4,1]);
D = smooth3(D);
p1 = patch(isosurface(x,y,z,D, 5,'verbose'),...
    'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
    'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight; lighting gouraud
```

[isosurface](#) | [isocaps](#) | [isonormals](#) | [smooth3](#) | [subvolume](#) | [reducepatch](#)

<b>Purpose</b>	Redraw current figure
<b>Syntax</b>	<code>refresh</code> <code>refresh(h)</code>
<b>Description</b>	<code>refresh</code> erases and redraws the current figure. <code>refresh(h)</code> redraws the figure identified by <code>h</code> .

# refreshdata

---

**Purpose** Refresh data in graph when data source is specified

**Syntax**

```
refreshdata  
refreshdata(figure_handle)  
refreshdata(object_handles)  
refreshdata(object_handles, 'workspace')
```

**Description** `refreshdata` evaluates any data source properties (XDataSource, YDataSource, or ZDataSource) on all objects in graphs in the current figure. If the specified data source has changed, the MATLAB software updates the graph to reflect this change.

---

**Note** The variable assigned to the data source property must be in the base workspace or you must specify the *workspace* option as 'caller'.

---

`refreshdata(figure_handle)` refreshes the data of the objects in the specified figure.

`refreshdata(object_handles)` refreshes the data of the objects specified in *object\_handles* or the children of those objects. Therefore, *object\_handles* can contain figure, axes, or plot object handles.

`refreshdata(object_handles, 'workspace')` enables you to specify whether the data source properties are evaluated in the base workspace or the workspace of the function in which `refreshdata` was called. *workspace* is a string that can be

- `base` — Evaluate the data source properties in the base workspace.
- `caller` — Evaluate the data source properties in the workspace of the function that called `refreshdata`.

**Tips** The Linked Plots feature (see documentation for `linkdata`) sets up data sources for graphs and synchronizes them with the workspace variables they display. When you use this feature, you do not also need to call

`refreshdata`, as it is essentially automatically triggered every time a data source changes.

If you are not using the Linked Plots feature, you need to set the `XDataSource`, `YDataSource`, and/or `ZDataSource` properties of a graph in order to use `refreshdata`. You can do that programmatically, as shown in the examples below, or use the Property Editor, one of the plotting tools. In the Property Editor, select the graph (e.g., a `lineseries` object) and type in (or select from the drop-down choices) the name(s) of the workspace variable(s) from which you want the plot to refresh, in the fields labelled **X Data Source**, **Y Data Source**, and/or **Z Data Source**. The call to `refreshdata` causes the graph to update.

## Examples

Plot a sine wave, identify data sources, and then modify its `YDataSource`:

```
x = 0:.1:8;
y = sin(x);
h = plot(x,y)
set(h, 'YDataSource', 'y')
set(h, 'XDataSource', 'x')
y = sin(x.^3);
refreshdata
```

Create a surface plot, identify a `ZDataSource` for it, and change the data to a different size.

```
Z = peaks(5);
h = surf(Z)
set(h, 'ZDataSource', 'Z')
pause(3)
Z = peaks(25);
refreshdata
```

## How To

- plot objects
- “Updating Plot Object Axis and Color Data”

# regexp

---

**Purpose** Match regular expression (case sensitive)

**Syntax** `startIndex = regexp(str,expression)`  
`[startIndex,endIndex] = regexp(str,expression)`

`out = regexp(str,expression,outkey)`  
`[out1,...,outN] =`  
`regexp(str,expression,outkey1,...,outkeyN)`

`___ = regexp( ___,option1,...,optionM)`

**Description** `startIndex = regexp(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexp(str,expression)` returns the starting and ending indices of all matches.

`out = regexp(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is `'match'`, then `regexp` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] =`  
`regexp(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match','tokens'`, then `regexp` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexp( ___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'ignorecase'` to perform a case-insensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

## Input Arguments

### str - Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If `str` and `expression` are both cell arrays, they must have the same dimensions.

### Data Types

char | cell

### expression - Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

### Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	'..ain' matches sequences of five consecutive characters that end with 'ain'.
[c <sub>1</sub> c <sub>2</sub> c <sub>3</sub> ]	Any character contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	'[rp.]ain' matches 'rain' or 'pain' or '.ain'.

# regexp

Metacharacter	Description	Example
<code>[^c<sub>1</sub>c<sub>2</sub>c<sub>3</sub>]</code>	Any character not contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[^*rp]ain</code> ' matches all four-letter sequences that end in 'ain', except 'rain' and 'pain' and <code>`*ain</code> '. For example, it matches 'gain', 'lain', or 'vain'.
<code>[c<sub>1</sub>-c<sub>2</sub>]</code>	Any character in the range of c <sub>1</sub> through c <sub>2</sub>	' <code>[A-G]</code> ' matches a single character in the range of A through G.
<code>\w</code>	Any alphabetic, numeric, or underscore character. For English character sets, <code>\w</code> is equivalent to <code>[a-zA-Z_0-9]</code>	' <code>\w*</code> ' identifies a word.
<code>\W</code>	Any character that is not alphabetic, numeric, or underscore. For English character sets, <code>\W</code> is equivalent to <code>[^a-zA-Z_0-9]</code>	' <code>\W*</code> ' identifies a substring that is not a word.
<code>\s</code>	Any white-space character; equivalent to <code>[\f\n\r\t\v]</code>	' <code>\w*n\s</code> ' matches words that end with the letter n, followed by a white-space character.
<code>\S</code>	Any non-white-space character; equivalent to <code>[^\f\n\r\t\v]</code>	' <code>\d\S</code> ' matches a numeric digit followed by any non-white-space character.
<code>\d</code>	Any numeric digit; equivalent to <code>[0-9]</code>	' <code>\d*</code> ' matches any number of consecutive digits.
<code>\D</code>	Any nondigit character; equivalent to <code>[^0-9]</code>	' <code>\w*\D&gt;</code> ' matches words that do not end with a numeric digit.

Metacharacter	Description	Example
<code>\oN</code> or <code>\o{N}</code>	Character of octal value N	' <code>\o{40}</code> ' matches the space character, defined by octal 40.
<code>\xN</code> or <code>\x{N}</code>	Character of hexadecimal value N	' <code>\x2C</code> ' matches the comma character, defined by hex 2C.

### Character Representation

Operator	Description
<code>\a</code>	Alarm (beep)
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

### Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
<code>expr*</code>	0 or more times consecutively.	' <code>\w*</code> ' matches a word of any length.
<code>expr?</code>	0 times or 1 time.	' <code>\w*(\ .m)?</code> ' matches words that optionally end with the extension <code>.m</code> .

# regex

Quantifier	Matches the expression when it occurs...	Example
<code>expr+</code>	1 or more times consecutively.	' <code>&lt;img src="\w+\.gif"&gt;</code> ' matches an <code>&lt;img&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{m,n}</code>	At least <code>m</code> times, but no more than <code>n</code> times consecutively. <code>{0,1}</code> is equivalent to <code>?</code> .	' <code>\S{4,8}</code> ' matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least <code>m</code> times consecutively. <code>{0,}</code> and <code>{1,}</code> are equivalent to <code>*</code> and <code>+</code> , respectively.	' <code>&lt;a href="\w{1,}\.html"&gt;</code> ' matches an <code>&lt;a&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly <code>n</code> times consecutively. Equivalent to <code>{n,n}</code> .	' <code>\d{4}</code> ' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. `q` represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*&gt;</code> ' matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :  ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> '
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*?&gt;</code> ' ends each match at the first occurrence of the closing bracket ( <code>&gt;</code> ):

Mode	Description	Example
		'<tr>'   '<td>'   '</td>'
exprq+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

### Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.

# regex

Grouping Operator	Description	Example
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(?:.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1 expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with let or tel.

## Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
^expr	Beginning of the input string.	'^M\w*' matches a word starting with M at the beginning of the string.
expr\$	End of the input string.	'\w*m\$' matches words ending with m at the end of the string.
\<expr	Beginning of a word.	'\<n\w*' matches any words starting with n.
expr\>	End of a word.	'\w*e\>' matches any words ending with e.

## Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(?:test)</code>	Look ahead for characters that match <code>test</code> .	<code>'\w*(?:ing)'</code> matches strings that are followed by <code>ing</code> , such as <code>'Fly'</code> and <code>'fall'</code> in the input string <code>'Flying, not falling.'</code>
<code>expr(?:!test)</code>	Look ahead for characters that do not match <code>test</code> .	<code>'i(?:ng)'</code> matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .
<code>(?&lt;=test)expr</code>	Look behind for characters that match <code>test</code> .	<code>'(?:re)\w*'</code> matches strings that follow <code>'re'</code> , such as <code>'new'</code> , <code>'use'</code> , and <code>'cycle'</code> in the input string <code>'renew, reuse, recycle'</code>
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match <code>test</code> .	<code>'(?:!\d)(\d)(?!\d)'</code> matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both <code>test</code> and <code>expr</code> .	<code>'(?:[a-z])[^aeiou]'</code> matches consonants.
<code>(?!test)expr</code>	Match <code>expr</code> and do not match <code>test</code> .	<code>'(?:[aeiou])[a-z]'</code> matches consonants.

### Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any,

to match next. These operators support logical OR, and if or if/else conditions.

Conditions can be tokens, lookahead operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
<code>expr1 expr2</code>	Match expression <code>expr1</code> or expression <code>expr2</code> . If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.	' <code>(let tel)\w+</code> ' matches words in a string that start with <code>let</code> or <code>tel</code> .
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	' <code>(?(?@ispc)[A-Z]:\\)</code> ' matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	' <code>Mr(s?)\..*?(?(1)her his)\w*</code> ' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

## Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
(expr)	Capture in a token the characters that match the enclosed expression.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
\N	Match the Nth token.	'<(\w+).*>.*</\1>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(N)expr1 expr2)	If the Nth token is found, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

Named Token Operator	Description	Example
(?<name>expr)	Capture in a named token the characters that match the enclosed expression.	'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(?(tag)\w+).*>.*</\ktag>'' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex)s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

---

**Note** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

---

## Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse expr and include the resulting string in the match expression.  When parsed, expr must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of expr, and one for the complete match.	'^(\d+)((?!\w{\$1}))' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching '5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by cmd, and include the string returned by the command in the match expression.	'(.{2,}).?(??@flip1r(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by cmd, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(?@disp(\$1))\1\w*' matches words that include double letters (such as pp), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
\$& or \$0	Portion of the input string that is currently a match
\$`	Portion of the input string that precedes the current match
\$'	Portion of the input string that follows the current match (use \$' ' to represent the string \$')
\$N	Nth token
\$<name>	Named token
\${cmd}	String returned when MATLAB executes the command, cmd

### Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<d\w+' includes a comment, and matches words that begin with a number.

### Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

# regexp

---

Flag	Description
(?-i)	Match letter case (default for regexp and regexprep).
(?i)	Do not match letter case (default for regexpi).
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (:), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

## Data Types

char | cell

**outkey - Keyword that indicates which outputs to return**

'start' | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
'start'	Starting indices of all matches, <code>startIndex</code>
'end'	Ending indices of all matches, <code>endIndex</code>
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in <code>expression</code>
'tokens'	Text of each captured token in <code>str</code>
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of <code>str</code>

**Data Types**

char

**option - Search option**

'once' | 'warnings' | 'ignorecase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors' | ...

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.

# regexp

Default	Override	Description
'matchcase'	'ignorecase'	Match letter case (default), or ignore case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With freespacing, use '\ ' and '\#' to match space and # characters.

## Data Types

char

## Output Arguments

### **startIndex** - Starting index of each match

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

### **endIndex** - Ending index of each match

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

**out - Information about matches**

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

Output Keyword	Output Description	Output Type and Dimensions
'start'	Starting indices of matches	For both 'start' and 'end': <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a row vector (or, if there are no matches, an empty array).</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>
'end'	Ending indices of matches	

Output Keyword	Output Description	Output Type and Dimensions
'tokenExtents'	Starting and ending indices of all tokens	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array, where <code>n</code> is the number of matches. Each cell contains an m-by-2 numeric array of indices, where <code>m</code> is the number of tokens in the match.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array, where each inner cell contains an m-by-2 numeric array.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul> <p>When you specify the 'once' option to return only one match, the output is either an m-by-2 numeric array or a cell array with the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index <code>N</code>, but is not found, then MATLAB returns extents for that token of <code>[N,N-1]</code>.</p>

Output Keyword	Output Description	Output Type and Dimensions
'match'	Text of each substring that matches the pattern in <code>expression</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array of strings, where <code>n</code> is the number of matches.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is either a string or a cell array of strings with the same dimensions as <code>str</code> and <code>expression</code>.</p>
'tokens'	Text of each captured token in <code>str</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array, where <code>n</code> is the number of matches. Each cell contains a 1-by-<code>m</code> cell array of strings, where <code>m</code> is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array, where each inner cell contains a 1-by-<code>m</code> cell array of strings.</li> </ul>

# regexp

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul> <p>When you specify the 'once' option to return only one match, the output is a 1-by-m cell array of strings or a cell array that has the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, ''.</p>
'names'	Name and text of each named token	<p>For all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n structure array, where n is the number of matches. The structure field names correspond to the token names.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n structure array.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul>
'split'	Text of nonmatching substrings of <code>str</code>	<p>For all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array of strings, where n is the number of nonmatching strings.</li></ul>

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>

## Examples

### Find Patterns in Single Strings

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car coat court CUT ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexp(str,expression)
```

```
startIndex =
     5     17
```

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.
- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression. The matching word `cat`

starts at index 5, and coat starts at index 17. The words CUT and CAT do not match because they are uppercase.

## Find Patterns in Multiple Strings

Find the location of capital letters and spaces within strings in a cell array.

```
str = {'Madrid, Spain', 'Romeo and Juliet', 'MATLAB is great'};
capExpr = '[A-Z]';
spaceExpr = '\s';
```

```
capStartIndex = regexp(str, capExpr);
spaceStartIndex = regexp(str, spaceExpr);
```

capStartIndex and spaceStartIndex are cell arrays because the input str is a cell array.

View the indices for the capital letters.

```
celldisp(capStartIndex)
```

```
capStartIndex{1} =
     1     9
```

```
capStartIndex{2} =
     1    11
```

```
capStartIndex{3} =
     1     2     3     4     5     6
```

View the indices for the spaces.

```
celldisp(spaceStartIndex)
```

```
spaceStartIndex{1} =
     8
```

```
spaceStartIndex{2} =
```

```

        6      10
spaceStartIndex{3} =
        7      10

```

### Return Substrings Using 'match' Keyword

Capture words within a string that contain the letter x.

```

str = 'EXTRA! The regexp function helps you relax.';
expression = '\w*x\w*';
matchStr = regexp(str,expression,'match')

matchStr =
    'regexp'    'relax'

```

The regular expression '\w\*x\w\*' specifies that the string:

- Begins with any number of alphanumeric or underscore characters, \w\*.
- Contains the lowercase letter x.
- Ends with any number of alphanumeric or underscore characters after the x, including none, as indicated by \w\*.

### Split String at Delimiter Using 'split' Keyword

Split a string into several substrings, where each substring is delimited by a ^ character.

```

str = ['Split ^this string into ^several pieces'];
expression = '^';
splitStr = regexp(str,expression,'split')

splitStr =
    'Split '    'this string into '    'several pieces'

```

Because the carat symbol has special meaning in regular expressions, precede it with the escape character, a backslash (\). To split a string

at other delimiters, such as a semicolon, you do not need to include the backslash.

## **Return Both Matching and Nonmatching Substrings**

Capture parts of a string that match a regular expression using the 'match' keyword, and the remaining parts that do not match using the 'split' keyword.

```
str = 'She sells sea shells by the seashore.';
expression = '[Ss]h.';
[match,noMatch] = regexp(str,expression,'match','split')
```

```
match =
    'She'    'she'    'sho'
```

```
noMatch =
    ''    ' sells sea '    'lls by the sea'    're.'
```

The regular expression '[Ss]h.' specifies that:

- S or s is the first character.
- h is the second character.
- The third character can be anything, including a space, as indicated by the dot (.).

When the first (or last) character in a string matches a regular expression, the first (or last) return value from the 'split' keyword is an empty string.

Optionally, reassemble the original string from the substrings.

```
combinedStr = strjoin(noMatch,match)
```

```
combinedStr =
She sells sea shells by the seashore.
```

## Capture Substrings of Matches Using Ordinal Tokens

Find the names of HTML tags by defining a token within a regular expression. Tokens are indicated with parentheses, ().

```
str = '<title>My Title</title><p>Here is some text.</p>';
expression = '<(\w+).*>.*</\1>';
[tokens,matches] = regexp(str,expression,'tokens','match');
```

The regular expression `<(\w+).*>.*</\1>` specifies this pattern:

- `<(\w+)` finds an opening angle bracket followed by one or more alphanumeric or underscore characters. Enclosing `\w+` in parentheses captures the name of the HTML tag in a token.
- `.*>` finds any number of additional characters, such as HTML attributes, and a closing angle bracket.
- `</\1>` finds the end tag corresponding to the first token (indicated by `\1`). The end tag has the form `</tagname>`.

View the tokens and matching substrings.

```
celldisp(tokens)
```

```
tokens{1}{1} =
    title
```

```
tokens{2}{1} =
    p
```

```
celldisp(matches)
```

```
matches{1} =
    <title>My Title</title>
```

```
matches{2} =
    <p>Here is some text.</p>
```

## Capture Substrings of Matches Using Named Tokens

Parse dates that can appear with either the day or the month first, in these forms: mm/dd/yyyy or dd-mm-yyyy. Use named tokens to identify each part of the date.

```
str = '01/11/2000 20-02-2020 03/30/2000 16-04-2020';  
expression = [ '(?<month>\d+)/(?<day>\d+)/(?<year>\d+)' | ...  
              '(?<day>\d+) - (?<month>\d+) - (?<year>\d+)' ];  
tokenNames = regexp(str,expression,'names');
```

The regular expression specifies this pattern:

- `(?<name>\d+)` finds one or more numeric digits and assigns the result to the token indicated by *name*.
- `|` is the logical or operator, which indicates that there are two possible patterns for dates. In the first pattern, slashes (/) separate the tokens. In the second pattern, hyphens (-) separate the tokens.

View the named tokens.

```
for k = 1:length(tokenNames)  
    disp(tokenNames(k))  
end
```

```
month: '01'  
day: '11'  
year: '2000'
```

```
month: '02'  
day: '20'  
year: '2020'
```

```
month: '03'  
day: '30'  
year: '2000'
```

```
month: '04'
```

```

    day: '16'
    year: '2020'

```

### Perform Case-Insensitive Matches

Find both uppercase and lowercase instances of a word.

By default, `regexp` performs case-sensitive matching.

```

str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexp(str,expression,'match')

```

```

matchStr =
    'lowercase'

```

The regular expression specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Ends with the literal text `case`.

The `regexpi` function uses the same syntax as `regexp`, but performs case-insensitive matching.

```

matchWithRegexpi = regexpi(str,expression,'match')

```

```

matchWithRegexpi =
    'UPPERCASE'    'lowercase'

```

Alternatively, disable case-sensitive matching for `regexp` using the `'ignorecase'` option.

```

matchWithIgnorecase = regexp(str,expression,'match','ignorecase')

```

```

matchWithIgnorecase =
    'UPPERCASE'    'lowercase'

```

For multiple expressions, disable case-sensitive matching for selected expressions using the `(?i)` search flag.

```
expression = {'(?-i)\w*case';...
              '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =
    lowercase
```

```
matchStr{2}{1} =
    UPPERCASE
```

```
matchStr{2}{2} =
    lowercase
```

## Parse Strings with Newline Characters

Create a string that contains a newline, \n, and parse the string using a regular expression.

```
str = sprintf('abc\n de');
expression = '.*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
    [1x7 char]
```

By default, the dot (.) matches every character, including the newline, and returns a single match that is equivalent to the original string.

Exclude newline characters from the match using the 'dotexceptnewline' option. This returns separate matches for each line of text.

```
matchStrNoNewline = regexp(str,expression,'match','dotexceptnewline')
```

```
matchStrNoNewline =
    'abc'      ' de'
```

Find the first or last character of each line using the ^ or \$ metacharacters and the 'lineanchors' option.

```
expression = '.$';
lastInLine = regexp(str,expression,'match','lineanchors')

lastInLine =
    'c'      'e'
```

## Definitions

### Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form dd-mmm-yyyy, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}
```

```
ans =
    '01'      'April'      '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')

mydate =
    day: '01'
    month: 'Apr'
    year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

## Algorithms

MATLAB parses each input string from left to right, attempting to match the text in the string with the first element of the regular expression. During this process, MATLAB skips over any text that does not match.

When MATLAB finds the first match, it continues parsing the string to match the second piece of the expression, and so on.

## Tips

- Use `strfind` to find an exact character match within a string. Use `regexp` to look for a pattern of characters.

## See Also

`regexpi` | `regexprep` | `regexptranslate` | `strfind` | `strjoin` | `strsplit` | `strrep`

## Concepts

- “Regular Expressions”
- “Lookahead Assertions in Regular Expressions”
- “Dynamic Regular Expressions”

## Purpose

Match regular expression (case insensitive)

## Syntax

```
startIndex = regexpi(str,expression)
[startIndex,endIndex] = regexpi(str,expression)
```

```
out = regexpi(str,expression,outkey)
[out1,...,outN] =
regexpi(str,expression,outkey1,...,outkeyN)
```

```
___ = regexpi( ___,option1,...,optionM)
```

## Description

`startIndex = regexpi(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression, without regard to letter case. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexpi(str,expression)` returns the starting and ending indices of all matches.

`out = regexpi(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is `'match'`, then `regexpi` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] = regexpi(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match'`, `'tokens'`, then `regexpi` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexpi( ___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'matchcase'` to perform a case-sensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

# regexpi

---

## Input Arguments

### **str - Input text**

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If **str** and **expression** are both cell arrays, they must have the same dimensions.

### **Data Types**

char | cell

### **expression - Regular expression**

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in **str**.

The following tables describe the elements of regular expressions.

### **Metacharacters**

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	'..ain' matches sequences of five consecutive characters that end with 'ain'.
[c <sub>1</sub> c <sub>2</sub> c <sub>3</sub> ]	Any character contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	'[rp.]ain' matches 'rain' or 'pain' or '.ain'.

Metacharacter	Description	Example
[ <sup>^</sup> c <sub>1</sub> c <sub>2</sub> c <sub>3</sub> ]	Any character not contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	'[ <sup>^</sup> *rp]ain' matches all four-letter sequences that end in 'ain', except 'rain' and 'pain' and `*ain'. For example, it matches 'gain', 'lain', or 'vain'.
[c <sub>1</sub> -c <sub>2</sub> ]	Any character in the range of c <sub>1</sub> through c <sub>2</sub>	'[A-G]' matches a single character in the range of A through G.
\w	Any alphabetic, numeric, or underscore character. For English character sets, \w is equivalent to [a-zA-Z_0-9]	'\w*' identifies a word.
\W	Any character that is not alphabetic, numeric, or underscore. For English character sets, \W is equivalent to [^a-zA-Z_0-9]	'\W*' identifies a substring that is not a word.
\s	Any white-space character; equivalent to [ \f\n\r\t\v]	'\w*n\s' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [^ \f\n\r\t\v]	'\d\S' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [0-9]	'\d*' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [^0-9]	'\w*\D\>' matches words that do not end with a numeric digit.

# regexpi

Metacharacter	Description	Example
<code>\oN</code> or <code>\o{N}</code>	Character of octal value N	' <code>\o{40}</code> ' matches the space character, defined by octal 40.
<code>\xN</code> or <code>\x{N}</code>	Character of hexadecimal value N	' <code>\x2C</code> ' matches the comma character, defined by hex 2C.

## Character Representation

Operator	Description
<code>\a</code>	Alarm (beep)
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

## Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
<code>expr*</code>	0 or more times consecutively.	' <code>\w*</code> ' matches a word of any length.
<code>expr?</code>	0 times or 1 time.	' <code>\w*(\ .m)?</code> ' matches words that optionally end with the extension <code>.m</code> .

Quantifier	Matches the expression when it occurs...	Example
<code>expr+</code>	1 or more times consecutively.	' <code>&lt;img src="\w+\.gif"&gt;</code> ' matches an <code>&lt;img&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{m,n}</code>	At least <code>m</code> times, but no more than <code>n</code> times consecutively. <code>{0,1}</code> is equivalent to <code>?</code> .	' <code>\S{4,8}</code> ' matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least <code>m</code> times consecutively. <code>{0,}</code> and <code>{1,}</code> are equivalent to <code>*</code> and <code>+</code> , respectively.	' <code>&lt;a href="\w{1,}\.html"&gt;</code> ' matches an <code>&lt;a&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly <code>n</code> times consecutively. Equivalent to <code>{n,n}</code> .	' <code>\d{4}</code> ' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. `q` represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*&gt;</code> ' matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :  ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> '
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*?&gt;</code> ' ends each match at the first occurrence of the closing bracket ( <code>&gt;</code> ):

# regexpi

Mode	Description	Example
		'<tr>'   '<td>'   '</td>'
exprq+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

## Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.

Grouping Operator	Description	Example
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(? :.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1 expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with let or tel.

### Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
^expr	Beginning of the input string.	'^M\w*' matches a word starting with M at the beginning of the string.
expr\$	End of the input string.	'\w*m\$' matches words ending with m at the end of the string.
\<expr	Beginning of a word.	'\<n\w*' matches any words starting with n.
expr\>	End of a word.	'\w*e\>' matches any words ending with e.

### Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

# regexpi

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(?=test)</code>	Look ahead for characters that match <code>test</code> .	<code>'\w*(?=ing)'</code> matches strings that are followed by <code>ing</code> , such as <code>'Fly'</code> and <code>'fall'</code> in the input string <code>'Flying, not falling.'</code>
<code>expr(?!test)</code>	Look ahead for characters that do not match <code>test</code> .	<code>'i(?!ng)'</code> matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .
<code>(?&lt;=test)expr</code>	Look behind for characters that match <code>test</code> .	<code>'(?&lt;=re)\w*'</code> matches strings that follow <code>'re'</code> , such as <code>'new'</code> , <code>'use'</code> , and <code>'cycle'</code> in the input string <code>'renew, reuse, recycle'</code>
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match <code>test</code> .	<code>'(?&lt;!\d)(\d)(?!\d)'</code> matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both <code>test</code> and <code>expr</code> .	<code>'(?=[a-z])[^aeiou]'</code> matches consonants.
<code>(?!test)expr</code>	Match <code>expr</code> and do not match <code>test</code> .	<code>'(?![aeiou])[a-z]'</code> matches consonants.

## Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any,

to match next. These operators support logical OR, and if or if/else conditions.

Conditions can be tokens, lookahead operators, or dynamic expressions of the form (?@cmd). Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
<code>expr1 expr2</code>	Match expression <code>expr1</code> or expression <code>expr2</code> . If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.	'(let tel)\w+' matches words in a string that start with <code>let</code> or <code>tel</code> .
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	'(?(@ispc)[A-Z]:\\)' matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	'Mr(s?)\.*?(?(1)her his)\w*' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

### Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

# regexpi

Ordinal Token Operator	Description	Example
(expr)	Capture in a token the characters that match the enclosed expression.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
\N	Match the Nth token.	'<(\w+).*>.*</\1>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(N)expr1 expr2)	If the Nth token is found, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

Named Token Operator	Description	Example
(?<name>expr)	Capture in a named token the characters that match the enclosed expression.	'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(?(tag)\w+).*>.*</\k<tag>>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex)s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

**Note** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

### Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse expr and include the resulting string in the match expression.  When parsed, expr must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of expr, and one for the complete match.	'^(\d+)(??\w{\$1})' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching '5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by cmd, and include the string returned by the command in the match expression.	'(.{2,}).?(??@fliplr(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by cmd, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(\w)(?@disp(\$1))\1\w*' matches words that include double letters (such as pp), and displays intermediate results.

# regexp

---

Within dynamic expressions, use the following operators to define replacement strings.

<b>Replacement String Operator</b>	<b>Description</b>
<code>\$&amp; or \$0</code>	Portion of the input string that is currently a match
<code>\$`</code>	Portion of the input string that precedes the current match
<code>\$'</code>	Portion of the input string that follows the current match (use <code>\$''</code> to represent the string <code>\$'</code> )
<code>\$N</code>	Nth token
<code>\$(name)</code>	Named token
<code>\$(cmd)</code>	String returned when MATLAB executes the command, <code>cmd</code>

## Comments

<b>Characters</b>	<b>Description</b>	<b>Example</b>
<code>(?#comment)</code>	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	<code>'(?# Initial digit)\&lt;\d\w+'</code> includes a comment, and matches words that begin with a number.

## Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
(?-i)	Match letter case (default for <code>regexp</code> and <code>regexprep</code> ).
(?i)	Do not match letter case (default for <code>regexpi</code> ).
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (:), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

### Data Types

char | cell

## **outkey - Keyword that indicates which outputs to return**

'start' | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'

Keyword that indicates which outputs to return, specified as one of the following strings.

<b>Output Keyword</b>	<b>Returns</b>
'start'	Starting indices of all matches, <code>startIndex</code>
'end'	Ending indices of all matches, <code>endIndex</code>
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in <code>expression</code>
'tokens'	Text of each captured token in <code>str</code>
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of <code>str</code>

## **Data Types**

char

## **option - Search option**

'once' | 'warnings' | 'matchcase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors' | ...

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

<b>Default</b>	<b>Override</b>	<b>Description</b>
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.

Default	Override	Description
'ignorecase'	'matchcase'	Ignore letter case (default), or match case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With freespacing, use '\ ' and '\#' to match space and # characters.

**Data Types**

char

**Output Arguments**

**startIndex - Starting index of each match**

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

**endIndex - Ending index of each match**

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

### **out - Information about matches**

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

<b>Output Keyword</b>	<b>Output Description</b>	<b>Output Type and Dimensions</b>
'start'	Starting indices of matches	For both 'start' and 'end': <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a row vector (or, if there are no matches, an empty array).</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul>
'end'	Ending indices of matches	

Output Keyword	Output Description	Output Type and Dimensions
'tokenExtents'	Starting and ending indices of all tokens	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array, where n is the number of matches. Each cell contains an m-by-2 numeric array of indices, where m is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array, where each inner cell contains an m-by-2 numeric array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is either an m-by-2 numeric array or a cell array with the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index N, but is not found, then MATLAB returns extents for that token of [N,N-1].</p>

# regexpi

Output Keyword	Output Description	Output Type and Dimensions
'match'	Text of each substring that matches the pattern in <code>expression</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array of strings, where <code>n</code> is the number of matches.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array of strings.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul> <p>When you specify the 'once' option to return only one match, the output is either a string or a cell array of strings with the same dimensions as <code>str</code> and <code>expression</code>.</p>
'tokens'	Text of each captured token in <code>str</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array, where <code>n</code> is the number of matches. Each cell contains a 1-by-<code>m</code> cell array of strings, where <code>m</code> is the number of tokens in the match.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array, where each inner cell contains a 1-by-<code>m</code> cell array of strings.</li></ul>

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"> <li>If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is a 1-by-m cell array of strings or a cell array that has the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, ''.</p>
'names'	Name and text of each named token	<p>For all matches:</p> <ul style="list-style-type: none"> <li>If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n structure array, where n is the number of matches. The structure field names correspond to the token names.</li> <li>If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n structure array.</li> <li>If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>
'split'	Text of nonmatching substrings of <code>str</code>	<p>For all matches:</p> <ul style="list-style-type: none"> <li>If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array of strings, where n is the number of nonmatching strings.</li> </ul>

# regexpi

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array of strings.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul>

## Examples

### Pattern Matching

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car COAT court cut ct CAT-scan';  
expression = 'c[aeiou]+t';  
startIndex = regexpi(str,expression)
```

```
startIndex =  
     5     17     28     35
```

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression.

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.

- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

## Case-Sensitive Match

Match letter case in all or part of an expression.

By default, `regexpi` performs case-insensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexpi(str,expression,'match')
```

```
matchStr =
    'UPPERCASE'    'lowercase'
```

Use the `regexp` function with the same syntax as `regexpi` to perform case-sensitive matching.

```
matchWithRegexp = regexp(str,expression,'match')
```

```
matchWithRegexp =
    'lowercase'
```

To disable case-sensitive matching for `regexp`, use the `'ignorecase'` option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
```

```
matchWithIgnorecase =
    'UPPERCASE'    'lowercase'
```

For multiple expressions, enable and disable case-insensitive matching for selected expressions using the `(?i)` and `(?-i)` search flags.

```
expression = {'(?-i)\w*case';...
              '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =  
    lowercase
```

```
matchStr{2}{1} =  
    UPPERCASE
```

```
matchStr{2}{2} =  
    lowercase
```

## Definitions

## Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form `dd-mmm-yyyy`, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';  
expression = '(\d+)-(\w+)-(\d+)';  
  
mydate = regexp(str,expression,'tokens');  
mydate{:}
```

```
ans =  
    '01'    'April'    '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';  
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';
```

```
mydate = regexp(str,expression,'names')
```

```
mydate =  
    day: '01'  
    month: 'Apr'  
    year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

## **Concepts**

- “Lookahead Assertions in Regular Expressions”
- “Dynamic Regular Expressions”

# regexprep

---

**Purpose** Replace string using regular expression

**Syntax** `newStr = regexprep(str,expression,replace)`  
`newStr =`  
`regexprep(str,expression,replace,option1,...optionM)`

**Description** `newStr = regexprep(str,expression,replace)` replaces the text in `str` that matches `expression` with the text described by `replace`. The `regexprep` function returns the updated text in `newStr`.

- If `str` is a string, then `newStr` is also a string, even when `expression` or `replace` is a cell array of strings. When `expression` is a cell array, `regexprep` applies the first expression to the string, and then applies each subsequent expression to the preceding result.
- If `str` is a cell array, then `newStr` is a cell array with the same dimensions as `str`. For each element of `str`, the `regexprep` function applies each expression in sequence.
- If there are no matches to `expression`, then `newStr` is equivalent to `str`.

`newStr =`  
`regexprep(str,expression,replace,option1,...optionM)` modifies the search using the specified options. For example, specify `'ignorecase'` to perform a case-insensitive match.

## **Input Arguments**

**str - Text to update**  
string | cell array of strings

Text to update, specified as a string or a cell array of strings.

**Data Types**  
char | cell

**expression - Regular expression**  
string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

**Metacharacters**

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	' <code>..ain</code> ' matches sequences of five consecutive characters that end with ' <code>ain</code> '.
[ <code>c<sub>1</sub>c<sub>2</sub>c<sub>3</sub></code> ]	Any character contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[rp.]ain</code> ' matches ' <code>rain</code> ' or ' <code>pain</code> ' or ' <code>.ain</code> '.
[ <code>^c<sub>1</sub>c<sub>2</sub>c<sub>3</sub></code> ]	Any character not contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[^*rp]ain</code> ' matches all four-letter sequences that end in ' <code>ain</code> ', except ' <code>rain</code> ' and ' <code>pain</code> ' and ' <code>*ain</code> '. For example, it matches ' <code>gain</code> ', ' <code>lain</code> ', or ' <code>vain</code> '.
[ <code>c<sub>1</sub>-c<sub>2</sub></code> ]	Any character in the range of <code>c<sub>1</sub></code> through <code>c<sub>2</sub></code>	' <code>[A-G]</code> ' matches a single character in the range of A through G.
<code>\w</code>	Any alphabetic, numeric, or underscore character. For English character sets, <code>\w</code> is equivalent to [ <code>a-zA-Z_0-9</code> ]	' <code>\w*</code> ' identifies a word.

Metacharacter	Description	Example
\W	Any character that is not alphabetic, numeric, or underscore. For English character sets, \W is equivalent to [^a-zA-Z_0-9]	'\W*' identifies a substring that is not a word.
\s	Any white-space character; equivalent to [ \f\n\r\t\v]	'\w*n\s' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [^ \f\n\r\t\v]	'\d\S' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [0-9]	'\d*' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [^0-9]	'\w*\D\>' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

## Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab

Operator	Description
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

### Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
<code>expr*</code>	0 or more times consecutively.	' <code>\w*</code> ' matches a word of any length.
<code>expr?</code>	0 times or 1 time.	' <code>\w*(\..m)?</code> ' matches words that optionally end with the extension <code>.m</code> .
<code>expr+</code>	1 or more times consecutively.	' <code>&lt;img src="\w+\..gif"&gt;</code> ' matches an <code>&lt;img&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{m,n}</code>	At least <code>m</code> times, but no more than <code>n</code> times consecutively. <code>{0,1}</code> is equivalent to <code>?</code> .	' <code>\S{4,8}</code> ' matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least <code>m</code> times consecutively. <code>{0,}</code> and <code>{1,}</code> are equivalent to <code>*</code> and <code>+</code> , respectively.	' <code>&lt;a href="\w{1,}\..html"&gt;</code> ' matches an <code>&lt;a&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly <code>n</code> times consecutively. Equivalent to <code>{n,n}</code> .	' <code>\d{4}</code> ' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. `q` represents any of the quantifiers in the previous table.

# regexprep

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*&gt;</code> ' matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :  ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> '
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*?&gt;</code> ' ends each match at the first occurrence of the closing bracket ( <code>&gt;</code> ):  ' <code>&lt;tr&gt;</code> '    ' <code>&lt;td&gt;</code> '    ' <code>&lt;/td&gt;</code> '
<code>exprq+</code>	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*+&gt;</code> ' does not return any matches, because the closing bracket is captured using <code>.*</code> , and is not rescanned.

## Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.
(?:>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?:>.* )Z' does not match 'AtoZ', although 'A(?:.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1 expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with let or tel.

**Anchors**

Anchors in the expression match the beginning or end of the string or word.

# regexprep

Anchor	Matches the...	Example
<code>^expr</code>	Beginning of the input string.	' <code>^M\w*</code> ' matches a word starting with <code>M</code> at the beginning of the string.
<code>expr\$</code>	End of the input string.	' <code>\w*m\$</code> ' matches words ending with <code>m</code> at the end of the string.
<code>\&lt;expr</code>	Beginning of a word.	' <code>\&lt;n\w*</code> ' matches any words starting with <code>n</code> .
<code>expr\&gt;</code>	End of a word.	' <code>\w*e\&gt;</code> ' matches any words ending with <code>e</code> .

## Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(?=test)</code>	Look ahead for characters that match <code>test</code> .	' <code>\w*(?=ing)</code> ' matches strings that are followed by <code>ing</code> , such as 'Fly' and 'fall' in the input string 'Flying, not falling.'
<code>expr(?!test)</code>	Look ahead for characters that do not match <code>test</code> .	' <code>i(?!ng)</code> ' matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .

Lookaround Assertion	Description	Example
<code>(?&lt;=test)expr</code>	Look behind for characters that match test..	'(?<=re)\w*' matches strings that follow 're', such as 'new', 'use', and 'cycle' in the input string 'renew, reuse, recycle'
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match test.	'(?<!\d)(\d)(?!\d)' matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both test and expr.	'(?=[a-z])[^aeiou]' matches consonants.
<code>(?!test)expr</code>	Match expr and do not match test.	'(?![aeiou])[a-z]' matches consonants.

### Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical OR, and if or if/else conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

# regexprep

Conditional Operator	Description	Example
<code>expr1 expr2</code>	Match expression <code>expr1</code> or expression <code>expr2</code> . If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.	' <code>(let tel)\w+</code> ' matches words in a string that start with <code>let</code> or <code>tel</code> .
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	' <code>(?(?@ispc)[A-Z]:\\)</code> ' matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	' <code>Mr(s?)\..*?(?(1)her his)\w*</code> ' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

## Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
<code>(expr)</code>	Capture in a token the characters that match the enclosed expression.	' <code>Joh?n\s(\w*)</code> ' captures a token that contains the last name of any person with the first name <code>John</code> or <code>Jon</code> .
<code>\N</code>	Match the Nth token.	' <code>&lt;(\w+).*&gt;.*&lt;/\1&gt;</code> ' captures tokens for HTML tags, such

Ordinal Token Operator	Description	Example
		as 'title' from the string '<title>Some text</title>'.
(?(N)expr1 expr2)	If the Nth token is found, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

Named Token Operator	Description	Example
(?<name>expr)	Capture in a named token the characters that match the enclosed expression.	'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(?(tag>\w+).*.*/\k<tag>)' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex>s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

---

**Note** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

---

## Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse expr and include the resulting string in the match expression.  When parsed, expr must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of expr, and one for the complete match.	'^(\d+)((?!\w{\$1}))' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching '5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by cmd, and include the string returned by the command in the match expression.	'(.{2,}).?(?@flip1r(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by cmd, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(?@disp(\$1))\1\w*' matches words that include double letters (such as pp), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
\$& or \$0	Portion of the input string that is currently a match
\$`	Portion of the input string that precedes the current match
\$'	Portion of the input string that follows the current match (use \$' ' to represent the string \$')
\$N	Nth token
\$<name>	Named token
\${cmd}	String returned when MATLAB executes the command, cmd

### Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<\d\w+' includes a comment, and matches words that begin with a number.

### Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
(?-i)	Match letter case (default for regexp and regexprep).
(?i)	Do not match letter case (default for regexpi).
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (:), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

### Data Types

char | cell

**replace - Replacement text**

string | cell array of strings

Replacement text, specified as a string or a cell array of strings, as follows:

- If `replace` is a single string and `expression` is a cell array of strings, then `regexprep` uses the same replacement text for each expression.
- If `replace` is a cell array of `N` strings and `expression` is a single string, then `regexprep` attempts `N` matches and replacements.
- If both `replace` and `expression` are cell arrays of strings, then they must contain the same number of elements. `regexprep` pairs each `replace` element with its matching element in `expression`.

The replacement text can include regular characters, special characters (such as tabs or new lines), or string operators, as shown in the following tables.

Replacement String Operator	Description
<code>\$&amp;</code> or <code>\$0</code>	Portion of the input string that is currently a match
<code>\$`</code>	Portion of the input string that precedes the current match
<code>\$'</code>	Portion of the input string that follows the current match (use <code>\$''</code> to represent the string <code>\$'</code> )
<code>\$N</code>	<code>N</code> th token
<code>\$&lt;name&gt;</code>	Named token
<code>\${cmd}</code>	String returned when MATLAB executes the command, <code>cmd</code>

Operator	Description
<code>\a</code>	Alarm (beep)
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

## Data Types

`char` | `cell`

## option - Search or replacement option

`'once'` | `N` | `'warnings'` | `'ignorecase'` | `'preserveCase'` | `'emptyMatch'` | `'dotexceptnewline'` | `'lineanchors'` | ...

Search or replacement option, specified as a string or an integer value, as shown in the following table.

Options come in sets: one option that corresponds to the default behavior, and one or two options that allow you to override the default. Specify only one option from a set. Options can appear in any order.

Default	Override	Description
<code>'all'</code>	<code>'once'</code>	Match and replace the expression as many times as possible (default), or only once.
	<code>N</code>	Replace only the Nth occurrence of the match, where N is an integer value.

Default	Override	Description
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'matchcase'	'ignorecase'	Match letter case (default), or ignore case while matching and replacing.
	'preserveCase'	Ignore case while matching, but preserve the case of corresponding characters in the original string while replacing.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalSpacing'	'freeSpacing'	Include space characters and comments when matching (default), or ignore them. With freeSpacing, use '\ ' and '\#' to match space and # characters.

**Data Types**

char

**Output Arguments**

**newStr - Updated text**

string | cell array of strings

Updated text, returned as a string or a cell array of strings. The data type of newStr is the same as the data type of str.

**Examples**

**Update a Single String**

Replace words that begin with M, end with y, and have at least one character between them.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
```

```
replace = 'April';  
  
newStr = regexprep(str,expression,replace)  
  
newStr =
```

```
My flowers may bloom in April
```

## **Include Tokens in Replacement Text**

Replace variations of the phrase 'walk up' by capturing the letters that follow 'walk' in a token.

```
str = 'I walk up, they walked up, we are walking up.';  
expression = 'walk(\w*) up';  
replace = 'ascend$1';
```

```
newStr = regexprep(str,expression,replace)  
  
newStr =
```

```
I ascend, they ascended, we are ascending.
```

## **Include Dynamic Expression in Replacement Text**

Replace lowercase letters at the beginning of sentences with their uppercase equivalents using the upper function.

```
str = 'here are two sentences. neither is capitalized.';  
expression = '^(|\.)\s*.';  
replace = '${upper($0)}';
```

```
newStr = regexprep(str,expression,replace)  
  
newStr =
```

```
Here are two sentences. Neither is capitalized.
```

The regular expression matches single characters (.) that follow the beginning of the string (^) or a period (\.) and any whitespace (\s\*).

The `replace` expression calls the upper function for the currently matching character (`$0`).

### Update Multiple Strings

Replace each occurrence of a double letter in a set of strings with the symbols `--`.

```
str = {
    'Whose woods these are I think I know.' ; ...
    'His house is in the village though;' ; ...
    'He will not see me stopping here' ; ...
    'To watch his woods fill up with snow.'};

expression = '(.)\1';
replace = '--';
newStr = regexprep(str,expression,replace)

newStr =

    'Whose w--ds these are I think I know.'
    'His house is in the vi--age though;'
    'He wi-- not s-- me sto--ing here'
    'To watch his w--ds fi-- up with snow.'
```

### Preserve Case in Original String

Ignore letter case in the regular expression when finding matches, but mimic the letter case of the original string when updating.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
replace = 'April';

newStr = regexprep(str,expression,replace,'preserveCase')

newStr =

My flowers april bloom in April
```

## Replace Zero-Length Matches

Insert text at the beginning of a string using the '^' operator, which returns a zero-length match, and the 'emptymatch' keyword.

```
str = 'abc';  
expression = '^';  
replace = '__';
```

```
newStr = regexprep(str,expression,replace,'emptymatch')
```

```
newStr =
```

```
__abc
```

## Concepts

- “Lookahead Assertions in Regular Expressions”
- “Tokens in Regular Expressions”
- “Dynamic Regular Expressions”

**Purpose** Translate string into regular expression

**Syntax** `s2 = regexptranslate(type, s1)`

**Description** `s2 = regexptranslate(type, s1)` translates string `s1` into a regular expression string `s2` that you can then use as input into one of the MATLAB regular expression functions such as `regexp`. The `type` input can be either one of the following strings that define the type of translation to be performed. See “Regular Expressions” in the MATLAB Programming Fundamentals documentation for more information.

Type	Description
'escape'	Translate all special characters (e.g., '\$', '.', '?', '[') in string <code>s1</code> so that they are treated as literal characters when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation inserts an escape character ('\') before each special character in <code>s1</code> . Return the new string in <code>s2</code> .
'wildcard'	Translate all wildcard and '.' characters in string <code>s1</code> so that they are treated as literal wildcards and periods when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation replaces all instances of '*' with '.', all instances of '?' with '.', and all instances of '.' with '\.'. Return the new string in <code>s2</code> .

## Examples

### Example 1 – Using the 'escape' Option

Because `regexp` interprets the sequence '\n' as a newline character, it cannot locate the two consecutive characters '\n' and '\n' in this string:

```
str = 'The sequence \n generates a new line';
pat = '\n';

regexp(str, pat)
ans =
     []
```

# regexptranslate

---

To have `regex` interpret the expression `expr` as the characters ``\`` and ``n``, first translate the expression using `regexptranslate`:

```
pat2 = regexptranslate('escape', pat)
pat2 =
    \\n

regex(str, pat2)
ans =
    14
```

## Example 2 – Using 'escape' In a Replacement String

Replace the word 'walk' with 'ascend' in this string, treating the characters '\$1' as a token designator:

```
str = 'I walk up, they walked up, we are walking up.';
pat = 'walk(\w*) up';

regexprep(str, pat, 'ascend$1')
ans =
    I ascend, they ascended, we are ascending.
```

Make another replacement on the same string, this time treating the '\$1' as literal characters:

```
regexprep(str, pat, regexptranslate('escape', 'ascend$1'))
ans =
    I ascend$1, they ascend$1, we are ascend$1.
```

## Example 3 – Using the 'wildcard' Option

Given the following string of filenames, pick out just the MAT-files. Use `regexptranslate` to interpret the '\*' wildcard as '\w+' instead of as a regular expression quantifier:

```
files = ['test1.mat, myfile.mat, newfile.txt, ' ...
        'jan30.mat, table3.xls'];
regex(str, regexptranslate('wildcard', '*.mat'), 'match')
ans =
```

```
'test1.mat' 'myfile.mat' 'jan30.mat'
```

To see the translation, you can type

```
regexptranslate('wildcard', '*.mat')  
ans =  
    \w+\.mat
```

## How To

- “Regular Expressions”

# registerevent

---

**Purpose** Associate event handler for COM object event at run time

**Syntax** `h.registerevent(eventhandler)`  
`registerevent(h, eventhandler)`

**Description** `h.registerevent(eventhandler)` registers event handler routines with their corresponding events. The `eventhandler` argument can be either a string that specifies the name of the event handler function, or a function handle that maps to that function. Strings used in the `eventhandler` argument are not case sensitive.

`registerevent(h, eventhandler)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Show events in the MATLAB sample control:

```
f = figure ('position', [100 200 200 200]);  
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.events
```

MATLAB displays all events associated with the instance of the control (output is formatted):

```
Click = void Click()  
DbClick = void DbClick()  
MouseDown = void MouseDown(int16 Button, int16 Shift,  
    Variant x, Variant y)  
Event_Args = void Event_Args(int16 typeshort,  
    int32 typelong, double typedouble, string typestring,  
    bool typebool)
```

---

Register all events with the same event handler routine, `sampev`:

```
h.registerevent('sampev');  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'Click'          'sampev'  
    'DblClick'      'sampev'  
    'MouseDown'     'sampev'  
    'Event_Args'    'sampev'
```

---

Register individual events:

```
%Unregister existing events  
h.unregisterallevents;  
%Register specific events  
h.registerevent({'click' 'myclick'; ...  
               'dblclick' 'my2click'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'click'          'myclick'  
    'dblclick'      'my2click'
```

---

Register events using a function handle (@sampev) instead of the function name:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200]);  
registerevent(h, @sampev);
```

[events \(COM\)](#) | [eventlisteners](#) | [unregisterevent](#) | [unregisterallevents](#) | [isevent](#)

## How To

- “Writing Event Handlers”

# rehash

---

**Purpose** Refresh function and file system path caches

**Syntax**

```
rehash  
rehash path  
rehash toolbox  
rehash pathreset  
rehash toolboxreset  
rehash toolboxcache
```

**Description** rehash with no arguments updates the MATLAB list of known files and classes for directories on the search path that are not in *matlabroot*/toolbox. It compares the timestamps for loaded functions against their timestamps on disk. It clears loaded functions if the files on disk are newer. All of this normally happens each time MATLAB displays the Command Window prompt. Use rehash with no arguments only when you run a program file that updates another program file, and the calling file needs to reuse the updated version of the second file before the calling file has finished running.

rehash **path** performs the same updates as rehash, but uses a different technique for detecting the files and directories that require updates. Run rehash path only if you receive a warning during MATLAB startup notifying you that MATLAB could not tell if a directory has changed, and you encounter problems with MATLAB not using the most current versions of your program files.

rehash **toolbox** performs the same updates as rehash path, except it updates the list of known files and classes for *all* directories on the search path, including those in *matlabroot*/toolbox. Run rehash toolbox when you change, add, or remove files in *matlabroot*/toolbox during a session. Typically, you should not make changes to files and directories in *matlabroot*/toolbox.

rehash **pathreset** performs the same updates as rehash **path**, and also ensures the known files and classes list follows precedence rules for shadowed functions.

`rehash toolboxreset` performs the same updates as `rehash toolbox`, and also ensures the known files and classes list follows precedence rules for shadowed functions.

`rehash toolboxcache` performs the same updates as `rehash toolbox`, and also updates the cache file. This is the equivalent of clicking the **Update Toolbox Path Cache** button in the General Preferences dialog box.

## How To

- “Toolbox Path Caching in MATLAB”
- “What Is the MATLAB Search Path?”

# release

---

**Purpose** Release COM interface

**Syntax** `h.release`  
`release(h)`

**Description** `h.release` releases the interface and all resources used by the interface. You must release the handle when you are done with the interface. A released interface is no longer valid. MATLAB generates an error if you try to use an object that represents that interface.

`release(h)` is an alternate syntax.

Releasing the interface does not delete the control itself (see the `delete` function), since other interfaces on that object might still be active.

COM functions are available on Microsoft Windows systems only.

**See Also** `delete (COM)` | `actxcontrol` | `actxserver`

**How To**

- Releasing Interfaces

**Purpose** Equality and sorting of handle objects

**Syntax**

```
TF = eq(H1,H2)
TF = ne(H1,H2)
TF = lt(H1,H2)
TF = le(H1,H2)
TF = gt(H1,H2)
TF = ge(H1,H2)
```

**Description**

```
TF = eq(H1,H2)
TF = ne(H1,H2)
TF = lt(H1,H2)
TF = le(H1,H2)
TF = gt(H1,H2)
TF = ge(H1,H2)
```

For each pair of input arrays (H1 and H2), a logical array of the same size is returned in which each element is an element-wise equality or comparison test result. These methods perform scalar expansion in the same way as the MATLAB built-in functions. See `relationaloperators` for more information.

You can make the following assumptions about the result of a handle comparison:

- The same two handles always compare as equal and the repeated comparison of any two handles always yields the same result in the same MATLAB session.
- Different handles are always not-equal.
- The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.
- If the input arrays belong to different classes (including the case where one input array belongs to a non-handle class such as `double`) then the comparison is always false.

## relationaloperators (handle)

---

- If a comparison is made between a handle object and an object of a dominant class, the method of the dominant class is invoked. You should generally test only like objects because a dominant class might not define one of these methods.
- An error occurs if the input arrays are not the same size and neither is scalar.

Use `isequal` when you want to determine if handle objects with different handles have the same data in all object properties.

### See Also

`handle` | `meta.class`

**Purpose**

Remainder after division

**Syntax**

`R = rem(X,Y)`

**Description**

`R = rem(X,Y)` returns the remainder after division of `X` by `Y`. In general, if `Y` does not equal 0, `R = rem(X,Y)` returns `X - n.*Y`, where `n = fix(X./Y)`. If `Y` is not an integer and the quotient `X./Y` is within roundoff error of an integer, then `n` is that integer. Inputs `X` and `Y` must have the same dimensions unless one of them is a scalar double. If one of the inputs has an integer data type, then the other input must be of the same integer data type or be a scalar double.

The following are true by convention:

- `rem(X,0)` is NaN.
- `rem(X,X)` for `X~=0` is 0.
- `rem(X,Y)` for `X~=Y` and `Y~=0` has the same sign as `X`.

**Input Arguments****X - Dividend**

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

**Y - Divisor**

scalar | vector | matrix | multidimensional array

Divisor, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

## Examples

### Remainder of Two Scalars

Compute the remainder after dividing 5 into 23.

```
X = 23;  
Y = 5;  
R = rem(X,Y)
```

```
R =
```

```
    3
```

### Remainder of a Vector

Create a vector, then use `rem` to find the remainder after dividing a scalar into each element of the vector.

```
X = 1:5;  
Y = 3;  
R = rem(X,Y)
```

```
R =
```

```
    1    2    0    1    2
```

When you specify one or more of the inputs as an array, the `rem` function acts on each array element independently.

### Remainder of Two Arrays

Create two 3-by-3 matrices, then use `rem` to find the remainder after dividing Y into X.

```
X = [1 2 3;4 5 6;7 8 9];  
Y = [9 8 7;6 5 4;3 2 1];  
R = rem(X,Y)
```

```
R =
```

```
    1    2    3
```

```

4     0     2
1     0     0

```

Inputs  $X$  and  $Y$  must have the same dimensions unless one is a scalar double.

### Forced Rounding in rem

If  $Y$  is not an integer and  $X./Y$  is within roundoff error of an integer, then `rem` rounds to that integer for its calculation. The size of the roundoff error is very small.

```

X = 2;
Y = 2 - eps(2)

```

```

Y =
    2.0000

```

It looks like  $Y$  is trivially equal to 2, but in fact there is an infinitesimal difference.

```

2 - Y
ans =
    4.4409e-16

```

This difference is forced to zero by `rem` if it is small enough.

```

R = rem(X,Y)
R =
    0

```

Make the difference a little larger and the forced rounding disappears.

```

Y = 2 - eps(4);

```

# rem

---

```
R = rem(X,Y)
```

```
R =
```

```
8.8818e-16
```

## Difference Between rem and mod

Define X and Y with different signs.

```
X = 5;
```

```
Y = -2;
```

Compute the remainder after division with `rem`, then compute the modulus after division with `mod`.

```
R = rem(X,Y)
```

```
R =
```

```
1
```

```
M = mod(X,Y)
```

```
M =
```

```
-1
```

`rem(X,Y)` and `mod(X,Y)` are equal if X and Y have the same sign, but differ by Y if X and Y have different signs. Notice that `rem` retains the sign of X, while `mod` retains the sign of Y.

**See Also** `mod`

<b>Purpose</b>	Remove key-value pairs from containers.Map object
<b>Syntax</b>	<code>remove(mapObj, keySet)</code>
<b>Description</b>	<code>remove(mapObj, keySet)</code> erases all specified keys, and the values associated with them, from <code>mapObj</code> . Input <code>keySet</code> can be a scalar key or a cell array of keys.
<b>Input Arguments</b>	<b>mapObj</b> Object of class <code>containers.Map</code> .  <b>keySet</b> Scalar value, string, or cell array that specifies keys in <code>mapObj</code> to delete.

## Examples **Remove Key-Value Pairs from a Map**

Create a map and view the keys and the Count property:

```
myKeys = {'a','b','c','d'};  
myValues = [1,2,3,4];  
mapObj = containers.Map(myKeys,myValues);
```

```
mapKeys = keys(mapObj)  
mapCount = mapObj.Count
```

The initial map contains four key-value pairs:

```
mapKeys =  
    'a'    'b'    'c'    'd'  
  
mapCount =  
                4
```

Remove the pairs corresponding to keys b and d:

```
keySet = {'b','d'};
```

# containers.Map.remove

---

```
remove(mapObj, keySet)

mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The modified map contains two key-value pairs:

```
mapKeys =
    'a'    'c'
```

```
mapCount =
                2
```

## See Also

**Purpose**

Remove categories from categorical array

**Syntax**

```
B = removecats(A)
B = removecats(A,oldcats)
```

**Description**

`B = removecats(A)` removes unused categories from the categorical array, `A`. The output categorical array, `B`, has the same size and values as `A`. However, `B` possibly has fewer categories.

`B = removecats(A,oldcats)` removes the categories specified by `oldcats`. The function `removecats` removes categories, but does not remove any elements of the array. Therefore, elements of `B`, whose values correspond to `oldcats`, are undefined.

**Input Arguments****A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**oldcats - Categories to remove**

string | cell array of strings

Categories to remove, specified as a string or cell array of strings. The default is all the unused categories from `A`.

**Examples****Remove All Unused Categories**

Create a categorical array representing political parties of four people.

```
A = categorical({'republican' 'democrat' 'democrat' 'republican'},...
               {'democrat' 'republican' 'independent'})
```

A =

```
      republican      democrat      democrat      republican
```

A is a 1-by-4 categorical array.

# removecats

---

Summarize the categorical array, A.

```
summary(A)
```

```
      democrat      republican      independent
           2                2                0
```

A has three categories. `democrat` appears twice in the array, `republican` appears twice in the array, and `independent` is unused.

Remove the unused category, `independent`.

```
B = removecats(A)
```

```
B =
```

```
      republican      democrat      democrat      republican
```

B has the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
      'democrat'
      'republican'
```

B has fewer categories than A.

## **Remove Categories with Corresponding Values Used in A**

Create a categorical array, A, containing modes of transportation.

```
A = categorical({'plane' 'car'; 'train' 'car'; 'plane' 'car'})
```

```
A =
```

```
      plane      car
```

```
    train    car
    plane    car
```

A is a 3-by-2 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
    'car'
    'plane'
    'train'
```

A has three categories, car, plane, and train.

Remove the category, train.

```
B = removecats(A, 'train')
```

```
B =
```

```
    plane    car
    <undefined>    car
    plane    car
```

The element that was from the category train is now undefined.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
    'car'
    'plane'
```

B has one fewer category than A.

# removecats

---

## Tips

- `~ismember(categories(A),unique(A))` returns logical true (1) for any unused category of A.

`categories` | `summary` | `addcats` | `iscategory` | `mergecats` |  
`renamecats` | `reordercats`

**Purpose** Remove timeseries objects from tscollection object

**Syntax** `tsc = removets(tsc,Name)`

**Description** `tsc = removets(tsc,Name)` removes one or more timeseries objects with the name specified in `Name` from the `tscollection` object `tsc`. `Name` can either be a string or a cell array of strings.

**Examples** The following example shows how to remove a time series from a `tscollection`.

**1** Create two timeseries objects, `ts1` and `ts2`.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');  
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

**2** Create a `tscollection` object `tsc`, which includes `ts1` and `ts2`.

```
tsc=tscollection({ts1 ts2});
```

**3** To view the members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time          1 seconds  
End time            5 seconds
```

```
Member Time Series Objects:
```

# removets

---

```
acceleration
speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of `ts1` and `ts2`, respectively.

- 4 Remove `ts2` from `tsc`.

```
tsc=removets(tsc,'speed');
```

- 5 To view the current members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time      1 seconds
End time        5 seconds
```

```
Member Time Series Objects:
acceleration
```

The remaining member of `tsc` is `acceleration`. The timeseries `speed` has been removed.

## Purpose

Rename categories in categorical array

## Syntax

```
B = renamecats(A,newnames)
B = renamecats(A,oldnames,newnames)
```

## Description

`B = renamecats(A,newnames)` renames all the categories in the categorical array, `A`. Elements of `B` use the new category names.

`B = renamecats(A,oldnames,newnames)` renames only the categories specified by `oldnames`.

## Input Arguments

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### **newnames - New category names for B**

string | cell array of strings

New category names for `B`, specified as a string or a cell array of strings. The new category names must be unique, and must not duplicate any existing names.

### **oldnames - Old category names from A**

string | cell array of strings

Old category names from `A`, specified as a string or a cell array of strings.

## Examples

### **Rename All Categories**

Create a categorical array containing states from New England.

```
A = categorical({'MA'; 'ME'; 'CT'; 'VT'; 'ME'; 'NH'; 'VT'; 'MA'; 'NH'; 'CT'; 'R
```

```
A =
```

```
    MA
```

## renamecats

---

```
ME
CT
VT
ME
NH
VT
MA
NH
CT
RI
```

A is an 11-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'CT'
'MA'
'ME'
'NH'
'RI'
'VT'
```

A has six categories.

Rename the categories to use the full state name instead of the abbreviation.

```
B = renamecats(A,{'Connecticut','Massachusetts',...
  'Maine','New Hampshire','Rhode Island' 'Vermont'})
```

```
B =
```

```
Massachusetts
Maine
```

```
Connecticut
Vermont
Maine
New Hampshire
Vermont
Massachusetts
New Hampshire
Connecticut
Rhode Island
```

Elements of **B** use the new category names.

Display the categories of **B**.

```
categories(B)
```

```
ans =
```

```
'Connecticut'
'Massachusetts'
'Maine'
'New Hampshire'
'Rhode Island'
'Vermont'
```

### **Rename One Category**

Create a categorical array containing colors.

```
A = categorical({'red' 'blue'; 'purple' 'white'; 'green' 'red'})
```

```
A =
```

```
red      blue
purple   white
green    red
```

**A** is a 3-by-2 categorical array.

## renamecats

---

Display the categories of A.

```
categories(A)
```

```
ans =  
  
    'blue'  
    'green'  
    'purple'  
    'red'  
    'white'
```

A has five categories that are listed in alphabetical order.

Change the category name from purple to violet.

```
B = renamecats(A, 'purple', 'violet')
```

```
B =  
  
    red      blue  
    violet   white  
    green    red
```

The element B(2,1) is violet instead of purple.

Display the categories of B.

```
categories(B)
```

```
ans =  
  
    'blue'  
    'green'  
    'violet'  
    'red'  
    'white'
```

`violet` replaces `purple` and the categories are no longer in alphabetical order. Note that the category has not changed its position.

## Tips

- Renaming categories does not change their position in `categories(B)`. Use `reordercats` to change the category ordering. For example, you can use `B = reordercats(B, sort(categories(B)))` to put the categories in alphabetical order.

## See Also

`categories` | `addcats` | `removecats` | `iscategory` | `mergecats`  
| `reordercats`

# reordercats

---

## Purpose

Reorder categories in categorical array

## Syntax

```
B = reordercats(A)
B = reordercats(A,neworder)
```

## Description

`B = reordercats(A)` reorders the categories in the categorical array, `A`, to be in alphanumeric order.

The order of the categories is used by functions such as `summary` and `hist`. Furthermore, if the categorical array is ordinal, the order of the categories defines their mathematical ordering. The first category specified is the smallest and the last category is the largest.

`B = reordercats(A,neworder)` puts the categories in the order specified by `neworder`.

## Input Arguments

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array. If `A` is an ordinal categorical array, a reordering of the categories changes the mathematical meaning. Consequently, the relational operators, such as greater than and less than, might return different results.

### **neworder - New category order for B**

cell array of strings

New category order for `B`, specified as a cell array of strings. `neworder` must be a permutation of `categories(A)`.

## Examples

### **Alphabetize Categories of Nonordinal Categorical Array**

Create two categorical arrays, `X` and `Y`.

```
X = categorical({'frog'; 'cat'; 'cat'; 'ant'; 'frog'})
```

```
Y = categorical({'deer'; 'bear'; 'eagle'; 'deer'})
```

```
X =  
  
    frog  
    cat  
    cat  
    ant  
    frog
```

```
Y =  
  
    deer  
    bear  
    eagle  
    deer
```

X is a 5-by-1 categorical array. The categories of X are the sorted unique values from the array: {'ant'; 'cat'; 'frog'}.

Y is a 4-by-1 categorical array. The categories of Y are the sorted unique values from the array: {'bear'; 'deer'; 'eagle'}.

Concatenate X and Y into a single categorical array, A.

```
A = [X;Y]
```

```
A =  
  
    frog  
    cat  
    cat  
    ant  
    frog  
    deer  
    deer  
    bear  
    eagle  
    deer
```

# reordercats

---

`vertcat` appends the values from `Y` to the values from `X`.

List the categories of the categorical array, `A`.

```
acats = categories(A)
```

```
acats =  
  
    'ant'  
    'cat'  
    'frog'  
    'bear'  
    'deer'  
    'eagle'
```

`vertcat` appends the categories of `Y` to the categories from `X`. The categories of `A` are *not* in alphabetical order.

Reorder the categories of `A` into alphabetical order.

```
B = reordercats(A)
```

```
B =  
  
    frog  
    cat  
    cat  
    ant  
    frog  
    deer  
    bear  
    eagle  
    deer
```

The output categorical array, `B`, has the same contents as the input categorical array, `A`.

List the categories of the categorical array, `B`.

```
bcats = categories(B)
```

```
bcats =  
  
    'ant'  
    'bear'  
    'cat'  
    'deer'  
    'eagle'  
    'frog'
```

The categories of B are in alphabetical order.

### **Reorder Categories in Nonordinal Categorical Array**

Create a categorical array containing the color of various items.

```
A = categorical({'red'; 'green'; 'blue'; 'red'; 'green'; 'red'; 'blue'; 'blue'})
```

```
A =  
  
    red  
    green  
    blue  
    red  
    green  
    red  
    blue  
    blue
```

A is an 8-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =  
  
    'blue'
```

# reordercats

---

```
'green'  
'red'
```

The categories of A are in alphabetical order and have no mathematical meaning.

Reorder the categories to match the order commonly used for colors.

```
B = reordercats(A,{'red','green','blue'})
```

```
B =
```

```
red  
green  
blue  
red  
green  
red  
blue  
blue
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'red'  
'green'  
'blue'
```

B is not ordinal and the order of the categories has no mathematical meaning. Although the categories appear in the order of the color spectrum, relational operations, such as greater than and less than, have no meaning.

## Reorder Categories in Ordinal Categorical Array

Create an ordinal categorical array, `A`, containing modes of transportation. Order the categories based on the average price of travel.

```
A = categorical({'plane'; 'car'; 'train'; 'car'; 'plane'; 'car'},...  
              {'car', 'train', 'plane'}, 'Ordinal', true)
```

```
A =
```

```
    plane  
     car  
    train  
     car  
    plane  
     car
```

`A` is a 6-by-1 ordinal categorical array.

Display the categories of `A`.

```
categories(A)
```

```
ans =
```

```
    'car'  
    'train'  
    'plane'
```

Since `A` is ordinal, `car < train < plane`.

Reorder the categories to reflect a decrease in the cost of train travel.

```
B = reordercats(A, {'train', 'car', 'plane'})
```

```
B =
```

```
    plane
```

# reordercats

---

```
car
train
car
plane
car
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
      'train'
      'car'
      'plane'
```

The mathematical ordering of the categories is now `train < car < plane`. The results from relational operations, `min`, and `max` reflect the new category ordering.

## Tips

- To convert the categorical array, B, to an ordinal categorical array, use `B = categorical(B, 'Ordinal', true)`. Furthermore, you can specify the order of the categories with `B = categorical(B, valueset, 'Ordinal', true)` where the order of the values in `valueset` defines the category order.

## See Also

```
categories | addcats | removecats | iscategory | mergecats
| renamecats
```

**Purpose** Rename file on FTP server

**Syntax** `rename(ftpobj,oldname,newname)`

**Description** `rename(ftpobj,oldname,newname)` changes the name of the file `oldname` to `newname` in the current folder on an FTP server.

**Input Arguments**

**ftpobj**

FTP object created by `ftp`.

**oldname**

String enclosed in single quotation marks that specifies the original name of the file.

**newname**

String enclosed in single quotation marks that specifies a new name for the file.

**Examples**

Suppose that hypothetical FTP server `ftp.testsite.com` contains a file named `testfile.m`. Rename the file to `final.m`:

```
test = ftp('ftp.testsite.com');
rename(test, 'testfile.m', 'final.m');
close(test);
```

**See Also**

`delete` | `dir` | `ftp` | `mget` | `mput`

# repmat

---

## Purpose

Replicate and tile array

## Syntax

```
B = repmat(A,n)
B = repmat(A,sz1,sz2,...,szN)
B = repmat(A,sz)
```

## Description

`B = repmat(A,n)` returns an  $n$ -by- $n$  tiling of `A`. The size of `B` is `size(A) * n`

`B = repmat(A,sz1,sz2,...,szN)` specifies a list of scalars, `sz1,sz2,...,szN`, to describe an N-D tiling of `A`. The size of `B` is `[size(A,1)*sz1, size(A,2)*sz2,...,size(A,n)*szN]`. For example, `repmat([1 2; 3 4],2,3)` returns a 4-by-6 matrix.

`B = repmat(A,sz)` specifies a row vector, `sz`, instead of a list of scalars, to describe the tiling of `A`. This syntax returns the same output as the previous syntax. For example, `repmat([1 2; 3 4],[2 3])` returns the same result as `repmat([1 2; 3 4],2,3)`.

## Input Arguments

### A - Input array

scalar | vector | array | cell array | table | structure | object

Input array, specified as a scalar, vector, array, cell array, table, structure, or object.

**Example:** 1

**Example:** `[1 2 3]`

**Example:** `[1 2; 3 4]`

**Example:** `{'foo',[20 30 40]}`

**Example:** `table(rand(5,1),rand(5,1))`

**Example:** `struct('Age',25,'Weight',110)`

### n - Uniform tiling factor

scalar

Uniform tiling factor, specified as a scalar value. The `n` argument creates an `n`-by-`n` tiling of `A`. If `n` is 0 or negative, the result is an empty array.

**Example:** 3

### **sz1, sz2, ..., szN - Tiling factors for each dimension of A**

two or more scalars

Tiling factors for each dimension of `A`, specified as two or more scalar values. If any tiling factor is 0 or negative, the result is an empty array.

**Example:** 2, 3

**Example:** 2, 3, 4, 2

### **sz - Tiling vector**

row vector

Tiling vector, specified as a row vector. If any value in `sz` is 0 or negative, the result is an empty array.

**Example:** [2 3]

**Example:** [2 3 4 2]

## Tips

- You can use `bsxfun` to tile arrays and perform a binary operation in a single pass. In some cases, `bsxfun` provides a simpler and more memory efficient solution. For example, to add the vectors, `x=1:5` and `y=(1:10)'` to produce a 10-by-5 array, use `bsxfun(@plus,x,y)` instead of `repmat(x,10,1) + repmat(y,1,5)`.
- You can use other functions to get the same result as `repmat` when `A` is a scalar of a certain type.

repmat Syntax	Equivalent Alternative
<code>repmat(NaN,m,n)</code>	<code>NaN(m,n)</code>
<code>repmat(single(inf),m,n)</code>	<code>inf(m,n,'single')</code>
<code>repmat(int8(0),m,n)</code>	<code>zeros(m,n,'int8')</code>

# repmat

repmat Syntax	Equivalent Alternative
<code>repmat(uint32(1),m,n)</code>	<code>ones(m,n,'uint32')</code>
<code>repmat(eps,m,n)</code>	<code>eps(ones(m,n))</code>

## Examples

### Replicate and Tile a Matrix

Create a diagonal matrix.

```
A = diag([100 200 300])
```

A =

```
100    0    0
   0   200    0
   0    0   300
```

Create a 2-by-2 tiling of A.

```
B = repmat(A,2)
```

B =

```
100    0    0   100    0    0
   0   200    0    0   200    0
   0    0   300    0    0   300
100    0    0   100    0    0
   0   200    0    0   200    0
   0    0   300    0    0   300
```

### Replicate and Tile an N-D Array

Create a 2-by-2-by-2 array.

```
A = zeros(2,2,2);
A(:,:,1) = diag([10 20]);
A(:,:,2) = diag([55 99]);
A
```

A(:, :, 1) =

10	0
0	20

A(:, :, 2) =

55	0
0	99

Create a 3-by-3 tiling of A.

B = repmat(A,3)

B(:, :, 1) =

10	0	10	0	10	0
0	20	0	20	0	20
10	0	10	0	10	0
0	20	0	20	0	20
10	0	10	0	10	0
0	20	0	20	0	20

B(:, :, 2) =

55	0	55	0	55	0
0	99	0	99	0	99
55	0	55	0	55	0
0	99	0	99	0	99
55	0	55	0	55	0
0	99	0	99	0	99

### Vertical Stack of Row Vectors

Create a row vector.

# repmat

---

```
A = 1:4
```

```
A =
```

```
    1    2    3    4
```

Create a vertical stack of four copies of A.

```
B = repmat(A,4,1)
```

```
B =
```

```
    1    2    3    4
    1    2    3    4
    1    2    3    4
    1    2    3    4
```

B contains 4 copies of A in the first dimension and 1 copy in the second dimension. This result is equivalent to `B = repmat(A,[4 1])`.

## Horizontal Stack of Column Vectors

Create a column vector.

```
A = (1:3)'
```

```
A =
```

```
    1
    2
    3
```

Create a horizontal stack of four copies of A.

```
B = repmat(A,1,4)
```

```
B =
```

```
    1    1    1    1
```

```

     2     2     2     2
     3     3     3     3

```

B contains 1 copy of A in the first dimension and 4 copies in the second dimension. This result is equivalent to `B = repmat(A,[1 4])`.

### Replicate and Tile a Complex Scalar Value

Define a complex scalar value.

```
A = 5+1i;
```

Create a 3-by-2 tiling of A.

```
B = repmat(A,[3 2])
```

```
B =
```

```

5.0000 + 1.0000i  5.0000 + 1.0000i
5.0000 + 1.0000i  5.0000 + 1.0000i
5.0000 + 1.0000i  5.0000 + 1.0000i

```

B contains 3 copies of A in the first dimension and 2 copies in the second dimension. This result is equivalent to `B = repmat(A,3,2)`.

### Replicate and Tile a Cell Array

Create a cell array containing a string and numeric values.

```
A = {'Values'; 10; 105}
```

```
A =
```

```

'Values'
 [ 10]
 [105]

```

Create a 3-by-2 tiling of A.

```
B = repmat(A,[3 2])
```

# repmat

---

```
B =  
  
    'Values'    'Values'  
    [    10]    [    10]  
    [   105]    [   105]  
    'Values'    'Values'  
    [    10]    [    10]  
    [   105]    [   105]  
    'Values'    'Values'  
    [    10]    [    10]  
    [   105]    [   105]
```

B contains 3 copies of A in the first dimension and 2 copies in the second dimension. This result is equivalent to `B = repmat(A,3,2)`.

**Purpose** Select or interpolate data in `tscollection` using new time vector

**Syntax**

```
tsc = resample(tsc,Time)
tsc = resample(tsc,Time,interp_method)
tsc = resample(tsc,Time,interp_method,code)
```

**Description**

`tsc = resample(tsc,Time)` resamples the `tscollection` object `tsc` on the new `Time` vector. When `tsc` uses date strings and `Time` is numeric, `Time` is treated as numerical specified relative to the `tsc.TimeInfo.StartDate` property and in the same units that `tsc` uses. The `resample` method uses the default interpolation method for each time series member.

`tsc = resample(tsc,Time,interp_method)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. Valid interpolation methods include 'linear' and 'zoh' (zero-order hold).

`tsc = resample(tsc,Time,interp_method,code)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. The integer `code` is a user-defined quality code for resampling, applied to all samples.

**Examples** The following example shows how to resample a `tscollection` that consists of two `timeseries` members.

**1** Create two `timeseries` objects.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

**2** Create a `tscollection` `tsc`.

```
tsc=tscollection({ts1 ts2});
```

The time vector of the collection `tsc` is `[1:5]`, which is the same as for `ts1` and `ts2` (individually).

## resample (tscollection)

---

- 3** Get the interpolation method for acceleration by typing

```
tsc.acceleration
```

MATLAB responds with

```
Time Series Object: acceleration
```

```
Time vector characteristics
```

```
Length          5
Start time      1 seconds
End time        5 seconds
```

```
Data characteristics
```

```
Interpolation method linear
Size                [1 1 5]
Data type            double
```

- 4** Set the interpolation method for speed to zero-order hold by typing

```
setinterpmethod(tsc.speed, 'zoh')
```

MATLAB responds with

```
Time Series Object: acceleration
```

```
Time vector characteristics
```

```
Length          5
Start time      1 seconds
End time        5 seconds
```

Data characteristics

Interpolation method	zoh
Size	[1 1 5]
Data type	double

- 5 Resample the time-series collection `tsc` by individually resampling each time-series member of the collection and using its interpolation method.

```
res_tsc=resample(tsc,[1 1.5 3.5 4.5 4.9])
```

## See Also

`getinterpmethod` | `setinterpmethod` | `tscollection`

# reset

---

**Purpose** Reset graphics object properties to their defaults

**Syntax** `reset(h)`

**Description** `reset(h)` resets all properties on the object identified by `h` to their default values. Properties that do not have default values are not affected.

To obtain the default value of a property defined on the root level, use this statement.

```
get(0, 'DefaultFigureColor')
```

If `h` is a figure, the MATLAB software does not reset `Position`, `Units`, `WindowStyle`, or `PaperUnits`. If `h` is an axes, MATLAB does not reset `Position` and `Units`.

**Examples** `reset(gca)` resets the properties of the current axes.

`reset(gcf)` resets the properties of the current figure.

**See Also** `cla` | `clf` | `gca` | `gcf` | `hold`

**Purpose** Reset random number stream

**Class** RandStream

**Syntax** reset(s)  
reset(s,seed)

**Description** reset(s) resets the generator for the random stream, s, to the internal state corresponding to its seed. This is similar to clearing s and recreating it using RandStream(Type,...), except that reset does not set the stream's NormalTransform, Antithetic, and FullPrecision properties to their original values.

reset(s,seed) resets the generator for the random stream, s, to the internal state corresponding to seed (the seed value), and it updates the seed property of s. The value of seed must be an integer between 0 and  $2^{32} - 1$ . Resetting a stream's seed can invalidate independence with other streams.

---

**Note** Resetting a stream should be used primarily for reproducing results.

---

## Examples

### Example 1

Reset a random number stream to its initial state. This does not create a random number stream, it simply resets the stream:

```
stream = RandStream('twister','Seed',0)
```

```
stream =
```

```
mt19937ar random stream  
      Seed: 0  
      NormalTransform: Ziggurat
```

## reset (RandStream)

---

```
reset(stream);  
stream.Seed
```

```
ans =
```

```
0
```

### Example 2

Reset a random number stream using a specific seed:

```
stream = RandStream('twister','Seed',0)
```

```
stream =
```

```
mt19937ar random stream  
      Seed: 0  
NormalTransform: Ziggurat
```

```
reset(stream,1);  
stream.Seed
```

```
ans =
```

```
1
```

## Purpose

Reshape array

## Syntax

```
B = reshape(A,m,n)
B = reshape(A,m,n,p,...)
B = reshape(A,[m n p ...])
B = reshape(A,...,[],...)
B = reshape(A,siz)
```

## Description

`B = reshape(A,m,n)` returns the  $m$ -by- $n$  matrix `B` whose elements are taken column-wise from `A`. An error results if `A` does not have  $m*n$  elements.

`B = reshape(A,m,n,p,...)` or `B = reshape(A,[m n p ...])` returns an  $n$ -dimensional array with the same elements as `A` but reshaped to have the size  $m$ -by- $n$ -by- $p$ -by-... The product of the specified dimensions,  $m*n*p*...$ , must be the same as `numel(A)`.

`B = reshape(A,...,[],...)` calculates the length of the dimension represented by the placeholder `[]`, such that the product of the dimensions equals `numel(A)`. The value of `numel(A)` must be evenly divisible by the product of the specified dimensions. You can use only one occurrence of `[]`.

`B = reshape(A,siz)` returns an  $n$ -dimensional array with the same elements as `A`, but reshaped to `siz`, a vector representing the dimensions of the reshaped array. The quantity `prod(siz)` must be the same as `numel(A)`.

## Examples

Reshape a 3-by-4 matrix into a 2-by-6 matrix.

```
A =
     1     4     7    10
     2     5     8    11
     3     6     9    12
```

```
B = reshape(A,2,6)
```

```
B =
```

# reshape

---

```
     1     3     5     7     9    11
     2     4     6     8    10    12
B = reshape(A,2,[])
```

```
B =
     1     3     5     7     9    11
     2     4     6     8    10    12
```

**Purpose** Convert between partial fraction expansion and polynomial coefficients

**Syntax**  
 $[r,p,k] = \text{residue}(b,a)$   
 $[b,a] = \text{residue}(r,p,k)$

**Description** The residue function converts a quotient of polynomials to pole-residue representation, and back again.

$[r,p,k] = \text{residue}(b,a)$  finds the residues, poles, and direct term of a partial fraction expansion of the ratio of two polynomials,  $b(s)$  and  $a(s)$ , of the form

$$\frac{b(s)}{a(s)} = \frac{b_1 s^m + b_2 s^{m-1} + b_3 s^{m-2} + \dots + b_{m+1}}{a_1 s^n + a_2 s^{n-1} + a_3 s^{n-2} + \dots + a_{n+1}}$$

where  $b_j$  and  $a_j$  are the  $j$ th elements of the input vectors  $b$  and  $a$ .

$[b,a] = \text{residue}(r,p,k)$  converts the partial fraction expansion back to the polynomials with coefficients in  $b$  and  $a$ .

**Definitions** If there are no multiple roots, then

$$\frac{b(s)}{a(s)} = \frac{r_1}{s-p_1} + \frac{r_2}{s-p_2} + \dots + \frac{r_n}{s-p_n} + k(s)$$

The number of poles  $n$  is

$$n = \text{length}(a) - 1 = \text{length}(r) = \text{length}(p)$$

The direct term coefficient vector is empty if  $\text{length}(b) < \text{length}(a)$ ; otherwise

$$\text{length}(k) = \text{length}(b) - \text{length}(a) + 1$$

If  $p(j) = \dots = p(j+m-1)$  is a pole of multiplicity  $m$ , then the expansion includes terms of the form

# residue

---

$$\frac{r_j}{s-p_j} + \frac{r_{j+1}}{(s-p_j)^2} + \dots + \frac{r_{j+m-1}}{(s-p_j)^m}$$

## Arguments

b, a	Vectors that specify the coefficients of the polynomials in descending powers of $s$
r	Column vector of residues
p	Column vector of poles
k	Row vector of direct terms

## Algorithms

It first obtains the poles with `roots`. Next, if the fraction is nonproper, the direct term `k` is found using `deconv`, which performs polynomial long division. Finally, the residues are determined by evaluating the polynomial with individual roots removed. For repeated roots, `resid2` computes the residues at the repeated root locations.

## Limitations

Numerically, the partial fraction expansion of a ratio of polynomials represents an ill-posed problem. If the denominator polynomial,  $a(s)$ , is near a polynomial with multiple roots, then small changes in the data, including roundoff errors, can make arbitrarily large changes in the resulting poles and residues. Problem formulations making use of state-space or zero-pole representations are preferable.

## Examples

If the ratio of two polynomials is expressed as

$$\frac{b(s)}{a(s)} = \frac{5s^3 + 3s^2 - 2s + 7}{-4s^3 + 8s + 3}$$

then

$$\begin{aligned} \mathbf{b} &= [ 5 \ 3 \ -2 \ 7 ] \\ \mathbf{a} &= [-4 \ 0 \ 8 \ 3 ] \end{aligned}$$

and you can calculate the partial fraction expansion as

```
[r, p, k] = residue(b,a)
```

```
r =
  -1.4167
  -0.6653
   1.3320
```

```
p =
   1.5737
  -1.1644
  -0.4093
```

```
k =
  -1.2500
```

Now, convert the partial fraction expansion back to polynomial coefficients.

```
[b,a] = residue(r,p,k)
```

```
b =
  -1.2500   -0.7500   0.5000  -1.7500
```

```
a =
   1.0000   -0.0000  -2.0000  -0.7500
```

The result can be expressed as

$$\frac{b(s)}{a(s)} = \frac{-1.25s^3 - 0.75s^2 + 0.50s - 1.75}{s^3 - 2.00s - 0.75}.$$

Note that the result is normalized for the leading coefficient in the denominator.

# rethrow

---

**Purpose** Reissue error

---

**Note** As of version 7.5, MATLAB supports error handling that is based on the `MException` class. Calling `rethrow` with a structure argument, as described on this page, is now replaced by calling `rethrow` with an `MException` object, as described on the reference page for `rethrow(MException)`. `rethrow` called with a structure input will be removed in a future version.

---

**Syntax** `rethrow(errorStruct)`

**Description** `rethrow(errorStruct)` reissues the error specified by `errorStruct`. The currently running function terminates and control returns to the keyboard (or to any enclosing `catch` block). The `errorStruct` argument must be a MATLAB structure containing at least the `message` and `identifier` fields:

Fieldname	Description
<code>message</code>	Text of the error message
<code>identifier</code>	Message identifier of the error message
<code>stack</code>	Information about the error from the program stack

See "Message Identifiers" in the MATLAB documentation for more information on the syntax and usage of message identifiers.

**Tips** The `errorStruct` input can contain the field `stack`, identical in format to the output of the `dbstack` command. If the `stack` field is present, the stack of the rethrown error will be set to that value. Otherwise, the stack will be set to the line at which the `rethrow` occurs.

## Examples

rethrow is usually used in conjunction with try-catch statements to reissue an error from a catch block after performing catch-related operations. For example,

```
try
  do_something
catch
  do_cleanup
  rethrow(previous_error)
end
```

## See Also

rethrow(MException) | throw(MException) |  
throwAsCaller(MException) | try | catch | error | assert | dbstop

# rethrow (MException)

---

**Purpose** Reissue existing exception

**Syntax** `rethrow(exception)`

**Description** `rethrow(exception)` forces an exception (i.e., error report) to be reissued by MATLAB after the error reporting process has been temporarily suspended to diagnose or remedy the problem. MATLAB typically responds to errors by terminating the currently running program. Errors occurring within a try block, however, bypass this mechanism and transfer control of the program to error handling code in the catch block instead. This enables you to write your own error handling procedures for parts of your program that require them.

The *exception* input is a scalar object of the MException class that contains information about the cause and location of the error.

The code segment below shows the format of a typical try/catch statement.

<code>try</code>	<code>try block</code>
<code>  program-code</code>	<code> </code>
<code>  program-code</code>	<code> </code>
<code>  :</code>	<code>∨</code>
<code>catch exception</code>	<code>catch block</code>
<code>  error-handling code</code>	<code> </code>
<code>  :</code>	<code> </code>
<code>  rethrow(exception)</code>	<code>∨</code>
<code>end</code>	

An error detected within the try block causes MATLAB to enter the corresponding catch block. The error record constructed by MATLAB in the process of reporting this error passes to the catch command in the statement

```
catch exception
```

Error handling code within the catch block uses the information in the error record to address the problem in some predefined manner. The

catch block shown here ends with a `rethrow` statement which throws the exception returned in the catch statement, and then terminates the function:

```
rethrow(exception)
```

The most significant difference between `rethrow` and other MATLAB functions that throw exceptions is in how `rethrow` handles a piece of the exception record called the *stack*. The stack keeps a record of where the error occurred and what functions were called in the process. It is a struct array composed of the following fields, where each element of the array represents an exception:

Fields of the Exception Stack	Description
<code>line</code>	Line number from which the exception was thrown.
<code>name</code>	Name of the function being executed at the time.
<code>file</code>	Name of the file containing that function.

Functions such as `error`, `assert`, or `throw`, create the stack with the location from which they were executed. Calling `rethrow`, however, preserves information from the original exception. In doing so, `rethrow` enables you to retrace the path taken to the source of the error.

## Tips

There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining techniques to throw an existing exception.

- Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.

## rethrow (MException)

---

- Reissue the original exception by throwing the initial error record unmodified. Use the `MException rethrow` method to do this.
- Collect additional information on the cause of the error, store it in a new or modified error record, and issue a new exception based on that record. Use the `MException addCause` and `throw` methods to do this.
- Make it appear that the error originated in the caller of the currently running function. Use the `MException throwAsCaller` method to do this.

`rethrow` can only issue a previously caught exception. Calling `rethrow` on an exception that was not previously thrown is an error.

### Examples

This example shows the difference between using `throw` and `rethrow` at the end of a catch block. The `combineArrays` function vertically concatenates arrays A and B. When the two arrays have rows of unequal length, the function throws an error.

The first time you run the function, comment out the `rethrow` command at the end of the catch block so that the function calls `throw` instead:

```
function C = combineArrays(A, B)
try
    catAlongDim1(A, B);                % Line 3
catch exception
    throw(exception)                  % Line 5
    % rethrow(exception)              % Line 6
end

function catAlongDim1(V1, V2)
    C = cat(1, V1, V2);                % Line 10
```

When MATLAB throws the exception, it reports an error on line 5 which is the line that calls `throw`. In some cases, that might be what you want but, in this case, it does not show the true source of the error.

```
A = 4:3:19;    B = 3:4:19;
combineArrays(A, B)
```

```
Error using combineArrays (line 5)
CAT arguments dimensions are not consistent.
```

Make the following changes to `combineArrays.m` so that you use `rethrow` instead:

```
% throw(exception)           % Line 5
rethrow(exception)           % Line 6
```

Run the function again. This time, line 10 is the first line reported which is where the MATLAB concatenation function `cat` was called and the exception originated. The next error reported is on line 3 which is where the call to `catAlongDim1` was called:

```
combineArrays(A, B)
```

```
Error using cat
CAT arguments dimensions are not consistent.
```

```
Error in combineArrays>catAlongDim1 (line 10)
    C = cat(1, V1, V2);           % Line 10
Error in combineArrays (line 3)
    catAlongDim1(A, B);           % Line 3
```

# return

---

**Purpose** Return to invoking function

**Syntax** return

**Description** return causes a normal return to the invoking function or to the keyboard. It also terminates keyboard mode.

**Examples** This determinant function uses return to handle the special case of an empty matrix:

```
function d = det(A)
%DET det(A) is the determinant of A.
if isempty(A)
    d = 1;
    return
else
    ...
end
```

**See Also** break | continue | disp | end | error | for | if | keyboard | switch | while

**Purpose** Write modified metadata to existing IFD

**Syntax** `tiffobj.rewriteDirectory()`

**Description** `tiffobj.rewriteDirectory()` writes modified metadata (tag) data to an existing directory. Use this tag when you want to change the value of a tag in an existing image file directory.

**Examples**      **Modify Value of Tag**

Write a sample TIFF file, `mytif.tif`. Create a TIFF object associated with this file.

```
imdata = peaks(256);  
imwrite(imdata, 'mytif.tif');  
t = Tiff('mytif.tif', 'r+');
```

Modify the value of a tag.

```
t.setTag('Software', 'MATLAB');  
t.rewriteDirectory();  
t.close();
```

**References**

This method corresponds to the `TIFFRewriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# rgb2hsv

---

**Purpose** Convert RGB colormap to HSV colormap

**Syntax**  
`cmap = rgb2hsv(M)`  
`hsv_image = rgb2hsv(rgb_image)`

**Description** `cmap = rgb2hsv(M)` converts an RGB colormap `M` to an HSV colormap `cmap`. Both colormaps are  $m$ -by-3 matrices. The elements of both colormaps are in the range 0 to 1.

The columns of the input matrix `M` represent intensities of red, green, and blue, respectively. The columns of the output matrix `cmap` represent hue, saturation, and value, respectively.

`hsv_image = rgb2hsv(rgb_image)` converts the RGB image to the equivalent HSV image. `RGB` is an  $m$ -by- $n$ -by-3 image array whose three planes contain the red, green, and blue components for the image. `HSV` is returned as an  $m$ -by- $n$ -by-3 image array whose three planes contain the hue, saturation, and value components for the image.

**See Also** `brighten` | `colormap` | `hsv2rgb` | `rgbplot`

**Purpose** Convert RGB image to indexed image

**Syntax**

```
[X,map] = rgb2ind( RGB,n)
X = rgb2ind( RGB, map)
[X,map] = rgb2ind( RGB, tol)
[ ___ ] = rgb2ind( ___,dither_option)
```

**Description**

`[X,map] = rgb2ind( RGB,n)` converts the RGB image to an indexed image `X` using minimum variance quantization and dithering. `map` contains at most `n` colors. `n` must be less than or equal to 65,536.

`X = rgb2ind( RGB, map)` converts the RGB image to an indexed image `X` with colormap `map` using the inverse colormap algorithm and dithering. `size(map,1)` must be less than or equal to 65,536.

`[X,map] = rgb2ind( RGB, tol)` converts the RGB image to an indexed image `X` using uniform quantization and dithering. `map` contains at most  $(\text{floor}(1/\text{tol})+1)^3$  colors. `tol` must be between 0.0 and 1.0.

`[ ___ ] = rgb2ind( ___,dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

'dither' (default)	Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution
'nodither'	Maps each color in the original image to the closest color in the new map. No dithering is performed.

**Note** The values in the resultant image `X` are indexes into the colormap `map` and should not be used in mathematical processing, such as filtering operations.

**Class Support**

The input image can be of class `uint8`, `uint16`, `single`, or `double`. If the length of `map` is less than or equal to 256, the output image is of class `uint8`. Otherwise, the output image is of class `uint16`.

## Tips

- If you specify `tol`, `rgb2ind` uses uniform quantization to convert the image. This method involves cutting the RGB color cube into smaller cubes of length `tol`.
- If you specify `n`, `rgb2ind` uses minimum variance quantization. This method involves cutting the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number you specify, the output colormap is also smaller.
- If you specify `map`, `rgb2ind` uses colormap mapping, which involves finding the colors in `map` that best match the colors in the RGB image.

## Algorithms

- **Uniform Quantization** — Uniform quantization cuts the RGB color cube into smaller cubes of length `tol`. For example, if you specify a `tol` of 0.1, the edges of the cubes are one-tenth the length of the RGB cube. The total number of small cubes is:

$$n = (\text{floor}(1/\text{tol})+1)^3$$

Each cube represents a single color in the output image. Therefore, the maximum length of the colormap is `n`. `rgb2ind` removes any colors that don't appear in the input image, so the actual colormap can be much smaller than `n`.

- **Minimum Variance Quantization** — Minimum variance quantization cuts the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number specified, the output colormap is also smaller.
- **Inverse Colormap** — The inverse colormap algorithm quantizes the specified colormap into 32 distinct levels per color component. Then, for each pixel in the input image, the closest color in the quantized colormap is found.

## Examples

Read and display a truecolor `uint8` PNG image of the MathWorks logo. Zoom in to see color variation better.

```
imfile = fullfile(matlabroot,...  
                  'toolbox','matlab','demos','html','logodemo_01.png');  
RGB = imread(imfile,'PNG');  
figure('Name','RGB Truecolor Image')  
imagesc(RGB)  
axis image  
zoom(4)
```

```
% Convert RGB to an indexed image with 32 colors  
[IND,map] = rgb2ind(RGB,32);
```

# rgb2ind

---

```
figure('Name','Indexed image with 32 Colors')
imagesc(IND)
colormap(map)
axis image
zoom(4)
```

# rgbplot

---

## Purpose

Plot colormap

## Syntax

```
rgbplot(cmap)
```

## Description

`rgbplot(cmap)` plots the three columns of `cmap`, where `cmap` is an  $m$ -by-3 colormap matrix. `rgbplot` draws the first column in red, the second in green, and the third in blue.

## Examples

Plot the RGB values of the copper colormap.

```
rgbplot(copper)
```

**See Also** `colormap`

# ribbon

---

## Purpose

Ribbon plot

## Syntax

```
ribbon(Y)
ribbon(X,Y)
ribbon(X,Y,width)
ribbon(axes_handle,...)
h = ribbon(...)
```

## Description

`ribbon(Y)` plots the columns of `Y` as three-dimensional ribbons of uniform width using `X = 1:size(Y,1)`. Ribbons advance along the  $x$ -axis centered on tick marks at unit intervals, three-quarters of a unit in width. Ribbon maps values in `X` to colors in `colormap` linearly. To change ribbon colors in the graph, change the `colormap`.

`ribbon(X,Y)` plots three dimensional ribbons for data in `Y`, centered at locations specified in `X`. `X` and `Y` are vectors or matrices of the same size. Additionally, `X` can be a row or a column vector, and `Y` a matrix with `length(X)` rows. When `Y` is a matrix, `ribbon` plots each column in `Y` as a ribbon at the corresponding `X` location.

`ribbon(X,Y,width)` specifies the width of the ribbons. The default is 0.75. If `width = 1`, the ribbons touch, leaving no space between them when viewed down the  $z$ -axis. If `width > 1`, ribbons overlap and can intersect.

`ribbon(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ribbon(...)` returns a vector of handles to surface graphics objects. `ribbon` returns one handle per strip.

## Examples

Create a ribbon plot of the peaks function.

```
[x,y] = meshgrid(-3:.5:3,-3:.1:3);
z = peaks(x,y);
```

```
ribbon(y,z)
xlabel('X')
ylabel('Y')
zlabel('Z')
colormap hsv
```

# rmappdata

---

**Purpose** Remove application-defined data

**Syntax** `rmappdata(h,name)`

**Description** `rmappdata(h,name)` removes the application-defined data name from the object specified by handle `h`.

**Tips** Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

**See Also** `getappdata` | `isappdata` | `setappdata`

**Purpose**

Remove folder

**Syntax**

```
rmdir(folderName)
rmdir(folderName,'s')
[status, message, messageid] = rmdir(folderName,'s')
```

**Description**

`rmdir(folderName)` removes the folder `folderName` from the current folder if `folderName` is empty. If `folderName` is not in the current folder, then specify the relative path or the full path for `folderName`.

`rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder. With the 's' option, `rmdir` attempts to remove all subfolders and files in `folderName` regardless of their write permissions.

`[status, message, messageid] = rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder, returning the status, a message, and the MATLAB message ID.

**Tips**

- If you specify the 's' flag or include a wildcard in the folder name, MATLAB produces an error if it is unable to remove all folders. The error message lists the folder and files that MATLAB could not remove.

**Input Arguments****folderName**

String specifying the absolute or relative path name of the folder you want to remove.

**Default:** None

**'s'**

Literal string that directs `rmdir` to remove all subfolders and files in the specified folder, regardless of their write permissions. The result for read-only files follows the practices of the operating system.

# rmdir

---

**Default:** `rmdir` does not remove subfolders and files in the specified folder.

## Output Arguments

### **status**

Logical scalar indicating the outcome of the `rmdir` operation. The status value is 1 if the operation was successful and 0 if it returned an error.

### **message**

String containing the warning or error message text if the operation is unsuccessful. An empty string, if the operation is successful.

### **messageid**

String containing the warning or error message ID, if the operation is unsuccessful. MATLAB returns an empty string if the operation is successful.

## Examples

These examples remove an empty folder, `myfiles`, assuming it is in the current folder:

```
% Remove myfiles from the current folder:
```

```
rmdir('myfiles')
```

```
% Use the relative path to remove myfiles. Assuming  
% the current folder is matlab/work and myfiles is in  
% d:/matlab/work/project, type this:
```

```
rmdir('project/myfiles')
```

```
% Use the full path to remove myfiles, assuming  
% the current folder is matlab/work and myfiles is in  
% d:/matlab/work/project:
```

```
rmdir('d:/matlab/work/project/myfiles')
```

---

This example removes the `myfiles` folder and its contents, assuming `myfiles` is in the current folder:

```
rmdir('myfiles','s')
```

---

This example unsuccessfully attempts to remove the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess, id]=rmdir('myfiles')
```

MATLAB returns:

```
stat =  
      0
```

```
mess =
```

```
No directories were removed.
```

```
id =
```

```
MATLAB:RMDIR:NoDirectoriesRemoved
```

---

This example successfully removes the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess]=rmdir('myfiles','s')
```

MATLAB returns:

```
stat =  
      1
```

```
mess =
```

# rmdir

---

..

**Alternatives** Open the Current Folder browser by running `filebrowser`. Then, in the Current Folder browser, right-click the folder name and select **Delete** from the context menu.

<b>Purpose</b>	Remove folder on FTP server
<b>Syntax</b>	<code>rmdir(ftpobj, folder)</code>
<b>Description</b>	<code>rmdir(ftpobj, folder)</code> removes the specified folder from the current folder on an FTP server.
<b>Input Arguments</b>	<p><b>ftpobj</b> FTP object created by <code>ftp</code>.</p> <p><b>folder</b> String enclosed in single quotation marks that specifies the name of the folder to delete.</p>
<b>Examples</b>	<p>Remove the folder <code>temp</code> from the hypothetical FTP server <code>ftp.testsite.com</code>:</p> <pre>test = ftp('ftp.testsite.com'); rmdir(test, 'temp');</pre>
<b>See Also</b>	<code>cd</code>   <code>delete</code>   <code>dir</code>   <code>ftp</code>   <code>mkdir</code>

# rmfield

---

**Purpose** Remove fields from structure

**Syntax** `s = rmfield(s,field)`

**Description** `s = rmfield(s,field)` removes the specified field or fields from structure array `s`. Specify multiple fields using a cell array of strings. The dimensions of `s` remain the same.

## Input Arguments

### **s** - Input structure

structure array

Input structure, specified as a structure array.

### Data Types

struct

### **field** - Field name or names

character array | cell array of strings

Field name or names, specified as a character array or a cell array of strings.

**Example:** `'f1'`

**Example:** `{'f1';'f2'}`

### Data Types

char | cell

## Examples

### Remove Single Field

Define a scalar structure with fields named `a`, `b`, and `c`.

```
s.a = 1;  
s.b = 2;  
s.c = 3;
```

Remove field `b`.

```
field = 'b';
```

```
s = rmfield(s,field)
```

```
s =  
    a: 1  
    c: 3
```

### Remove Multiple Fields

Define a scalar structure with fields `first`, `second`, `third`, and `fourth`.

```
S.first = 1;  
S.second = 2;  
S.third = 3;  
S.fourth = 4;
```

Remove fields `first` and `fourth`.

```
fields = {'first','fourth'};  
S = rmfield(S,fields)
```

```
S =  
    second: 2  
    third: 3
```

# rmpath

---

<b>Purpose</b>	Remove folders from search path
<b>Syntax</b>	<code>rmpath(folderName)</code>
<b>Description</b>	<code>rmpath(folderName)</code> removes the specified folder from the search path.
<b>Input Arguments</b>	<p><b>folderName - Name of folder</b> string</p> <p>Name of folder to remove from the search path, specified as a string. Use the full path name for <code>folderName</code>.</p> <p><b>Example:</b> <code>'c:\matlab\work'</code></p> <p><b>Example:</b> <code>'/home/user/matlab'</code></p>
<b>Examples</b>	<p><b>Remove Folder from Search Path</b></p> <p>Remove <code>/usr/local/matlab/mytools</code> from the search path.</p> <pre>rmpath('/usr/local/matlab/mytools')</pre>
<b>See Also</b>	<code>addpath</code>   <code>savepath</code>   <code>path</code>
<b>Concepts</b>	<ul style="list-style-type: none"><li>• “What Is the MATLAB Search Path?”</li></ul>

**Purpose**

Remove preference

**Syntax**

```
rmpref('group','pref')  
rmpref('group',{'pref1','pref2',... 'prefn'})  
rmpref('group')
```

**Description**

`rmpref('group','pref')` removes the preference specified by `group` and `pref`. It is an error to remove a preference that does not exist.

`rmpref('group',{'pref1','pref2',... 'prefn'})` removes each preference specified in the cell array of preference names. It is an error if any of the preferences do not exist.

`rmpref('group')` removes all the preferences for the specified group. It is an error to remove a group that does not exist.

**Examples**

```
addpref('mytoolbox','version','1.0')  
rmpref('mytoolbox')
```

**See Also**

`addpref` | `getpref` | `ispref` | `setpref` | `uigetpref` | `uisetpref`

**Purpose** Control random number generation

**Syntax**

```
rng(sd)
rng('shuffle')
rng(sd, generator)
rng('shuffle', generator)
rng('default')
scurr = rng
rng(s)
sprex = rng(...)
```

## Description

---

**Note** To use the `rng` function instead of `rand` or `randn` with the 'seed', 'state', or 'twister' inputs, see the documentation on “Replace Discouraged Syntaxes of `rand` and `randn`”

---

`rng(sd)` seeds the random number generator using the nonnegative integer `sd` so that `rand`, `randi`, and `randn` produce a predictable sequence of numbers.

`rng('shuffle')` seeds the random number generator based on the current time so that `rand`, `randi`, and `randn` produce a different sequence of numbers after each time you call `rng`.

`rng(sd, generator)` and `rng('shuffle', generator)` additionally specify the type of the random number generator used by `rand`, `randi`, and `randn`. The generator input is one of:

Generator	Description
'twister'	Mersenne Twister
'combRecursive'	Combined Multiple Recursive
'multFibonacci'	Multiplicative Lagged Fibonacci
'v5uniform'	Legacy MATLAB 5.0 uniform generator

Generator	Description
'v5normal'	Legacy MATLAB 5.0 normal generator
'v4'	Legacy MATLAB 4.0 generator

`rng('default')` puts the settings of the random number generator used by `rand`, `randi`, and `randn` to their default values so that they produce the same random numbers as if you restarted MATLAB. In this release, the default settings are the Mersenne Twister with seed 0.

`scurr = rng` returns the current settings of the random number generator used by `rand`, `randi`, and `randn`. The settings are returned in a structure `scurr` with fields `'Type'`, `'Seed'`, and `'State'`.

`rng(s)` restores the settings of the random number generator used by `rand`, `randi`, and `randn` back to the values captured previously with a command such as `s = rng`.

`sprev = rng(...)` returns the previous settings of the random number generator used by `rand`, `randi`, and `randn` before changing the settings.

## Examples

### Example 1 — Retrieve and Restore Generator Settings

Save the current generator settings in `s`:

```
s = rng;
```

Call `rand` to generate a vector of random values:

```
x = rand(1,5)
```

```
x =
```

```
    0.8147    0.9058    0.1270    0.9134    0.6324
```

Restore the original generator settings by calling `rng`. Generate a new set of random values and verify that `x` and `y` are equal:

```
rng(s);
y = rand(1,5)
```

```
y =  
    0.8147    0.9058    0.1270    0.9134    0.6324
```

## Example 2 – Restore Settings for Legacy Generator

Use the legacy generator.

```
sprev = rng(0, 'v5uniform')
```

```
sprev =  
    Type: 'twister'  
    Seed: 0  
    State: [625x1 uint32]
```

```
x = rand
```

```
x =  
    0.9501
```

Restore the previous settings by calling `rng`:

```
rng(sprev)
```

### Related Examples

- “Generate Random Numbers That Are Repeatable”
- “Generate Random Numbers That Are Different”

### Concepts

- “Why Do Random Numbers Repeat After Startup?”

**Purpose** Root

**Description** The root is a graphics object that corresponds to the computer screen. There is only one root object and it has no parent. The children of the root object are figures.

The root object exists when you start MATLAB; you never have to create it and you cannot destroy it. Use `set` and `get` to access the root properties.

**Object Hierarchy**

**See Also** [diary](#) | [echo](#) | [figure](#) | [format](#) | [gcf](#) | [get](#) | [set](#) | [Root Properties](#)

# Root Properties

---

**Purpose** Root properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

## Root Properties

This section provides a description of properties. Curly braces { } enclose default values.

BusyAction

cancel | {queue}

Not used by the root object.

ButtonDownFcn

string

Not used by the root object.

CallbackObject

handle (read-only)

*Handle of current callback's object.* Contains the handle of the object whose callback routine is currently executing. If no callback routines are executing, this property contains an empty double array [ ]. See also the `gco` command.

Children

vector of handles

*Handles of child objects.* A vector containing the handles of all nonhidden figure objects (see `HandleVisibility` for more

information). You can change the order of the handles and thereby change the sorting order of the figures on the display.

## Clipping

{on} | off

*Clipping mode.* This property has no effect on the root object.

## CommandWindowSize

[columns rows]

---

**Note** The `CommandWindowSize` root property will be removed in a future release. To determine the number of columns and rows that display in the Command Window, given its current size, call `matlab.desktop.commandwindow.size`.

---

*Current size of command window.* Size of the MATLAB command window, in a two-element vector. The first element is the number of columns wide and the second element is the number of rows tall.

For example, a value of `[50,25]` means that 50 characters can display across the Command Window, and 25 lines can display without scrolling.

Enabling the Command Window Display preference **Set matrix display width to eighty columns** forces the returned value for number of columns wide to be 80 regardless of the window width.

## CreateFcn

The root object does not use this property.

## CurrentFigure

figure handle

*Handle of the current figure,* which is the one most recently created, clicked in, or made current with the statement:

# Root Properties

---

```
figure(h) % h is a figure handle
```

which re-sorts the figure to the top of the figures displayed on the screen, or:

```
set(0, 'CurrentFigure', h)
```

which does not re-sort the figures. In these statements, `h` is the handle of an existing figure. If there are no figure objects:

```
get(0, 'CurrentFigure')
```

returns an empty double array. Note, however, that `gcf` always returns a figure handle. Calling `gcf` creates a new figure if there are no existing figure objects that can become the current figure (for example, figures with hidden handles cannot become the current figure).

DeleteFcn  
string

This property is not used because you cannot delete the root object.

Diary  
on | {off}

*Diary file mode.* When this property is on, MATLAB maintains a file (whose name is specified by the `DiaryFile` property) that saves a copy of all keyboard input and most of the resulting output. See also the `diary` command.

DiaryFile  
string

*Diary file name.* The default name is `diary`. Set this property to the name of the file MATLAB uses write the command-line diary when the `Diary` property is set to on.

Echo  
on | {off}

*Script echoing mode.* When Echo is on, MATLAB displays each line of a script file as it executes. See also the `echo` command.

ErrorMessage  
string

*Text of last error message.* Contains the last error message issued by MATLAB.

FixedWidthFontName  
font name

*Fixed-width font to use for axes, text, and uicontrols whose FontName is set to FixedWidth.* MATLAB uses the font name specified for this property as the value for axes, text, and uicontrol FontName properties when their FontName property is FixedWidth.

Specifying the font name with this property eliminates the need to hardcode font names in MATLAB applications and thereby enables these applications to run without modification in locales where non-ASCII character sets are required. In these cases, MATLAB attempts to set the value of FixedWidthFontName to the correct value for a given locale.

MATLAB application developers should not change this property, but should create axes, text, and uicontrols with FontName properties set to FixedWidth when they want to use a fixed-width font for these objects.

MATLAB end users can set this property if they do not want to use the preselected value. Courier is the default in locales that use Latin-based characters.

Format  
short | {shortE} | long | longE | bank |  
hex | + | rat

# Root Properties

---

*Output format mode.* Format used to display numbers. See also the `format` command.

- `short` — Fixed-point format with 5 digits
- `shortE` — Floating-point format with 5 digits
- `shortG` — Fixed- or floating-point format displaying as many significant figures as possible with 5 digits
- `long` — Scaled fixed-point format with 15 digits
- `longE` — Floating-point format with 15 digits
- `longG` — Fixed- or floating-point format displaying as many significant figures as possible with 15 digits
- `bank` — Fixed-format of dollars and cents
- `hex` — Hexadecimal format
- `+` — Displays + and - symbols
- `rat` — Approximation by ratio of small integers

`FormatSpacing`  
`compact` | `{loose}`

*Output format spacing* (see also `format` command).

- `compact` — Suppress extra line feeds for more compact display.
- `loose` — Display extra line feeds for a more readable display.

`HandleVisibility`  
`{on}` | `callback` | `off`

This property is not useful on the root object because the handle is always 0.

`HitTest`  
`{on}` | `off`

This property is not useful on the root object.

Interruptible  
{on} | off

This property is not useful on the root object.

Language  
string

System environment setting.

MonitorPositions

*Width and height of monitors, in pixels.* Contains information about the size and relative location of monitors connected to your computer. The information returned by the `MonitorPosition` property depends on which computer system you are using.

## Windows Systems

Windows systems define one monitor as device 1, which becomes the reference by which MATLAB determines other monitor positions. The position data is of the form:

```
[xmin2,ymin2,xmax2,ymax2;  
 xmin1,ymin1,xmax1,ymax1]
```

The values for minimum and maximum are relative to the origin.

The following picture show the values returned when querying the `MonitorPositions` property on a Windows system having two monitors arranged as shown.

# Root Properties

Windows System with Two Monitors

```
get(0, 'MonitorPosition')
```

```
-1279  1  0  1024  
1  1  1920  1200
```

The `MonitorPositions` property contains an n-by-4 array, with each row representing a monitor position. The first row is the n<sup>th</sup> monitor and the last row corresponds to device 1.

The monitor labeled as device 1 in the Windows control panel remains the reference monitor that defines the position of the origin however you reposition the monitors.

## Linux Systems

On Linux systems, the upper-left corner of a rectangle enclosing the system monitors forms the origin. The position data is of the form:

```
[xp yp widthp heightp;  
 xs ys widths heights]
```

Where the values represent the offset from the left (x), the offset from the top (y), and the width and height of the monitor. The `MonitorPositions` property contains an n-by-4 array, with each row representing a monitor position. The first row is the position of the primary monitor.

The following picture show the values returned when querying the `MonitorPositions` property on a Linux system that has two monitors arranged as shown.

```
get(0, 'MonitorPosition')
```

```
1281  0    1920  1200  
  1    503  1280  1024
```

# Root Properties

---

MATLAB on Linux reads control panel settings only at startup. MATLAB does not recognize changes made to the arrangement of monitors during a MATLAB session.

## Macintosh Systems

MATLAB on Macintosh systems recognize only the main monitor. The position data is of the form:

[x,y,width,height-menuHeight]

Where the values are  $x = 0$ ,  $y = 0$ , monitor width, and monitor height minus the height of the menubar.

The main monitor is determined by which display has the menu bar. The **System Preferences Displays** control panel provides a way to arrange representations of multiple displays, and set one as the main monitor. To make another display the main monitor, drag the representation of the menu bar in the panel from the default display to the other display.

Parent  
handle

*Handle of parent object.* This property always contains an empty double array, because the root object has no parent.

PointerLocation  
[x,y]

*Current location of pointer.* A vector containing the  $x$ - and  $y$ -coordinates of the pointer position, measured from the lower left corner of the screen. Move the pointer by changing the values of this property. The `Units` property determines the units of this measurement.

PointerLocation always contains the current pointer location, even if the pointer is not in a MATLAB window. A callback

routine querying the `PointerLocation` property can get a value that is different from the location of the pointer when the callback was triggered. This difference results from delays in callback execution caused by competition for system resources.

On Apple Macintosh platforms, you cannot change the pointer location using the `set` command.

## `PointerWindow`

handle (read-only)

*Handle of window containing the pointer.* MATLAB sets this property to the handle of the figure containing the pointer. If the pointer is not in a MATLAB window, the value of this property is 0. A callback routine querying the `PointerWindow` can get the wrong window handle if you move the pointer to another window before the callback executes. This error results from delays in callback execution caused by competition for system resources.

## `RecursionLimit`

integer

*Number of nested MATLAB file calls.* The limit of the number of nested calls to MATLAB files that MATLAB makes before stopping (or potentially running out of memory). By default the value is set to a large value. Setting this property to a smaller value (something like 150, for example) should prevent MATLAB from running out of memory and instead causes MATLAB to issue an error when it reaches the limit.

## `ScreenDepth`

bits per pixel

*Screen depth.* The depth of the display bitmap (the number of bits per pixel). The maximum number of simultaneously displayed colors on the current graphics device is 2 raised to this power.

# Root Properties

---

`ScreenDepth` supersedes the `BlackAndWhite` property. To override automatic hardware checking, set this property to 1. Then MATLAB assumes the display is monochrome. Setting `ScreenDepth` to 1 is useful if MATLAB is running on color hardware but is being displayed on a monochrome terminal. Such a situation can cause MATLAB to determine erroneously that the display is color.

`ScreenPixelsPerInch`  
Display resolution

*DPI setting for your display.* Contains the setting of your display resolution specified in your system preferences.

`ScreenSize`  
four-element rectangle vector (read-only)

*Screen size.* A four-element vector:

[left,bottom,width,height]

that defines the display size. `left` and `bottom` are 0 for all Units except pixels, in which case `left` and `bottom` are both 1. `width` and `height` are the screen dimensions in units specified by the `Units` property.

## Determining Screen Size

Note that the screen size in absolute units (for example, inches) is determined by dividing the number of pixels in width and height by the screen DPI (see the `ScreenPixelPerInch` property). This value is approximate and might not represent the actual size of the screen.

Note that the `ScreenSize` property is static. Its values are read-only at MATLAB startup and not updated if system display settings change. Also, the values returned might not represent

the usable screen size for application developers due to the presence of other GUIs, such as the Microsoft Windows task bar.

**Selected**  
on | off

This property has no effect on the root object.

**SelectionHighlight**  
{on} | off

This property has no effect on the root object.

**ShowHiddenHandles**  
on | {off}

*Show or hide handles marked as hidden.* When set to on, this property disables handle hiding and exposes all object handles regardless of the setting of an object's `HandleVisibility` property. When set to off, all objects so marked remain hidden within the graphics hierarchy.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. While it is not necessary to identify the root object with a tag (since its handle is always 0), you can use this property to store any string value, which you can later retrieve using `get`.

**Type**  
string (read-only)

*Class of graphics object.* For the root object, `Type` is always the string `root`.

**UIContextMenu**  
handle

# Root Properties

---

This property is not used by the root object.

## Units

{pixels} | normalized | inches | centimeters | points  
| characters

*Unit of measurement.* Specifies the units MATLAB uses to interpret size and location data contained in the `PointerLocation` and `ScreenSize` properties. All units are measured from the lower left corner of the screen.

- `normalized` — Map the lower left corner of the screen to (0,0) and the upper right corner to (1.0,1.0).
- `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $1/72$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter x, and the height of one `characters` unit is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your operation, so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Data you want to associate with the root object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Object visibility.* This property has no effect on the root object.

## See Also

root object

**Purpose**

Polynomial roots

**Syntax**

`r = roots(c)`

**Description**

`r = roots(c)` returns a column vector whose elements are the roots of the polynomial `c`.

Row vector `c` contains the coefficients of a polynomial, ordered in descending powers. If `c` has  $n+1$  components, the polynomial it represents is  $c_1s^n + \dots + c_n s + c_{n+1}$ .

**Tips**

Note the relationship of this function to `p = poly(r)`, which returns a row vector whose elements are the coefficients of the polynomial. For vectors, `roots` and `poly` are inverse functions of each other, up to ordering, scaling, and roundoff error.

**Examples**

The polynomial  $s^3 - 6s^2 - 72s - 27$  is represented in MATLAB software as

```
p = [1 -6 -72 -27]
```

The roots of this polynomial are returned in a column vector by

```
r = roots(p)
```

```
r =
    12.1229
    -5.7345
    -0.3884
```

**Algorithms**

The algorithm simply involves computing the eigenvalues of the companion matrix:

```
A = diag(ones(n-1,1),-1);
A(1,:) = -c(2:n+1)./c(1);
eig(A)
```

## roots

---

It is possible to prove that the results produced are the exact eigenvalues of a matrix within roundoff error of the companion matrix  $A$ , but this does not mean that they are the exact roots of a polynomial with coefficients within roundoff error of those in  $c$ .

### **See Also**

`fzero` | `poly` | `residue`

**Purpose**

Angle histogram plot

**Syntax**

```
rose(theta)
rose(theta,x)
rose(theta,nbins)
rose(axes_handle,...)
h = rose(...)
[tout,rout] = rose(...)
```

**Description**

`rose(theta)` creates an angle histogram, which is a polar plot showing the distribution of values grouped according to their numeric range, showing the distribution of `theta` in 20 angle bins or less. The vector `theta`, expressed in radians, determines the angle of each bin from the origin. The length of each bin reflects the number of elements in `theta` that fall within a group, which ranges from 0 to the greatest number of elements deposited in any one bin.

`rose(theta,x)` uses the vector `x` to specify the number and the locations of bins. `length(x)` is the number of bins and the values of `x` specify the center angle of each bin. For example, if `x` is a five-element vector, `rose` distributes the elements of `theta` in five bins centered at the specified `x` values.

`rose(theta,nbins)` plots `nbins` equally spaced bins in the range `[0, 2*pi]`. The default is 20.

`rose(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = rose(...)` returns the handle of the line object used to create the graph.

`[tout,rout] = rose(...)` returns the vectors `tout` and `rout` so `polar(tout,rout)` generates the histogram for the data. This syntax does not generate a plot.

## Examples

### Create Rose Histogram

Load the `sunspot.dat` data set which contains the 2-column matrix `sunspot`. Store the second column of the data set as `theta`.

```
load sunspot.dat  
theta = sunspot(:,2);
```

Create a rose histogram of `theta` using 12 bins.

```
figure  
rose(theta,12)
```

# rosser

---

**Purpose** Classic symmetric eigenvalue test problem

**Syntax** A = rosser

**Description** A = rosser returns the Rosser matrix. The matrix is 8-by-8 with integer elements. It has:

- A double eigenvalue
- Three nearly equal eigenvalues
- Dominant eigenvalues of opposite sign
- A zero eigenvalue
- A small, nonzero eigenvalue

## Examples

```
rosser
```

```
ans =
```

```
  611   196  -192   407    -8   -52   -49    29
  196   899   113  -192   -71   -43    -8   -44
 -192   113   899   196    61    49    8    52
  407  -192   196   611    8    44    59   -23
   -8   -71    61    8   411  -599   208   208
  -52   -43    49    44  -599   411   208   208
  -49    -8    8    59   208   208    99  -911
   29   -44    52   -23   208   208  -911    99
```

**Purpose** Rotate matrix 90 degrees

**Syntax**  $B = \text{rot90}(A)$   
 $B = \text{rot90}(A, k)$

**Description**  $B = \text{rot90}(A)$  rotates matrix  $A$  counterclockwise by 90 degrees.  
 $B = \text{rot90}(A, k)$  rotates matrix  $A$  counterclockwise by  $k \cdot 90$  degrees, where  $k$  is an integer.

**Examples** The matrix

$X =$

1	2	3
4	5	6
7	8	9

rotated by 90 degrees is

$Y = \text{rot90}(X)$

$Y =$

3	6	9
2	5	8
1	4	7

**See Also** [flipdim](#) | [fliplr](#) | [flipud](#)

# rotate

---

**Purpose** Rotate object about specified origin and direction

**Syntax** `rotate(h,direction,alpha)`  
`rotate(...,origin)`

**Description** The rotate function rotates a graphics object in three-dimensional space.

`rotate(h,direction,alpha)` rotates the graphics object `h` by `alpha` degrees. `direction` is a two- or three-element vector that describes the axis of rotation in conjunction with the origin of the axis of rotation. The default origin of the axis of rotation is the center of the plot box. This point is not necessarily the origin of the axes.

Positive `alpha` is defined as the righthand-rule angle about the direction vector as it extends from the origin of rotation.

If `h` is an array of handles, all objects must be children of the same axes.

`rotate(...,origin)` specifies the origin of the axis of rotation as a three-element vector `[x0,y0,z0]`.

**Tips** The rotation transformation modifies the object's data. This technique is different from that used by `view` and `rotate3d`, which modify only the viewpoint.

The axis of rotation is defined by an origin of rotation and a point `P`. Specify `P` as the spherical coordinates `[theta phi]` or as the Cartesian coordinates `[xp,yp,zp]`.

In the two-element form for direction,  $\theta$  is the angle in the  $x$ - $y$  plane counterclockwise from the positive  $x$ -axis.  $\phi$  is the elevation of the direction vector from the  $x$ - $y$  plane.

The three-element form for direction specifies the axis direction using Cartesian coordinates. The direction vector is the vector from the origin of rotation to P.

# rotate

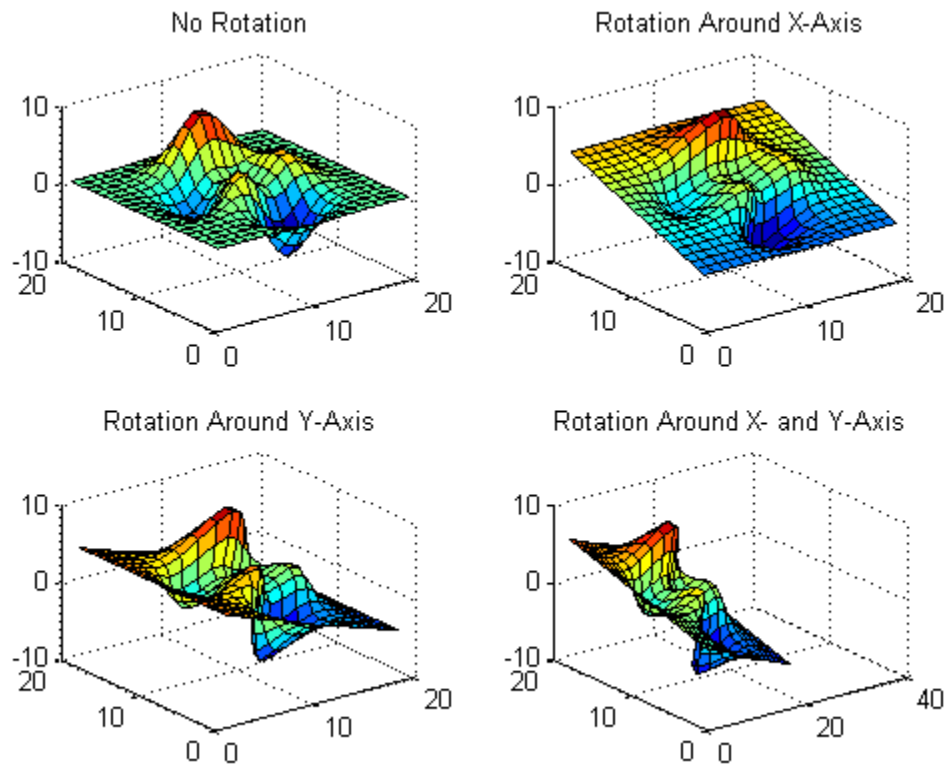

---

## Examples

Create a 2-by-2 set of surface plots and rotate them around their  $x$  and  $y$  axes.

```
figure
sp11 = subplot(2,2,1);
h11 = surf(sp11, peaks(20));
title('No Rotation')
sp12 = subplot(2,2,2);
h12 = surf(sp12, peaks(20));
title('Rotation Around X-Axis')
zdir = [1 0 0];
rotate(h12,zdir,25)
sp21 = subplot(2,2,3);
h21 = surf(sp21, peaks(20));
title('Rotation Around Y-Axis')
zdir = [0 1 0];
rotate(h21,zdir,25)
sp22 = subplot(2,2,4);
h22 = surf(sp22, peaks(20));
title('Rotation Around X- and Y-Axis')
zdir = [1 1 0];
rotate(h22,zdir,25)
```

**Tips**

rotate changes the values of the Xdata, Ydata, and Zdata properties to rotate graphics objects.

rotate3d | sph2cart | view | CameraPosition | CameraTarget | CameraUpVector | CameraViewAngle

# rotate3d

---

**Purpose** Rotate 3-D view using mouse

**Syntax**

```
rotate3d on
rotate3d off
rotate3d
rotate3d(figure_handle,...)
rotate3d(axes_handle,...)
h = rotate3d(figure_handle)
```

**Description**

`rotate3d on` enables mouse-base rotation on all axes within the current figure.

`rotate3d off` disables interactive axes rotation in the current figure.

`rotate3d` toggles interactive axes rotation in the current figure.

`rotate3d(figure_handle,...)` enables rotation within the specified figure instead of the current figure.

`rotate3d(axes_handle,...)` enables rotation only in the specified axes.

`h = rotate3d(figure_handle)` returns a `rotate3d mode object` for figure `figure_handle` for you to customize the mode's behavior.

## Using Rotate Mode Objects

You access the following properties of rotate mode objects via `get` and modify some of them using `set`.

- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set
- `Enable 'on' | 'off'` — Specifies whether this figure mode is currently enabled on the figure
- `RotateStyle 'orbit' | 'box'` — Sets the method of rotation
  - 'orbit' rotates the entire axes; 'box' rotates a plot-box outline of the axes.

## Rotate3D Mode Callbacks

You can program the following callbacks for rotate3d mode operations.

- **ButtonDownFilter** <function\_handle> — Function to intercept ButtonDown events

The application can inhibit the rotate operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to handle callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj          handle to the object that has been clicked on
% event_obj    handle to event data object (empty in this release)
% res [output] logical flag to determine whether the rotate
                operation should take place or the 'ButtonDownFcn'
                property of the object should take precedence
```

- **ActionPreCallback** <function\_handle> — Function to execute before rotating

Set this callback to listen to when a rotate operation will start. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data
```

The event data has the following field:

Axes	The handle of the axes that is being panned
------	---------------------------------------------

- **ActionPostCallback** <function\_handle> — Function to execute after rotating

# rotate3d

---

Set this callback to listen to when a rotate operation has finished. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

## Rotate3D Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesRotate(h,axes)` — Function querying permission to rotate axes

Calling the function `isAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, as input will return a logical array of the same dimension as the `axes` handle vector which indicate whether a rotate operation is permitted on the axes objects.

- `setAllowAxesRotate(h,axes,flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, will either allow or disallow a rotate operation on the axes objects.

## Examples

### Example 1

Rotate the plot using the mouse:

```
surf(peaks);
rotate3d on;
```

### Example 2

Rotate the plot using the "Plot Box" rotate style:

```
surf(peaks);  
h = rotate3d;  
set(h,'RotateStyle','box','Enable','on');
```

### Example 3

Create two axes as subplots and then prevent one from rotating:

```
ax1 = subplot(1,2,1);  
surf(peaks);  
h = rotate3d;  
set(h,'Enable','on')  
ax2 = subplot(1,2,2);  
surf(membrane);  
setAllowAxesRotate(h,ax2,false); % disable rotating for second plot
```

### Example 4

Create a `ButtonDown` callback for rotate mode objects to trigger.

Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd  
% Allow a line to have its own 'ButtonDownFcn' callback  
hLine = plot(rand(1,10));  
set(hLine,'ButtonDownFcn','disp(''This executes'')');  
set(hLine,'Tag','DoNotIgnore');  
h = rotate3d;  
set(h,'ButtonDownFilter',@mycallback);  
set(h,'Enable','on');  
% mouse-click on the line  
function [flag] = mycallback(obj,event_obj)  
% If the tag of the object is 'DoNotIgnore', then return true  
objTag = get(obj,'Tag');  
if strcmpi(objTag,'DoNotIgnore')  
    flag = true;  
else  
    flag = false;  
end
```

## Example 5

Create callbacks for pre- and post-buttonDown events for rotate3D mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd2
% Listen to rotate events
surf(peaks);
h = rotate3d;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');

function myprecallback(obj,evd)
disp('A rotation is about to occur.');
```

```
function mypostcallback(obj,evd)
newView = round(get(evd.Axes,'View'));
msgbox(sprintf('The new view is [%d %d].',newView));
```

## Tips

When enabled, rotate3d provides continuous rotation of axes and the objects it contains through mouse movement. A numeric readout appears in the lower left corner of the figure during rotation, showing the current azimuth and elevation of the axes. Releasing the mouse button removes the animated box and the readout. This differs from the camorbit function in that while the rotate3d tool modifies the View property of the axes, the camorbit function fixes the aspect ratio and modifies the CameraTarget, CameraPosition and CameraUpVector properties of the axes. See [Axes Properties](#) for more information.

You can also enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

You can create a rotate3d mode object once and use it to customize the behavior of different axes, as example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure’s callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure’s callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different 3-D rotation behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse will carry over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the Rotate3D tool  on the figure toolbar to enable and disable rotate3D mode on a plot, or select **Rotate 3D** from the figure’s **Tools** menu. For details, see “Rotate in 3-D”.

## See Also

`camorbit` | `pan` | `rotate` | `view` | `zoom` | `Axes Properties`

# round

---

**Purpose** Round to nearest integer

**Syntax**  $Y = \text{round}(X)$

**Description**  $Y = \text{round}(X)$  rounds the elements of  $X$  to the nearest integers. Positive elements with a fractional part of 0.5 round up to the nearest positive integer. Negative elements with a fractional part of -0.5 round down to the nearest negative integer. For complex  $X$ , the imaginary and real parts are rounded independently.

## Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]
```

```
a =  
Columns 1 through 4  
-1.9000          -0.2000          3.4000          5.6000  
Columns 5 through 6  
7.0000          2.4000 + 3.6000i
```

```
round(a)
```

```
ans =  
Columns 1 through 4  
-2.0000          0          3.0000          6.0000  
Columns 5 through 6  
7.0000          2.0000 + 4.0000i
```

<b>Purpose</b>	Apply function to table rows
<b>Syntax</b>	<code>B = rowfun(func,A)</code> <code>B = rowfun(func,A,Name,Value)</code>
<b>Description</b>	<p><code>B = rowfun(func,A)</code> applies the function <code>func</code> to each row of the table <code>A</code> and returns the results in the table <code>B</code>.</p> <p><code>func</code> accepts <code>size(A,2)</code> inputs.</p> <p><code>B = rowfun(func,A,Name,Value)</code> applies the function <code>func</code> to each row of the table <code>A</code> with additional options specified by one or more <code>Name,Value</code> pair arguments.</p> <p>For example, you can specify which variables to pass to the function <code>func</code> and how to call <code>func</code>.</p>
<b>Input Arguments</b>	<p><b>func - Function</b> function handle</p> <p>Function, specified as a function handle. You can define the function in a file or as an anonymous function. If <code>func</code> corresponds to more than one function file (that is, if <code>func</code> represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.</p> <p><code>func</code> can accept no more than <code>size(A,2)</code> inputs. By default, <code>rowfun</code> returns the first output of <code>func</code>. To return more than one output from <code>func</code>, use the 'NumOutputs' or 'OutputVariableNames' name-value pair arguments.</p> <p><b>Example:</b> <code>func = @(x,y) x.^2+y.^2;</code> takes two inputs and finds the sum of the squares.</p> <p><b>A - Input table</b> table</p> <p>Input table, specified as a table.</p>

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'InputVariables', 2` uses only the second variable in `A` as an input to `func`.

## **'InputVariables' - Variables of A to pass to func**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `rowfun` only passes the variables in `A` where the specified function returns 1 (`true`).

## **'GroupingVariables' - One or more variables in A that define groups of rows**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in `A` that have the same grouping variable values belong to the same group. `rowfun` applies `func` to each group of rows, rather than separately to each row of `A`. The output, `B`, contains one row for each group.

**'SeparateInputs' - Indicator for calling func with separate inputs**`true (default) | false | 1 | 0`

Indicator for calling `func` with separate inputs, specified as the comma-separated pair consisting of `'SeparateInputs'` and either `true`, `false`, `1`, or `0`.

`true`                    `func` expects separate inputs. `rowfun` calls `func` with `size(A,2)` inputs, one argument for each data variable.

This is the default behavior.

`false`                   `func` expects one vector containing all inputs. `rowfun` creates the input vector to `func` by concatenating the values in each row of `A`.

**'ExtractCellContents' - Indicator to pass values from cell variables to func**`false (default) | true | 0 | 1`

Indicator to pass values from cell variables to `func`, specified as the comma-separated pair consisting of `'ExtractCellContents'` and either `false`, `true`, `0`, or `1`.

`true`                    `rowfun` extracts the contents of a variable in `A` whose data type is `cell` and passes the values, rather than the cells, to `func`

For grouped computation, the values within each group in a cell variable must allow vertical concatenation.

`false`                   `rowfun` passes the cells of a variable in `A` whose data type is `cell` to `func`.

This is the default behavior.

**'OutputVariableNames' - Variable names for outputs of func**`string | cell array of nonempty, distinct strings`

Variable names for outputs of `func`, specified as the comma-separated pair consisting of `'OutputVariableNames'` and a string or a cell array of nonempty, distinct strings. The number of strings must equal the number of outputs desired from `func`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of  $N$  strings of the form `{'Var1' ... 'VarN'}` where  $N$  is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

### **'NumOutputs' - Number of outputs from func**

0 | positive integer

Number of outputs from `func`, specified as the comma-separated pair consisting of `'NumOutputs'` and 0 or a positive integer. The integer must be less than or equal to the possible number of outputs from `func`.

**Example:** `'NumOutputs',2` causes `rowfun` to call `func` with two outputs.

### **'OutputFormat' - Format of B**

`'table'` (default) | `'uniform'` | `'cell'`

Format of `B`, specified as the comma-separated pair consisting of `'OutputFormat'` and either the string `'table'`, `'uniform'`, or `'cell'`.

`'table'` `rowfun` returns a table with one variable for each output of `func`. For grouped computation, `B`, also contains the grouping variables.

`'table'` allows you to use a function that returns values of different sizes or data types. However, for ungrouped computation, all of the outputs from `func` must have one row each time it is called. For grouped computation, all of the outputs from `func` must have the same number of rows.

This is the default output format.

'uniform' rowfun concatenates the values returned by `func` into a vector. All of the outputs from `func` must be scalars with the same data type.

'cell' rowfun returns `B` as a cell array. 'cell' allows you to use a function that returns values of different sizes or data types.

### 'ErrorHandler' - Function to call if func fails

function handle

Function to call if `func` fails, specified as the comma-separated pair consisting of 'ErrorHandler' and a function handle. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Row or group index at which the error occurred.

- The set of input arguments to function `func` at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
warning(S.identifier, S.message);
A = NaN; B = NaN;
```

## Output Arguments

### B - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Apply Function with Single Output to Rows

Apply the function `hypot` to each row of the 5-by-2 table `A` to find the shortest distance between the variables `x` and `y`.

Create a table, `A`, with two variables of numeric data.

```
x = gallery('integerdata',10,[5,1],2);  
y = gallery('integerdata',10,[5,1],8);
```

```
A = table(x,y)
```

```
A =
```

```
    x     y  
    —     —  
    9     1  
    4     5  
    3     2  
    7     3  
    1    10
```

Apply the function, `hypot` to each row of `A`. The function `hypot` takes two inputs and returns one output.

```
B = rowfun(@hypot,A,'OutputVariableNames','z')
```

```
B =
```

```
    z  
    —
```

```

9.0554
6.4031
3.6056
7.6158
10.05

```

B is a table.

Append the function output, B, to the input table, A.

```
[A B]
```

```
ans =
```

```

x      y      z
-----
9       1    9.0554
4       5    6.4031
3       2    3.6056
7       3    7.6158
1      10   10.05

```

### Apply Function with Multiple Outputs to Rows

Define and apply a geometric Brownian motion model to a range of parameters.

Create a function in a file named `gbmSim.m` that contains the following code.

```

function [m,mtrue,s,strue] = gbmSim(mu,sigma)
% Discrete approximation to geometric Brownian motion
%
% [m,mtrue,s,strue] = gbmSim(mu,sigma) computes the
% simulated mean, true mean, simulated standard deviation,
% and true standard deviation based on the parameters mu and sigma.

```

```
numReplicates = 1000; numSteps = 100;
y0 = 1;
t1 = 1;
dt = t1 / numSteps;
y1 = y0*prod(1 + mu*dt + sigma*sqrt(dt)*randn(numSteps,numReplicates));
m = mean(y1); s = std(y1);
% Theoretical values
mtrue = y0 * exp(mu*t1); strue = mtrue * sqrt(exp(sigma^2*t1) - 1);
```

gbmSim accepts two inputs, mu and sigma, and returns four outputs, m, mtrue, s, and strue.

Define the table, params, containing the parameters to input to the Brownian Motion Model.

```
mu = [-.5; -.25; 0; .25; .5];
sigma = [.1; .2; .3; .2; .1];
```

```
params = table(mu,sigma)
```

```
params =
```

mu	sigma
-0.5	0.1
-0.25	0.2
0	0.3
0.25	0.2
0.5	0.1

Apply the function, gbmSim to the rows of the table, params.

```
stats = rowfun(@gbmSim,params,'OutputVariableNames',{'simulatedMean' 'trueMean' 'simulatedStd' 'trueStd'})
```

```
stats =
```

simulatedMean	trueMean	simulatedStd	trueStd
---------------	----------	--------------	---------

0.60501	0.60653	0.05808	0.060805
0.77916	0.7788	0.161	0.15733
1.0024	1	0.3048	0.30688
1.2795	1.284	0.25851	0.25939
1.6498	1.6487	0.16285	0.16529

The 4 strings specified by the 'OutputVariableNames' name-value pair argument indicate that rowfun should obtain 4 outputs from gbmSim. You can specify fewer output variable names to return fewer outputs from gbmSim.

Append the function output, stats, to the input, params.

```
[params stats]
```

```
ans =
```

mu	sigma	simulatedMean	trueMean	simulatedStd	trueStd
-0.5	0.1	0.60501	0.60653	0.05808	0.060805
-0.25	0.2	0.77916	0.7788	0.161	0.15733
0	0.3	1.0024	1	0.3048	0.30688
0.25	0.2	1.2795	1.284	0.25851	0.25939
0.5	0.1	1.6498	1.6487	0.16285	0.16529

## Apply Function to Groups of Rows

Create a table, A, where g is a grouping variable.

```
g = gallery('integerdata',3,[15,1],1);
x = gallery('uniformdata',[15,1],9);
y = gallery('uniformdata',[15,1],2);
```

```
A = table(g,x,y)
```

```
A =
```

g	x	y
3	0.24756	0.87516
3	0.4358	0.3179
3	0.97755	0.27323
2	0.85995	0.6765
3	0.30063	0.071171
2	0.26589	0.19659
3	0.13338	0.52908
2	0.7425	0.17176
1	0.85692	0.86996
2	0.24286	0.24369
3	0.19492	0.84291
2	0.39076	0.55766
1	0.29683	0.35681
1	0.39031	0.2324
2	0.18726	0.6476

Define the anonymous function, `func`, to compute the average difference between `x` and `y`.

```
func = @(x,y) mean(x-y);
```

Find the average difference between variables in groups 1, 2, and 3 defined by the grouping variable, `g`.

```
B = rowfun(func,A,...  
    'GroupingVariable','g',...  
    'OutputVariableName','MeanDiff')
```

B =

	g	GroupCount	MeanDiff
1	1	3	0.028298

2	2	6	0.032569
3	3	6	-0.10327

The variable `GroupCount` indicates the number of rows in `A` for each group.

**Concepts**

- “Anonymous Functions”

# rref

---

**Purpose** Reduced row echelon form

**Syntax**  
`R = rref(A)`  
`[R, jb] = rref(A)`  
`[R, jb] = rref(A, tol)`

**Description** `R = rref(A)` produces the reduced row echelon form of `A` using Gauss Jordan elimination with partial pivoting. A default tolerance of `(max(size(A))*eps *norm(A, inf))` tests for negligible column elements.

`[R, jb] = rref(A)` also returns a vector `jb` such that:

- `r = length(jb)` is this algorithm's idea of the rank of `A`.
- `x(jb)` are the pivot variables in a linear system `Ax = b`.
- `A(:, jb)` is a basis for the range of `A`.
- `R(1:r, jb)` is the `r`-by-`r` identity matrix.

`[R, jb] = rref(A, tol)` uses the given tolerance in the rank tests.

Roundoff errors may cause this algorithm to compute a different value for the rank than `rank`, `orth` and `null`. Additionally, use `mldivide` to solve linear systems when high precision is required.

**Examples** Use `rref` on a rank-deficient magic square:

```
A = magic(4), R = rref(A)
```

```
A =  
 16   2   3  13  
  5  11  10   8  
  9   7   6  12  
  4  14  15   1
```

```
R =  
  1   0   0   1  
  0   1   0   3
```

$$\begin{array}{cccc} 0 & 0 & 1 & -3 \\ 0 & 0 & 0 & 0 \end{array}$$

**See Also**[inv](#) | [lu](#) | [rank](#)

# rsf2csf

---

**Purpose** Convert real Schur form to complex Schur form

**Syntax** `[U,T] = rsf2csf(U,T)`

**Description** The *complex Schur form* of a matrix is upper triangular with the eigenvalues of the matrix on the diagonal. The *real Schur form* has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal.

`[U,T] = rsf2csf(U,T)` converts the real Schur form to the complex form.

Arguments `U` and `T` represent the unitary and Schur forms of a matrix `A`, respectively, that satisfy the relationships:  $A = U^*T^*U'$  and  $U' * U = \text{eye}(\text{size}(A))$ . See `schur` for details.

## Examples

Given matrix `A`,

```
1    1    1    3
1    2    1    1
1    1    3    1
-2   1    1    4
```

with the eigenvalues

```
4.8121    1.9202 + 1.4742i    1.9202 + 1.4742i    1.3474
```

Generating the Schur form of `A` and converting to the complex Schur form

```
[u,t] = schur(A);
[U,T] = rsf2csf(u,t)
```

yields a triangular matrix `T` whose diagonal (underlined here for readability) consists of the eigenvalues of `A`.

`U =`

-0.4916	-0.2756 - 0.4411i	0.2133 + 0.5699i	-0.3428
-0.4980	-0.1012 + 0.2163i	-0.1046 + 0.2093i	0.8001
-0.6751	0.1842 + 0.3860i	-0.1867 - 0.3808i	-0.4260
-0.2337	0.2635 - 0.6481i	0.3134 - 0.5448i	0.2466

T =

4.8121	-0.9697 + 1.0778i	-0.5212 + 2.0051i	-1.0067
0	1.9202 + 1.4742i	2.3355	0.1117 + 1.6547i
0	0	1.9202 - 1.4742i	0.8002 + 0.2310i
0	0	0	1.3474

schur

# run

---

**Purpose** Run MATLAB script

**Syntax** `run(scriptname)`

**Description** `run(scriptname)` runs the MATLAB script specified by `scriptname`.

**Input Arguments** **scriptname - Full or relative script path**  
*string*

Full or relative script path to a MATLAB script, specified as a string. `scriptname` can specify any file type that MATLAB can execute, such as MATLAB script files, Simulink models, or MEX-files.

- Tips**
- `run` executes scripts not currently on the MATLAB path. However, you should use `cd` or `addpath` to navigate to or to add the appropriate folder, making a script executable by entering its name alone.
  - `scriptname` can access any variables in the current workspace.
  - `run` changes to the folder that contains the script, executes it, and resets back to the original folder. If the script itself changes folders, then `run` does not revert to the original folder, unless `scriptname` changes to the folder in which this script resides.
  - If `scriptname` corresponds to both a `.m` file and a P-file residing in the same folder, then `run` executes the P-file. This occurs even if you specify `scriptname` with a `.m` extension.
  - If a script is not on the MATLAB path, executing the `run` command caches the script. In the same session and after calling `run`, you can edit the script using an external editor. Call `clear scriptname` before calling `run` again to use the changed version of the script rather than the cached version. If you edit the script with the MATLAB editor, `run` executes the changed version and there is no need to call `clear scriptname`.

**Examples** **Run Script Not on Current Path**

Create a temporary folder and copy an example MATLAB script to it.

```
tmp = tempname;  
mkdir(tmp);  
runtmp = fullfile(tmp,'buckyball.m');  
demodir = fullfile(matlabroot,'toolbox','matlab',...  
    'demos','buckydem.m');  
copyfile(demodir,runtmp);
```

Run the new script.

```
run(runtmp)
```

# run

---

## See Also

`cd` | `path` | `addpath` | `pwd`

## Concepts

- “Files and Folders that MATLAB Accesses”

**Purpose**

Run set of tests

**Syntax**

```
results = runtests(tests)
results = runtests(tests, 'Recursively', r)
```

**Description**

`results = runtests(tests)` runs a set of tests, and returns the results as a `TestResult` object.

`results = runtests(tests, 'Recursively', r)` indicates whether to run tests in subfolders or subpackages.

**Input Arguments**

**tests - Array of tests**

string | cell array of strings

Suite of tests specified as a string or cell array of strings. Each string in the cell array can contain the name of a test class, a test file, a package that containing your test classes, or a folder containing your test files.

**Example:** `'mypackage.MyTestClass'`

**Example:** `'ATestFile.m'`

**Example:** `pwd`

**Example:**

```
{ 'mypackage.MyTestClass', 'ATestFile.m', pwd, 'mypackage.subpackage' }
```

**r - Indicator to run tests in subfolders and subpackages**

false (default) | true | 0 | 1

Indicator to run tests in subfolders and subpackages, specified as `false` or `true` (0 or 1). By default `runtests` runs tests in the specified folder or package and not in their subfolders or subpackages.

**Examples**

**Run Tests Using File Name**

Create the test file shown below, and save it as `runtestsExampeTest.m` on your MATLAB path.

```
function tests = runtestsExampleTest
tests = functiontests(localfunctions);
```

```
function testFunctionOne(testCase)
```

Run the tests.

```
results = runtests('runtestsExampleTest.m');
```

```
Running runtestsExampleTest
```

```
.
```

```
Done runtestsExampleTest
```

---

## Run Tests in Subdirectory

If it doesn't already exist, create the test file, `runtestsExampleTest.m`, in the example above.

Create a subdirectory, `tmpTest`, and, in that directory, create the following `runtestsExampleSubFolderTest.m` file.

```
function tests = runtestsExampleSubFolderTest
tests = functiontests(localfunctions);
```

```
function testFunctionTwo(testCase)
```

Run the tests from the directory above `tmpTest` by setting `'Recursively'` to true.

```
results = runtests(pwd, 'Recursively', true);
```

```
Running runtestsExampleTest
```

```
.
```

```
Done runtestsExampleTest
```

---

```
Running runtestsExampleSubFolderTest
```

```
.
```

```
Done runtestsExampleSubFolderTest
```

---

`runtests` ran the tests in both the current directory and the subdirectory.

If you do not specify the 'Recursively' property for the `runtests` function, it does not run the test in the subdirectory.

```
results = runtests(pwd);
```

```
Running runtestsExampleTest
```

```
.
```

```
Done runtestsExampleTest
```

---

# save

---

**Purpose** Save workspace variables to file

**Syntax**

```
save(filename)
save(filename,variables)
save(filename,variables,fmt)
save(filename,variables,version)
save(filename,variables,'-append')

save filename
```

**Description** `save(filename)` saves all variables from the current workspace in a MATLAB formatted binary file (MAT-file) called `filename`. If `filename` already exists, `save` overwrites the file.

`save(filename,variables)` saves only the variables or fields of a structure array specified by `variables`.

`save(filename,variables,fmt)` saves in the file format specified by `fmt`. The `variables` argument is optional. If you do not specify `variables`, the `save` function saves all variables in the workspace.

`save(filename,variables,version)` saves to the MAT-file version specified by `version`. The `variables` argument is optional, as described above.

`save(filename,variables,'-append')` adds new variables to an existing file, and does not overwrite it. The `variables` argument is optional, as described above.

To append to a Version 6 MAT-file, you must also include `'-v6'` as an input argument.

`save filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses

or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to save a file named `test.mat`, these statements are equivalent:

```
save test.mat          % command form
save('test.mat')     % function form
```

You can include any of the inputs described in previous syntaxes. For example, to save the variable named `X`:

```
save test.mat X        % command form
save('test.mat','X') % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

## Input Arguments

### **filename** - Name of file

`'matlab.mat'` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `save` function saves to a file named `matlab.mat`.

If `filename` has no extension (that is, no text after a period), and the value of `format` is `-mat` (the default), then MATLAB appends `.mat`. If `filename` does not include a full path, MATLAB saves to the current folder. You must have permission to write to the file.

When using the command form of `save`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, save `'filename withspace.mat'`.

**Example:** `'myFile.mat'`

### **Data Types**

char

### **variables** - Names of variables to save

# save

string

Names of variables to save, specified as one or more strings. When using the command form of `save`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of variables Input	Variables to Save
<code>var1,...,varN</code>	Save the listed variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>save('filename.mat','A*')</code> saves all variables in the file that start with A.
<code>'-regexp',expr1,...,exprN</code>	Save only the variables whose names match the regular expressions, specified as strings. For example, <code>save('filename.mat','-regexp','^Mon','^Tues')</code> saves only the variables in the file whose names begin with Mon or Tues.
<code>'-struct',structName</code>	Store the fields of the scalar structure specified by <code>structName</code> as individual variables in the file. For example, <code>save('filename.mat','-struct','S')</code> saves the scalar structure, S.
<code>'-struct',structName,field1,field2,...,fieldN</code>	Store the specified fields of the specified scalar structure as individual variables in the file. For example, <code>save('filename.mat','-struct','S','a','b')</code> saves the fields S.a and S.b.
<code>'-struct',structName,'-regexp',reg1,...,regN</code>	Store only the fields whose names match the regular expressions, specified as strings.

## Data Types

char

### fmt - File format

```
'-mat' (default) | '-ascii' | '-ascii','-tabs' |
'-ascii','-double' | '-ascii','-double','-tabs'
```

File format, specified as one of the following strings. When using the command form of `save`, you do not need to enclose input strings in single quotes, for example, `save myFile.txt -ascii -tabs`.

Value of <code>fmt</code>	File Format
'-mat'	Binary MAT-file format.
'-ascii'	Text format with 8 digits of precision.
'-ascii','-tabs'	Tab-delimited text format with 8 digits of precision.
'-ascii','-double'	Text format with 16 digits of precision.
'-ascii','-double','-tabs'	Tab-delimited text format with 16 digits of precision.

For MAT-files, data saved on one machine and loaded on another machine retains as much accuracy and range as the different machine floating-point formats allow.

Use one of the text formats to save MATLAB numeric values to text files. In this case:

- Each variable must be a two-dimensional double array.
- The output includes only the real component of complex numbers.
- MATLAB writes data from each variable sequentially to the file. If you plan to use the `load` function to read the file, all variables must have the same number of columns. The `load` function creates a single variable from the file.

If you specify a text format and any variable is a two-dimensional character array, then MATLAB translates characters to their corresponding internal ASCII codes. For example, 'abc' appears in a text file as:

```
9.7000000e+001 9.8000000e+001 9.9000000e+001
```

**version - MAT-file version**

```
'-v7.3' | '-v7' | '-v6' | '-v4'
```

MAT-file version, specified as one of the following strings. When using the command form of `save`, you do not need to enclose input strings in single quotes.

<b>Value of version</b>	<b>Can Load in MATLAB Versions</b>	<b>Supported Features</b>
'-v7.3'	7.3 (R2006b) or later	Version 7.0 features, plus support for data items greater than or equal to 2 GB on 64-bit systems.
'-v7'	7.0 (R14) or later	Version 6 features, plus data compression and Unicode character encoding. Unicode encoding enables file sharing between systems that use different default character encoding schemes.
'-v6'	5 (R8) or later	Version 4 features, plus <i>N</i> -dimensional arrays, cell arrays and structures, and variable names greater than 19 characters.
'-v4'	all	Two-dimensional double, character, and sparse arrays.

If any data items require features that the specified version does not support, MATLAB does not save those items and issues a warning. You

cannot specify a version later than your current version of MATLAB software.

To view or set the default version for MAT-files, select a **MAT-file save format** option in the General Preferences.

## Examples

### Save All Workspace Variables to MAT-File

Save all variables from the workspace in a binary MAT-file, `test.mat`. If `filename` is a variable, you must use function syntax.

```
filename = 'test.mat';  
save(filename)
```

Otherwise, you also can use command syntax.

```
save test.mat
```

Remove the variables from the workspace, and then retrieve the data with the `load` function.

```
clear  
load('test.mat')
```

### Save Specific Variables to MAT-File

Create and save two variables, `p` and `q`, to a file called `pqfile.mat`.

```
p = rand(1,10);  
q = ones(10);  
save('pqfile.mat','p','q')
```

MATLAB saves the variables to the file, `pqfile.mat`, in the current folder.

You also can use command syntax to save the variables, `p` and `q`.

```
save pqfile.mat p q
```

## Save Data to ASCII File

Create two variables, save them to an ASCII file, and then view the contents of the file.

```
p = rand(1,10);
q = ones(10);
save('pqfile.txt','p','q','-ascii')
type('pqfile.txt')
```

The type function displays the contents of the file.

Alternatively, use command syntax for the save operation.

```
save pqfile.txt p q -ascii
```

## Save Structure Fields as Individual Variables

Create a structure, `s1`, that contains three fields, `a`, `b`, and `c`.

```
s1.a = 12.7;
s1.b = {'abc',[4 5; 6 7]};
s1.c = 'Hello!';
```

Save the fields of structure `s1` as individual variables in a file called `newstruct.mat`.

```
save('newstruct.mat','-struct','s1');
```

Check the contents of the file using the `whos` function.

```
disp('Contents of newstruct.mat:')
whos('-file','newstruct.mat')
```

```
Contents of newstruct.mat:
  Name      Size      Bytes  Class  Attributes
  a         1x1         8  double
  b         1x2        262  cell
```

```
c          1x6          12 char
```

### Save Variables to Version 7.3 MAT-File

Create two variables and save them to a version 7.3 MAT-file called `example.mat`.

```
A = rand(5);
B = magic(10);
save('example.mat', 'A', 'B', '-v7.3')
```

You also can use command syntax for the save operation.

```
save example.mat A B -v7.3
```

### Append Variable to MAT-File

Save two variables to a MAT-file. Then, append a third variable to the same file.

```
p = rand(1,10);
q = ones(10);
save('test.mat', 'p', 'q')
```

View the contents of the MAT-file.

```
whos('-file','test.mat')
```

Name	Size	Bytes	Class	Attributes
p	1x10	80	double	
q	10x10	800	double	

Create a new variable, `a`, and append it to the MAT-file.

```
a = 50;
save('test.mat', 'a', '-append')
```

View the contents of the MAT-file.

```
whos('-file','test.mat')
```

## save

---

Name	Size	Bytes	Class	Attributes
a	1x1	8	double	
p	1x10	80	double	
q	10x10	800	double	

The variable, `a`, is appended to `test.mat`, without overwriting the previous variables, `p` and `q`.

---

**Note** To append to a Version 6 MAT-file, specify both `'-v6'` and `'-append'`. For example, to save variable `a` to the file, `test.mat`, call:

```
save('test.mat','a','-v6','-append')
```

---

### Tips

- For more flexibility in creating ASCII files, use `dlmwrite` or `fprintf`.

### Concepts

- “What Is the MATLAB Workspace?”
- “Save, Load, and Delete Workspace Variables”
- “Write to Delimited Data Files”
- “Regular Expressions”

**Purpose** Serialize control object to file

**Syntax** `h.save('filename')`  
`save(h, 'filename')`

**Description** `h.save('filename')` saves the COM control object, `h`, to the file specified in the string, `filename`.  
`save(h, 'filename')` is an alternate syntax for the same operation.

---

**Note** The COM save function is only supported for controls at this time.

---

**Tips** COM functions are available on Microsoft Windows systems only.

**Examples** Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';  
h.Radius = 50;  
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');  
h.get
```

MATLAB displays the original values:

```
ans =  
    Label: 'Label'  
    Radius: 20
```

## save (COM)

---

### **See Also**

load (COM) | actxcontrol | actxserver | release | delete (COM)

**Purpose** Save serial port objects and variables to file

**Syntax** `save filename`  
`save filename obj1 obj2...`

**Description** `save filename` saves all MATLAB variables to the file `filename`. If an extension is not specified for `filename`, then the `.mat` extension is used.

`save filename obj1 obj2...` saves the serial port objects `obj1 obj2...` to the file `filename`.

**Tips** You can use `save` in the functional form as well as the command form shown above. When using the functional form, you must specify the filename and serial port objects as strings. For example, to save the serial port object `s` to the file `MySerial.mat` on a Windows platform

```
s = serial('COM1');  
save('MySerial','s')
```

Any data that is associated with the serial port object is not automatically stored in the file. For example, suppose there is data in the input buffer for `obj`. To save that data to a file, you must bring it into the MATLAB workspace using one of the synchronous read functions, and then save to the file using a separate variable name. You can also save data to a text file with the `record` function.

You return objects and variables to the MATLAB workspace with the `load` command. Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

**Examples** This example illustrates how to use the command and functional form of `save` on a Windows platform.

```
s = serial('COM1');  
set(s,'BaudRate',2400,'StopBits',1)  
save MySerial1 s
```

## save (serial)

---

```
set(s, 'BytesAvailableFcn', @mycallback)
save('MySerial2', 's')
```

load | record | Status

**Purpose** Save figure or Simulink block diagram using specified format

**Alternatives** Use **File > Save As** on the figure window menu to access the Save As dialog, in which you can select a graphics format. For details, see “Exporting in a Specific Graphics Format” in the MATLAB Graphics documentation. Sizes of files written to image formats by this GUI and by `saveas` can differ due to disparate resolution settings.

**Syntax**

```
saveas(h, 'filename.ext')
saveas(h, 'filename', 'format')
```

**Description** `saveas(h, 'filename.ext')` saves the figure or Simulink block diagram with the handle `h` to the file `filename.ext`. The format of the file is determined by the extension, `ext`. Allowable values for `ext` are listed in this table.

You can pass the handle of any Handle Graphics object to `saveas`, which then saves the parent figure to the object you specified should `h` not be a figure handle. This means that `saveas` cannot save a subplot without also saving all subplots in its parent figure.

Text Value	Format
ai	Adobe Illustrator '88 Support for this format will be removed in a future release.
bmp	Windows bitmap
emf	Enhanced metafile
eps	EPS Level 1
fig	MATLAB figure (invalid for Simulink block diagrams)
jpg	JPEG image (invalid for Simulink block diagrams)
m	MATLAB file (invalid for Simulink block diagrams)

Text Value	Format
pbm	Portable bitmap
pcx	Paintbrush 24-bit
pdf	Portable Document Format
pgm	Portable Graymap
png	Portable Network Graphics
ppm	Portable Pixmap
tif	TIFF image, compressed

`saveas(h, 'filename', 'format')` saves the figure or Simulink block diagram with the handle `h` to the file called `filename` using the specified `format`. The filename can have an extension, but the extension is not used to define the file format. If no extension is specified, the standard extension corresponding to the specified format is automatically appended to the filename.

Allowable values for `format` are the extensions in the table above and the device drivers and graphic formats supported by `print`. The drivers and graphic formats supported by `print` include additional file formats not listed in the table above. When using a `print` device type to specify format for `saveas`, do not prefix it with `-d`.

## Tips

You can use `open` to open files saved using `saveas` with an `m` or `fig` extension. Other `saveas` and `print` formats are not supported by `open`. Both the **Save As** and **Export Setup** dialog boxes that you access from a figure's **File** menu use `saveas` with the `format` argument, and support all device and file types listed above.

---

**Note** Whenever you specify a format for saving a figure with the **Save As** menu item, that file format is used again the next time you save that figure or a new one. If you do not want to save in the previously-used format, use **Save As** and be sure to set the **Save as type** drop-down menu to the kind of file you want to write. However, saving a figure with the `saveas` function and a format does not change the **Save as type** setting in the GUI.

---

If you want to control the size or resolution of figures saved in image (bit-mapped) formats, such as BMP or JPG, use the `print` command and specify dots-per-inch resolution with the `r` switch.

## Examples

### Example 1: Specify File Extension

Save the current figure that you annotated using the Plot Editor to a file named `pred_prej` using the MATLAB `fig` format. This allows you to open the file `pred_prej.fig` at a later time and continue editing it with the Plot Editor.

```
saveas(gcf, 'pred_prej.fig')
```

### Example 2: Specify File Format but No Extension

Save the current figure, using a Portable Document format, to the file `logo`. Use the `pdf` extension from the above table to specify the format. The file created is `logo.pdf`.

```
saveas(gcf, 'logo', 'pdf')
```

The file created is `logo.pdf`. MATLAB automatically appends the `pdf` extension because no extension was specified.

### Example 3: Specify File Format and Extension

Save the current figure to the file `star.eps` using the Level 2 Color PostScript format. If you use `doc print` or `help print`, you can see from

the table for print device types that the device type for this format is -dpsc2. The file created is `star.eps`.

```
saveas(gcf, 'star.eps', 'psc2')
```

In another example, save the current Simulink block diagram to the file `trans.tiff` using the TIFF format with no compression. From the table for print device types, you can see that the device type for this format is `-dtiffn`. The file created is `trans.tiff`.

```
saveas(gcf, 'trans.tiff', 'tiffn')
```

### Example 4: Saving a Simulink Diagram

Save a Simulink diagram from command line. The file is saved as `counters.bmp`

```
sldemo_tank  
saveas(get_param('sldemo_tank','Handle'),'topmodel.bmp');
```

Using `get_param`, get the handle of the model and save using the `saveas` command. The file can be saved in any desired standard image formats.

---

<b>Purpose</b>	Save figure to FIG-file
<b>Syntax</b>	<code>savefig(filename)</code> <code>savefig(h,filename)</code>
<b>Description</b>	<p><code>savefig(filename)</code> saves the current figure to a FIG-file named <code>filename</code>.</p> <p><code>savefig(h,filename)</code> saves one or more figures referred to by <code>h</code>, where <code>h</code> can be a single figure handle or an array of figure handles.</p>
<b>Input Arguments</b>	<p><b>h - Handle to one or more figures</b> single figure handle   array of figure handles</p> <p>Handle to one or more figures, specified as a single figure handle or an array of figure handles.</p> <p><b>filename - file name</b> 'Untitled.fig' (default)   string</p> <p>File name, specified as a string. If you do not specify a file name, then MATLAB saves the file as <code>Untitled.fig</code>, which is the default.</p> <p>If the specified string does not include a <code>.fig</code> file extension, then MATLAB appends the extension. <code>savefig</code> does not accept other file extensions.</p> <p><b>Example:</b> 'ExampleFile.fig'</p>
<b>Examples</b>	<p><b>Save Current Figure to FIG-File</b></p> <p>Create a surface plot of the peaks function. Save the figure to the file <code>PeaksFile.fig</code>. Close the figure after saving it.</p> <pre>figure; surf(peaks); savefig('PeaksFile.fig'); close(gcf)</pre>

To open the figure, use the command `openfig('PeaksFile.fig')`.

## Save Multiple Figures to FIG-File

Create two plots and store the figure handles in array `h`. Save the figures to the file `TwoFiguresFile.fig`. Close the figures after saving them.

```
h(1) = figure;  
z = peaks;  
surf(z)
```

```
h(2) = figure;  
plot(z)
```

```
savefig(h, 'TwoFiguresFile.fig');  
close(h)
```

To open the two figures, use the command `openfig('TwoFiguresFile.fig')`.

## Tips

- You must use MATLAB to open files saved using `savefig`. To open the file, pass the file name to the function `openfig`, `hgload`, or `open`. For example,

```
openfig('ExampleFile.fig')
```

opens the file, `ExampleFile.fig`, in MATLAB.

- `savefig` saves the full MATLAB figure. To save only part of a figure, such as an axes, or to save handles in addition to the data, use the `save` function to create a MAT-file.

`openfig` | `save` | `open` | `load`

<b>Purpose</b>	Modify save process for object
<b>Syntax</b>	<code>b = saveobj(a)</code>
<b>Description</b>	<p><code>b = saveobj(a)</code> is called by the <code>save</code> function if the class of <code>a</code> defines a <code>saveobj</code> method. <code>save</code> writes the returned value, <code>b</code>, to the MAT-file.</p> <p>Define a <code>loadobj</code> method to take the appropriate action when loading the object.</p> <p>If <code>A</code> is an array of objects, MATLAB invokes <code>saveobj</code> separately for each object saved.</p>

## Examples

Call the superclass `saveobj` method from the subclass implementation of `saveobj` with the following syntax:

```
classdef mySub < super
    methods
        function sobj = saveobj(obj)
            % Call superclass saveobj method
            sobj = saveobj@super(obj);
            % Perform subclass save operations
            ...
        end
        ...
    end
    ...
end
```

See “Saving and Loading Objects from Class Hierarchies”.

---

Update object when saved:

```
function b = saveobj(a)
    % If the object does not have an account number,
    % call method to add account number to AccountNumber property
    if isempty(a.AccountNumber)
        a.AccountNumber = getAccountNumber(a);
    end
end
```

# saveobj

---

```
end  
b = a;  
end
```

See “Maintaining Class Compatibility”.

## Tutorials

- “Control Save and Load”

<b>Purpose</b>	Save current search path
<b>Alternatives</b>	As an alternative to the <code>savepath</code> function, use the Set Path dialog box.
<b>Syntax</b>	<pre>savepath savepath folderName/pathdef.m status = savepath...</pre>
<b>Description</b>	<p><code>savepath</code> updates the MATLAB search path for all users on the system so that the path can be reused in a future session. <code>savepath</code> saves the search path to the <code>pathdef.m</code> file that MATLAB located at startup, or to the current folder if a <code>pathdef.m</code> file exists there. To save the search path programmatically each time you exit MATLAB, use <code>savepath</code> in a <code>finish.m</code> file. On a Windows system with User Account Control (UAC) enabled, UAC might prompt you to allow the update operation because it requires administrator-level permission.</p> <p><code>savepath folderName/pathdef.m</code> saves the current search path to <code>pathdef.m</code> located in <code>folderName</code>. Use this form of the syntax if you do not have write access to the current <code>pathdef.m</code>. If you do not specify <code>folderName</code>, MATLAB saves <code>pathdef.m</code> in the current folder. <code>folderName</code> can be a relative or absolute path. To use the saved search path automatically in a future session, make <code>folderName</code> be the startup folder for MATLAB.</p> <p><code>status = savepath...</code> returns 0 when <code>savepath</code> was successful and 1 when <code>savepath</code> failed.</p>
<b>Examples</b>	<p>Save the current search path to <code>pathdef.m</code>, located in <code>I:/my_matlab_files</code>:</p> <pre>savepath I:/my_matlab_files/pathdef.m</pre>
<b>See Also</b>	<code>addpath</code>   <code>cd</code>   <code>dir</code>   <code>finish</code>   <code>genpath</code>   <code>matlabroot</code>   <code>pathsep</code>   <code>pathtool</code>   <code>rehash</code>   <code>restoredefaultpath</code>   <code>rmpath</code>   <code>startup</code>   <code>userpath</code>   <code>what</code>

# savepath

## How To

- “Running a Script When Exiting MATLAB”
- “What Is the MATLAB Search Path?”

**Purpose**

scatter plot

**Syntax**

```
scatter(X,Y)
scatter(X,Y,S)
scatter(X,Y,S,C)
scatter( __ , 'fill' )
scatter( __ , markertype)
scatter( __ , Name, Value)

scatter(axes_handle, __ )

h = scatter( __ )
```

**Description**

`scatter(X,Y)` displays circles at the locations specified by the vectors `X` and `Y`. This type of graph is also known as a bubble plot.

`scatter(X,Y,S)` draws each circle with the size specified by `S`. To plot each circle with equal size, specify `S` as a scalar. To plot each circle with a specific size, specify `S` as a vector with length equal to the length of `X` and `Y`.

`scatter(X,Y,S,C)` draws each circle with the color specified by `C`.

- If `C` is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If `C` is a three column matrix with the number of rows in `C` equal to the length of `X` and `Y`, then each row of `C` specifies an RGB color value for the corresponding circle.
- If `C` is a vector with length equal to the length of `X` and `Y`, then the values in `C` are linearly mapped to the colors in the current colormap.

`scatter( __ , 'fill' )` fills in the circles, using any of the input argument combinations in the previous syntaxes.

# scatter

---

`scatter( ___, markertype )` specifies the marker type.

`scatter( ___, Name, Value )` specifies scattergroup property settings using one or more Name, Value pair arguments.

`scatter( axes_handle, ___ )` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The `axes_handle` option can precede any of the input argument combinations in the previous syntaxes.

`h = scatter( ___ )` returns the scattergroup object handle, `h`.

## Input Arguments

### **X - Value of data to display on x-axis**

vector

Value of data to display on the x-axis, specified as a vector. X and Y must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Y - Value of data to display on y-axis**

vector

Value of data to display on the y-axis, specified as a vector. X and Y must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **S - Marker area**

36 (default) | scalar | row or column vector | []

Marker area, specified as a scalar, a row or column vector, or []. The values in S must be positive. The units for area are points squared.

- If **S** is a scalar, then `scatter` plots all markers with the specified area.
- If **S** is a row or column vector, then each entry in **S** specifies the area for the corresponding marker. The length of **S** must equal the length of **X** and **Y**, and corresponding entries in **X**, **Y**, and **S** determine the location and area of each marker.
- If **S** is empty, then the default size of 36 points squared is used.

**Example:** 50

**Example:** [36,25,25,17,46]

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### C - Marker color

[0 0 1] (blue) (default) | color string | RGB row vector | three-column matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify **C** as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'

# scatter

RGB Vector	Short Name	Long Name
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'k'

Example: [1,2,3,4]

Example: reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

## markertype - Marker type

'o' (default) | string

Marker type, specified as a string. This table lists the supported marker types.

Specifier	Marker Type
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle

Specifier	Marker Type
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'p'

### Data Types

char

### axes\_handle - Axes handle

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** 'MarkerFaceColor', 'red' sets the marker face color to red.

For more information on these settings see `scattergroup`.

### 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar in points. The scalar sets the width size of the marker edge.

Example: 'LineWidth',0.75

## 'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector  
| string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'MarkerEdgeColor',[1 .8 .1]

## 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

# scatter

---

## Output Arguments

### **h** - Scattergroup object handle

scalar

Scattergroup object handle, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the scattergroup object.

## Examples

### **Create Scatter Plot**

Set up vector `x` to contain equally spaced values between 0 and  $3\pi$ . Initialize the random-number generator to make the output of `rand` repeatable, and set up vector `y` to contain cosine values with random noise.

```
x = linspace(0,3*pi,200);  
rng(0,'twister');  
y = cos(x)+ rand(1,200);
```

Create a scatter plot using the two vector inputs.

```
figure  
scatter(x,y)
```

scatter plots entries in  $x$  against corresponding entries in  $y$ .

### Vary Circle Size

Load sample data from `seamount` to get vectors  $x$  and  $y$ . Create a scatter plot and vary circle size. Use `zoom` to zoom in on the scatter plot.

```
figure
load seamount
s = linspace(1,50,length(x));
scatter(x,y,s)
```

# scatter

Corresponding entries in `x`, `y`, and `s` determine the location and size of each marker.

## Vary Circle Color

Load sample data from `seamount` to get vectors `x` and `y`. Create a scatter plot and vary the circle color. Use `zoom` to zoom in on the scatter plot.

figure

```
load seamount
s = 10;
c = linspace(1,10,length(x));
scatter(x,y,s,c)
zoom(2)
```

Corresponding entries in  $x$ ,  $y$ , and  $c$  determine the location and color of each marker. Since  $s$  is a scalar, all markers are plotted with equal size.

## Vary Circle Size and Color

Load sample data from seamount to get vectors  $x$ ,  $y$ , and  $z$ . Create a scatter plot and vary the circle size and color. Fill in the circles and use `zoom` to zoom in on the scatter plot.

```
figure
load seamount
s = sqrt(-z/2);
c = z;
scatter(x,y,s,c,'fill')
zoom(2)
```

Each circle is plotted with a specific size and color determined by the vectors  $s$  and  $c$ , respectively.

### Specify Marker Symbol

Initialize the random-number generator to make the output of `rand` repeatable. Set up vectors  $x$  and  $y$  as sine and cosine values with random noise.

```
rng(0,'twister');  
theta = linspace(0,2*pi,150);
```

## scatter

---

```
x = sin(theta) + 0.75*rand(1,150);  
y = cos(theta) + 0.75*rand(1,150);
```

Create a scatter plot and set the marker type to diamonds with an area of 140 points squared.

```
figure  
s = 140;  
scatter(x,y,s,'d')
```

To fill in the diamonds, use the 'fill' option.

### Specify Marker Properties

Initialize the random-number generator to make the output of rand repeatable. Set up vectors x and y as sine and cosine values with random noise.

```
rng(0, 'twister');  
theta = linspace(0, 2*pi, 300);  
x = sin(theta) + 0.75*rand(1, 300);  
y = cos(theta) + 0.75*rand(1, 300);
```

Create a scatter plot and set the marker size, edge color, face color, and line width.

```
figure  
s = 40;  
scatter(x, y, s, 'MarkerEdgeColor', 'b', ...  
        'MarkerFaceColor', 'c', ...  
        'LineWidth', 1.5)
```

## scatter

---

### Specify Scatter Plot Axes

Load the sample data from `seamount` to get vectors `x`, `y`, and `z`.

```
load seamount
```

Create a figure with handles to two subplots. Create a scatter plot in the first subplot using the axes handle. In the second subplot, create another scatter plot from the same data sample and use `zoom` to zoom in on the plot.

```
figure
hs(1) = subplot(1,2,1);
hs(2) = subplot(1,2,2);
s = 30;
c = z;
scatter(hs(1),x,y,s,c,'fill','d')
scatter(hs(2),x,y,s,c,'fill','d')
zoom(4)
```

## Set Marker Properties Using the Handle

Create a scatter plot and get the scattergroup object handle, h.

```
figure
theta = linspace(0,1,500);
x = exp(theta).*sin(100*theta);
y = exp(theta).*cos(100*theta);
h = scatter(x,y);
```

Use the handle to set the marker edge color, face color, and line width.

```
set(h,'MarkerEdgeColor','b',...
     'MarkerFaceColor',[0 .5 .5],...
     'LineWidth',0.6)
```

# scatter3

---

**Purpose** 3-D scatter plot

**Syntax**

```
scatter3(X,Y,Z)
scatter3(X,Y,Z,S)
scatter3(X,Y,Z,S,C)
scatter3( __ , 'fill' )
scatter3( __ , markertype)
scatter3( __ , Name, Value)

scatter3(axes_handle, __ )

h = scatter3( __ )
```

**Description** `scatter3(X,Y,Z)` displays circles at the locations specified by the vectors `X`, `Y`, and `Z`.

`scatter3(X,Y,Z,S)` draws each circle with the size specified by `S`. To plot each circle with equal size, specify `S` as a scalar. To plot each circle with a specific size, specify `S` as a vector.

`scatter3(X,Y,Z,S,C)` draws each circle with the color specified by `C`.

- If `C` is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If `C` is a three column matrix with the number of rows in `C` equal to the length of `X`, `Y`, and `Z`, then each row of `C` specifies an RGB color value for the corresponding circle.
- If `C` is a vector with length equal to the length of `X`, `Y`, and `Z`, then the values in `C` are linearly mapped to the colors in the current colormap.

`scatter3( __ , 'fill' )` fills in the circles, using any of the input argument combinations in the previous syntaxes.

`scatter3( __ , markertype)` specifies the marker type.

`scatter3( ___, Name, Value)` specifies scattergroup property settings using one or more `Name, Value` pair arguments.

`scatter3(axes_handle, ___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The `axes_handle` option can precede any of the input argument combinations in the previous syntaxes.

`h = scatter3( ___)` returns the scattergroup object handle, `h`.

## **Input Arguments**

### **X - Value of data to display on x-axis**

vector

Value of data to display on the *x*-axis, specified as a vector. *X*, *Y*, and *Z* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Y - Value of data to display on y-axis**

(default) | vector

Value of data to display on the *y*-axis, specified as a vector. *X*, *Y*, and *Z* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Z - Value of data to display on z-axis**

(default) | vector

Value of data to display on the *z*-axis, specified as a vector. *X*, *Y*, and *Z* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

## **S - Marker area**

36 (default) | scalar | vector | []

Marker area, specified as a scalar, a vector, or []. The values in **S** must be positive. The units for area are points squared.

- If **S** is a scalar, then `scatter3` plots all markers with the specified area.
- If **S** is a row or column vector, then each entry in **S** specifies the area for the corresponding marker. The length of **S** must equal the length of **X**, **Y** and **Z**. Corresponding entries in **X**, **Y**, **Z** and **S** determine the location and area of each marker.
- If **S** is empty, then the default size of 36 points squared is used.

**Example:** 50

**Example:** [36,25,25,17,46]

## **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

## **C - Marker color**

[0 0 1] (blue) (default) | color string | RGB row vector | three-column  
matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify **C** as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'y'

Example: [1,2,3,4]

Example: reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

#### markertype - Marker type

'o' (default) | string

Marker type, specified as a string. The table below lists the supported marker types.

Specifier	Marker Type
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross

Specifier	Marker Type
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

## **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'MarkerFaceColor', 'red'` sets the marker face color to red.

For more information on these properties see `scattergroup`.

## **'LineWidth' - Line width**

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the marker edge.

**Example:** 'LineWidth',0.75

### 'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector  
| string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

# scatter3

Example: 'MarkerEdgeColor',[1 .8 .1]

## 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

## Output Arguments

### **h - Scattergroup object handle**

scalar

Scattergroup object handle, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the scattergroup.

## Examples

### **Create 3-D Scatter Plot**

Create a 3-D scatter plot. Use sphere to set up vectors x, y, and z.

```
figure
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
scatter3(x,y,z)
```

## scatter3

---

### Vary Marker Size

Use sphere to set up vectors x, y, and z.

```
[X,Y,Z] = sphere(16);  
x = [0.5*X(:); 0.75*X(:); X(:)];  
y = [0.5*Y(:); 0.75*Y(:); Y(:)];  
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Set up vector s to specify the marker sizes.

```
S = repmat([100,50,5],numel(X),1);  
s = S(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure  
scatter3(x,y,z,s)  
view(40,35)
```

## scatter3

---

Corresponding entries in `x`, `y`, `z`, and `s` determine the location and size of each marker.

### Vary Marker Color

Use `sphere` to set up vectors `x`, `y`, and `z`.

```
[X,Y,Z] = sphere(16);  
x = [0.5*X(:); 0.75*X(:); X(:)];  
y = [0.5*Y(:); 0.75*Y(:); Y(:)];  
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Set up vectors `s` and `c` to specify the size and color of each marker.

```
S = repmat([50,25,10], numel(X), 1);  
C = repmat([1,2,3], numel(X), 1);  
s = S(:);  
c = C(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure  
scatter3(x,y,z,s,c)  
view(40,35)
```

Corresponding entries in  $x$ ,  $y$ ,  $z$ , and  $c$  determine the location and color of each marker.

### Fill in Markers

Initialize the random-number generator to make the output of `rand` repeatable. Set up vectors  $x$  and  $y$  as cosine and sine values with random noise.

```
rng(0, 'twister');  
z = linspace(0, 4*pi, 250);
```

## scatter3

---

```
x = 2*cos(z) + rand(1,250);  
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and fill in the markers. Use `view` to change the angle of the axes in the figure.

```
figure  
scatter3(x,y,z,'fill')  
view(-30,10)
```

### Set Marker Type

Initialize the random-number generator to make the output of rand repeatable. Set up vectors x and y as cosine and sine values with random noise.

```
rng(0, 'twister');  
z = linspace(0, 4*pi, 250);  
x = 2*cos(z) + rand(1, 250);  
y = 2*sin(z) + rand(1, 250);
```

Create a 3-D scatter plot and set the marker type. Use view to change the angle of the axes in the figure.

```
figure  
scatter3(x, y, z, '*')  
view(-30, 10)
```

# scatter3

## Set Marker Properties

Initialize the random-number generator to make the output of rand repeatable. Set up vectors x and y as cosine and sine values with random noise.

```
rng(0, 'twister');  
z = linspace(0, 4*pi, 250);  
x = 2*cos(z) + rand(1, 250);  
y = 2*sin(z) + rand(1, 250);
```

Create a 3-D scatter plot and set the marker edge color and the marker face color. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,'MarkerEdgeColor','k','MarkerFaceColor',[0 .75 .75])
view(-30,10)
```

### Specify 3-D Scatter Plot Axes

Load the `seamount` data set to get vectors `x`, `y`, and `z`.

# scatter3

```
load seamount
```

Create a figure with handles to two subplots. In each subplot create a 3-D scatter plot and specify the marker properties for each scatter plot.

```
figure  
hs(1) = subplot(2,1,1);  
hs(2) = subplot(2,1,2);  
scatter3(hs(1),x,y,z,'MarkerFaceColor',[0 .75 .75])  
scatter3(hs(2),x,y,z,'*')
```

## Set Marker Properties Using the Handle

Use sphere to set up vectors x, y, and z.

```
[X,Y,Z] = sphere(16);  
x = [0.5*X(:); 0.75*X(:); X(:)];  
y = [0.5*Y(:); 0.75*Y(:); Y(:)];  
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Set up vectors s and c to specify the size and color for each marker.

```
S = repmat([70,50,20],numel(X),1);  
C = repmat([1,2,3],numel(X),1);  
s = S(:);  
c = C(:);
```

Create a 3-D scatter plot and get the object handle.

```
figure  
h = scatter3(x,y,z,s,c);
```

Use the object handle to set the marker face color.

```
set(h,'MarkerFaceColor',[0 .5 .5])
```

## scatter3

[scatter](#) | [plot3scattergroup](#) | [ColorSpec](#) | [LineStyle](#)

## Purpose

Define scattergroup properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for scattergroup objects.

See Plot Objects for information on scattergroup objects.

## Scattergroup Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of scattergroup objects in legends.* Specifies whether this scattergroup object is represented in a figure legend.

Querying the Annotation property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the scattergroup object is displayed in a figure legend.

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Include the scattergroup object in a legend as one entry, but not its children objects
off	Do not include the scattergroup or its children in a legend (default)
children	Include only the children of the scattergroup as separate entries in the legend

# Scattergroup Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

# Scattergroup Properties

---

## CData

vector | m-by-3 matrix | ColorSpec

*Color of markers.* When CData is a vector the same length as XData and YData, the values in CData are linearly mapped to the colors in the current colormap. When CData is a `length(XData)-by-3` matrix, it specifies the colors of the markers as RGB values.

## CDataSource

string (MATLAB variable)

*Link CData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the CData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change CData.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## Children

array of graphics object handles

*Children of the scattergroup object.* An array containing the handle of a patch object parented to the scattergroup object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

# Scattergroup Properties

---

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## `DisplayName`

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the scattergroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

# Scattergroup Properties

---

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

# Scattergroup Properties

---

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the markers that compose the scatter plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

on | {off}

*Select the object by clicking markers or area of extent.* Select plot objects by:

- Clicking scatter markers (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the scatter markers to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the scatter markers).

Interruptible  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Scattergroup Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

**LineWidth**  
size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.

**Marker**  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the **Marker** property independently from the **LineStyle** property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square

Specifier	Marker Type
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — Defines color to use.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `CData` property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.

# Scattergroup Properties

---

- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

## Parent

handle of parent axes, `hgggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgggroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

## SelectionHighlight

`{on}` | `off`

*Object highlighted when selected.*

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

## SizeData

square points

*Size of markers in square points.* Area of the marker in the scatter graph in units of points. Since there are 72 points to one inch, to

specify a marker that has an area of one square inch you would use a value of  $72^2$ .

**SizeDataSource**  
string (MATLAB variable)

*Link SizeData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the **SizeData**.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change **SizeData**.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the **Tag** property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the **Tag** property.

# Scattergroup Properties

---

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stemseries objects, `Type` is `'hggroup'`. The following statement finds all the `hggroup` objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- **on** — Object and all children of the object are visible unless the child object's **Visible** property is **off**.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

**XData**

array

*X-coordinates of scatter markers.* The **scatter** function draws individual markers at each *x*-axis location in the **XData** array. The input argument **X** in the **scatter** function calling syntax assigns values to **XData**.

**XDataSource**

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the **XData**. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to **refreshdata** when you set this property. Changing workspace variables used as an object's **XDataSource** does not change the object's **XData** values, but you can use **refreshdata** to force an update of the object's data. **refreshdata** also lets you specify that the data source variable be evaluated in the workspace of a function from which you call **refreshdata**.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# Scattergroup Properties

---

## YData

scalar | vector | matrix

*Y-coordinates of scatter markers.* The `scatter` function draws individual markers at each *y*-axis location in the YData array.

The input argument *Y* in the `scatter` function calling syntax assigns values to YData.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector

*Z-coordinates.* A vector defining the *z*-coordinates for the graph. *XData* and *YData* must be the same length and have the same number of rows.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the *ZData*. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's *ZDataSource* does not change the object's *ZData* values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# schur

---

**Purpose** Schur decomposition

**Syntax**  
`T = schur(A)`  
`T = schur(A, flag)`  
`[U, T] = schur(A, ...)`

**Description** The `schur` command computes the Schur form of a matrix.  
`T = schur(A)` returns the Schur matrix `T`.  
`T = schur(A, flag)` for real matrix `A`, returns a Schur matrix `T` in one of two forms depending on the value of `flag`:

'complex'	<code>T</code> is triangular and is complex if <code>A</code> is real and has complex eigenvalues.
'real'	<code>T</code> has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal. 'real' is the default when <code>A</code> is real.

If `A` is complex, `schur` returns the complex Schur form in matrix `T` and `flag` is ignored. The complex Schur form is upper triangular with the eigenvalues of `A` on the diagonal.

The function `rsf2csf` converts the real Schur form to the complex Schur form.

`[U, T] = schur(A, ...)` also returns a unitary matrix `U` so that  $A = U^*T^*U'$  and  $U' * U = \text{eye}(\text{size}(A))$ .

**Examples** `H` is a 3-by-3 eigenvalue test matrix:

```
H = [ -149   -50   -154
       537   180   546
       -27    -9   -25 ]
```

Its Schur form is

```
schur(H)
```

```
ans =  
    1.0000   -7.1119  -815.8706  
         0    2.0000  -55.0236  
         0         0    3.0000
```

The eigenvalues, which in this case are 1, 2, and 3, are on the diagonal. The fact that the off-diagonal elements are so large indicates that this matrix has poorly conditioned eigenvalues; small changes in the matrix elements produce relatively large changes in its eigenvalues.

**See Also**

`eig` | `hess` | `qz` | `rsf2csf`

# script

---

**Purpose** Sequence of MATLAB statements in file

**Description** A script file is an external file that contains a sequence of MATLAB statements. By typing the filename, you can obtain subsequent MATLAB input from the file. Script files have a filename extension of `.m`.

Scripts are the simplest kind of MATLAB program. They are useful for automating blocks of MATLAB commands, such as computations you have to perform repeatedly from the command line. Scripts can operate on existing data in the workspace, or they can create new data on which to operate. Although scripts do not return output arguments, any variables that they create remain in the workspace, so you can use them in further computations. In addition, scripts can produce graphical output using commands like `plot`.

Scripts can contain any series of MATLAB statements. They require no declarations or begin/end delimiters.

Like any MATLAB program, scripts can contain comments. Any text following a percent sign (`%`) on a given line is comment text. Comments can appear on lines by themselves, or you can append them to the end of any executable line.

## Purpose

Scattered data interpolation

## Description

Use `scatteredInterpolant` to perform interpolation on a 2-D or 3-D “Scattered Data” on page 1-5586 set. For example, you can pass a set of  $(x, y)$  points and values,  $v$ , to `scatteredInterpolant`, and it returns a surface of the form  $v = F(x, y)$ . This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point,  $(xq, yq)$ , to produce an interpolated value,  $vq$ .

Use `scatteredInterpolant` to create the “Interpolant” on page 1-5586,  $F$ . Then, you can evaluate  $F$  at specific points using any of the following syntaxes:

- $Vq = F(Pq)$  specifies the query points in the matrix  $Pq$ . Each row in  $Pq$  contains the coordinates of a query point.
- $Vq = F(Xq, Yq)$  and  $Vq = F(Xq, Yq, Zq)$  specify the query points as two or three matrices of equal size.
- $Vq = F(\{xq, yq\})$  and  $Vq = F(\{xq, yq, zq\})$  specify the query points as “Grid Vectors” on page 1-5586. The interpolated values are returned in  $Vq$ . Use this syntax to conserve memory when you want to query a large grid of points.

## Construction

$F = \text{scatteredInterpolant}(x, y, v)$  creates an interpolant that fits a surface of the form  $v = F(x, y)$ . Vectors  $x$  and  $y$  specify the  $(x, y)$  coordinates of the sample points.  $v$  is a vector that contains the sample values associated with the points,  $(x, y)$ .

$F = \text{scatteredInterpolant}(x, y, z, v)$  creates a 3-D interpolant of the form  $v = F(x, y, z)$ .

$F = \text{scatteredInterpolant}(P, v)$  specifies the coordinates of the sample points as an array. The rows of  $P$  contain the  $(x, y)$  or  $(x, y, z)$  coordinates for the values in  $v$ .

$F = \text{scatteredInterpolant}(\_, \text{Method})$  specifies a string that describes an interpolation method: 'nearest', 'linear', or 'natural'. Specify `Method` as the last input argument in any of the first three syntaxes.

# scatteredInterpolant

---

`F = scatteredInterpolant( ____, Method, ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `Method` can be one of three strings: 'nearest', 'linear', or 'natural'. Specify `ExtrapolationMethod` as one of the following strings: 'nearest', 'linear', or 'none'. Pass `Method` and `ExtrapolationMethod` together as the last two input arguments in any of the first three syntaxes.

`F = scatteredInterpolant()` creates an empty scattered data interpolant. Use `F.Points = P` to initialize `F` with the points in matrix `P`. Use `F.Values = v` to initialize `F` with the values in `v`.

## Input Arguments

**x**

Sample points *x*-coordinates, specified as a vector of the same size as `v`.

**y**

Sample points *y*-coordinates, specified as a vector of the same size as `v`.

**z**

Sample points *z*-coordinates, specified as a vector of the same size as `v`.

**P**

Sample points array, specified as an *m*-by-*n* matrix, where *m* is the number of points and *n* is the dimension of the space where the points reside. Each row of `P` contains the (*x*, *y*) or (*x*, *y*, *z*) coordinates of a sample point.

**v**

Sample values vector, specified as a vector of that defines the values at the sample points.

## Method

Interpolation method, specified as one of these strings.

Method String	Description
'linear' (default)	Linear interpolation.
'nearest'	Nearest neighbor interpolation.
'natural'	Natural neighbor interpolation.

## ExtrapolationMethod

Extrapolation method, specified as one of these strings.

ExtrapolationMethod String	Description
'linear'	Linear extrapolation based on boundary gradients. Default when Method is
'nearest'	Nearest neighbor extrapolation. This method evaluates to the value of the nearest neighbor on the boundary. Default when Method = 'nearest'.
'none'	No extrapolation. Any queries outside the convex hull of F.Points return NaN.

## Properties

### Points

Array of sample points (locations) for the values in F.Values. Each row of F.Points contains the  $(x, y)$  or  $(x, y, z)$  coordinates of a sample point.

### Values

Vector of values associated with each point in F.Points.

### Method

A string specifying the method used to interpolate the data: 'nearest', 'linear', or 'natural'.

# scatteredInterpolant

---

## ExtrapolationMethod

A string specifying the method used to extrapolate the data: 'nearest', 'linear', or 'none'. A value of 'none' indicates that extrapolation is disabled.

## Definitions

### Interpolant

Interpolating function that you can evaluate at query locations.

### Scattered Data

A set of points that have no structure among their relative locations.

### Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

### Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices X and Y. You can represent the same grid using the grid vectors, `xg` and `yg`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Indexing

`scatteredInterpolant` supports index-based editing of the properties of `F`. You can add or remove points in `F.Points` and update the corresponding values in `F.Values`. For example, `F.Points(5,:) = []` removes the fifth point, and `F.Values(5) = []` removes the corresponding value.

## Examples

### 2-D Interpolation

Define 200 random points.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);  
x = xy(:,1);
```

```
y = xy(:,2);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v);
```

Evaluate the interpolant at query locations ( $xq$ ,  $yq$ ).

```
ti = -2:.25:2;  
[xq,yq] = meshgrid(ti,ti);  
vq = F(xq,yq);
```

Plot the result.

```
figure  
mesh(xq,yq,vq);  
hold on;  
plot3(x,y,v,'o');  
hold off;
```

# scatteredInterpolant

## 2-D Extrapolation

Query the interpolant at a single point outside the convex hull using nearest neighbor extrapolation.

Define a matrix of 200 random points.

```
P = -2.5 + 5*gallery('uniformdata',[200 2],0);
```

Sample an exponential function. These are the sample values for the interpolant.

```
x = P(:,1);  
y = P(:,2);  
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant, specifying linear interpolation and nearest neighbor extrapolation.

```
F = scatteredInterpolant(P,v,'linear','nearest')
```

```
F =
```

```
scatteredInterpolant with properties:
```

```
Points: [200x2 double]
```

```
Values: [200x1 double]
```

```
Method: 'linear'
```

```
ExtrapolationMethod: 'nearest'
```

Evaluate the interpolant outside the convex hull.

```
vq = F(3.0, -1.5)
```

```
vq =
```

```
0.0031
```

Disable extrapolation and evaluate F at the same point.

```
F.ExtrapolationMethod = 'none';
```

```
vq = F(3.0, -1.5)
```

```
vq =
```

```
NaN
```

# scatteredInterpolant

---

## Replacement of Sample Values

Replace the elements in the Values property when you want to change the values at the sample points. You get immediate results when you evaluate the new interpolant because the original triangulation has not changed.

Create 50 random points.

```
x = -2.5 + 5*gallery('uniformdata',[50 1],0);  
y = -2.5 + 5*gallery('uniformdata',[50 1],1);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v)
```

```
F =
```

```
scatteredInterpolant with properties:
```

```
          Points: [50x2 double]  
          Values: [50x1 double]  
          Method: 'linear'  
  ExtrapolationMethod: 'linear'
```

Evaluate the interpolant at (1.40,1.90).

```
F(1.40,1.90)
```

```
ans =
```

```
0.0029
```

Change the interpolant sample values.

```
vnew = x.^2 + y.^2;  
F.Values = vnew;
```

Evaluate the interpolant at (1.40,1.90).

```
F(1.40,1.90)
```

```
ans =
```

```
6.1109
```

## How To

- [Class Attributes](#)
- [Property Attributes](#)
- [“Interpolating Gridded Data”](#)

**Purpose** Secant of argument in radians

**Syntax**  $Y = \sec(X)$

**Description** The `sec` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.  $Y = \sec(X)$  returns an array the same size as  $X$  containing the secant of the elements of  $X$ .

**Examples** Graph the secant over the domains  $-\pi/2 < x < \pi/2$  and  $\pi/2 < x < 3\pi/2$ .

```
x1 = -pi/2+0.01:0.01:pi/2-0.01;  
x2 = pi/2+0.01:0.01:(3*pi/2)-0.01;  
plot(x1,sec(x1),x2,sec(x2)), grid on
```

The expression `sec(pi/2)` does not evaluate as infinite but as the reciprocal of the floating-point accuracy `eps`, because `pi` is a floating-point approximation to the exact value of  $\pi$ .

**Secant**

The secant of  $z$  is

$$\sec(z) = \frac{1}{\cos(z)}.$$

**See Also**

# secd

---

<b>Purpose</b>	Secant of argument in degrees
<b>Syntax</b>	$Y = \text{secd}(X)$
<b>Description</b>	$Y = \text{secd}(X)$ returns the secant of the elements of $X$ , which are expressed in degrees.
<b>Input Arguments</b>	<b>X - Angle in degrees</b> scalar value   vector   matrix   N-D array  Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The <code>secd</code> operation is element-wise when $X$ is nonscalar.  <b>Example:</b>  <b>Data Types</b> single   double <b>Complex Number Support:</b> Yes
<b>Output Arguments</b>	<b>Y - Secant of angle</b> scalar value   vector   matrix   N-D array  Secant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as $X$ .
<b>Examples</b>	<b>Secant of 90 degrees compared to secant of <math>\pi/2</math> radians</b>  <code>secd(90)</code>  <code>ans =</code>  Inf  <code>sec(pi/2)</code>  <code>ans =</code>  1.6331e+16

$\text{secd}(90)$  is infinite, whereas  $\text{sec}(\pi/2)$  is large but finite.

### **Secant of vector of complex angles, specified in degrees**

```
z = [35+i 15+2i 10+3i];  
y = secd(z)
```

y =

```
1.2204 + 0.0149i  1.0346 + 0.0097i  1.0140 + 0.0094i
```

# sech

---

**Purpose** Hyperbolic secant

**Syntax**  $Y = \operatorname{sech}(X)$

**Description** The sech function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \operatorname{sech}(X)$  returns an array the same size as  $X$  containing the hyperbolic secant of the elements of  $X$ .

**Examples** Graph the hyperbolic secant over the domain  $-2\pi \leq x \leq 2\pi$ .

```
x = -2*pi:0.01:2*pi;  
plot(x,sech(x)), grid on
```

**Definitions** **Hyperbolic Secant**

The hyperbolic secant of  $z$  is

$$\operatorname{sech}(z) = \frac{1}{\operatorname{cosh}(z)}.$$

**See Also**

asech | sec | sinh | cosh

# selectmoveresize

---

**Purpose** Select, move, resize, or copy axes and uicontrol graphics objects

**Syntax** `A = selectmoveresize`  
`set(gca, 'ButtonDownFcn', 'selectmoveresize')`

**Description** `selectmoveresize` is useful as the callback routine for axes and uicontrol button down functions. When executed, it selects the object and allows you to move, resize, and copy it.

`A = selectmoveresize` returns a structure array containing

- `A.Type`: a string containing the action type, which can be `Select`, `Move`, `Resize`, or `Copy`
- `A.Handles`: a list of the selected handles, or, for a `Copy`, an `m-by-2` matrix containing the original handles in the first column and the new handles in the second column

`set(gca, 'ButtonDownFcn', 'selectmoveresize')` sets the `ButtonDownFcn` property of the current axes to `selectmoveresize`:

**See Also** `axes` | `uicontrol`

**Purpose** Semilogarithmic plot

**Syntax**

```
semilogx(Y)
semilogx(X1,Y1,...)
semilogx(X1,Y1,LineStyle,...)
semilogx(...,'PropertyName',PropertyValue,...)
h = semilogx(...)
```

**Description** semilogx plot data as logarithmic scales for the *x*-axis.

`semilogx(Y)` creates a plot using a base 10 logarithmic scale for the *x*-axis and a linear scale for the *y*-axis. It plots the columns of *Y* versus their index if *Y* contains real numbers. `semilogx(Y)` is equivalent to `semilogx(real(Y), imag(Y))` if *Y* contains complex numbers. `semilogx` ignores the imaginary component in all other uses of this function.

`semilogx(X1,Y1,...)` plots all *Y<sub>n</sub>* versus *X<sub>n</sub>* pairs. If only one of *X<sub>n</sub>* or *Y<sub>n</sub>* is a matrix, `semilogx` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogx(X1,Y1,LineStyle,...)` plots all lines defined by the *X<sub>n</sub>*, *Y<sub>n</sub>*, *LineStyle* triples. *LineStyle* determines line style, marker symbol, and color of the plotted lines.

`semilogx(...,'PropertyName',PropertyValue,...)` sets property values for all `lineseries` graphics objects created by `semilogx`.

`h = semilogx(...)` return a vector of handles to `lineseries` graphics objects, one handle per line.

## Tips

If you do not specify a color when plotting more than one line, `semilogx` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, \textit{LineStyle}$  triples; for example,

```
semilogx(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

## Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

## Examples

### Logarithmic Scale for x-Axis

Create a plot with a logarithmic scale for the x-axis and a linear scale for the y-axis.

```
x = 0:1000;  
y = log(x);  
  
figure  
semilogx(x,y)
```

**See Also**

`line` | `LineSpec` | `loglog` | `plot` | `semilogy`

# semilogy

---

## Purpose

Semilogarithmic plot

## Syntax

```
semilogy(Y)
semilogy(X1,Y1,...)
semilogy(X1,Y1,LineStyle,...)
semilogy(...,'PropertyName',PropertyValue,...)
h = semilogy(...)
```

## Description

`semilogy` plots data with logarithmic scale for the  $y$ -axis.

`semilogy(Y)` creates a plot using a base 10 logarithmic scale for the  $y$ -axis and a linear scale for the  $x$ -axis. It plots the columns of  $Y$  versus their index if  $Y$  contains real numbers. `semilogy(Y)` is equivalent to `semilogy(real(Y), imag(Y))` if  $Y$  contains complex numbers. `semilogy` ignores the imaginary component in all other uses of this function.

`semilogy(X1,Y1,...)` plots all  $Y_n$  versus  $X_n$  pairs. If only one of  $X_n$  or  $Y_n$  is a matrix, `semilogy` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogy(X1,Y1,LineStyle,...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples. `LineStyle` determines line style, marker symbol, and color of the plotted lines.

`semilogy(...,'PropertyName',PropertyValue,...)` sets property values for all `lineseries` graphics objects created by `semilogy`.

`h = semilogy(...)` returns a vector of handles to `lineseries` graphics objects, one handle per line.

**Tips**

If you do not specify a color when plotting more than one line, `semilogy` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, LineSpec$  triples; for example,

```
semilogy(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

**Renderer Support**

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

**Examples****Logarithmic Scale for y-Axis**

Create a plot with a logarithmic scale for the y-axis and a linear scale for the x-axis.

```
x = 0:0.1:10;  
y = exp(x);
```

```
figure  
semilogy(x,y);
```

# semilogy

---

**See Also**      `line` | `LineSpec` | `loglog` | `plot` | `semilogx`

**Purpose** Send email message to address list

**Syntax**

```
sendmail(recipients,subject)
sendmail(recipients,subject,message)
sendmail(recipients,subject,message,attachments)
```

**Description** `sendmail(recipients,subject)` sends email to recipients with the specified subject. The recipients input is a string for a single address, or a cell array of strings for multiple addresses.

`sendmail(recipients,subject,message)` includes the specified message. If message is a string, sendmail automatically wraps text at 75 characters. To force a line break in the message text, use 10, as shown in the Examples. If message is a cell array of strings, each cell represents a new line of text.

`sendmail(recipients,subject,message,attachments)` attaches the files listed in the string or cell array attachments.

## Tips

- The sendmail function does not support HTML-formatted messages. However, you can send HTML files as attachments.
- If sendmail cannot determine your email address or outgoing SMTP mail server from your system registry, specify those settings using the setpref function. For example:

```
setpref('Internet','SMTP_Server','my_server.example.com');
setpref('Internet','E_mail','my_email@example.com');
```

To identify the SMTP server for the call to setpref, check the preferences for your electronic mail application, or consult your email system administrator. If you cannot easily determine the server name, try 'mail', which is a common default, such as:

```
setpref('Internet','SMTP_Server','mail');
```

- By default, the sendmail function does not support email servers that require authentication. To support these servers, change your

# sendmail

---

system settings and set preferences for the SMTP user name and password, with commands in the following form:

```
props = java.lang.System.getProperties();
props.setProperty('mail.smtp.auth', 'true');

setpref('Internet', 'SMTP_Username', 'myaddress@example.com');
setpref('Internet', 'SMTP_Password', 'mypassword');
```

- To override the default character encoding, set the preference for email character encoding as follows:

```
setpref('Internet', 'E_mail_Charset', encoding);
```

where *encoding* is a string specifying the character encoding, such as 'SJIS'.

## Examples

Send a message with two attachments to a hypothetical email address:

```
sendmail('user@otherdomain.com', ...
        'Test subject', 'Test message', ...
        {'folder/attach1.html', 'attach2.doc'});
```

---

Send a message with forced line breaks (using 10) to a hypothetical email address:

```
sendmail('user@otherdomain.com', 'New subject', ...
        ['Line1 of message' 10 'Line2 of message' 10 ...
        'Line3 of message' 10 'Line4 of message']);
```

The resulting message is:

```
Line1 of message
Line2 of message
Line3 of message
Line4 of message
```

Gmail™ servers require authentication and an encrypted connection (SSL) on port 465. Change your system settings to use your Gmail server and send a test message to your Gmail account:

```
% Modify these two lines to reflect
% your account and password.
myaddress = 'myaddress@gmail.com';
mypassword = 'mypassword';

setpref('Internet', 'E_mail', myaddress);
setpref('Internet', 'SMTP_Server', 'smtp.gmail.com');
setpref('Internet', 'SMTP_Username', myaddress);
setpref('Internet', 'SMTP_Password', mypassword);

props = java.lang.System.getProperties;
props.setProperty('mail.smtp.auth', 'true');
props.setProperty('mail.smtp.socketFactory.class', ...
    'javax.net.ssl.SSLSocketFactory');
props.setProperty('mail.smtp.socketFactory.port', '465');

sendmail(myaddress, 'Gmail Test', 'This is a test message.');
```

## Alternatives

On Windows systems with Microsoft Outlook®, you can send email directly through Outlook by accessing the COM server with actxserver. For an example, see Solution 1-RTY6J.

## How To

- “Specify Proxy Server Settings for Connecting to the Internet”

# serial

---

**Purpose** Create serial port object

**Syntax**  
`obj = serial('port')`  
`obj = serial('port', 'PropertyName', PropertyValue, ...)`

**Description** `obj = serial('port')` creates a serial port object associated with the serial port specified by *port*. If *port* does not exist, or if it is in use, you will not be able to connect the serial port object to the device.

*Port* object name will depend upon the platform that the serial port is on. `instrhwinfo('serial')` provides a list of available serial ports. This list is an example of serial constructors on different platforms:

Platform	Serial Port Constructor
Linux and Linux 64	<code>serial('/dev/ttyS0');</code>
Mac OS X 64	<code>serial('/dev/tty.KeySerial1');</code>
Windows 32 and Windows 64	<code>serial('com1');</code>

`obj = serial('port', 'PropertyName', PropertyValue, ...)` creates a serial port object with the specified property names and property values. If an invalid property name or property value is specified, an error is returned and the serial port object is not created.

**Tips** When you create a serial port object, these property values are automatically configured:

- The **Type** property is given by `serial`.
- The **Name** property is given by concatenating `Serial` with the port specified in the `serial` function.
- The **Port** property is given by the port specified in the `serial` function.

You can specify the property names and property values using any format supported by the `set` function. For example, you can use property name/property value cell array pairs. Additionally, you can

specify property names without regard to case, and you can make use of property name completion. For example, the following commands are all valid on a Windows platform.

```
s = serial('COM1','BaudRate',4800);
s = serial('COM1','baudrate',4800);
s = serial('COM1','BAUD',4800);
```

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can use with `serial`.

Before you can communicate with the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt a read or write operation while the object is not connected to the device. You can connect only one serial port object to a given serial port.

## Examples

This example creates the serial port object `s1` associated with the serial port COM1 on a Windows platform.

```
s1 = serial('COM1');
```

The `Type`, `Name`, and `Port` properties are automatically configured.

```
get(s1,{'Type','Name','Port'})
ans =
    'serial'    'Serial-COM1'    'COM1'
```

To specify properties during object creation

```
s2 = serial('COM2','BaudRate',1200,'DataBits',7);
```

## See Also

[fclose](#) | [fopen](#) | [Name](#) | [Port](#) | [Status](#) | [Type](#)

# serialbreak

---

**Purpose** Send break to device connected to serial port

**Syntax** `serialbreak(obj)`  
`serialbreak(obj,time)`

**Description** `serialbreak(obj)` sends a break of 10 milliseconds to the device connected to the serial port object, `obj`.  
`serialbreak(obj,time)` sends a break to the device with a duration, in milliseconds, specified by `time`. Note that the duration of the break might be inaccurate under some operating systems.

**Tips** For some devices, the break signal provides a way to clear the hardware buffer.

Before you can send a break to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to send a break while `obj` is not connected to the device.

`serialbreak` is a synchronous function, and blocks the command line until execution is complete.

If you issue `serialbreak` while data is being asynchronously written, an error is returned. In this case, you must call the `stopasync` function or wait for the write operation to complete.

**See Also** `fopen` | `stopasync` | `Status`

**Purpose** Set Handle Graphics object properties

**Syntax**

```
set(H, 'PropertyName', PropertyValue, ...)  
set(H, a)  
set(H, pn, pv, ...)  
set(H, pn, MxN_pv)  
a = set(h)  
pv = set(h, 'PropertyName')
```

## Description

---

**Note** Do not use the `set` function on Java objects as it will cause a memory leak. For more information, see “Accessing Private and Public Data”

---

`set(H, 'PropertyName', PropertyValue, ...)` sets the named properties to the specified values on the object(s) identified by H. H can be a vector of handles, in which case `set` sets the properties' values for all the objects.

`set(H, a)` sets the named properties to the specified values on the object(s) identified by H. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties.

`set(H, pn, pv, ...)` sets the named properties specified in the cell array `pn` to the corresponding value in the cell array `pv` for all objects identified in H.

`set(H, pn, MxN_pv)` sets `n` property values on each of `m` graphics objects, where `m = length(H)` and `n` is equal to the number of property names contained in the cell array `pn`. This allows you to set a given group of properties to different values on each object.

`a = set(h)` returns the user-settable properties and possible values for the object identified by `h`. `a` is a structure array whose field names are the object's property names and whose field values are the possible values of the corresponding properties. If you do not specify an output

argument, the MATLAB software displays the information on the screen. `h` must be scalar.

`pv = set(h, 'PropertyName')` returns the possible values for the named property. If the possible values are strings, `set` returns each in a cell of the cell array `pv`. For other properties, `set` returns a statement indicating that `PropertyName` does not have a fixed set of property values. If you do not specify an output argument, MATLAB displays the information on the screen. `h` must be scalar.

---

**Note** Consult the specific object page (figure, axes, and so on) to determine what properties you can set.

---

## Tips

You can use any combination of property name/property value pairs, structure arrays, and cell arrays in one call to `set`.

### Setting Property Units

Note that if you are setting both the `FontSize` and the `FontUnits` properties in one function call, you must set the `FontUnits` property first so that the MATLAB software can correctly interpret the specified `FontSize`. The same applies to figure and axes units — always set the `Units` property before setting properties whose values you want to be interpreted in those units. For example,

```
f = figure('Units','characters',...
          'Position',[30 30 120 35]);
```

## Examples

Set the `Color` property of the current axes to blue.

```
axes;
set(gca,'Color','b')
```

Change all the lines in a plot to black.

```
plot(peaks)
set(findobj('Type','line'),'Color','k')
```

You can define a group of properties in a structure to better organize your code. For example, these statements define a structure called `active`, which contains a set of property definitions used for the `uicontrol` objects in a particular figure. When this figure becomes the current figure, MATLAB changes the colors and enables the controls.

```
active.BackgroundColor = [.7 .7 .7];
active.Enable = 'on';
active.ForegroundColor = [0 0 0];

if gcf == control_fig_handle
    set(findobj(control_fig_handle,'Type','uicontrol'),active)
end
```

You can use cell arrays to set properties to different values on each object. For example, these statements define a cell array to set three properties,

```
PropName(1) = {'BackgroundColor'};
PropName(2) = {'Enable'};
PropName(3) = {'ForegroundColor'};
```

These statements define a cell array containing three values for each of three objects (i.e., a 3-by-3 cell array).

```
PropVal(1,1) = {[.5 .5 .5]};
PropVal(1,2) = {'off'};
PropVal(1,3) = {[.9 .9 .9]};
PropVal(2,1) = {[1 0 0]};
PropVal(2,2) = {'on'};
PropVal(2,3) = {[1 1 1]};
PropVal(3,1) = {[.7 .7 .7]};
PropVal(3,2) = {'on'};
PropVal(3,3) = {[0 0 0]};
```

Now pass the arguments to `set`,

```
set(H,PropName,PropVal)
```

where `length(H) = 3` and each element is the handle to a uicontrol.

## **Setting Different Values for the Same Property on Multiple Objects**

Suppose you want to set the value of the `Tag` property on five line objects, each to a different value. Note how the value cell array needs to be transposed to have the proper shape.

```
h = plot(rand(5));  
set(h,{'Tag'},{'line1','line2','line3','line4','line5'})
```

## **See Also**

`findobj` | `gca` | `gcf` | `gco` | `gcbo` | `get`

**Purpose** Set property values for audioplayer object

**Syntax**

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

**Description** `set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

**Tips** The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

**Examples** View the list of properties that you can set for an audioplayer object:

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj)
```

---

Set the `Tag` and `UserData` properties of an audioplayer object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

# audioplayer.set

---

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj, newValues)

% View the values all properties.
get(handelObj)
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the Tag property for an object called handelObj (as created in the Examples):

```
handelObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(handelObj, 'Tag', 'This is my tag.');
```

# set (hgsetget)

---

**Purpose** Assign property values to handle objects derived from hgsetget class

**Syntax**

```
set(H, 'PropertyName', value, ...)  
set(H, pn, pv)  
set(H, S)  
S = set(h)
```

**Description**

`set(H, 'PropertyName', value, ...)` sets the named property to the specified value for the objects in the handle array `H`.

`set(H, pn, pv)` sets the named properties specified in the cell array of strings `pn` to the corresponding values in the cell array `pv` for all objects specified in `H`. The cell array `pn` must be 1-by-`n` (where `n` is the number of property names), but the cell array `pv` can be `m`-by-`n` where `m` is equal to `length(H)`. `set` updates each object with the associated set of values for the list of property names contained in.

`set(H, S)` sets the properties identified by each field name of struct `S` with the values contained in `S`. `S` is a struct whose field names are object property names.

`S = set(h)` returns the user-settable properties of scalar `h`. `S` is a struct whose field names are the object's property names and whose values are empty cell arrays.

Override the hgsetget class `setdisp` method to change how MATLAB displays this information.

**See Also** `handle` | `hgsetget` | `set` | `get` (`hgsetget`)

**How To**

- “Implementing a Set/Get Interface for Properties”

**Purpose** Set property values for video reader object

**Syntax**

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

**Description** `set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

**Tips** The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

## **Examples** **View Settable Properties**

View the list of properties that you can set for a video reader object.

```
xyloObj = VideoReader('xylophone.mp4');
set(xyloObj)
```

```
General Settings:
  Tag
  UserData
```

## Set Object Properties

Set the `Tag` and `UserData` properties of a video reader object using a structure array.

```
newValues.Tag = 'My Tag';  
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

```
xyloObj = VideoReader('xylophone.mp4');  
set(xyloObj, newValues)
```

View the values all properties.

```
get(xyloObj)
```

```
General Settings:
```

```
Duration = 4.7000  
Name = xylophone.mp4  
Path = matlabroot\toolbox\matlab\audiovideo  
Tag = My Tag  
Type = VideoReader  
UserData = {'My User Data' [3.1416] [1 2 3 4]}
```

```
Video Settings:
```

```
BitsPerPixel = 24  
FrameRate = 30  
Height = 240  
NumberOfFrames = 141  
VideoFormat = RGB24  
Width = 320
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for a reader object called `xyloObj` (as created in the Examples):

```
xyloObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(xyloObj, 'Tag', 'This is my tag.');
```

## See Also

VideoReader | get

# set (RandStream)

---

**Purpose** Set random number stream property

**Class** RandStream

**Syntax**

```
set(stream, 'PropertyName', Value)
set(stream, 'Property1', Value1, 'Property2', Value2, ...)
set(stream, A)
A = set(stream, 'Property')
set(stream, 'Property')
A = set(stream)
set(stream)
```

**Description**

`set(stream, 'PropertyName', Value)` sets the property 'PropertyName' of the random stream `stream` to the value `Value`.

`set(stream, 'Property1', Value1, 'Property2', Value2, ...)` sets multiple random stream property values with a single statement.

`set(stream, A)` where `A` is a structure whose field names are property names of the random stream `stream` sets the properties of `stream` named by each field with the values contained in those fields.

`A = set(stream, 'Property')` or `set(stream, 'Property')` displays possible values for the specified property of `stream`.

`A = set(stream)` or `set(stream)` displays or returns all writable properties of `stream` and their possible values.

**See Also** RandStream | get (RandStream) | rand | randn | randi

**Purpose** Configure or display serial port object properties

**Syntax**

```
set(obj)
props = set(obj)
set(obj, 'PropertyName')
props = set(obj, 'PropertyName')
set(obj, 'PropertyName', PropertyValue, ...)
set(obj, PN, PV)
set(obj, S)
```

**Description** `set(obj)` displays all configurable properties values for the serial port object, `obj`. If a property has a finite list of possible string values, then these values are also displayed.

`props = set(obj)` returns all configurable properties and their possible values for `obj` to `props`. `props` is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values. If the property does not have a finite set of possible values, then the cell array is empty.

`set(obj, 'PropertyName')` displays the valid values for *PropertyName* if it possesses a finite list of string values.

`props = set(obj, 'PropertyName')` returns the valid values for *PropertyName* to `props`. `props` is a cell array of possible string values or an empty cell array if *PropertyName* does not have a finite list of possible values.

`set(obj, 'PropertyName', PropertyValue, ...)` configures multiple property values with a single command.

`set(obj, PN, PV)` configures the properties specified in the cell array of strings `PN` to the corresponding values in the cell array `PV`. `PN` must be a vector. `PV` can be `m-by-n` where `m` is equal to the number of serial port objects in `obj` and `n` is equal to the length of `PN`.

`set(obj, S)` configures the named properties to the specified values for `obj`. `S` is a structure whose field names are serial port object properties, and whose field values are the values of the corresponding properties.

# set (serial)

---

## Tips

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can configure with `set`.

You can use any combination of property name/property value pairs, structures, and cell arrays in one call to `set`. Additionally, you can specify a property name without regard to case, and you can make use of property name completion. For example, if `s` is a serial port object, then the following commands are all valid.

```
set(s, 'BaudRate')
set(s, 'baudrate')
set(s, 'BAUD')
```

If you use the `help` command to display help for `set`, then you need to supply the pathname shown below.

```
help serial/set
```

## Examples

This example illustrates some of the ways you can use `set` to configure or return property values for the serial port object `s`, on a Windows platform.

```
s = serial('COM1');
set(s, 'BaudRate', 9600, 'Parity', 'even')
set(s, {'StopBits', 'RecordName'}, {2, 'sydney.txt'})
set(s, 'Parity')
[ {none} | odd | even | mark | space ]
```

## See Also

`get`

**Purpose**

Set properties of tscollection object

**Syntax**

```
set(tsc, 'Property', Value)
set(tsc, 'Property1', Value1, 'Property2', Value2, ...)
set(tsc, 'Property')
```

**Description**

set(tsc, 'Property', Value) sets the property 'Property' of the tscollection tsc to the value Value. The following syntax is equivalent:

```
tsc.Property = Value
```

set(tsc, 'Property1', Value1, 'Property2', Value2, ...) sets multiple property values for tsc with a single statement.

set(tsc, 'Property') displays values for the specified property in the time-series collection tsc.

set(tsc) displays all properties and values of the tscollection object tsc.

**See Also**

get (tscollection)

# setabstime (tscollection)

---

**Purpose** Set times of tscollection object as date strings

**Syntax**

```
tsc = setabstime(tsc,Times)
tsc = setabstime(tsc,Times,format)
```

**Description** `tsc = setabstime(tsc,Times)` sets the times in `tsc` using the date strings `Times`. `Times` must be either a cell array of strings, or a char array containing valid date or time values in the same date format.

`tsc = setabstime(tsc,Times,format)` specifies the date-string format used in `Times` explicitly.

**Examples** **1** Create a tscollection object.

```
tsc = tscollection(timeseries(rand(3,1)))
```

**2** Set the absolute time vector.

```
tsc = setabstime(tsc,{'12-DEC-2005 12:34:56',...
                    '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
```

**See Also** `datestr` | `tscollection` | `getabstime (tscollection)`

**Purpose** Specify application-defined data

**Syntax** `setappdata(h, 'name', value)`

**Description** `setappdata(h, 'name', value)` sets application-defined data for the object with handle `h`. The application-defined data, which is created if it does not already exist, is assigned the specified name and value. The value can be any type of data.

**Definitions** Application-defined data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

**See Also** `getappdata` | `isappdata` | `rmappdata`

# RandStream.setDefaultStream

---

**Purpose** Set default random number stream

---

**Note** `RandStream.setDefaultStream` has been removed. Use `RandStream.setGlobalStream` instead. The shared global stream used by `rand`, `randi`, and `randn`, referred to in former versions of MATLAB as the *default stream* is now referred to as the *global stream*.

---

**Syntax** `prevstream = RandStream.setDefaultStream(stream)`

**Description** `prevstream = RandStream.setDefaultStream(stream)` returns the current global random number stream, and designates the random number stream `stream` as the new random number stream to be used by the `rand`, `randi`, and `randn` functions.

**Purpose**

Set difference of two arrays

**Syntax**

```
C = setdiff(A,B)
C = setdiff(A,B,'rows')
[C,ia] = setdiff(A,B)
[C,ia] = setdiff(A,B,'rows')

[C,ia] = setdiff(__,setOrder)
[C,ia] = setdiff(A,B,'legacy')
[C,ia] = setdiff(A,B,'rows','legacy')
```

**Description**

`C = setdiff(A,B)` returns the data in A that is not in B.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `setdiff` returns the values in A that are not in B. The values of C are in sorted order.
- If A and B are tables, then `setdiff` returns the rows from A that are not in B, with repetitions removed. The rows of table C are in sorted order.

`C = setdiff(A,B,'rows')` treats each row of A and each row of B as single entities and returns the rows from A that are not in B. The rows of C are in sorted order.

The 'rows' option does not support cell arrays.

`[C,ia] = setdiff(A,B)` also returns the index vector `ia`.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `C = A(ia)`.
- If A and B are tables, then `C = A(ia,:)`.

`[C,ia] = setdiff(A,B,'rows')` also returns the index vector `ia`, such that `C = A(ia,:)`.

# setdiff

---

`[C,ia] = setdiff(___,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`. If no value is specified, the default is `'sorted'`.

`[C,ia] = setdiff(A,B,'legacy')` and `[C,ia] = setdiff(A,B,'rows','legacy')` preserve the behavior of the `setdiff` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

## Input Arguments

### A,B - Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays  
| cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, cell arrays of strings, or tables.

`A` and `B` must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of `C` are the sorted union of the categories from `A` and `B`.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

If `A` and `B` are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, A and B can be objects with the following class methods:

- sort (or sortrows for the 'rows' option)
- eq
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### setOrder - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: C = setdiff([4 1 3 2],[2 1],'sorted') returns C = [3 4].
'stable'	The values (or rows) in C return in the same order as in A. For example: C = setdiff([4 1 3 2],[2 1],'stable') returns C = [4 3].

## Output Arguments

### C - Difference of A and B

vector | matrix | table

Difference of A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of C when the inputs are vectors or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified and A is a row vector, then C is a row vector.

# setdiff

---

- If the 'rows' flag is not specified and A is not a row vector, then C is a column vector.
- If the 'rows' flag is specified, then C is a matrix containing the rows of A that are not in B.
- If all the values (or rows) of A are also in B, then C is an empty matrix.

The class of C is the same as the class of A, unless:

- A is a character array and B is a cell array of strings, in which case C is a cell array of strings.
- A is a cell array of strings or single string and B is a categorical array, in which case C is a categorical array.

## **ia - Index to A**

column vector

Index to A, returned as a column vector when the 'legacy' flag is not specified. `ia` identifies the values (or rows) in A that are not in B. If there is a repeated value (or row) appearing exclusively in A, then `ia` contains the index to the first occurrence of the value (or row).

## **Examples**

### **Difference of Two Vectors**

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in A that are not in B.

```
C = setdiff(A,B)
```

```
C =
```

```
     1     3     5
```

### **Difference of Two Tables**

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

A =

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false
4	D	true
5	E	false

B =

Var1	Var2	Var3
1	A	false
3	C	false
5	E	false
7	G	false
9	I	false

Find the rows in A that are not in B.

```
C = setdiff(A,B)
```

C =

Var1	Var2	Var3
2	B	true
4	D	true

### **Difference of Two Vectors and Indices to Different Values**

Define two vectors with values in common.

# setdiff

---

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in A that are not in B as well as the index vector `ia`, such that `C = A(ia)`.

```
[C,ia] = setdiff(A,B)
```

```
C =
```

```
     1     3     5
```

```
ia =
```

```
     4  
     1  
     5
```

## Difference of Two Tables and Indices to Different Rows

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...  
  'VariableNames',{'Gender' 'Age' 'Height'},...  
  'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =
```

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Fred	M	52	68
Betty	F	31	64
Bob	M	46	61
Judy	F	35	64

Define a table, B, with the same variables as A.

```
B = table(['F';'M';'F';'F'],[64;68;62;58],[31;47;35;23],...  
  'VariableNames',{'Gender' 'Height' 'Age'},...
```

```
'RowNames',{ 'Meg' 'Joe' 'Beth' 'Amy' })
```

```
B =
```

	Gender	Height	Age
	-----	-----	---
Meg	F	64	31
Joe	M	68	47
Beth	F	62	35
Amy	F	58	23

Find the rows in A that are not in B, as well as the index vector `ia`, such that `C = A(ia,:)`.

```
[C,ia] = setdiff(A,B)
```

```
C =
```

	Gender	Age	Height
	-----	---	-----
Judy	F	35	64
Ted	M	27	74
Bob	M	46	61
Fred	M	52	68

```
ia =
```

```
5
1
4
2
```

The rows of C are in sorted order first by Gender and next by Age.

### **Difference of Rows in Two Matrices**

Define two matrices with rows in common.

# setdiff

---

```
A = [7 9 7; 0 0 0; 7 9 7; 5 5 5; 1 4 5];  
B = [0 0 0; 5 5 5];
```

Find the rows from A that are not in B as well as the index vector `ia`, such that `C = A(ia,:)`.

```
[C,ia] = setdiff(A,B,'rows')
```

```
C =
```

```
     1     4     5  
     7     9     7
```

```
ia =
```

```
     5  
     1
```

## Difference of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` or `'sorted'` when the order of the values in C are important.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];  
[C,ia] = setdiff(A,B,'stable')
```

```
C =
```

```
     3     1     5
```

```
ia =
```

```
     1  
     4  
     5
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia] = setdiff(A,B,'sorted')

C =

     1     3     5

ia =

     4
     1
     5
```

### Difference of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN];
```

Find the set difference of A and B.

```
C = setdiff(A,B)

C =
```

```
NaN NaN
```

setdiff treats NaN values as distinct.

### Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

# setdiff

---

Find the strings in A that are not in B.

```
[C,ia] = setdiff(A,B)
```

```
C =
```

```
    'dog'    'fish'
```

```
ia =
```

```
    1  
    3
```

`setdiff` treats trailing white space in cell arrays of strings as distinct characters.

## **Difference of Char and Cell Array of Strings**

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];  
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings, B.

```
B={'dog', 'cat', 'fish', 'horse'};  
class(B)
```

```
ans =
```

```
cell
```

Find the strings in A that are not in B.

```
C = setdiff(A,B)
```

```
C =  
  
    'fox'  
    'pig'
```

The result, `C`, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

### Preserve Legacy Behavior of `setdiff`

Use the `'legacy'` flag to preserve the behavior of `setdiff` from R2012b and prior releases in your code.

Find the difference of `A` and `B` with the current behavior.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];  
[C1,ia1] = setdiff(A,B)
```

```
C1 =  
  
     1     3     5
```

```
ia1 =
```

```
     4  
     1  
     5
```

Find the difference of `A` and `B`, and preserve the legacy behavior.

```
[C2,ia2] = setdiff(A,B,'legacy')
```

```
C2 =
```

# setdiff

---

```
      1     3     5
ia2 =
      7     1     5
```

## Tips

- To find the set difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `setdiff(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

| `sort`

## Concepts

- “Combine Categorical Arrays”

<b>Purpose</b>	Make specified IFD current IFD
<b>Syntax</b>	<code>tiffobj.setDirectory(dirNum)</code>
<b>Description</b>	<code>tiffobj.setDirectory(dirNum)</code> sets the image file directory (IFD) specified by <code>dirNum</code> as the current IFD. Tiff object methods operate on the current IFD. The directory index number is one-based.
<b>Examples</b>	<p>Open a TIFF file and move to an IFD in the file by specifying its index number. The TIFF file should contain multiple images.</p> <pre>t = Tiff('example.tif', 'r'); t.setDirectory(2); t.close();</pre>
<b>References</b>	This method corresponds to the <code>TIFFSetDirectory</code> function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at <a href="#">LibTIFF - TIFF Library and Utilities</a> .
<b>See Also</b>	<code>Tiff.currentDirectory</code>   <code>Tiff.nextDirectory</code>
<b>Tutorials</b>	<ul style="list-style-type: none"><li>• “Exporting Image Data and Metadata to TIFF Files”</li><li>• “Reading Image Data and Metadata from TIFF Files”</li></ul>

# setdisp (hgsetget)

---

<b>Purpose</b>	Override to change command window display
<b>Syntax</b>	setdisp(H)
<b>Description</b>	setdisp(H) called by <code>set</code> when <code>set</code> is called with no output arguments and a single input argument that is a handle array. Override this <code>hgsetget</code> class method in a subclass to change how property information is displayed in the command window.
<b>See Also</b>	<code>hgsetget</code>   <code>set</code> ( <code>hgsetget</code> )
<b>How To</b>	<ul style="list-style-type: none"><li>• “Implementing a Set/Get Interface for Properties”</li></ul>

<b>Purpose</b>	Set environment variable
<b>Syntax</b>	<pre>setenv(name,value) setenv(name)</pre>
<b>Description</b>	<p><code>setenv(name,value)</code> sets the value of an environment variable belonging to the underlying operating system. Inputs <code>name</code> and <code>value</code> are both strings. If <code>name</code> already exists as an environment variable, then <code>setenv</code> replaces its current value with the string given in <code>value</code>. If <code>name</code> does not exist, <code>setenv</code> creates a new environment variable called <code>name</code> and assigns <code>value</code> to it.</p> <p><code>setenv(name)</code> is equivalent to <code>setenv(name, '')</code> and assigns a null value to the variable <code>name</code>. On the Microsoft Windows platform, this is equivalent to undefining the variable. On most UNIX platforms, it is possible to have an environment variable defined as empty.</p> <p>The maximum number of characters in <code>name</code> is <math>2^{15} - 2</math> (or 32766). If <code>name</code> contains the character <code>=</code>, <code>setenv</code> throws an error. The behavior of environment variables with <code>=</code> in the name is not well-defined.</p> <p>On all platforms, <code>setenv</code> passes the <code>name</code> and <code>value</code> strings to the operating system unchanged. Special characters such as <code>;</code>, <code>/</code>, <code>:</code>, <code>\$</code>, <code>%</code>, etc. are left unexpanded and intact in the variable value.</p> <p>Values assigned to variables using <code>setenv</code> are picked up by any process that is spawned using the MATLAB <code>system</code>, <code>unix</code>, <code>dos</code> or <code>!</code> functions. You can retrieve any value set with <code>setenv</code> by using <code>getenv(name)</code>.</p>
<b>Examples</b>	<pre>% Set and retrieve a new value for the environment variable TEMP:  setenv('TEMP', 'C:\TEMP'); getenv('TEMP')  % Append the Perl\bin folder to your system PATH variable:  setenv('PATH', [getenv('PATH') ';D:\Perl\bin']);</pre>
<b>See Also</b>	<pre>getenv   system   unix   dos   !</pre>

# setfield

---

**Purpose** Assign values to structure array field

**Syntax**

```
s = setfield(s, 'field', value)
s = setfield(s, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ...,
    fIndxN}, value)
```

**Description** `s = setfield(s, 'field', value)`, where `s` is a 1-by-1 structure, sets the contents of the specified field, equivalent to `s.field = value`. If `s` does not contain the specified `field`, the `setfield` function creates the field and assigns the specified value. Pass field references as strings.

`s = setfield(s, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN}, value)` sets the contents of the specified field, equivalent to `s(sIndx1, ..., sIndxM).field(fIndx1, ..., fIndxN) = value`. The `setfield` function supports multiple sets of `field` and `fIndx` inputs. If structure `s` or any of the fields is a nonscalar structure, the `Indx` inputs associated with that input are required. Otherwise, the `Indx` inputs are optional. If you specify a single colon operator for an index input, enclose it in single quotation marks: `':'`.

- Tips**
- For most cases, add data to a structure array by indexing rather than using the `setfield` function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.
  - Call `setfield` to simplify references to structure arrays with nested fields, as shown in the Examples section.

**Examples** Add values to a structure that contains nested fields:

```
grades = [];
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student}
newGrades_Doe = [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];
```

```
grades = setfield(grades, {level}, ...
                 fieldnames{:}, {10, 21:30}, ...
                 newGrades_Doe);

% View the new contents.
grades(level).(semester).(subject).(student)(10, 21:30)
```

---

Using the structure defined in the previous example, remove the tenth row of the specified field:

```
grades = setfield(grades, {level}, fieldnames{:}, {10,':'}, []);
```

**How To**

- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

# setpixelposition

---

## Purpose

Set component position in pixels

## Syntax

```
setpixelposition(handle,position)
setpixelposition(handle,position,recursive)
```

## Description

`setpixelposition(handle,position)` sets the position of the component specified by `handle`, to the specified position relative to its parent. `position` is a four-element vector that specifies the location and size of the component: [pixels from left, pixels from bottom, pixels across, pixels high].

`setpixelposition(handle,position,recursive)` sets the position as above. If Boolean `recursive` is true, the position is set relative to the parent figure of `handle`.

## Examples

This example first creates a push button within a panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton','Units','normalized',...
              'String','Push Button','Position',[.1 .1 .5 .2]);
```

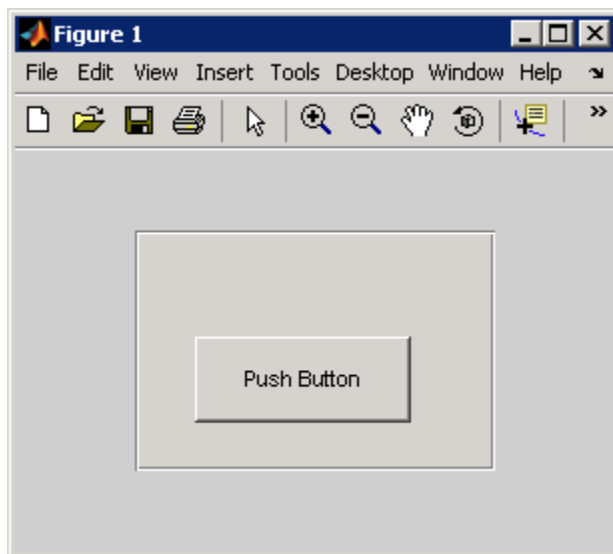

The example then retrieves the position of the push button and changes its position with respect to the panel.

```
pos1 = getpixelposition(h1);  
setpixelposition(h1,pos1 + [10 10 25 25]);
```

# setpixelposition

---

**See Also** [getpixelposition](#) | [uicontrol](#) | [uipanel](#)

---

<b>Purpose</b>	Set preference
<b>Syntax</b>	<pre>setpref('group','pref',val) setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,..., valn})</pre>
<b>Description</b>	<p><code>setpref('group','pref',val)</code> sets the preference specified by <code>group</code> and <code>pref</code> to the value <code>val</code>. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects. Setting a preference that does not yet exist causes it to be created.</p> <p><code>group</code> labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g., <code>'MathWorks_GUIDE_ApplicationPrefs'</code>. The input argument <code>pref</code> identifies an individual preference in that group, and must be a legal variable name.</p> <p><code>setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})</code> sets each preference specified in the cell array of names to the corresponding value.</p>

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

## Examples

Use `addpref` to create a preference group called `mytoolbox` and a preference within it called `version`, and then modify the contents of `version` using `setpref`:

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')
```

```
ans =
1.0
```

```
setpref('mytoolbox','version',{'1.0','beta'})
```

# setpref

---

```
getpref('mytoolbox','version')
```

```
ans =  
    '1.0'    'beta'
```

## See Also

**Purpose** Set string flag

---

**Note** `setstr` is not recommended. Use `char` instead.

---

**Description** This MATLAB 4 function has been renamed `char` in MATLAB 5.

# Tiff.setSubDirectory

---

**Purpose** Make subIFD specified by byte offset current IFD

**Syntax** `tiffobj.setSubDirectory(offset)`

**Description** `tiffobj.setSubDirectory(offset)` sets the subimage file directory (subIFD) specified by `offset` the current IFD. The offset value is given in bytes. Use this method when you want to access subIFDs linked through the SubIFD tag.

## **Examples**      **Set Subimage File Directory**

Open a TIFF file and read the value of the SubIFD tag in the current IFD. The SubIFD tag contains byte offsets that specify the location of subIFDs in the IFD. The TIFF file should contain subIFDs.

```
t = Tiff('example.tif', 'r');
```

Read the value of the SubIFD tag to get subdirectory offsets.

```
offsets = t.getTag('SubIFD');
```

Set one of the subdirectories (if more than one) as the current directory.

```
t.setSubDirectory(offsets(1));  
t.close();
```

**References** This method corresponds to the `TIFFSetSubDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.setDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Set value of tag

**Syntax** `tiffobj.setTag(tagId,tagValue)`  
`tiffobj.setTag(tagStruct)`

**Description** `tiffobj.setTag(tagId,tagValue)` sets the value of the TIFF tag specified by `tagId` to the value specified by `tagValue`. You can specify `tagId` as a character string ('ImageWidth') or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

`tiffobj.setTag(tagStruct)` sets the values of all of the tags with `name/value` fields in `tagStruct`. The names of fields in `tagStruct` must be the name of TIFF tags.

---

**Note** If you are modifying a tag rather than creating it, you must use the `Tiff.rewriteDirectory` method after using the `Tiff.setTag` method.

---

## Examples **Set Tag Values**

Write TIFF tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a Tiff object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');  
t = Tiff('myfile.tif','w');
```

Set tag values by specifying the numeric tag identifier. Use the `TagID` property to obtain the tag identifier.

```
t.setTag(Tiff.TagID.ImageLength,size(imdata,1));
```

# Tiff.setTag

---

```
t.setTag(Tiff.TagID.ImageWidth, size(imdata,2));
```

Set tag values by specifying the tag name.

```
t.setTag('Photometric', Tiff.Photometric.RGB);  
t.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.Chunky);
```

Create a structure with fields named after TIFF tags and assign values to the fields. Pass this structure to the `setTag` method to set the values of these tags.

```
tagStruct.BitsPerSample = 8;  
tagStruct.SamplesPerPixel = 3;  
tagStruct.TileWidth = 128;  
tagStruct.TileLength = 128;  
tagStruct.Compression = Tiff.Compression.JPEG;  
tagStruct.Software = 'MATLAB';  
t.setTag(tagStruct);
```

Write the image data to the TIFF file.

```
t.write(imdata);  
t.close();
```

## References

This method corresponds to the `TIFFSetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**Purpose** Change name of timeseries object in tscollection

**Syntax** `tsc = settimeseriesnames(tsc,old,new)`

**Description** `tsc = settimeseriesnames(tsc,old,new)` replaces the old name of timeseries object with the new name in tsc.

**See Also** `tscollection`

# setxor

---

**Purpose** Set exclusive OR of two arrays

**Syntax**

```
C = setxor(A,B)
C = setxor(A,B,'rows')
[C,ia,ib] = setxor(A,B)
[C,ia,ib] = setxor(A,B,'rows')

[C,ia,ib] = setxor(__,setOrder)

[C,ia,ib] = setxor(A,B,'legacy')

[C,ia,ib] = setxor(A,B,'rows','legacy')
```

**Description** `C = setxor(A,B)` returns the data of A and B that are not in their intersection (the symmetric difference).

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `setxor` returns the values that occur in A or B, but not both. The values of C are in sorted order.
- If A and B are tables, then `setxor` returns the rows that occur in one or the other of the two tables, but not both. The rows of table C are in sorted order.

`C = setxor(A,B,'rows')` treats each row of A and each row of B as single entities and returns the rows of matrices A and B that are not in their intersection. The rows of C are in sorted order.

The 'rows' option does not support cell arrays.

`[C,ia,ib] = setxor(A,B)` also returns index vectors `ia` and `ib`.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then C is a sorted combination of the elements `A(ia)` and `B(ib)`.

- If A and B are tables, then C is a sorted combination of the rows of A(ia,:) and B(ib,:).

`[C,ia,ib] = setxor(A,B,'rows')` also returns index vectors `ia` and `ib`, such that C is a sorted combination of the rows of A(ia,:) and B(ib,:).

`[C,ia,ib] = setxor(___,setOrder)` returns C in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of C in sorted order. `setOrder='stable'` returns the values (or rows) of C in the same order as A and B. If no value is specified, the default is 'sorted'.

`[C,ia,ib] = setxor(A,B,'legacy')` and `[C,ia,ib] = setxor(A,B,'rows','legacy')` preserve the behavior of the `setxor` function from R2012b and prior releases.

The 'legacy' option does not support categorical arrays or tables.

## Input Arguments

### A,B - Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays  
| cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, cell arrays of strings, or tables.

A and B must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is

performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the 'rows' option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, A and B can be objects with the following class methods:

- sort (or sortrows for the 'rows' option)
- eq
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### **setOrder - Order flag**

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

<b>Order Flag</b>	<b>Meaning</b>
'sorted'	The values (or rows) in C return in sorted order. For example: C = setxor([5 1 3],[4 1 2],'sorted') returns C = [2 3 4 5].
'stable'	The values (or rows) in C return in the same order as in A and B. For example: C = setxor([5 1 3],[4 1 2],'stable') returns C = [5 3 4 2].

## Output Arguments

### **C** - Symmetric difference array

vector | matrix | table

Symmetric difference array, returned as a vector, matrix, or table. If the inputs **A** and **B** are tables, the order of the variables in the resulting table, **C**, is the same as the order of the variables in **A**.

The following describes the shape of **C** when the inputs are vector or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then **C** is a column vector unless both **A** and **B** are row vectors.
- If the 'rows' flag is not specified and both **A** and **B** are row vectors, then **C** is a row vector.
- If the 'rows' flag is specified, then **C** is a matrix containing the rows of **A** and **B** that are not in the intersection.
- If all the values (or rows) of **A** are also in **B**, then **C** is an empty matrix.

The class of the inputs **A** and **B** determines the class of **C**:

- If the class of **A** and **B** are the same, then **C** is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then **C** is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then **C** is `double`.
- If you combine a cell array of strings with `char`, then **C** is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then **C** is a categorical array.

### **ia** - Index to **A**

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** identifies the values (or rows) in **A** that contribute to the symmetric difference. If there is a repeated value (or row) appearing

exclusively in A, then `ia` contains the index to the first occurrence of the value (or row).

## **ib - Index to B**

column vector

Index to B, returned as a column vector when the 'legacy' flag is not specified. `ib` identifies the values (or rows) in B that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in B, then `ib` contains the index to the first occurrence of the value (or row).

## **Examples**

### **Symmetric Difference of Two Vectors**

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of A and B that are not in their intersection.

```
C = setxor(A,B)
```

```
C =
```

```
     2     3     4     5
```

### **Symmetric Difference of Two Tables**

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
```

```
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false

```

4      D      true
5      E      false

```

B =

```

Var1   Var2   Var3
----   ----   -----
1      A      false
3      C      false
5      E      false
7      G      false
9      I      false

```

Find the rows of A and B that are not in their intersection.

```
C = setxor(A,B)
```

C =

```

Var1   Var2   Var3
----   ----   -----
2      B      true
4      D      true
7      G      false
9      I      false

```

### Symmetric Difference of Two Vectors and Indices to Different Values

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of A and B that are not in their intersection as well as the index vectors ia and ib.

```
[C,ia,ib] = setxor(A,B)
```

```
C =  
  
      2      3      4      5
```

```
ia =  
  
      3  
      1
```

```
ib =  
  
      3  
      1
```

C is a sorted combination of the elements A(ia) and B(ib).

## **Symmetric Difference of Two Tables and Indices to Different Rows**

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F'],[27;52;31],[74;68;64],...  
  'VariableNames',{'Gender' 'Age' 'Height'},...  
  'RowNames',{'Ted' 'Fred' 'Betty'})
```

```
A =  
  
      Gender      Age      Height  
      -----      ---      -  
      Ted      M      27      74  
      Fred      M      52      68  
      Betty      F      31      64
```

Define a table, B, with the same variables as A.

```
B = table(['F';'M'],[64;68],[31;47],...)
```

```
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe'})
```

B =

	Gender	Height	Age
	-----	-----	---
Meg	F	64	31
Joe	M	68	47

Find the rows of A and B that are not in their intersection, as well as the index vectors *ia* and *ib*.

```
[C,ia,ib] = setxor(A,B)
```

C =

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Joe	M	47	68
Fred	M	52	68

*ia* =

```
1
2
```

*ib* =

```
2
```

C is a sorted combination of the elements A(*ia*,:) and B(*ib*,:).

## Symmetric Difference of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 8 9; 7 7 1; 7 7 1; 1 2 3; 4 5 6];  
B = [1 2 3; 4 5 6; 7 7 2];
```

Find the rows of A and B that are not in their intersection as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B,'rows')
```

C =

```
    7    7    1  
    7    7    2  
    7    8    9
```

ia =

```
    2  
    1
```

ib =

```
    3
```

C is a sorted combination of the rows of `A(ia,:)` and `B(ib,:)`.

## Symmetric Difference of Two Vectors in Specified Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as A and B.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

```
[C,ia,ib] = setxor(A,B,'stable')
```

```
C =
```

```
    5    3    4    2
```

```
ia =
```

```
    1  
    3
```

```
ib =
```

```
    1  
    3
```

Alternatively, you can specify 'sorted' order.

```
[C,ia,ib] = setxor(A,B,'sorted')
```

```
C =
```

```
    2    3    4    5
```

```
ia =
```

```
    3  
    1
```

```
ib =
```

```
    3  
    1
```

## Symmetric Difference of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the symmetric difference of vectors A and B.

```
C = setxor(A,B)
```

```
C =
```

```
NaN NaN NaN NaN
```

The `setxor` function treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Find the strings that are not in the intersection of A and B.

```
[C,ia,ib] = setxor(A,B)
```

```
C =
```

```
'dog' 'dog ' 'fish' 'fish '
```

```
ia =
```

```
1  
3
```

```
ib =
```

```
    1  
    3
```

setxor treats trailing white space in cell arrays of strings as distinct characters.

### **Symmetric Difference of Vectors of Different Classes and Shapes**

Create a column vector character array.

```
A = ['A'; 'B'; 'C'], class(A)
```

```
A =
```

```
A  
B  
C
```

```
ans =
```

```
char
```

Create a row vector containing elements of numeric type double.

```
B = [66 67 68], class(B)
```

```
B =
```

```
    66    67    68
```

```
ans =
```

```
double
```

Find the symmetric difference of A and B.

```
C = setxor(A,B)
```

```
C =
```

```
A
```

```
D
```

The result is a column vector character array.

```
class(C)
```

```
ans =
```

```
char
```

## **Symmetric Difference of Char and Cell Array of Strings**

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
```

```
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings, B.

```
B={'dog', 'cat', 'fish', 'horse'};
```

```
class(B)
```

```
ans =
```

```
cell
```

Find the strings that are not in the intersection of A and B.

```
C = setxor(A,B)
```

```
C =
```

```
    'fish'  
    'fox'  
    'horse'  
    'pig'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

### Preserve Legacy Behavior of setxor

Use the 'legacy' flag to preserve the behavior of setxor from R2012b and prior releases in your code.

Find the symmetric difference of A and B with the current behavior.

```
A = [5 1 3 3 3]; B = [4 1 2 2];
```

```
[C1,ia1,ib1] = setxor(A,B)
```

```
C1 =
```

```
     2     3     4     5
```

```
ia1 =
```

```
     3  
     1
```

# setxor

---

```
ib1 =  
  
     3  
     1
```

Find the symmetric difference and preserve the legacy behavior.

```
[C2,ia2,ib2] = setxor(A,B,'legacy')
```

```
C2 =  
  
     2     3     4     5
```

```
ia2 =  
  
     5     1
```

```
ib2 =  
  
     4     1
```

## Tips

- To find the symmetric difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `setxor(A(:,vars),B(:,vars))`, where `vars` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

## Concepts

- “Combine Categorical Arrays”

<b>Purpose</b>	Set color shading properties
<b>Syntax</b>	<pre>shading flat shading faceted shading interp shading(axes_handle,...)</pre>
<b>Description</b>	<p>The shading function controls the color shading of surface and patch graphics objects.</p> <p><code>shading flat</code> each mesh line segment and face has a constant color determined by the color value at the endpoint of the segment or the corner of the face that has the smallest index or indices.</p> <p><code>shading faceted</code> flat shading with superimposed black mesh lines. This is the default shading mode.</p> <p><code>shading interp</code> varies the color in each line segment and face by interpolating the colormap index or true color value across the line or face.</p> <p><code>shading(axes_handle,...)</code> applies the shading type to the objects in the axes specified by <code>axes_handle</code>, instead of the current axes. Use quoted strings when using a function form. For example:</p> <pre>shading(gca, 'interp')</pre>
<b>Examples</b>	<p>Compare a flat, faceted, and interpolated-shaded sphere.</p> <pre>subplot(3,1,1) sphere(16) axis square shading flat title('Flat Shading')</pre> <pre>subplot(3,1,2) sphere(16) axis square shading faceted</pre>

# shading

---

```
title('Faceted Shading')  
  
subplot(3,1,3)  
sphere(16)  
axis square  
shading interp  
title('Interpolated Shading')
```

Flat Shading

Faceted Shading

Interpolated Shading

# shading

---

## Algorithms

`shading` sets the `EdgeColor` and `FaceColor` properties of all surface and patch graphics objects in the current axes. `shading` sets the appropriate values, depending on whether the surface or patch objects represent meshes or solid surfaces.

| `surf` | `patch` | `surface`

**Purpose** Show most recent graph window

**Syntax** shg

**Description** shg makes the current figure visible and raises it above all other figures on the screen. This is identical to using the command `figure(gcf)`.

**See Also** figure | gca | gcf

# shiftdim

---

**Purpose** Shift dimensions

**Syntax** `B = shiftdim(X,n)`  
`[B,nshifts] = shiftdim(X)`

**Description** `B = shiftdim(X,n)` shifts the dimensions of `X` by `n`. When `n` is positive, `shiftdim` shifts the dimensions to the left and wraps the `n` leading dimensions to the end. When `n` is negative, `shiftdim` shifts the dimensions to the right and pads with singletons.

`[B,nshifts] = shiftdim(X)` returns the array `B` with the same number of elements as `X` but with any leading singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. `nshifts` is the number of dimensions that are removed.

If `X` is a scalar, `shiftdim` has no effect.

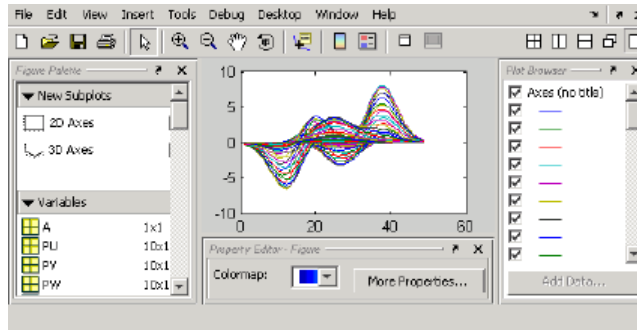

**Examples** The `shiftdim` command is handy for creating functions that, like `sum` or `diff`, work along the first nonsingleton dimension.

```
a = rand(1,1,3,1,2);  
[b,n] = shiftdim(a); % b is 3-by-1-by-2 and n is 2.  
c = shiftdim(b,-n); % c == a.  
d = shiftdim(a,3); % d is 1-by-2-by-1-by-1-by-3.
```

**See Also** `circshift` | `reshape` | `squeeze` | `permute` | `ipermute`

**Purpose** Show or hide figure plot tool

**Syntax**

```
showplottool('tool')
showplottool('on','tool')
showplottool('off','tool')
showplottool('toggle','tool')
showplottool('figure_handle',...)
```

**Description** `showplottool('tool')` shows the specified plot tool on the current figure. `tool` can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

`showplottool('on','tool')` shows the specified plot tool on the current figure.

`showplottool('off','tool')` hides the specified plot tool on the current figure.

`showplottool('toggle','tool')` toggles the visibility of the specified plot tool on the current figure.

`showplottool('figure_handle',...)` operates on the specified figure instead of the current figure.

# showplottool

---

---

**Note** When you dock, undock, resize, or reposition a plotting tool and then close it, it will still be configured as you left it the next time you open it. There is no command to reset plotting tools to their original, default locations.

---

## Alternatives

Click the larger Plotting Tools icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Plotting Tools — Interactive Plotting”.

## See Also

`figurepalette` | `plotbrowser` | `plottools` | `propertyeditor`

## Purpose

Reduce size of patch faces

## Syntax

```
shrinkfaces(p,sf)
nfv = shrinkfaces(p,sf)
nfv = shrinkfaces(fv,sf)
shrinkfaces(p)
nfv = shrinkfaces(f,v,sf)
[nf,nv] = shrinkfaces(...)
```

## Description

`shrinkfaces(p,sf)` shrinks the area of the faces in patch `p` to shrink factor `sf`. A shrink factor of 0.6 shrinks each face to 60% of its original area. If the patch contains shared vertices, the MATLAB software creates nonshared vertices before performing the face-area reduction.

`nfv = shrinkfaces(p,sf)` returns the face and vertex data in the struct `nfv`, but does not set the `Faces` and `Vertices` properties of patch `p`.

`nfv = shrinkfaces(fv,sf)` uses the face and vertex data from the struct `fv`.

`shrinkfaces(p)` and `shrinkfaces(fv)` (without specifying a shrink factor) assume a shrink factor of 0.3.

`nfv = shrinkfaces(f,v,sf)` uses the face and vertex data from the arrays `f` and `v`.

`[nf,nv] = shrinkfaces(...)` returns the face and vertex data in two separate arrays instead of a struct.

## Examples

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). Two isosurfaces provide a before and after view of the effects of shrinking the face size.

- First `reducevolume` samples the flow data at every other point and then `isosurface` generates the faces and vertices data.
- The `patch` command accepts the face/vertex struct and draws the first (`p1`) isosurface.

# shrinkfaces

---

- Use the `daspect`, `view`, and `axis` commands to set up the view and then add a title.
- The `shrinkfaces` command modifies the face/vertex data and passes it directly to `patch`.

```
[x,y,z,v] = flow;  
[x,y,z,v] = reducevolume(x,y,z,v,2);  
fv = isosurface(x,y,z,v,-3);  
p1 = patch(fv);  
set(p1,'FaceColor','red','EdgeColor',[.5,.5,.5]);  
daspect([1 1 1]); view(3); axis tight  
title('Original')
```

```
figure  
p2 = patch(shrinkfaces(fv,.3));  
set(p2,'FaceColor','red','EdgeColor',[.5,.5,.5]);  
daspect([1 1 1]); view(3); axis tight  
title('After Shrinking')
```

# shrinkfaces

---

## See Also

**Purpose** Signum function

**Syntax** `Y = sign(X)`

**Description** `Y = sign(X)` returns an array `Y` the same size as `X`, where each element of `Y` is:

- 1 if the corresponding element of `X` is greater than zero
- 0 if the corresponding element of `X` equals zero
- -1 if the corresponding element of `X` is less than zero

For nonzero complex `X`, `sign(X) = X./abs(X)`.

**See Also** `abs` | `conj` | `imag` | `real`

# sin

---

**Purpose** Sine of argument in radians

**Syntax**  $Y = \sin(X)$

**Description**  $Y = \sin(X)$  returns the circular sine of the elements of  $X$ . The `sin` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

**Examples** Graph the sine function over the domain  $-\pi \leq x \leq \pi$ .

```
x = -pi:0.01:pi;  
plot(x,sin(x)), grid on
```

**Definitions** **Sine**

The sine of an angle is

$$\sin(x) = \frac{e^{ix} - e^{-ix}}{2i}$$

### Sine of Complex Angle

For complex values, sine is

$$\sin(x + iy) = \sin(x) \cosh(y) + i \cos(x) \sinh(y)$$

### See Also

[sind](#) | [asin](#) | [asind](#) | [sinh](#)

# sind

---

<b>Purpose</b>	Sine of argument in degrees
<b>Syntax</b>	$Y = \text{sind}(X)$
<b>Description</b>	$Y = \text{sind}(X)$ returns the sine of the elements in $X$ , which are expressed in degrees.
<b>Input Arguments</b>	<b>X - Angle in degrees</b> scalar value   vector   matrix   N-D array  Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The <code>sind</code> operation is element-wise when $X$ is nonscalar.  <b>Data Types</b> single   double <b>Complex Number Support:</b> Yes
<b>Output Arguments</b>	<b>Y - Sine of angle</b> scalar value   vector   matrix   N-D array  Sine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as $X$ .
<b>Examples</b>	<b>Sine of 180 degrees compared to sine of radians</b>  <code>sind(180)</code>  <code>ans =</code>  0  <code>sin(pi)</code>  <code>ans =</code>  1.2246e-16

**Sine of vector of complex angles, specified in degrees**

```
z = [90+i 15+2i 10+3i];  
y = sind(z)
```

```
y =
```

```
1.0002      0.2590 + 0.0337i    0.1739 + 0.0516i
```

**See Also**

[sin](#) | [asind](#) | [asin](#)

# single

---

**Purpose** Convert to single precision

**Syntax** `B = single(A)`

**Description** `B = single(A)` converts the matrix `A` to single precision, returning that value in `B`. `A` can be any numeric object (such as a `double`). If `A` is already single precision, `single` has no effect. Single-precision quantities require less storage than double-precision quantities, but have less precision and a smaller range.

The `single` class is primarily meant to be used to store single-precision values. Hence most operations that manipulate arrays without changing their elements are defined. Examples are `reshape`, `size`, the relational operators, subscripted assignment, and subscripted reference.

You can define your own methods for the `single` class by placing the appropriately named method in an `@single` folder within a folder on your path.

## Examples

```
a = magic(4);  
b = single(a);
```

```
whos  
  Name      Size      Bytes  Class  
  
  a         4x4         128  double array  
  b         4x4          64  single array
```

**See Also** `double`

**Purpose** Hyperbolic sine of argument in radians

**Syntax**  $Y = \sinh(X)$

**Description** The sinh function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \sinh(X)$  returns the hyperbolic sine of the elements of  $X$ .

**Examples** Graph the hyperbolic sine function over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;  
plot(x,sinh(x)), grid on
```

### Hyperbolic Sine

The hyperbolic sine of  $z$  is

# sinh

---

$$\sinh(z) = \frac{e^z - e^{-z}}{2}.$$

**Purpose**

Array dimensions

**Syntax**

```
d = size(X)
[m,n] = size(X)
m = size(X,dim)
[d1,d2,d3,...,dn] = size(X),
```

**Description**

`d = size(X)` returns the sizes of each dimension of array `X` in a vector, `d`, with `ndims(X)` elements.

- If `X` is a scalar, then `size(X)` returns the vector `[1 1]`. Scalars are regarded as a 1-by-1 arrays in MATLAB.
- If `X` is a table, `size(X)` returns a two-element row vector consisting of the number of rows and the number of variables in the table. Variables in the table can have multiple columns, but `size` only counts the variables and rows.

`[m,n] = size(X)` returns the size of matrix `X` in separate variables `m` and `n`.

`m = size(X,dim)` returns the size of the dimension of `X` specified by scalar `dim`.

`[d1,d2,d3,...,dn] = size(X)`, for `n > 1`, returns the sizes of the dimensions of the array `X` in the variables `d1,d2,d3,...,dn`, provided the number of output arguments `n` equals `ndims(X)`. If `n` does not equal `ndims(X)`, the following exceptions hold:

- |                              |                                                                                                                                                                                                                                                                               |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n &lt; ndims(X)</code> | <code>di</code> equals the size of the <code>i</code> th dimension of <code>X</code> for $0 < i < n$ , but <code>dn</code> equals the product of the sizes of the remaining dimensions of <code>X</code> , that is, dimensions <code>n</code> through <code>ndims(X)</code> . |
| <code>n &gt; ndims(X)</code> | <code>size</code> returns ones in the “extra” variables, that is, those corresponding to <code>ndims(X)+1</code> through <code>n</code> .                                                                                                                                     |

# size

---

---

**Note** For a Java array, `size` returns the length of the Java array as the number of rows. The number of columns is always 1. For a Java array of arrays, the result describes only the top level array.

---

## Examples

### Size of Dimensions in 3-D Array

Find the size of `rand(2,3,4)`.

```
d = size(rand(2,3,4))
```

```
d =
```

```
     2     3     4
```

The size is output as a single vector.

Find the size of the second dimension of `rand(2,3,4)`.

```
m = size(rand(2,3,4),2)
```

```
m =
```

```
     3
```

The size is output as a scalar.

Assign the size of each dimension to a separate variable.

```
[m,n,p] = size(rand(2,3,4))
```

```
m =
```

```
     2
```

```
n =
```

3

p =

4

**Size of Table**

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
X = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

X =

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the size of the table.

```
d = size(X)
```

d =

5 4

# size

---

`size` counts four variables, even though the variable `BloodPressure` contains two columns.

## **Specify Different Number of Outputs than `ndims(X)`**

Assign the size of each dimension to a separate variable where the number of outputs matches the number of dimensions.

```
X = ones(3,4,5);  
[d1,d2,d3] = size(X)
```

```
d1 =
```

```
3
```

```
d2 =
```

```
4
```

```
d3 =
```

```
5
```

There is one output for each dimension of `X`.

Specify fewer output variables than `ndims(X)`.

```
[d1,d2] = size(X)
```

```
d1 =
```

```
3
```

```
d2 =
```

```
20
```

The “extra” dimensions are collapsed into a single product.

Specify more output variables than `ndims(X)`.

```
[d1,d2,d3,d4,d5,d6] = size(X)
```

```
d1 =
```

```
    3
```

```
d2 =
```

```
    4
```

```
d3 =
```

```
    5
```

```
d4 =
```

```
    1
```

```
d5 =
```

```
    1
```

```
d6 =
```

```
    1
```

The “extra” variables all represent singleton dimensions.

# size

---

## See Also

`exist` | `length` | `numel` | `whos`

## Purpose

Size of containers.Map object

## Syntax

```
dim = size(mapObj,1)
dimVector = size(mapObj)
[dim1,dim2,...,dimN] = size(mapObj)
```

## Description

`dim = size(mapObj,1)` returns a scalar numeric value that indicates the number of key-value pairs in `mapObj`. If you call `size` with a numeric second input argument other than 1, the `size` method returns the scalar numeric value 1.

`dimVector = size(mapObj)` returns a two-element vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

`[dim1,dim2,...,dimN] = size(mapObj)` returns `[k,1,...,1]`.

## Input Arguments

### mapObj

Object of class `containers.Map`.

## Output Arguments

### dim

Scalar numeric value that indicates the number of key-value pairs in `mapObj`.

### dimVector

Two-element numeric vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

### [dim1,dim2,...,dimN]

Numeric scalar values. Variable `dim1` equals `k`, where `k` is the number of key-value pairs in `mapObj`. All other outputs equal 1.

## Examples

### Determine the Size of a Map

Construct a map and find the number of key-value pairs:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
```

## containers.Map.size

---

```
mapObj = containers.Map(myKeys,myValues);  
dim = size(mapObj,1)
```

This code returns a scalar numeric value:

```
dim =  
    3
```

If you do not specify a second input argument,

```
dimVector = size(mapObj)
```

then the `size` method returns a vector:

```
dimVector =  
    3     1
```

### See Also

[containers.Map](#) | [isKey](#) | [keys](#) | [length](#) | [values](#)

## Purpose

Array dimensions

## Syntax

```
allDims = size(matObj,variable)
[dim1,...,dimN] = size(matObj,variable)
selectedDim = size(matObj,variable,dim)
```

## Description

`allDims = size(matObj,variable)` returns the size of each dimension of the specified variable in the file corresponding to `matObj`. Output `allDims` is a 1-by-`m` vector, where `m = ndims(variable)`.

`[dim1,...,dimN] = size(matObj,variable)` returns the sizes of each dimension in separate output variables `dim1,...,dimN`.

`selectedDim = size(matObj,variable,dim)` returns the size of the specified dimension.

## Tips

- Do not call `size` with the syntax `size(matObj.variable)`. This syntax loads the entire contents of the variable into memory. For very large variables, this load operation results in Out of Memory errors.

## Input Arguments

### **matObj**

Object created by the `matfile` function.

### **variable**

String enclosed in single quotation marks that specifies the name of a variable in the MAT-file corresponding to `matObj`.

### **dim**

Nonzero positive scalar integer that specifies a dimension of the variable.

## Output Arguments

### **allDims**

1-by-`m` vector of sizes of the dimensions of the specified variable, where `m = ndims(variable)`.

### **dim1,...,dimN**

Scalar numeric values, where `dimK` contains the size of the `K`th dimension of variable:

- If `N < ndims(variable)`, then `dimN`, equals the product of the sizes of dimensions `N` through `ndims(variable)`.
- If `N > ndims(variable)`, the `size` method returns ones in the output variables corresponding to dimensions `ndims(variable)+1` through `N`.

## **selectedDim**

Scalar numeric value that contains the size of the selected dimension for the specified variable.

## **Examples**

Find the size of the matrix `topo` in `topography.mat` without loading any data:

```
matObj = matfile('topography.mat');  
[nrows,ncols] = size(matObj,'topo');
```

---

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';  
matObj = matfile(filename);  
[nrows,ncols] = size(matObj,'stocks');  
  
avgs = zeros(1,ncols);  
for idx = 1:ncols  
    avgs(idx) = mean(matObj.stocks(:,idx));  
end
```

---

Create a three-dimensional array, and call the `size` method with different numbers of output arguments:

```
matObj = matfile('temp.mat','Writable',true);
matObj.X = rand(2,3,4);

d = size(matObj,'X')
d2 = size(matObj,'X',2)
[m,n] = size(matObj,'X')
[m1,m2,m3,m4] = size(matObj,'X')
```

This code returns

```
d =
     2     3     4

d2 =
     3

m =
     2
n =
    12

m1 =
     2
m2 =
     3
m3 =
     4
m4 =
     1
```

## See Also

[matfile](#) | [whos](#)

# size (serial)

---

**Purpose** Size of serial port object array

**Syntax**

```
d = size(obj)
[m,n] = size(obj)
[m1,m2,m3,...,mn] = size(obj)
m = size(obj,dim)
```

**Description**

`d = size(obj)` returns the two-element row vector `d` containing the number of rows and columns in the serial port object, `obj`.

`[m,n] = size(obj)` returns the number of rows, `m` and columns, `n` in separate output variables.

`[m1,m2,m3,...,mn] = size(obj)` returns the length of the first `n` dimensions of `obj`.

`m = size(obj,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(obj,1)` returns the number of rows.

**See Also** `length`

## Purpose

(Will be removed) Size of triangulation matrix

---

**Note** `size(TriRep)` will be removed in a future release. Use `size(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

## Syntax

`size(TR)`

## Description

`size(TR)` provides size information for a triangulation matrix. The matrix is of size `mtri-by-nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex (triangle/tetrahedron, etc).

## Input Arguments

`TR`                  Triangulation matrix

## Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## See Also

`size` | `delaunayTriangulation` | `triangulation`

## size (tscollection)

---

<b>Purpose</b>	Size of tscollection object
<b>Syntax</b>	<code>size(tsc)</code>
<b>Description</b>	<code>size(tsc)</code> returns <code>[n m]</code> , where <code>n</code> is the length of the time vector and <code>m</code> is the number of tscollection members.
<b>See Also</b>	<code>length (tscollection)</code>   <code>isempty (tscollection)</code>   <code>tscollection</code>

**Purpose**

Volumetric slice plot

**Syntax**

```
slice(V, sx, sy, sz)
slice(X, Y, Z, V, sx, sy, sz)
slice(V, XI, YI, ZI)
slice(X, Y, Z, V, XI, YI, ZI)
slice(..., 'method')
slice(axes_handle, ...)
h = slice(...)
```

**Description**

`slice` displays orthogonal slice planes through volumetric data.

`slice(V, sx, sy, sz)` draws slices along the  $x$ ,  $y$ ,  $z$  directions in the volume  $V$  at the points in the vectors  $sx$ ,  $sy$ , and  $sz$ .  $V$  is an  $m$ -by- $n$ -by- $p$  volume array containing data values at the default location  $X = 1:n$ ,  $Y = 1:m$ ,  $Z = 1:p$ . Each element in the vectors  $sx$ ,  $sy$ , and  $sz$  defines a slice plane in the  $x$ -,  $y$ -, or  $z$ -axis direction.

`slice(X, Y, Z, V, sx, sy, sz)` draws slices of the volume  $V$ .  $X$ ,  $Y$ , and  $Z$  are three-dimensional arrays specifying the coordinates for  $V$ .  $X$ ,  $Y$ , and  $Z$  must be monotonic and orthogonally spaced (as if produced by the function `meshgrid`). The color at each point is determined by 3-D interpolation into the volume  $V$ .

`slice(V, XI, YI, ZI)` draws data in the volume  $V$  for the slices defined by  $XI$ ,  $YI$ , and  $ZI$ .  $XI$ ,  $YI$ , and  $ZI$  are matrices that define a surface, and the volume is evaluated at the surface points.  $XI$ ,  $YI$ , and  $ZI$  must all be the same size.

`slice(X, Y, Z, V, XI, YI, ZI)` draws slices through the volume  $V$  along the surface defined by the arrays  $XI$ ,  $YI$ ,  $ZI$ .

`slice(..., 'method')` specifies the interpolation method. `'method'` is `'linear'`, `'cubic'`, or `'nearest'`.

- `linear` specifies trilinear interpolation (the default).

# slice

---

- `cubic` specifies tricubic interpolation.
- `nearest` specifies nearest-neighbor interpolation.

`slice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes object (`gca`). The axes `clim` property is set to span the finite values of `V`.

`h = slice(...)` returns a vector of handles to surface graphics objects.

## Tips

The color drawn at each point is determined by interpolation into the volume `V`.

## Examples

Visualize the function

$$v = xe^{(-x^2-y^2-z^2)}$$

over the range  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ ,  $-2 \leq z \leq 2$ :

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);  
v = x.*exp(-x.^2-y.^2-z.^2);  
xslice = [-1.2,.8,2]; yslice = 2; zslice = [-2,0];  
slice(x,y,z,v,xslice,yslice,zslice)  
colormap hsv
```

### Slicing At Arbitrary Angles

You can also create slices that are oriented in arbitrary planes. To do this,

- Create a slice surface in the domain of the volume (`surf`, `linspace`).
- Orient this surface with respect to the axes (`rotate`).
- Get the `XData`, `YData`, and `ZData` of the surface (`get`).
- Use this data to draw the slice plane within the volume.

For example, these statements slice the volume in the first example with a rotated plane. Placing these commands within a `for` loop “passes” the plane through the volume along the  $z$ -axis.

```
for i = -2:.5:2
    hsp = surf(linspace(-2,2,20),linspace(-2,2,20),zeros(20)+i);
    rotate(hsp,[1,-1,1],30)
```

# slice

---

```
xd = get(hsp, 'XData');  
yd = get(hsp, 'YData');  
zd = get(hsp, 'ZData');  
delete(hsp)  
slice(x,y,z,v,[-2,2],2,-2) % Draw some volume boundaries  
hold on  
slice(x,y,z,v,xd,yd,zd)  
hold off  
axis tight  
view(-5,10)  
drawnow  
end
```

The following picture illustrates three positions of the same slice surface as it passes through the volume.

## Slicing with a Nonplanar Surface

You can slice the volume with any surface. This example probes the volume created in the previous example by passing a spherical slice surface through the volume.

```
[xsp,ysp,zsp] = sphere;
% Draw some volume boundaries
% Draw some volume boundaries
slice(x,y,z,v,[-2,2],2,-2)
for i = -3:.2:3
    hsp = surface(xsp+i,ysp,zsp);
    rotate(hsp,[1 0 0],90)
    xd = get(hsp,'XData');
    yd = get(hsp,'YData');
    zd = get(hsp,'ZData');
    delete(hsp)
    hold on
    hslicer = slice(x,y,z,v,xd,yd,zd);
    axis tight
    xlim([-3,3])
    view(-10,35)
    drawnow
    delete(hslicer)
    hold off
end
```

The following picture illustrates three positions of the spherical slice surface as it passes through the volume.

# slice

## How To

- Exploring Volumes with Slice Planes

**Purpose** Smooth 3-D data

## Syntax

## Description

`W = smooth3(V)` smooths the input data `V` and returns the smoothed data in `W`.

`W = smooth3(V, 'filter')` *filter* determines the convolution kernel and can be the strings

- 'gaussian'
- 'box' (default)

`W = smooth3(V, 'filter', size)` sets the size of the convolution kernel (default is [3 3 3]). If `size` is scalar, then `size` is interpreted as [size, size, size].

`W = smooth3(V, 'filter', size, sd)` sets an attribute of the convolution kernel. When *filter* is gaussian, `sd` is the standard deviation (default is .65).

## Examples

This example smooths some random 3-D data and then creates an isosurface with end caps.

```
rng(9, 'twister')
data = rand(10,10,10);
data = smooth3(data, 'box', 5);
patch(isocaps(data, .5), 'FaceColor', 'interp', 'EdgeColor', 'none');
p1 = patch(isosurface(data, .5), 'FaceColor', 'blue', 'EdgeColor', 'none');
isonormals(data, p1)
view(3);
axis vis3d tight
camlight left;
lighting phong
```

# smooth3

---

## See Also

## How To

- [Displaying an Isosurface](#)

<b>Purpose</b>	Force snapshot of image for inclusion in published document
<b>Syntax</b>	snapnow
<b>Description</b>	The snapnow command forces a snapshot of the image or plot that the code has most recently generated for presentation in a published document. The output appears in the published document at the end of the cell that contains the snapnow command. When used outside the context of publishing a file, snapnow has the same behavior as drawnow. That is, if you run a file that contains the snapnow command, the MATLAB software interprets it as though it were a drawnow command.
<b>Examples</b>	<p>This example demonstrates the difference between publishing code that contains the snapnow command and running that code. The first image shows the results of publishing the code and the second image shows the results of running the code.</p> <p>Suppose you have a file that contains the following code:</p> <pre>%% Scale magic Data and %% Display as Image:  for i=1:3     imagesc(magic(i))     snapnow end</pre> <p>When you publish the code to HTML, the published document contains a title, a table of contents, the commented text, the code, and each of the three images produced by the for loop. (In the published document shown, the size of the images have been reduced.)</p>

## Scale magic Data and

### Contents

- [Display as Image:](#)

### Display as Image:

```
for i=1:3
    imagesc(magic(i))
    snapnow
end
```

When you run the code, a single Figure window opens and MATLAB updates the image within this window as it evaluates each iteration of the for loop. Each successive image replaces the one that preceded it, so that the Figure window appears as follows when the code evaluation completes.

`drawnow`

**Concepts**

- “Image Snapshot”

# sort

**Purpose** Sort array elements in ascending or descending order

**Syntax**

```
B = sort(A)
B = sort(A,dim)
B = sort(...,mode)
[B,IX] = sort(A,...)
```

**Description** `B = sort(A)` sorts the elements along different dimensions of an array, and arranges those elements in ascending order.

If A is a ...	sort(A) ...
Vector	Sorts the elements of A.
Matrix	Sorts each column of A.
Multidimensional array	Sorts A along the first non-singleton dimension, and returns an array of sorted vectors.
Cell array of strings	Sorts the strings in ascending ASCII dictionary order, and returns a vector cell array of strings. The sort is case-sensitive; uppercase letters appear in the output before lowercase. You cannot use the <code>dim</code> or <code>mode</code> options with a cell array.

Integer, floating-point, logical, character, and categorical arrays are permitted. Floating-point arrays can be complex. For elements of A with identical values, the order of these elements is preserved in the sorted list. When A is complex, the elements are sorted by magnitude, i.e., `abs(A)`, and where magnitudes are equal, further sorted by phase angle, i.e., `angle(A)`, on the interval  $[-\pi, \pi]$ . If A includes any NaN or undefined categorical array elements, `sort` places these at the high end.

`B = sort(A,dim)` sorts the elements along the dimension of A specified by a scalar `dim`.

`B = sort(...,mode)` sorts the elements in the specified direction, depending on the value of `mode`.

'ascend' Ascending order (default)

'descend' Descending order

`[B,IX] = sort(A,...)` also returns an array of indices `IX`, where `size(IX) == size(A)`. If `A` is a vector, `B = A(IX)`. If `A` is an `m`-by-`n` matrix, then each column of `IX` is a permutation vector of the corresponding column of `A`, such that

```
for j = 1:n
    B(:,j) = A(IX(:,j),j);
end
```

If `A` has repeated elements of equal value, the returned indices preserve the original ordering.

### Sorting Complex Entries

If `A` has complex entries `r` and `s`, `sort` orders them according to the following rule: `r` appears before `s` in `sort(A)` if either of the following hold:

- $\text{abs}(r) < \text{abs}(s)$
- $\text{abs}(r) = \text{abs}(s)$  and  $\text{angle}(r) < \text{angle}(s)$

where  $-\pi < \text{angle}(r) \leq \pi$

For example,

```
v = [1 -1 i -i];
angle(v)
```

```
ans =
```

```
0    3.1416    1.5708   -1.5708
```

```
sort(v)
```

```
ans =
```

```
0 - 1.0000i    1.0000
```

# sort

---

0 + 1.0000i -1.0000

---

**Note** sort uses a different rule for ordering complex numbers than do the relational operators. See the Relational Operators reference page for more information.

---

## Examples

### Example 1

Sort horizontal vector A:

```
A = [78 23 10 100 45 5 6];
```

```
sort(A)
```

```
ans =  
     5     6    10    23    45    78   100
```

### Example 2

Sort matrix A in each dimension:

```
A = [ 3 7 5  
     0 4 2 ];
```

```
sort(A,1)
```

```
ans =  
     0     4     2  
     3     7     5
```

```
sort(A,2)
```

```
ans =  
     3     5     7  
     0     2     4
```

Sort it again, this time returning an array of indices for the result:

```
[B, IX] = sort(A, 2)
```

```
B =  
    3    5    7  
    0    2    4
```

```
IX =  
    1    3    2  
    1    3    2
```

### Example 3

Sort each column of matrix A in descending order:

```
A = [ 3  7  5  
      6  8  3  
      0  4  2 ];
```

```
sort(A,1,'descend')
```

```
ans =  
    6    8    5  
    3    7    3  
    0    4    2
```

This is equivalent to

```
sort(A,'descend')
```

```
ans =  
    6    8    5  
    3    7    3  
    0    4    2
```

[issorted](#) | [max](#) | [mean](#) | [median](#) | [min](#) | [sortrows](#) | [unique](#)

# sortrows

---

**Purpose** Sort rows in ascending order

**Syntax**

```
B = sortrows(A)
B = sortrows(A,column)
[B,index] = sortrows(A,...)

tblB = sortrows(tblA)
tblB = sortrows(tblA,'RowNames')
tblB = sortrows(tblA,vars)

tblB = sortrows(tblA,mode)

tblB = sortrows(tblA,'RowNames',mode)
tblB = sortrows(tblA,vars,mode)

[tblB,index] = sortrows(tblA,...)
```

**Description** `B = sortrows(A)` sorts the rows of `A` in ascending order. Argument `A` must be either a matrix or a column vector.

For strings, this is the familiar dictionary sort.

When `A` is complex, `sortrows` sorts the elements by magnitude, and, where magnitudes are equal, further sorts by phase angle on the interval  $[-\pi, \pi]$ .

`B = sortrows(A,column)` sorts the matrix based on the columns specified in the vector, `column`. If an element of `column` is positive, MATLAB sorts the corresponding column of matrix `A` in ascending order. If an element of `column` is negative, MATLAB sorts the corresponding column in descending order. For example, `sortrows(A,[2 -3])` sorts the rows of `A` first in ascending order for the second column, and then by descending order for the third column.

`[B,index] = sortrows(A,...)` also returns an index vector `index`.

If *A* is a column vector, then  $B = A(\text{index})$ . If *A* is an *m*-by-*n* matrix, then  $B = A(\text{index}, :)$ .

`tblB = sortrows(tblA)` sorts the rows of a table, `tblA`, in ascending order first by the first variable, next by the second variable, and so on. Each variable in `tblA` must be a valid input to `sort` or `sortrows`.

`tblB = sortrows(tblA, 'RowNames')` sorts the rows of `tblA` by the row names. If `tblA.Properties.RowNames` is empty, `sortrows(tblA, 'RowNames')` returns `tblA`.

`tblB = sortrows(tblA, vars)` sorts by the variables specified by `vars`. You can specify the input argument, `vars`, as an integer, a vector of integers, a variable name, a cell array containing one or more variable names, or a logical vector.

If an element of `vars` is a positive integer, `sortrows` sorts the corresponding variable in `tblA` in ascending order. If an element of `vars` is a negative integer, `sortrows` sorts the corresponding variable in `tblA` in descending order. If you provide the mode input argument, MATLAB ignores the sign of an integer.

`tblB = sortrows(tblA, mode)` and `tblB = sortrows(tblA, 'RowNames', mode)` sorts `tblA` in the direction specified by `mode`. The single string, `'ascend'`, indicates ascending order (default) and `'descend'` indicates descending order.

`tblB = sortrows(tblA, vars, mode)` sorts `tblA` in the direction specified by `mode`. You can specify `mode` as a single string or a cell array of strings containing `'ascend'` for ascending order (default) or `'descend'` for descending order.

When `mode` is a single string, `sortrows` sorts in the specified direction for all variables in `vars`.

When `mode` is a cell array of strings, `sortrows` sorts in the specified direction for each variable in `vars`.

`[tblB,index] = sortrows(tblA,...)` also returns an index vector, `index`, such that `tblB = tblA(index,:)`.

## Examples

### Sort Rows of Matrix

Start with an arbitrary matrix, `A`:

```
A = floor(gallery('uniformdata',[6 7],0)*100);  
A(1:4,1) = 95; A(5:6,1) = 76; A(2:4,2) = 7; A(3,3) = 73
```

```
A =  
    95    45    92    41    13     1    84  
    95     7    73    89    20    74    52  
    95     7    73     5    19    44    20  
    95     7    40    35    60    93    67  
    76    61    93    81    27    46    83  
    76    79    91     0    19    41     1
```

When called with only a single input argument, `sortrows` bases the sort on the first column of the matrix. For any rows that have equal elements in a particular column, (e.g., `A(1:4,1)` for this matrix), sorting is based on the column immediately to the right, (`A(1:4,2)` in this case):

```
B = sortrows(A)
```

```
B =  
    76    61    93    81    27    46    83  
    76    79    91     0    19    41     1  
    95     7    40    35    60    93    67  
    95     7    73     5    19    44    20  
    95     7    73    89    20    74    52  
    95    45    92    41    13     1    84
```

When called with two input arguments, `sortrows` bases the sort entirely on the column specified in the second argument. Rows that have equal elements in the specified column, (e.g., `A(2:4, :)`, if sorting matrix `A` by column 2) remain in their original order:

```
C = sortrows(A,2)
```

```
C =
    95     7    73    89    20    74    52
    95     7    73     5    19    44    20
    95     7    40    35    60    93    67
    95    45    92    41    13     1    84
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
```

This example specifies two columns to sort by: columns 1 and 7. This tells `sortrows` to sort by column 1 first, and then for any rows with equal values in column 1, to sort by column 7:

```
D = sortrows(A,[1 7])
```

```
D =
    76    79    91     0    19    41     1
    76    61    93    81    27    46    83
    95     7    73     5    19    44    20
    95     7    73    89    20    74    52
    95     7    40    35    60    93    67
    95    45    92    41    13     1    84
```

Sort the matrix using the values in column 4 this time and in reverse order:

```
E = sortrows(A, -4)
```

```
E =
    95     7    73    89    20    74    52
    76    61    93    81    27    46    83
    95    45    92    41    13     1    84
```

# sortrows

---

```
95    7    40    35    60    93    67
95    7    73     5    19    44    20
76   79    91     0    19    41     1
```

## Sort Rows of Table

Sort the rows of a table by the variable values in ascending order.

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
tblA =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table.

```
tblB = sortrows(tblA)
```

```
tblB =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Williams	38	64	131	125	83
Smith	38	71	176	124	93

Jones	40	67	133	117	75
Johnson	43	69	163	109	77
Brown	49	64	119	122	80

The sortrows function sorts the rows in ascending order first by the variable Age, and then by the variable Height.

### Sort Rows of Table By Row Names

Create a table with four variables listing patient information for five people.

```

LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

```

```
tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

tblA =

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table by the row names and return an index vector such that tblB = tblA(index,:).

```
[tblB,index] = sortrows(tblA,'RowNames')
```

tblB =

Age	Height	Weight	BloodPressure
-----	--------	--------	---------------

# sortrows

---

```
      Brown      49      64      119      122      80
      Johnson    43      69      163      109      77
      Jones      40      67      133      117      75
      Smith      38      71      176      124      93
      Williams   38      64      131      125      83
```

```
index =
```

```
5
2
4
1
3
```

The `sortrows` function sorts the rows in ascending order by the row names.

## Sort Rows of Table By Variables

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
tblA =
```

```
      Age      Height      Weight      BloodPressure
      ---      -
      Smith    38      71      176      124      93
      Johnson  43      69      163      109      77
```

Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table in ascending order by Height, and then descending order by Weight. Also, return an index vector such that `tblB = tblA(index,:)`.

```
[tblB,index] = sortrows(tblA,{'Height','Weight'},{'ascend','descend'})
```

tblB =

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	
Williams	38	64	131	125	83
Brown	49	64	119	122	80
Jones	40	67	133	117	75
Johnson	43	69	163	109	77
Smith	38	71	176	124	93

index =

- 3
- 5
- 4
- 2
- 1

[issorted](#) | [sort](#)

# sound

---

## Purpose

Convert matrix of signal data to sound

## Syntax

```
sound(y)
sound(y,Fs)
sound(y,Fs,nBits)
```

## Description

`sound(y)` sends audio signal `y` to the speaker at the default sample rate of 8192 hertz.

`sound(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`sound(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

## Input Arguments

### **y** - Audio data

column vector | `m`-by-2 matrix

Audio data, specified as an `m`-by-1 column vector for single-channel (mono) audio, or an `m`-by-2 matrix for stereo playback, where `m` is the number of audio samples. If `y` is an `m`-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

### Data Types

double

### **Fs** - Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data `y`, specified as a positive number between 80 and 1000000.

### Data Types

single | double

### **nBits** - Bit depth of sample values

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

## Examples

### Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;  
sound(y);
```

### Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;  
sound(y, 2*Fs);
```

### Play Sample Data with Specific Bit Depth

```
load handel.mat;  
nBits = 16;  
sound(y, Fs, nBits);
```

MATLAB plays the audio with a bit depth of 16 bits per sample, if this is supported on your system.

## Tips

- The `sound` function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

## See Also

# sound

---

## **Concepts**

- “Characteristics of Audio Files”
- “Play Audio”

**Purpose**

Scale data and play as sound

**Syntax**

```
soundsc(y)
soundsc(y,Fs)
soundsc(y,Fs,nBits)

soundsc( __ ,yRange)
```

**Description**

`soundsc(y)` scales the values of audio signal `y` to fit in the range from  $-1.0$  to  $1.0$ , and then sends the data to the speaker at the default sample rate of 8192 hertz. By first scaling the data, `soundsc` plays the audio as loudly as possible without clipping. The mean of the dynamic range of the data is set to zero.

`soundsc(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`soundsc(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

`soundsc( __ ,yRange)`, where `yRange` is a vector of the form `[low,high]`, linearly scales the values in `y` between `low` and `high` to the full sound range `[-1.0,1.0]`. Values outside `[low,high]` are not clipped. You can use `yRange` with any of the input arguments in the above syntaxes.

**Input Arguments****y - Audio data**

column vector | m-by-2 matrix

Audio data, specified as an `m`-by-1 column vector for single-channel (mono) audio, or an `m`-by-2 matrix for stereo playback, where `m` is the number of audio samples. If `y` is an `m`-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

**Data Types**

double

## **Fs - Sample rate**

8192 (default) | positive number

Sample rate, in hertz, of audio data  $y$ , specified as a positive number between 80 and 1000000.

## **Data Types**

single | double

## **nBits - Bit depth of sample values**

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

## **yRange - Range of audio data to scale**

$[\min(y), \max(y)]$  (default) | two-element vector

Range of audio data to scale, specified as a two-element vector of the form  $[\text{low}, \text{high}]$ , where  $\text{low}$  and  $\text{high}$  are the lower and upper limits of the range.

**Example:**  $[-0.8, 0.8]$

## **Data Types**

double

## **Examples**

### **Play Sample Data at Default Sample Rate**

Load the example file `gong.mat`, which contains sample data  $y$  and rate  $F_s$ , and listen to the audio.

```
load gong.mat;  
soundsc(y);
```

### **Play Sample Data at Specific Sample Rate**

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
```

```
soundsc(y, 2*Fs);
```

### Play Sample Data with Specific Bit Depth

```
load handel.mat;  
nBits = 16;  
soundsc(y,Fs,nBits);
```

MATLAB plays the scaled audio with a bit depth of 16 bits per sample.

### Scale Selected Audio Data

```
load handel.mat;  
yRange = [-0.7,0.7];  
soundsc(y,yRange);
```

### Tips

- The sound function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

# spalloc

---

**Purpose** Allocate space for sparse matrix

**Syntax** `S = spalloc(m,n,nzmax)`

**Description** `S = spalloc(m,n,nzmax)` creates an all zero sparse matrix `S` of size `m`-by-`n` with room to hold `nzmax` nonzeros. The matrix can then be generated column by column without requiring repeated storage allocation as the number of nonzeros grows.

`spalloc(m,n,nzmax)` is shorthand for

```
sparse([],[],[],m,n,nzmax)
```

**Examples** To generate efficiently a sparse matrix that has an average of at most three nonzero elements per column

```
S = spalloc(n,n,3*n);  
for j = 1:n  
    S(:,j) = [zeros(n-3,1)' round(rand(3,1))']';end
```

---

<b>Purpose</b>	Create sparse matrix
<b>Syntax</b>	<pre>S = sparse(A) S = sparse(i,j,s,m,n,nzmax) S = sparse(i,j,s,m,n) S = sparse(i,j,s) S = sparse(m,n)</pre>
<b>Description</b>	<p>The <code>sparse</code> function generates matrices in the MATLAB sparse storage organization.</p> <p><code>S = sparse(A)</code> converts a full matrix to sparse form by squeezing out any zero elements. If <code>S</code> is already sparse, <code>sparse(S)</code> returns <code>S</code>.</p> <p><code>S = sparse(i,j,s,m,n,nzmax)</code> uses vectors <code>i</code>, <code>j</code>, and <code>s</code> to generate an <code>m</code>-by-<code>n</code> sparse matrix such that <math>S(i(k),j(k)) = s(k)</math>, with space allocated for <code>nzmax</code> nonzeros. Vectors <code>i</code>, <code>j</code>, and <code>s</code> are all the same length. Any elements of <code>s</code> that are zero are ignored, along with the corresponding values of <code>i</code> and <code>j</code>. Any elements of <code>s</code> that have duplicate values of <code>i</code> and <code>j</code> are added together.</p> <hr/> <p><b>Note</b> If any value in <code>i</code> or <code>j</code> is larger than <math>2^{31}-1</math> for 32-bit platforms, or <math>2^{48}-1</math> on 64-bit platforms, then the sparse matrix cannot be constructed.</p> <hr/> <p>To simplify this six-argument call, you can pass scalars for the argument <code>s</code> and one of the arguments <code>i</code> or <code>j</code>—in which case they are expanded so that <code>i</code>, <code>j</code>, and <code>s</code> all have the same length.</p> <p><code>S = sparse(i,j,s,m,n)</code> uses <code>nzmax = length(s)</code>.</p> <p><code>S = sparse(i,j,s)</code> uses <code>m = max(i)</code> and <code>n = max(j)</code>. The maxima are computed before any zeros in <code>s</code> are removed, so one of the rows of <code>[i j s]</code> might be <code>[m n 0]</code>.</p> <p><code>S = sparse(m,n)</code> abbreviates <code>sparse([],[],[],m,n,0)</code>. This generates the ultimate sparse matrix, an <code>m</code>-by-<code>n</code> all zero matrix.</p>

## Tips

All of the MATLAB built-in arithmetic, logical, and indexing operations can be applied to sparse matrices, or to mixtures of sparse and full matrices. Operations on sparse matrices return sparse matrices and operations on full matrices return full matrices.

In most cases, operations on mixtures of sparse and full matrices return full matrices. The exceptions include situations where the result of a mixed operation is structurally sparse, for example,  $A * S$  is at least as sparse as  $S$ .

## Examples

`S = sparse(1:n,1:n,1)` generates a sparse representation of the  $n$ -by- $n$  identity matrix. The same  $S$  results from `S = sparse(eye(n,n))`, but this would also temporarily generate a full  $n$ -by- $n$  matrix with most of its elements equal to zero.

`B = sparse(10000,10000,pi)` is probably not very useful, but is legal and works; it sets up a 10000-by-10000 matrix with only one nonzero element. Don't try `full(B)`; it requires 800 megabytes of storage.

This dissects and then reassembles a sparse matrix:

```
[i,j,s] = find(S);  
[m,n] = size(S);  
S = sparse(i,j,s,m,n);
```

So does this, if the last row and column have nonzero entries:

```
[i,j,s] = find(S);  
S = sparse(i,j,s);
```

`diag` | `find` | `full` | `issparse` | `nnz` | `nonzeros` | `nzmax` | `spones` | `sprandn` | `sprandsym` | `spy`

**Purpose** Form least squares augmented system

**Syntax**  
 $S = \text{spaugment}(A, c)$   
 $S = \text{spaugment}(A)$

**Description**  $S = \text{spaugment}(A, c)$  creates the sparse, square, symmetric indefinite matrix  $S = [c \cdot I \ A; \ A' \ 0]$ . The matrix  $S$  is related to the least squares problem

$$\min \text{norm}(b - A \cdot x)$$

by

$$r = b - A \cdot x$$

$$S * [r/c; x] = [b; 0]$$

The optimum value of the residual scaling factor  $c$ , involves  $\min(\text{svd}(A))$  and  $\text{norm}(r)$ , which are usually too expensive to compute.

$S = \text{spaugment}(A)$  without a specified value of  $c$ , uses  $\max(\max(\text{abs}(A))) / 1000$ .

---

**Note** In previous versions of MATLAB product, the augmented matrix was used by sparse linear equation solvers, `\` and `/`, for nonsquare problems. Now, MATLAB software performs a least squares solve using the `qr` factorization of  $A$  instead.

---

# spconvert

---

**Purpose** Import matrix from sparse matrix external format

**Syntax** `S = spconvert(D)`

**Description** `spconvert` is used to create sparse matrices from a simple sparse format easily produced by non-MATLAB sparse programs. `spconvert` is the second step in the process:

- 1 Load an ASCII data file containing `[i, j, v]` or `[i, j, re, im]` as rows into a MATLAB variable.
- 2 Convert that variable into a MATLAB sparse matrix.

`S = spconvert(D)` converts a matrix `D` with rows containing `[i, j, s]` or `[i, j, r, s]` to the corresponding sparse matrix. `D` must have an `nnz` or `nnz+1` row and three or four columns. Three elements per row generate a real matrix and four elements per row generate a complex matrix. A row of the form `[m n 0]` or `[m n 0 0]` anywhere in `D` can be used to specify `size(S)`. If `D` is already sparse, no conversion is done, so `spconvert` can be used after `D` is loaded from either a MAT-file or an ASCII file.

**Examples** Suppose the ASCII file `uphill.dat` contains

```
1    1    1.0000000000000000
1    2    0.5000000000000000
2    2    0.3333333333333333
1    3    0.3333333333333333
2    3    0.2500000000000000
3    3    0.2000000000000000
1    4    0.2500000000000000
2    4    0.2000000000000000
3    4    0.1666666666666667
4    4    0.142857142857143
4    4    0.0000000000000000
```

Then the statements

```
load uphill.dat
H = spconvert(uphill)
```

```
H =
(1,1)      1.0000
(1,2)      0.5000
(2,2)      0.3333
(1,3)      0.3333
(2,3)      0.2500
(3,3)      0.2000
(1,4)      0.2500
(2,4)      0.2000
(3,4)      0.1667
(4,4)      0.1429
```

recreate `sparse(triu(hilb(4)))`, possibly with roundoff errors. In this case, the last line of the input file is not necessary because the earlier lines already specify that the matrix is at least 4-by-4.

# spdiags

---

**Purpose** Extract and create sparse band and diagonal matrices

**Syntax**

```
B = spdiags(A)
[B,d] = spdiags(A)
B = spdiags(A,d)
A = spdiags(B,d,A)
A = spdiags(B,d,m,n)
```

**Description** The `spdiags` function generalizes the function `diag`. Four different operations, distinguished by the number of input arguments, are possible.

`B = spdiags(A)` extracts all nonzero diagonals from the  $m$ -by- $n$  matrix  $A$ .  $B$  is a  $\min(m,n)$ -by- $p$  matrix whose columns are the  $p$  nonzero diagonals of  $A$ .

`[B,d] = spdiags(A)` returns a vector  $d$  of length  $p$ , whose integer components specify the diagonals in  $A$ .

`B = spdiags(A,d)` extracts the diagonals specified by  $d$ .

`A = spdiags(B,d,A)` replaces the diagonals specified by  $d$  with the columns of  $B$ . The output is sparse.

`A = spdiags(B,d,m,n)` creates an  $m$ -by- $n$  sparse matrix by taking the columns of  $B$  and placing them along the diagonals specified by  $d$ .

---

**Note** In this syntax, if a column of  $B$  is longer than the diagonal it is replacing, and  $m \geq n$ , `spdiags` takes elements of super-diagonals from the lower part of the column of  $B$ , and elements of sub-diagonals from the upper part of the column of  $B$ . However, if  $m < n$ , then super-diagonals are from the upper part of the column of  $B$ , and sub-diagonals from the lower part. (See “Example 5A” on page 1-5748 and “Example 5B” on page 1-5750, below).

---

**Arguments** The `spdiags` function deals with three matrices, in various combinations, as both input and output.

- A An  $m$ -by- $n$  matrix, usually (but not necessarily) sparse, with its nonzero or specified elements located on  $p$  diagonals.
- B A  $\min(m, n)$ -by- $p$  matrix, usually (but not necessarily) full, whose columns are the diagonals of  $A$ .
- d A vector of length  $p$  whose integer components specify the diagonals in  $A$ .

Roughly,  $A$ ,  $B$ , and  $d$  are related by

```
for k = 1:p
    B(:,k) = diag(A,d(k))
end
```

Some elements of  $B$ , corresponding to positions outside of  $A$ , are not defined by these loops. They are not referenced when  $B$  is input and are set to zero when  $B$  is output.

### How the Diagonals of $A$ are Listed in the Vector $d$

An  $m$ -by- $n$  matrix  $A$  has  $m+n-1$  diagonals. These are specified in the vector  $d$  using indices from  $-m+1$  to  $n-1$ . For example, if  $A$  is 5-by-6, it has 10 diagonals, which are specified in the vector  $d$  using the indices -4, -3, ... 4, 5. The following diagram illustrates this for a vector of all ones.

# spdiags

---

## Examples

### Example 1

For the following matrix,

```
A=[0 5 0 10 0 0;...
0 0 6 0 11 0;...
3 0 0 7 0 12;...
1 4 0 0 8 0;...
0 2 5 0 0 9]
```

A =

0	5	0	10	0	0
0	0	6	0	11	0
3	0	0	7	0	12
1	4	0	0	8	0
0	2	5	0	0	9

the command

```
[B, d] =spdiags(A)
```

returns

B =

0	0	5	10
0	0	6	11
0	3	7	12
1	4	8	0
2	5	9	0

d =

```
-3
-2
1
```

The columns of the first output **B** contain the nonzero diagonals of **A**. The second output **d** lists the indices of the nonzero diagonals of **A**, as shown in the following diagram. See “How the Diagonals of **A** are Listed in the Vector **d**” on page 1-5743.

Note that the longest nonzero diagonal in **A** is contained in column 3 of **B**. The other nonzero diagonals of **A** have extra zeros added to their corresponding columns in **B**, to give all columns of **B** the same length. For the nonzero diagonals below the main diagonal of **A**, extra zeros are added at the tops of columns. For the nonzero diagonals above the main diagonal of **A**, extra zeros are added at the bottoms of columns. This is illustrated by the following diagram.

## Example 2

This example generates a sparse tridiagonal representation of the classic second difference operator on  $n$  points.

```
e = ones(n,1);
A = spdiags([e -2*e e], -1:1, n, n)
```

Turn it into Wilkinson's test matrix (see gallery):

```
A = spdiags(abs(-(n-1)/2:(n-1)/2)', 0, A)
```

Finally, recover the three diagonals:

```
B = spdiags(A)
```

## Example 3

The second example is not square.

```
A = [11  0  13  0
      0  22  0  24
```

```

    0    0   33    0
   41    0    0   44
    0   52    0    0
    0    0   63    0
    0    0    0   74]

```

Here  $m = 7$ ,  $n = 4$ , and  $p = 3$ .

The statement `[B,d] = spdiags(A)` produces `d = [-3 0 2]'` and

```

B = [ 41   11    0
      52   22    0
      63   33   13
      74   44   24]

```

Conversely, with the above `B` and `d`, the expression `spdiags(B,d,7,4)` reproduces the original `A`.

#### Example 4

This example shows how `spdiags` creates the diagonals when the columns of `B` are longer than the diagonals they are replacing.

```
B = repmat((1:6)', [1 7])
```

```
B =
```

```

 1  1  1  1  1  1  1
 2  2  2  2  2  2  2
 3  3  3  3  3  3  3
 4  4  4  4  4  4  4
 5  5  5  5  5  5  5
 6  6  6  6  6  6  6

```

```
d = [-4 -2 -1 0 3 4 5];
```

```
A = spdiags(B,d,6,6);
```

```
full(A)
```

```
ans =
```

```
1 0 0 4 5 6
1 2 0 0 5 6
1 2 3 0 0 6
0 2 3 4 0 0
1 0 3 4 5 0
0 2 0 4 5 6
```

## Example 5A

This example illustrates the use of the syntax `A = spdiags(B,d,m,n)`, under three conditions:

- `m` is equal to `n`
- `m` is greater than `n`
- `m` is less than `n`

The command used in this example is

```
A = full(spdiags(B, [-2 0 2], m, n))
```

where `B` is the 5-by-3 matrix shown below. The resulting matrix `A` has dimensions `m`-by-`n`, and has nonzero diagonals at `[-2 0 2]` (a sub-diagonal at -2, the main diagonal, and a super-diagonal at 2).

```
B =
 1   6  11
 2   7  12
 3   8  13
 4   9  14
 5  10  15
```

The first and third columns of matrix `B` are used to create the sub- and super-diagonals of `A` respectively. In all three cases though, these two outer columns of `B` are longer than the resulting diagonals of `A`. Because of this, only a part of the columns is used in `A`.

When `m == n` or `m > n`, `spdiags` takes elements of the super-diagonal in `A` from the lower part of the corresponding column of `B`, and elements

of the sub-diagonal in A from the upper part of the corresponding column of B.

When  $m < n$ , spdiags does the opposite, taking elements of the super-diagonal in A from the upper part of the corresponding column of B, and elements of the sub-diagonal in A from the lower part of the corresponding column of B.

**Part 1 – m is equal to n.**

A = full(spdiags(B, [-2 0 2], 5, 5))

Matrix B			Matrix A					
1	6	11		6	0	13	0	0
2	7	12		0	7	0	14	0
3	8	13	== spdiags ==>	1	0	8	0	15
4	9	14		0	2	0	9	0
5	10	15		0	0	3	0	10

A(3,1), A(4,2), and A(5,3) are taken from the upper part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the lower part of B(:,3).

**Part 2 – m is greater than n.**

A = full(spdiags(B, [-2 0 2], 5, 4))

Matrix B			Matrix A				
1	6	11		6	0	13	0
2	7	12		0	7	0	14
3	8	13	== spdiags ==>	1	0	8	0
4	9	14		0	2	0	9
5	10	15		0	0	3	0

Same as in Part A.

**Part 3 – m is less than n.**

A = full(spdiags(B, [-2 0 2], 4, 5))

Matrix B				Matrix A				
1	6	11		6	0	11	0	0
2	7	12		0	7	0	12	0
3	8	13	== spdiags ==>	3	0	8	0	13
4	9	14		0	4	0	9	0
5	10	15						

A(3,1) and A(4,2) are taken from the lower part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the upper part of B(:,3).

### Example 5B

Extract the diagonals from the first part of this example back into a column format using the command

```
B = spdiags(A)
```

You can see that in each case the original columns are restored (minus those elements that had overflowed the super- and sub-diagonals of matrix A).

### Part 1.

Matrix A						Matrix B		
6	0	13	0	0		1	6	0
0	7	0	14	0		2	7	0
1	0	8	0	15	== spdiags ==>	3	8	13
0	2	0	9	0		0	9	14
0	0	3	0	10		0	10	15

### Part 2.

Matrix A					Matrix B		
6	0	13	0		1	6	0
0	7	0	14		2	7	0
1	0	8	0	== spdiags ==>	3	8	13

```
0  2  0  9          0  9 14
0  0  3  0
```

### Part 3.

```
          Matrix A          Matrix B
6   0  11  0   0          0   6  11
0   7   0 12   0          0   7  12
3   0   8   0 13 == spdiags => 3   8  13
0   4   0   9   0          4   9   0
```

[diag](#) | [speye](#)

# specular

---

**Purpose** Calculate specular reflectance

**Syntax** `R = specular(Nx,Ny,Nz,S,V)`

**Description** `R = specular(Nx,Ny,Nz,S,V)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` and `V` specify the direction to the light source and to the viewer, respectively. You can specify these directions as three vectors `[x,y,z]` or two vectors `[Theta Phi]` (in spherical coordinates).

The specular highlight is strongest when the normal vector is in the direction of  $(S+V)/2$  where `S` is the source direction, and `V` is the view direction.

The surface spread exponent can be specified by including a sixth argument as in `specular(Nx,Ny,Nz,S,V,spread)`.

---

<b>Purpose</b>	Sparse identity matrix
<b>Syntax</b>	<code>S = speye(m,n)</code> <code>S = speye([m n])</code> <code>S = speye(n)</code> <code>S = speye</code>
<b>Description</b>	<code>S = speye(m,n)</code> and <code>S = speye([m n])</code> form an m-by-n sparse matrix with 1s on the main diagonal. <code>S = speye(n)</code> abbreviates <code>speye(n,n)</code> . <code>S = speye</code> returns the sparse form of the 1-by-1 identity matrix.
<b>Examples</b>	<code>I = speye(1000)</code> forms the sparse representation of the 1000-by-1000 identity matrix, which requires only about 16 kilobytes of storage. This is the same final result as <code>I = sparse(eye(1000,1000))</code> , but the latter requires eight megabytes for temporary storage for the full representation.
<b>See Also</b>	<code>spalloc</code>   <code>spones</code>   <code>spdiags</code>   <code>sprand</code>   <code>sprandn</code>

# spfun

---

**Purpose** Apply function to nonzero sparse matrix elements

**Syntax** `f = spfun(fun,S)`

**Description** The `spfun` function selectively applies a function to only the *nonzero* elements of a sparse matrix `S`, preserving the sparsity pattern of the original matrix (except for underflow or if `fun` returns zero for some nonzero elements of `S`).

`f = spfun(fun,S)` evaluates `fun(S)` on the elements of `S` that are nonzero. `fun` is a function handle.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

**Tips** Functions that operate element-by-element, like those in the `elfun` directory, are the most appropriate functions to use with `spfun`.

**Examples** Given the 4-by-4 sparse diagonal matrix

```
S = spdiags([1:4]',0,4,4)
```

```
S =  
  (1,1)      1  
  (2,2)      2  
  (3,3)      3  
  (4,4)      4
```

Because `fun` returns nonzero values for all nonzero element of `S`, `f = spfun(@exp,S)` has the same sparsity pattern as `S`.

```
f =  
  (1,1)      2.7183  
  (2,2)      7.3891  
  (3,3)     20.0855  
  (4,4)     54.5982
```

whereas `exp(S)` has 1s where `S` has 0s.

```
full(exp(S))
```

```
ans =
```

```
  2.7183    1.0000    1.0000    1.0000  
  1.0000    7.3891    1.0000    1.0000  
  1.0000    1.0000   20.0855    1.0000  
  1.0000    1.0000    1.0000   54.5982
```

**See Also**

```
function_handle
```

# sph2cart

---

**Purpose** Transform spherical coordinates to Cartesian

**Syntax** `[x,y,z] = sph2cart(azimuth,elevation,r)`

**Description** `[x,y,z] = sph2cart(azimuth,elevation,r)` transforms the corresponding elements of spherical coordinate arrays to Cartesian, or  $xyz$ , coordinates. `azimuth`, `elevation`, and `r` must all be the same size (or any of them can be scalar). `azimuth` and `elevation` are angular displacements in radians. `azimuth` is the counterclockwise angle in the  $x$ - $y$  plane measured from the positive  $x$ -axis. `elevation` is the elevation angle from the  $x$ - $y$  plane.

**Algorithms** The mapping from spherical coordinates to three-dimensional Cartesian coordinates is

```
x = r .* cos(elevation) .* cos(azimuth)
y = r .* cos(elevation) .* sin(azimuth)
z = r .* sin(elevation)
```

**See Also** `cart2pol` | `cart2sph` | `pol2cart`

## Purpose

Generate sphere

## Syntax

```
sphere  
sphere(n)  
[X,Y,Z] = sphere(n)
```

## Description

The sphere function generates the  $x$ -,  $y$ -, and  $z$ -coordinates of a unit sphere for use with `surf` and `mesh`.

`sphere` generates a sphere consisting of 20-by-20 faces.

`sphere(n)` draws a `surf` plot of an  $n$ -by- $n$  sphere in the current figure.

`[X,Y,Z] = sphere(n)` returns the coordinates of a sphere in three matrices that are  $(n+1)$ -by- $(n+1)$  in size. You draw the sphere with `surf(X,Y,Z)` or `mesh(X,Y,Z)`.

## Examples

Generate and plot a sphere.

```
figure  
sphere  
axis equal
```

# sphere

---

---

Plot multiple spheres, translating centers away from the origin:

```
figure
[x,y,z] = sphere;
surf(x,y,z) % sphere centered at origin
hold on
surf(x+3,y-2,z) % sphere centered at (3,-2,0)
surf(x,y+1,z-3) % sphere centered at (0,1,-3)
daspect([1 1 1])
```

**See Also**

[cylinder](#) | [axis](#)

# spinmap

---

**Purpose** Spin colormap

**Syntax** spinmap  
spinmap(t)  
spinmap(t,inc)  
spinmap('inf')

**Description** The spinmap function shifts the colormap RGB values by some incremental value. For example, if the increment equals 1, color 1 becomes color 2, color 2 becomes color 3, etc.

spinmap cyclically rotates the colormap for approximately five seconds using an incremental value of 2.

spinmap(t) rotates the colormap for approximately 10\*t seconds. The amount of time specified by t depends on your hardware configuration (e.g., if you are running MATLAB software over a network).

spinmap(t,inc) rotates the colormap for approximately 10\*t seconds and specifies an increment inc by which the colormap shifts. When inc is 1, the rotation appears smoother than the default (i.e., 2). Increments greater than 2 are less smooth than the default. A negative increment (e.g., -2) rotates the colormap in a negative direction.

spinmap('inf') rotates the colormap for an infinite amount of time. To break the loop, press **Ctrl+C**.

**See Also** colormap | colormapeditor

**Purpose** Cubic spline data interpolation

**Syntax**  
`yy = spline(x,Y,xx)`  
`pp = spline(x,Y)`

**Description** `yy = spline(x,Y,xx)` uses a cubic spline interpolation to find `yy`, the values of the underlying function `Y` at the values of the interpolant `xx`. For the interpolation, the independent variable is assumed to be the final dimension of `Y` with the breakpoints defined by `x`.

The sizes of `xx` and `yy` are related as follows:

- If `Y` is a scalar or vector, `yy` has the same size as `xx`.
- If `Y` is an array that is not a vector,
  - If `xx` is a scalar or vector, `size(yy)` equals `[d1, d2, ..., dk, length(xx)]`.
  - If `xx` is an array of size `[m1,m2,...,mj]`, `size(yy)` equals `[d1,d2,...,dk,m1,m2,...,mj]`.

`pp = spline(x,Y)` returns the piecewise polynomial form of the cubic spline interpolant for later use with `ppval` and the spline utility `unmkpp`. `x` must be a vector. `Y` can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If `x` and `Y` are vectors of the same size, the not-a-knot end conditions are used.
- If `x` or `Y` is a scalar, it is expanded to have the same length as the other and the not-a-knot end conditions are used. (See Exceptions (1) below).
- If `Y` is a vector that contains two more values than `x` has entries, the first and last value in `Y` are used as the endslopes for the cubic spline. (See Exceptions (2) below.)

## Exceptions

- 1 If  $Y$  is a vector that contains two more values than  $x$  has entries, the first and last value in  $Y$  are used as the endslopes for the cubic spline. If  $Y$  is a vector, this means
  - $f(x) = Y(2:\text{end}-1)$
  - $df(\min(x)) = Y(1)$
  - $df(\max(x)) = Y(\text{end})$
- 2 If  $Y$  is a matrix or an N-dimensional array with  $\text{size}(Y,N)$  equal to  $\text{length}(x)+2$ , the following hold:
  - $f(x(j))$  matches the value  $Y(:, \dots, :, j+1)$  for  $j=1:\text{length}(x)$
  - $Df(\min(x))$  matches  $Y(:, :, \dots, 1)$
  - $Df(\max(x))$  matches  $Y(:, :, \dots, \text{end})$

---

**Note** You can also perform spline interpolation using the `interp1` function with the command `interp1(x,y,xx,'spline')`. Note that while `spline` performs interpolation on rows of an input matrix, `interp1` performs interpolation on columns of an input matrix.

---

## Examples

### Example 1

This generates a sine curve, then samples the spline over a finer mesh.

```
x = 0:10;  
y = sin(x);  
xx = 0:.25:10;  
yy = spline(x,y,xx);  
plot(x,y,'o',xx,yy)
```

### Example 2

This illustrates the use of clamped or complete spline interpolation where end slopes are prescribed. Zero slopes at the ends of an interpolant to the values of a certain distribution are enforced.

```
x = -4:4;  
y = [0 .15 1.12 2.36 2.36 1.46 .49 .06 0];  
cs = spline(x,[0 y 0]);  
xx = linspace(-4,4,101);  
plot(x,y,'o',xx,ppval(cs,xx),'-');
```

# spline

## Example 3

The two vectors

```
t = 1900:10:1990;  
p = [ 75.995  91.972  105.711  123.203  131.669 ...  
      150.697  179.323  203.212  226.505  249.633 ];
```

represent the census years from 1900 to 1990 and the corresponding United States population in millions of people. The expression

```
spline(t,p,2000)
```

uses the cubic spline to extrapolate and predict the population in the year 2000. The result is

```
ans =  
    270.6060
```

### Example 4

The statements

```
x = pi*[0:.5:2];  
y = [0 1 0 -1 0 1 0;  
     1 0 1 0 -1 0 1];  
pp = spline(x,y);  
yy = ppval(pp, linspace(0,2*pi,101));  
plot(yy(1,:),yy(2,:), '-b',y(1,2:5),y(2,2:5),'or'), axis equal
```

generate the plot of a circle, with the five data points  $y(:,2), \dots, y(:,6)$  marked with o's. Note that this  $y$  contains two more values (i.e., two more columns) than does  $x$ , hence  $y(:,1)$  and  $y(:,end)$  are used as endslopes.

## Example 5

The following code generates sine and cosine curves, then samples the splines over a finer mesh.

```
x = 0:.25:1;
Y = [sin(x); cos(x)];
xx = 0:.1:1;
YY = spline(x,Y,xx);
plot(x,Y(1,:), 'o',xx,YY(1,:), '-'); hold on;
plot(x,Y(2,:), 'o',xx,YY(2,:), '-'); hold off;
```

## Algorithms

A tridiagonal linear system (with, possibly, several right sides) is being solved for the information needed to describe the coefficients of the various cubic polynomials which make up the interpolating spline. spline uses the functions ppval, mkpp, and unmkpp. These routines

form a small suite of functions for working with piecewise polynomials. For access to more advanced features, see the `interp1` reference page, the command-line help for these functions, and the Curve Fitting Toolbox™ spline functions.

# spones

---

**Purpose**

Replace nonzero sparse matrix elements with ones

**Syntax**

`R = spones(S)`

**Description**

`R = spones(S)` generates a matrix `R` with the same sparsity structure as `S`, but with 1's in the nonzero positions.

**Examples**

`c = sum(spones(S))` is the number of nonzeros in each column.

`r = sum(spones(S'))'` is the number of nonzeros in each row.

`sum(c)` and `sum(r)` are equal, and are equal to `nnz(S)`.

**See Also**

`nnz` | `spalloc` | `spfun`

**Purpose** Set parameters for sparse matrix routines

**Syntax**

```
spparms('key',value)
spparms
values = spparms
[keys,values] = spparms
spparms(values)
value = spparms('key')
spparms('default')
spparms('tight')
```

**Description** spparms('key',value) sets one or more of the *tunable* parameters used in the sparse routines. In ordinary use, you should never need to deal with this function.

The meanings of the key parameters are

'spumoni'	Sparse Monitor flag:
0	Produces no diagnostic output, the default
1	Produces information about choice of algorithm based on matrix structure, and about storage allocation
2	Also produces very detailed information about the sparse matrix algorithms
'thr_rel', 'thr_abs'	Minimum degree threshold is thr_rel*mindegree + thr_abs.
'exact_d'	Nonzero to use exact degrees in minimum degree. Zero to use approximate degrees.
'supernd'	If positive, minimum degree amalgamates the supernodes every supernd stages.
'rreduce'	If positive, minimum degree does row reduction every rreduce stages.

# spparms

---

'wh_frac'	Rows with density > wh_frac are ignored in colmmd.
'autommd'	Nonzero to use minimum degree (MMD) orderings with QR-based \ and /.
'autoamd'	Nonzero to use colamd ordering with the LU-based \ and /, and to use amd with Cholesky-based \ and /.
'piv_tol'	Pivot tolerance used by the LU-based \ and /.
'bandden'	Band density used by \ and / for banded matrices. Band density is defined as (# nonzeros in the band)/(# nonzeros in a full band). If bandden = 1.0, never use band solver. If bandden = 0.0, always use band solver. Default is 0.5.
'umfpack'	Nonzero to use UMFPACK instead of the v4 LU-based solver in \ and /.
'sym_tol'	Symmetric pivot tolerance. See lu for more information about the role of the symmetric pivot tolerance.

spparms, by itself, prints a description of the current settings.

values = spparms returns a vector whose components give the current settings.

[keys, values] = spparms returns that vector, and also returns a character matrix whose rows are the keywords for the parameters.

spparms(values), with no output argument, sets all the parameters to the values specified by the argument vector.

value = spparms('key') returns the current setting of one parameter.

spparms('default') sets all the parameters to their default settings.

spparms('tight') sets the minimum degree ordering parameters to their *tight* settings, which can lead to orderings with less fill-in, but which make the ordering functions themselves use more execution time.

The key parameters for default and tight settings are

	<b>Keyword</b>	<b>Default</b>	<b>Tight</b>
values(1)	'spumoni'	0.0	
values(2)	'thr_rel'	1.1	1.0
values(3)	'thr_abs'	1.0	0.0
values(4)	'exact_d'	0.0	1.0
values(5)	'supernd'	3.0	1.0
values(6)	'rreduce'	3.0	1.0
values(7)	'wh_frac'	0.5	0.5
values(8)	'autommd'	1.0	
values(9)	'autoamd'	1.0	
values(10)	'piv_tol'	0.1	
values(11)	'bandden'	0.5	
values(12)	'umfpack'	1.0	
values(13)	'sym_tol'	0.001

# sprand

---

**Purpose** Sparse uniformly distributed random matrix

**Syntax**  
R = sprand(S)  
R = sprand(m,n,density)  
R = sprand(m,n,density,rc)

**Description** R = sprand(S) has the same sparsity structure as S, but uniformly distributed random entries.

R = sprand(m,n,density) is a random, m-by-n, sparse matrix with approximately  $\text{density} * m * n$  uniformly distributed nonzero entries ( $0 \leq \text{density} \leq 1$ ).

R = sprand(m,n,density,rc) also has reciprocal condition number approximately equal to rc. R is constructed from a sum of matrices of rank one.

If rc is a vector of length lr, where  $lr \leq \min(m,n)$ , then R has rc as its first lr singular values, all others are zero. In this case, R is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

**Tips**

- sprand uses the same random number generator as rand, randi, and randn. You control this generator with rng.

**See Also** sprandn | sprandsym

---

<b>Purpose</b>	Sparse normally distributed random matrix
<b>Syntax</b>	<pre>R = sprandn(S) R = sprandn(m,n,density) R = sprandn(m,n,density,rc)</pre>
<b>Description</b>	<p><code>R = sprandn(S)</code> has the same sparsity structure as <code>S</code>, but normally distributed random entries with mean 0 and variance 1.</p> <p><code>R = sprandn(m,n,density)</code> is a random, <code>m</code>-by-<code>n</code>, sparse matrix with approximately <code>density*m*n</code> normally distributed nonzero entries (<code>0 &lt;= density &lt;= 1</code>).</p> <p><code>R = sprandn(m,n,density,rc)</code> also has reciprocal condition number approximately equal to <code>rc</code>. <code>R</code> is constructed from a sum of matrices of rank one.</p> <p>If <code>rc</code> is a vector of length <code>lr</code>, where <code>lr &lt;= min(m,n)</code>, then <code>R</code> has <code>rc</code> as its first <code>lr</code> singular values, all others are zero. <b>Tips</b>	<ul style="list-style-type: none"><li>• <code>sprandn</code> uses the same random number generator as <code>rand</code>, <code>randi</code>, and <code>randn</code>. You control this generator with <code>rng</code>.</li></ul>
<b>See Also</b>	<code>sprand</code>   <code>sprandsym</code>

# sprandsym

---

**Purpose** Sparse symmetric random matrix

**Syntax**

```
R = sprandsym(S)
R = sprandsym(n,density)
R = sprandsym(n,density,rc)
R = sprandsym(n,density,rc,kind)
R = sprandsym(S,[],rc,3)
```

**Description**

`R = sprandsym(S)` returns a symmetric random matrix whose lower triangle and diagonal have the same structure as `S`. Its elements are normally distributed, with mean 0 and variance 1.

`R = sprandsym(n,density)` returns a symmetric random, `n`-by-`n`, sparse matrix with approximately `density*n*n` nonzeros; each entry is the sum of one or more normally distributed random samples, and  $0 \leq \text{density} \leq 1$ .

`R = sprandsym(n,density,rc)` returns a matrix with a reciprocal condition number equal to `rc`. The distribution of entries is nonuniform; it is roughly symmetric about 0; all are in  $[-1,1]$ .

If `rc` is a vector of length `n`, then `R` has eigenvalues `rc`. Thus, if `rc` is a positive (nonnegative) vector then `R` is a positive (nonnegative) definite matrix. In either case, `R` is generated by random Jacobi rotations applied to a diagonal matrix with the given eigenvalues or condition number. It has a great deal of topological and algebraic structure.

`R = sprandsym(n,density,rc,kind)` is positive definite.

- If `kind = 1`, `R` is generated by random Jacobi rotation of a positive definite diagonal matrix. `R` has the desired condition number exactly.
- If `kind = 2`, `R` is a shifted sum of outer products. `R` has the desired condition number only approximately, but has less structure.

`R = sprandsym(S,[],rc,3)` has the same structure as the matrix `S` and approximate condition number  $1/\text{rc}$ .

**Tips** `sprandsym` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

**See Also**

sprand | sprandn

# sprank

---

**Purpose** Structural rank

**Syntax** `r = sprank(A)`

**Description** `r = sprank(A)` is the structural rank of the sparse matrix `A`. For all values of `A`,

`sprank(A) >= rank(full(A))`

In exact arithmetic, `sprank(A) == rank(full(sprandn(A)))` with a probability of one.

## Examples

```
A = [1 0 2 0
     2 0 4 0];
```

```
A = sparse(A);
```

```
sprank(A)
```

```
ans =
     2
```

```
rank(full(A))
```

```
ans =
     1
```

## See Also

`dmperm`

**Purpose** Format data into string

**Syntax**

```
str = sprintf(formatSpec,A1,...,An)
[str,errmsg] = sprintf(formatSpec,A1,...,An)
```

**Description** `str = sprintf(formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec` in column order, and returns the results to string `str`.

`[str,errmsg] = sprintf(formatSpec,A1,...,An)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is empty.

## Input Arguments

### **formatSpec - Format of the output fields**

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%O	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F

# sprintf

Value Type	Conversion	Details
Floating-point number	%f	Fixed-point notation
	%e	Exponential notation, such as 3.141593e+00
	%E	Same as %e, but uppercase, such as 3.141593E+00
	%g	The more compact of %e or %f, with no trailing zeros
	%G	The more compact of %E or %f, with no trailing zeros
	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value Example: %bx prints pi as 400921fb54442d18
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value Example: %tx prints pi as 40490fdb
Characters	%c	Single character
	%s	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Identifier

Order for processing inputs. Use the syntax *n*\$, where *n* represents the position of the value in the input list.

For example, '%3\$s %2\$s %1\$s %2\$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

'-' Left-justify. Example: %*-5.2f*

'+' Print sign character (+) for positive values. Example: %*+5.2f*

' ' Pad to field width with spaces before the value. Example: % *5.2f*

'0' Pad to field width with zeros. Example: %*05.2f*

'#' Modify selected numeric conversions:

- For %*o*, %*x*, or %*X*, print 0, 0*x*, or 0*X* prefix.
- For %*f*, %*e*, or %*E*, print decimal point even when precision is 0.
- For %*g* or %*G*, do not remove trailing zeros or decimal point.

Example: %*#5.0f*

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%*12d*', *intmax*) is equivalent to ('%*\*d*', *12*, *intmax*).

- Precision

# sprintf

---

For %f, %e, or %E:      Number of digits to the right of the decimal point.

Example: '%6.4f' prints pi as '3.1416'

For %g or %G            Number of significant digits.

Example: '%6.4g' prints pi as ' 3.142'

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%6.4f', pi) is equivalent to ('%\*.4f', 6, 4, pi).

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include '' in formatSpec.
- Control characters, including:

%%            Percent character

\\            Backslash

\a            Alarm

\b            Backspace

\f            Form feed

\n            New line

\r            Carriage return

\t            Horizontal tab

\v            Vertical tab

\x*N*        Character whose ASCII code is the hexadecimal number, *N*

\w            Character whose ASCII code is the octal number, *N*

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.
- If you apply a string conversion (%s) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, '%s' converts [65 66 67] to ABC.

### **A1,...,An - Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

## **Output Arguments**

### **str - Formatted text**

string

Formatted text, returned as a string.

### **errmsg - Error message**

string

Error message, returned as a string, when the operation is unsuccessful. Otherwise, errmsg is empty.

## **Tips**

- The sprintf function is similar to fprintf, but fprintf prints to a file or to the Command Window.
- Format specifiers for the reading functions sscanf and fscanf differ from the formats for the writing functions sprintf and fprintf. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

# sprintf

---

## Examples

### Floating-Point Formats

Format a floating-point number using %e, %f, and %g specifiers.

```
A = 1/eps;  
str_e = sprintf('%0.5e',A)  
str_f = sprintf('%0.5f',A)  
str_g = sprintf('%0.5g',A)
```

```
str_e =  
4.50360e+15
```

```
str_f =  
4503599627370496.00000
```

```
str_g =  
4.5036e+15
```

### Literal Text and Array Inputs

Combine literal text with array values to create a string.

```
formatSpec = 'The array is %dx%d.';  
A1 = 2;  
A2 = 3;  
str = sprintf(formatSpec,A1,A2)
```

```
str =  
The array is 2x3.
```

### Integer Format with Floating-Point Inputs

Explicitly convert double-precision values to integers.

```
str = sprintf('%d',round(pi))
```

```
str =  
3
```

## Field Width

Specify the minimum width of the printed value.

```
str = sprintf('%025d',[123456])
```

```
str =  
000000000000000000000000123456
```

The 0 flag in the %025d format specifier requests leading zeros in the output.

## Position Identifier (n\$)

Reorder the input values using the n\$ position identifier.

```
A1 = 'X';  
A2 = 'Y';  
A3 = 'Z';  
formatSpec = ' %3$s %2$s %1$s';  
str = sprintf(formatSpec,A1,A2,A3)
```

```
str =  
 Z Y X
```

## Cell Array Inputs

Create a string from values in a cell array.

```
C = { 1, 2, 3 ;  
      'AA', 'BB', 'CC' };  
  
str = sprintf(' %d %s',C{:})
```

```
str =  
 1 AA 2 BB 3 CC
```

The syntax C{:} creates a comma-separated list of arrays that contain the contents of each cell from C in column order. For example, C{1}==1 and C{2}=='AA'.

## Concepts

- “Formatting Strings”

**Purpose** Visualize sparsity pattern

**Syntax**

```
spy(S)
spy(S,markersize)
spy(S,'LineStyle')
spy(S,'LineStyle',markersize)
```

**Description**

`spy(S)` plots the sparsity pattern of any matrix `S`.

`spy(S,markersize)`, where `markersize` is an integer, plots the sparsity pattern using markers of the specified point size.

`spy(S,'LineStyle')`, where `LineStyle` is a string, uses the specified plot marker type and color.

`spy(S,'LineStyle',markersize)` uses the specified type, color, and size for the plot markers.

`S` is usually a sparse matrix, but full matrices are acceptable, in which case the locations of the nonzero elements are plotted.

---

**Note** `spy` replaces `format +`, which takes much more space to display essentially the same information.

---

**Examples**

This example plots the 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster Fuller geodesic dome. This matrix also represents the soccer ball and the carbon-60 molecule.

```
B = bucky;
spy(B)
```

**See Also**

`find` | `gplot` | `LineSpec` | `symamd` | `symrcm`

**Purpose** Square root

**Syntax** `B = sqrt(X)`

**Description** `B = sqrt(X)` returns the square root of each element of the array `X`. For the elements of `X` that are negative or complex, `sqrt(X)` produces complex results.

**Tips** See `sqrtm` for the matrix square root.

**Examples**

```
sqrt((-2:2)')
ans =
    0 + 1.4142i
    0 + 1.0000i
    0
    1.0000
    1.4142
```

**See Also** `nthroot` | `sqrtm` | `realsqrt`

# sqrtm

---

**Purpose** Matrix square root

**Syntax**  
`X = sqrtm(A)`  
`[X, resnorm] = sqrtm(A)`  
`[X, alpha, condest] = sqrtm(A)`

**Description** `X = sqrtm(A)` is the principal square root of the matrix `A`, i.e.  $X^2 = A$ . `X` is the unique square root for which every eigenvalue has nonnegative real part. If `A` has any eigenvalues with negative real parts then a complex result is produced. If `A` is singular then `A` may not have a square root. A warning is printed if exact singularity is detected.

`[X, resnorm] = sqrtm(A)` does not print any warning, and returns the residual,  $\text{norm}(A - X^2, 'fro') / \text{norm}(A, 'fro')$ .

`[X, alpha, condest] = sqrtm(A)` returns a stability factor `alpha` and an estimate `condest` of the matrix square root condition number of `X`. The residual  $\text{norm}(A - X^2, 'fro') / \text{norm}(A, 'fro')$  is bounded approximately by  $n \cdot \alpha \cdot \text{eps}$  and the Frobenius norm relative error in `X` is bounded approximately by  $n \cdot \alpha \cdot \text{condest} \cdot \text{eps}$ , where  $n = \max(\text{size}(A))$ .

**Tips** If `A` is real, symmetric and positive definite, or complex, Hermitian and positive definite, then so is the computed matrix square root.

Some matrices, like `A = [0 1; 0 0]`, do not have any square roots, real or complex, and `sqrtm` cannot be expected to produce one.

## Examples **Example 1**

A matrix representation of the fourth difference operator is

`A =`

5	-4	1	0	0
-4	6	-4	1	0
1	-4	6	-4	1
0	1	-4	6	-4
0	0	1	-4	5

This matrix is symmetric and positive definite. Its unique positive definite square root,  $Y = \text{sqrtm}(A)$ , is a representation of the second difference operator.

$$Y = \begin{bmatrix} 2 & -1 & -0 & -0 & -0 \\ -1 & 2 & -1 & 0 & -0 \\ 0 & -1 & 2 & -1 & 0 \\ -0 & 0 & -1 & 2 & -1 \\ -0 & -0 & -0 & -1 & 2 \end{bmatrix}$$

### Example 2

The matrix

$$A = \begin{bmatrix} 7 & 10 \\ 15 & 22 \end{bmatrix}$$

has four square roots. Two of them are

$$Y1 = \begin{bmatrix} 1.5667 & 1.7408 \\ 2.6112 & 4.1779 \end{bmatrix}$$

and

$$Y2 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$$

The other two are  $-Y1$  and  $-Y2$ . All four can be obtained from the eigenvalues and vectors of  $A$ .

$$[V,D] = \text{eig}(A);$$

$$D = \begin{bmatrix} 0.1386 & 0 \\ 0 & 28.8614 \end{bmatrix}$$

# sqrtm

---

The four square roots of the diagonal matrix D result from the four choices of sign in

$$S = \begin{pmatrix} -0.3723 & 0 \\ 0 & -5.3723 \end{pmatrix}$$

All four Ys are of the form

$$Y = V*S/V$$

The sqrtm function chooses the two plus signs and produces Y1, even though Y2 is more natural because its entries are integers.

## See Also

expm | funm | logm

**Purpose** Remove singleton dimensions

**Syntax** `B = squeeze(A)`

**Description** `B = squeeze(A)` returns an array `B` with the same elements as `A`, but with all singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. Two-dimensional arrays are unaffected by `squeeze`; if `A` is a row or column vector or a scalar (1-by-1) value, then `B = A`.

**Examples** Consider the 2-by-1-by-3 array `Y = rand(2,1,3)`. This array has a singleton column dimension — that is, there's only one column per page.

`Y =`

```
Y(:,:,1) =      Y(:,:,2) =
    0.5194      0.0346
    0.8310      0.0535
```

```
Y(:,:,3) =
    0.5297
    0.6711
```

The command `Z = squeeze(Y)` yields a 2-by-3 matrix:

```
Z =
    0.5194    0.0346    0.5297
    0.8310    0.0535    0.6711
```

Consider the 1-by-1-by-5 array `mat= repmat(1,[1,1,5])`. This array has only one scalar value per page.

`mat =`

```
mat(:,:,1) =  mat(:,:,2) =
    1          1
```

# squeeze

---

```
mat(:,:,3) =   mat(:,:,4) =
```

```
    1    1
```

```
mat(:,:,5) =
```

```
    1
```

The command `squeeze(mat)` yields a 5-by-1 matrix:

```
squeeze(mat)
```

```
ans =
```

```
    1  
    1  
    1  
    1  
    1
```

```
size(squeeze(mat))
```

```
ans =
```

```
    5    1
```

## See Also

reshape | shiftdim
```

**Purpose**

Convert state-space filter parameters to transfer function form

**Syntax**

`[b,a] = ss2tf(A,B,C,D,iu)`

**Description**

`ss2tf` converts a state-space representation of a given system to an equivalent transfer function representation.

`[b,a] = ss2tf(A,B,C,D,iu)` returns the transfer function

$$H(s) = \frac{B(s)}{A(s)} = C(sI - A)^{-1}B + D$$

of the system

$$\dot{x} = Ax + Bu$$

$$y = Cx + Du$$

from the `iu`-th input. Vector `a` contains the coefficients of the denominator in descending powers of  $s$ . The numerator coefficients are returned in array `b` with as many rows as there are outputs  $y$ . `ss2tf` also works with systems in discrete time, in which case it returns the  $z$ -transform representation.

The `ss2tf` function is part of the standard MATLAB language.

# sscanf

---

**Purpose** Read formatted data from string

**Syntax**

```
A = sscanf(str, format)
A = sscanf(str, format, sizeA)
[A, count] = sscanf(...)
[A, count, errmsg] = sscanf(...)
[A, count, errmsg, nextindex] = sscanf(...)
```

**Description** `A = sscanf(str, format)` reads data from string *str*, converts it according to the *format*, and returns the results in array *A*. The `sscanf` function reapplies the *format* until either reaching the end of *str* or failing to match the *format*. If `sscanf` cannot match the *format* to the data, it reads only the portion that matches into *A* and stops processing. If *str* is a character array with more than one row, `sscanf` reads the characters in column order.

`A = sscanf(str, format, sizeA)` reads *sizeA* elements into *A*, where *sizeA* can be an integer or can have the form  $[m,n]$ .

`[A, count] = sscanf(...)` returns the number of elements that `sscanf` successfully reads.

`[A, count, errmsg] = sscanf(...)` returns an error message string when the operation is unsuccessful. Otherwise, *errmsg* is an empty string.

`[A, count, errmsg, nextindex] = sscanf(...)` returns one more than the number of characters scanned in *str*.

**Tips**

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

**Input Arguments**

**format** String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.

Field Type	Specifier	Details
Integer, signed	%d	Base 10
	%i	Base determined from the values. Defaults to base 10. If initial digits are 0x or 0X, it is base 16. If initial digit is 0, it is base 8.
	%ld or %li	64-bit values, base 10, 8, or 16
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal)
	%lu, %lo, %lx	64-bit values, base 10, 8, or 16
Floating-point number	%f	Floating-point fields can contain any of the following (not case sensitive): Inf, -Inf, NaN, or -NaN.
	%e	
	%g	
Character string	%s	Read series of characters, until find white space.
	%c	Read any single character, including white space. (To read multiple characters, specify field length.)
	%[...]	Read only characters in the brackets, until the first nonmatching character or white space.

Optionally:

- To skip fields, insert an asterisk (\*) after the percent sign (%). For example, to skip integers, specify %\*d.

- To specify the maximum width of a field, insert a number. For example, %10c reads exactly 10 characters at a time, including white space.
- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from 'pi=3.14159', specify a *format* of 'pi=%f'.

## sizeA

Dimensions of the output array *A*. Specify in one of the following forms:

<i>inf</i>	Read to the end of the input string. (default)
<i>n</i>	Read at most <i>n</i> elements.
$[m,n]$	Read at most $m*n$ elements in column order. <i>n</i> can be <i>inf</i> , but <i>m</i> cannot.

When the *format* includes %s, *A* can contain more than *n* columns. *n* refers to elements, not characters.

## str

Character string.

## Output Arguments

### A

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class `int64`. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class `uint64`. Otherwise, *A* is of class `double`. If *sizeA* is *inf* or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (%c or %s), *A* is a character array. If *sizeA* is *inf* or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with `char(0)`.

- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of `'%*d %s'`).

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

**count**

Number of elements `sscanf` reads into *A*.

**errmsg**

An error message string when `sscanf` cannot open the specified file. Otherwise, an empty string.

**nextindex**

`sscanf` counts the number of characters `sscanf` reads from *str*, and then adds one.

**Examples**

**Example 1**

Read multiple floating-point values from a string:

```
s = '2.7183 3.1416';
A = sscanf(s, '%f ');
A =
    2.7183
    3.1416
```

**Example 2**

Read an octal integer from a string, identified by the `'0'` prefix, using `%i` to preserve the sign:

```
sscanf('-010', '%i')
ans =
```

-8

### Example 3

Read numeric values from a two-dimensional character array. By default, `sscanf` reads characters in column order. To preserve the original order of the values, read one row at a time.

```
mixed = ['abc 45 6 ghi'; 'def 7 89 jkl'];

[nrows, ncols] = size(mixed);
for k = 1:nrows
    nums(k,:) = sscanf(mixed(k,:), '%*s %d %d %*s', [1, inf]);
end;

% type the variable name to see the result
nums =
    45     6
     7    89
```

### Example 4

`sscanf` finds one match for `%s`

```
[str count] = sscanf('ThisIsOneString', '%s')
str =
    ThisIsOneString
count =
    1
```

`sscanf` finds four matches for `%s`. Because it does not match space characters, there are no spaces in the output string:

```
[str count] = sscanf('These Are Four Strings', '%s')
str =
    TheseAreFourStrings
count =
    4
```

sscanf finds five word matches for %s and four space character matches for %c. Because the %c specifier does match a space character, the output string does include spaces:

```
[str count] = sscanf('Five strings and four spaces', '%s%c')
str =
    Five strings and four spaces
count =
     9
```

sscanf finds three word matches for %s and two numeric matches for %d. Because the format specifier has a mixed %d and %s format, sscanf converts all nonnumeric characters to numeric:

```
[str count] = sscanf('5 strings and 4 spaces', '%d%s%s%d%s');
str'
Columns 1 through 9
     5    115    116    114    105    110    103    115     97
Columns 10 through 18
    110    100     4    115    112     97     99    101    115
count
count =
     5
```

### Example 5

```
[str, count] = sscanf('one two three', '%c')
str =
    one two three
count =
    13
```

```
[str, count] = sscanf('one two three', '%13c')
str =
    one two three
count =
     1
```

# sscanf

---

```
[str, count] = sscanf('one two three', '%s')
str =
    onetwothree
count =
     3
```

```
[str, count] = sscanf('one two three', '%1s')
str =
    onetwothree
count =
    11
```

## Example 6

```
tempString = '78 F 72 F 64 F 66 F 49 F';
```

```
degrees = char(176);
tempNumeric = sscanf(tempString, ['%d' degrees 'F'])
tempNumeric =
     78     72     64     66     49
```

## See Also

[fscanf](#) | [sprintf](#) | [textscan](#)

**Purpose**

Stack data from multiple variables into single variable

**Syntax**

```
T = stack(W,vars)
T = stack(W,vars,Name,Value)
[T,iw] = stack( ___ )
```

**Description**

`T = stack(W,vars)` converts the wide table, `W`, into an equivalent table, `T`, that is in tall format. `stack` stacks up multiple variables from `W`, specified by `vars`, into a single variable in `T`. In general, `T` contains fewer variables, but more rows, than `W`.

The output table, `T`, contains a new categorical variable to indicate which variable in `W` the stacked data in each row came from. `stack` replicates data from the variables in `W` that are not stacked.

`T = stack(W,vars,Name,Value)` converts the table, `W`, to tall format with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify variable names for the new and stacked variables in `W`.

`[T,iw] = stack( ___ )` also returns an index vector, `iw`, indicating the correspondence between rows in `T` and rows in `W`. You can use any of the previous input arguments.

**Input Arguments****W - Wide table**

table

Wide table, specified as a table.

**vars - Variables in W to stack**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in `W` to stack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

**Example:** `'NewDataVariableName'`, `'StackedData'` names the new data variable `StackedData`.

## **'ConstantVariables' - Variables other than vars to include in the output**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables other than `vars` to include in the output, specified as the comma-separated pair consisting of `'ConstantVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. `stack` replicates the data from the constant variables for each stacked entry from a row.

The default is all the variables in `W` not specified by `vars`. You can specify the `'ConstantVariables'` name-value pair argument to exclude variables not specified by `vars` or `'ConstantVariables'` from the output table, `T`.

## **'NewDataVariableName' - Name for the new data variable in T**

string

Name for the new data variable in `T`, specified as the comma-separated pair consisting of `'NewDataVariableName'` and a string. The default is a concatenation of the names of the variables from `W` that are stacked up.

## **'IndexVariableName' - Name for the new indicator variable in T**

string

Name for the new indicator variable in `T`, specified as the comma-separated pair consisting of `'IndexVariableName'` and a string. The default is a name based on `NewDataVariableName`.

## Output Arguments

### T - Tall table

table

Tall table, returned as a table. T contains a stacked data variable, a categorical indicator variable, and any constant variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

stack assigns the variable units and variable description property values from the first variable listed in `vars` to the corresponding `T.Properties.VariableUnits` and `T.Properties.VariableDescriptions` values for the new data variable.

### iw - Index to W

column vector

Index to W, returned as a column vector. The index vector, `iw`, identifies the row in the input table, `W`, containing the corresponding data. `stack` creates the `j`th row in the output table, `T`, using `W(iw(j),vars)`.

## Examples

### Stack Three Variables into One

Create a table containing test scores from three separate tests.

```
Test1 = [93;57;87;89];
Test2 = [89;77;92;86];
Test3 = [95;62;89;91];
```

```
W = table(Test1,Test2,Test3)
```

W =

Test1	Test2	Test3
93	89	95

# stack

---

57	77	62
87	92	89
89	86	91

The table contains four rows and three variables.

Stack the test scores into a single variable.

```
T = stack(W,1:3)
```

```
T =
```

<u>Test1_Test2_Test3_Indicator</u>	<u>Test1_Test2_Test3</u>
Test1	93
Test2	89
Test3	95
Test1	57
Test2	77
Test3	62
Test1	87
Test2	92
Test3	89
Test1	89
Test2	86
Test3	91

T contains twelve rows and two variables.

The categorical variable, `Test1_Test2_Test3_Indicator`, identifies which test corresponds to the score in the stacked data variable, `Test1_Test2_Test3`.

## Stack Variables and Specify Variable Names

Create a table indicating the amount of snowfall at three locations from five separate storms.

```
Storm = [1;2;3;4;5];
Date = {'12/25/11';'1/2/12';'1/23/12';'2/7/12';'2/15/12'};
Natick = [20;5;13;0;17];
Boston = [18;9;21;5;12];
Worcester = [26;10;16;3;15];
```

```
W = table(Storm,Date,Natick,Boston,Worcester)
```

```
W =
```

Storm	Date	Natick	Boston	Worcester
1	'12/25/11'	20	18	26
2	'1/2/12'	5	9	10
3	'1/23/12'	13	21	16
4	'2/7/12'	0	5	3
5	'2/15/12'	17	12	15

The variables `Storm` and `Date` contain data that is constant at each location.

Stack the variables `Natick`, `Boston`, and `Worcester` into a single variable. Name the variable containing the stacked data, `Snowfall`, and name the new indicator variable, `Town`.

```
T = stack(W,{'Natick','Boston','Worcester'},...
          'NewDataVariableName','Snowfall',...
          'IndexVariableName','Town')
```

```
T =
```

Storm	Date	Town	Snowfall
1	'12/25/11'	Natick	20
1	'12/25/11'	Boston	18
1	'12/25/11'	Worcester	26

```
2      '1/2/12'      Natick      5
2      '1/2/12'      Boston      9
2      '1/2/12'      Worcester   10
3      '1/23/12'     Natick     13
3      '1/23/12'     Boston     21
3      '1/23/12'     Worcester  16
4      '2/7/12'      Natick      0
4      '2/7/12'      Boston      5
4      '2/7/12'      Worcester   3
5      '2/15/12'     Natick     17
5      '2/15/12'     Boston     12
5      '2/15/12'     Worcester  15
```

T contains three rows for each storm, and `stack` repeats the data in the constant variables, `Storm` and `Date`, accordingly.

The categorical variable, `Town`, identifies which variable in `W` contains the corresponding `Snowfall` data.

## Stack Variables and Output an Index Vector

Create a table containing estimated influenza rates along the east coast of the United States. Create a different variable for the Northeast, Mid Atlantic, and South Atlantic. Data Source: Google Flu Trends (<http://www.google.org/flutrends>).

```
Month = {'October'; 'November'; 'December'; ...
         'January'; 'February'; 'March'};
Year = [2005*ones(3,1); 2006*ones(3,1)];
NE = [1.1902; 1.3610; 1.5003; 1.7772; 2.1350; 2.2345];
MidAtl = [1.1865; 1.4120; 1.6043; 1.8830; 2.1227; 1.9920];
SATl = [1.2730; 1.5820; 1.8625; 1.9540; 2.4803; 2.0203];
```

```
fluW = table(Month,Year,NE,MidAtl,SATl)
```

```
fluW =
```

```
      Month      Year      NE      MidAtl      SATl
```

'October'	2005	1.1902	1.1865	1.273
'November'	2005	1.361	1.412	1.582
'December'	2005	1.5003	1.6043	1.8625
'January'	2006	1.7772	1.883	1.954
'February'	2006	2.135	2.1227	2.4803
'March'	2006	2.2345	1.992	2.0203

The variables `Month` and `Year` contain data that is constant across the row.

Stack the variables `NE`, `MidAtl`, and `SAtl` into a single variable called `FluRate`. Name the new indicator variable `Region` and output an index vector, `ifluW`, to indicate the correspondence between rows in the input wide table, `fluW`, and the output tall table, `fluT`.

```
[fluT,ifluW] = stack(fluW,3:5,...
    'NewDataVariableName','FluRate',...
    'IndexVariableName','Region')
```

```
fluT =
```

Month	Year	Region	FluRate
'October'	2005	NE	1.1902
'October'	2005	MidAtl	1.1865
'October'	2005	SAtl	1.273
'November'	2005	NE	1.361
'November'	2005	MidAtl	1.412
'November'	2005	SAtl	1.582
'December'	2005	NE	1.5003
'December'	2005	MidAtl	1.6043
'December'	2005	SAtl	1.8625
'January'	2006	NE	1.7772
'January'	2006	MidAtl	1.883
'January'	2006	SAtl	1.954

'February'	2006	NE	2.135
'February'	2006	MidAtl	2.1227
'February'	2006	SAtl	2.4803
'March'	2006	NE	2.2345
'March'	2006	MidAtl	1.992
'March'	2006	SAtl	2.0203

```
ifluW =
```

```
1  
1  
1  
2  
2  
2  
3  
3  
3  
4  
4  
4  
5  
5  
5  
6  
6  
6
```

`ifluW(5)` is 2. The fifth row in the output table, `fluT`, contains data from the second row in the input table `fluW`.

## Tips

- You can specify more than one group of data variables in `W`, and each group becomes a stacked data variable in `T`. Use a cell array to contain multiple values for `vars`, and a cell array of strings to contain multiple values for the `'NewDataVariableName'` name-value pair argument. All groups must contain the same number of variables.

**See Also**

`unstack` | `join`

# stairs

---

**Purpose** Stairstep graph

**Syntax**

```
stairs(Y)
stairs(X,Y)
stairs( ___,LineStyleSpec)
stairs( ___,Name,Value)

stairs(axes_handle, ___)

h = stairs( ___)

[xb,yb] = stairs( ___)

```

**Description** `stairs(Y)` draws a stairstep graph of the elements in `Y`.

- If `Y` is a vector, then the `x`-axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stairs` draws one line per matrix column and the `x`-axis scale ranges from 1 to the number of rows in `Y`.

`stairs(X,Y)` plots the elements in `Y` at the locations specified in `X`. The inputs `X` and `Y` must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

`stairs( ___,LineStyleSpec)` specifies a line style, marker symbol, and color. Use this option with any of the input argument combinations in the previous syntaxes.

`stairs( ___,Name,Value)` specifies stairseries properties using one or more `Name,Value` pair arguments.

`stairs(axes_handle, ___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle`, can precede any of the input argument combinations in the previous syntaxes.

`h = stairs( ___ )` returns a vector of stairseries object handles in `h`. When multiple stairseries are present, you can make changes to properties of a specific stairseries by specifying a particular handle.

`[xb,yb] = stairs( ___ )` does not create a plot, but returns matrices `xb` and `yb` of the same size, such that `plot(xb,yb)` plots the staircase graph.

## Input Arguments

### Y - Elements to plot

vector or matrix

Elements to plot, specified as a vector or matrix. When `Y` is a vector, `stairs` creates one stairseries. When `Y` is a matrix, `stairs` draws one line per matrix column and creates a separate stairseries for each column.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### X - Locations to plot elements in Y

vector or matrix

Locations to plot elements in `Y`, specified as a vector or matrix. When `Y` is a vector, `X` must be a vector of the same size. When `Y` is a matrix, `X` must be a matrix of the same size, or a vector whose length equals the number of rows in `Y`.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### LineStyle - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

**Example:** `':*r'`

## Data Types

char

## axes\_handle - Axes handle

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Marker', 's', 'MarkerFaceColor', 'red'` plots the staircase graph with red square markers.

For more information on `stairs` properties see `stairs`.

## 'LineStyle' - Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
<code>'-'</code>	Solid line (default)
<code>'--'</code>	Dashed line
<code>':'</code>	Dotted line

Specifier	Line Style
'- . '	Dash-dot line
'none'	No line

Example: 'LineStyle','- . '

### 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar in points.

Example: 'LineWidth',0.75

### 'Color' - Color

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'Color', [0 1 0]

Example: 'Color', 'green'

Example: 'Color', 'g'

## 'Marker' - Marker symbol

'none' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

Example: 'Marker', '+'

**Example:** 'Marker', 'diamond'

### 'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector  
| string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerEdgeColor',[1 .8 .1]

### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

**'MarkerSize' - Marker size**

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'MarkerSize',7

**Output Arguments****h - Stairseries object handle**

scalar or column vector

Stairseries object handle, specified as a scalar or column vector. This is a unique identifier, which you can use to query and modify the properties of a specific stairseries.

**xb - x values for use with plot**

vector or matrix

x values for use with plot, specified as a vector or matrix. xb contains the appropriate values such that `plot(xb,yb)` creates the staircase graph.

**yb - y values for use with plot**

vector or matrix

y values for use with plot, specified as a vector or matrix. yb contains the appropriate values such that `plot(xb,yb)` creates the staircase graph.

**Examples****Plot a Single Data Series**

Create a staircase plot of sine evaluated at 40 equally spaced values between 0 and  $4\pi$ .

```
figure
X = linspace(0,4*pi,40);
Y = sin(X);
stairs(Y)
```

# stairs

The length of  $Y$  automatically determines and generates the  $x$ -axis scale.

## Plot Multiple Data Series

Create a staircase plot of two cosine functions evaluated at 50 equally spaced values between 0 and  $4\pi$ .

```
figure
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
stairs(Y)
```

The number of rows in  $Y$  automatically determines and generates the  $x$ -axis scale.

### Plot a Single Data Series at Specified $x$ Values

Create a staircase plot of a sine wave evaluated at equally spaced values between 0 and  $4\pi$ . Specify the set of  $x$  values for the plot.

```
figure
X = linspace(0,4*pi,40);
Y = sin(X);
```

# stairs

stairs(X,Y)

The entries in Y are plotted against the corresponding entries in X.

## Plot Multiple Data Series at Specified x Values

Create a staircase plot of two cosine waves evaluated at equally spaced values between 0 and  $4\pi$ . Specify the set of x values for the plot.

```
figure  
X = linspace(0,4*pi,50)';
```

```
Y = [0.5*cos(X), 2*cos(X)];  
stairs(X,Y)
```

The first vector input,  $X$ , determines the  $x$ -axis positions for both data series.

### Plot Multiple Data Series at Unique Sets of $x$ Values

Create a staircase plot of two sine waves evaluated at different values. Specify a unique set of  $x$  values for plotting each data series.

# stairs

---

```
figure
x1 = linspace(0,2*pi)';
x2 = linspace(0,pi)';
X = [x1,x2];
Y = [sin(5*x1),exp(x2).*sin(5*x2)];
stairs(X,Y)
```

Each column of X is plotted against the corresponding column of Y.

### Specify the Line Style, Marker Symbol and Color

Create a staircase plot and set the line style to a dot-dashed line, the marker symbol to circles, and the color to red.

```
figure
X = linspace(0,4*pi,20);
Y = sin(X);
stairs(Y, '-.or')
```

## Specify Additional Style Options

Create a staircase plot and set the line width to 2 points, the marker symbols to diamonds, and the marker face color to cyan using Name,Value pair arguments.

```
figure
X = linspace(0,4*pi,20);
Y = sin(X);
stairs(Y,'LineWidth',2,'Marker','d','MarkerFaceColor','c')
```

### Specify Axes for Stairstep Plots

Create two subplots and return the handles to the axes, `s(1)` and `s(2)`.

```
figure  
s(1) = subplot(2,1,1);  
s(2) = subplot(2,1,2);
```

Create a stairstep plot in each subplot by referring to the axes handles.

```
X = linspace(0,2*pi);  
Y1 = 5*sin(X);  
Y2 = sin(5*X);  
stairs(s(1),X,Y1)  
stairs(s(2),X,Y2)
```

# stairs

## Return Stairseries Handle

Create a stairstep plot of two data series and return the handle to each stairseries.

```
figure
X = linspace(0,1,30)';
Y = [cos(10*X), exp(X).*sin(10*X)];
h = stairs(X,Y);
```

Specify the markers of the first series to small circles and the second series to magenta filled circles by referring to the handles.

```
set(h(1), 'Marker', 'o', 'MarkerSize', 4)  
set(h(2), 'Marker', 'o', 'MarkerFaceColor', 'm')
```

### Create a Stairstep Plot using plot

Evaluate two cosine functions at 40 equally spaced values between 0 and  $4\pi$  and create a stairstep plot using plot.

# stairs

---

Use `stairs` to get `xb` and `yb`.

```
figure
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
[xb,yb] = stairs(X,Y);
```

`stairs` returns two matrices of the same size, but no plot.

Use `plot` to create the staircase plot with `xb` and `yb`.

```
plot(xb,yb)
```

# Stairseries Properties

---

**Purpose** Define stairseries properties

**Modifying Properties** You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for stairseries objects.

See Plot Objects for information on stairseries objects.

## Stairseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

Annotation

`hg.Annotation` object (read-only)

*Control the display of stairseries objects in legends.* Specifies whether this stairseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stairseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the stairseries object in a legend as one entry, but not its children objects
off	Do not include the stairseries or its children in a legend (default)
children	Include only the children of the stairseries as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

# Stairseries Properties

---

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

The expression executes in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the stairseries object.* An array containing the handles of all line objects parented to the stairseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (black).

See the [ColorSpec](#) reference page for more information on specifying color. See “[Adding Arrows and Lines to Graphs](#)”.

# Stairseries Properties

---

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcb0`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the stairseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EraseMode`  
{normal} | none | xor | background

# Stairseries Properties

---

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property,

# Stairseries Properties

---

figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stairstep graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`  
`on | {off}`

Select the object by clicking lines or area of extent. Select plot objects by:

- Clicking lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is off, you must click the lines to select the object. When `HitTestArea` is on, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses the stairstep graph).

`Interruptible`  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Stairseries Properties

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of stairseries object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line

Specifier	Line Style
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

#### `LineWidth`

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.

#### `Marker`

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

#### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond

# Stairseries Properties

---

Specifier	Marker Type
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' 'H'	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Makes the interior of the marker transparent, allowing the background to show through.
- auto — Sets the fill color to the axes Color property. If the axes Color property is none, sets the fill color to the figure Color.

MarkerSize  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the '.' symbol) at one-third the specified size.

---

Parent  
handle of parent axes, hggroup, or hgtransform

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

Selected  
on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight  
{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.

# Stairseries Properties

---

- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For `stairseries` objects, `Type` is `'hgroup'`. The following statement finds all the `hgroup` objects in the current axes object.

```
t = findobj(gca, 'Type', 'hgroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu`

function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

**UserData**  
array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

**Visible**  
{on} | off

*Visibility of object and its children.*

- **on** — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

**XData**  
array

*X-axis location of stairs.* The `stairs` function uses `XData` to label the *x*-axis. `XData` can be either a matrix equal in size to `YData` or a vector equal in length to the number of rows in `YData`. That is, `length(XData) == size(YData,1)`.

If you do not specify `XData` (which the input argument `X`), the `stairs` function uses the indices of `YData` to create the staircase graph. See the `XDataMode` property for related information.

**XDataMode**  
{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the `X` input

# Stairseries Properties

---

argument), MATLAB sets this property to `manual` and uses the specified values to label the  $x$ -axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the  $x$ -axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

## `XDataSource`

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## `YData`

scalar | vector | matrix

*Stairs plot data.* `YData` contains the data plotted in the stairstep graph. Each value in `YData` is represented by a marker in the stairstep graph. If `YData` is a matrix, the `stairs` function creates a line for each column in the matrix.

The input argument `Y` in the `stairs` function calling syntax assigns values to `YData`.

## `YDataSource`

MATLAB variable, as a string

*Link `YData` to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# standardizeMissing

---

**Purpose** Insert missing value indicators into table

**Syntax**  
B = standardizeMissing(A,id)  
B = standardizeMissing(A,id,'DataVariables',vars)

**Description** B = standardizeMissing(A,id) replaces all instances of the values specified in id occurring within table A with the standard missing value indicators. B is a table.

The standard missing value indicators depend on the data type:

- NaN for double and single floating-point arrays
- <undefined> for categorical arrays
- empty string, { ' ' }, for cell arrays of strings
- blank string, [ ' ' ], for character arrays

standardizeMissing checks double and single variables in A against numeric values from id and checks string and categorical variables in A against strings from id. The function standardizeMissing ignores integer data types because they cannot contain NaN.

B = standardizeMissing(A,id,'DataVariables',vars) replaces values only in variables specified by vars.

## Input Arguments

### A - Input table

table

Input table, specified as a table.

### id - Nonstandard missing value indicators

numeric vector | string | cell array containing numeric values and strings

Nonstandard missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings.

### vars - Subset of variables to consider

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Subset of variables to consider, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

## Output Arguments

### B - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Replace All Instances of Specified Values

Create a table containing Inf and 'N/A' to represent missing values.

```
dblVar = [NaN;3;Inf;7;9];
cellstrVar = {'one';'three';'';'NA';'nine'};
charVar = ['A';'C';'E';' ';'I'];
categoryVar = categorical({'red';'yellow';'blue';'violet';''});
```

```
A = table(dblVar,cellstrVar,charVar,categoryVar)
```

A =

dblVar	cellstrVar	charVar	categoryVar
NaN	'one'	A	red
3	'three'	C	yellow
Inf	''	E	blue
7	'NA'		violet
9	'nine'	I	<undefined>

Replace all instances of Inf with NaN and replace all instances of 'NA' with the empty string, ''.

# standardizeMissing

---

```
B = standardizeMissing(A, {Inf, 'NA'})
```

```
B =
```

dblVar	cellstrVar	charVar	categoryVar
NaN	'one'	A	red
3	'three'	C	yellow
NaN	''	E	blue
7	''		violet
9	'nine'	I	<undefined>

## Replace Only Values in Specified Variables

Replace instances of `Inf`, and `'N/A'`, occurring in specified variables of a table, with the standard missing value indicators.

Create a table containing `Inf` and `'N/A'` to represent missing values.

```
a = {'alpha'; 'bravo'; 'charlie'; ''; 'N/A'};  
x = [1; NaN; 3; Inf; 5];  
y = [57; 732; 93; 1398; Inf];
```

```
A = table(a, x, y)
```

```
A =
```

a	x	y
'alpha'	1	57
'bravo'	NaN	732
'charlie'	3	93
''	Inf	1398
'N/A'	5	Inf

For the variables `a` and `x`, replace instances of `Inf` with `NaN` and `'N/A'` with the empty string, `''`.

```
B = standardizeMissing(A,{Inf,'N/A'},'DataVariables',{ 'a', 'x' })
```

```
B =
```

a	x	y
'alpha'	1	57
'bravo'	NaN	732
'charlie'	3	93
''	NaN	1398
''	5	Inf

Inf in the variable y remains unchanged because y is not included in the 'DataVariables' name-value pair argument.

## Algorithms

`standardizeMissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `standardizeMissing` does not ignore white space. All strings must match exactly a string specified in `id`.
- For character arrays, `standardizeMissing` ignores trailing white space.
- For categorical arrays, `standardizeMissing` ignores leading and trailing white space.

# startup

---

**Purpose** Startup file for user-defined options

**Syntax** startup

**Description** startup executes commands of your choosing when the MATLAB program starts.

Create a `startup.m` file in your MATLAB “Startup Folder” on page 1-5852 and put in the file any commands you want executed at MATLAB startup. For example, your `startup.m` file might include physical constants, defaults for Handle Graphics properties, engineering conversion factors, or anything else you want predefined in your workspace.

**Algorithms** The MATLAB program executes the `matlabrc.m` file when it starts. `matlabrc.m` invokes `startup.m`, if it exists on the MATLAB search path. You can extend this process to create additional startup files, if needed. MathWorks does not recommend modifying the `matlabrc.m` file, except perhaps by system administrators in network configurations.

## Startup Folder

The current folder in the MATLAB application when it starts. See “MATLAB Startup Folder”.

**See Also** finish | matlabrc | matlabroot | path | quit | userpath

**Concepts**

- “Specifying Startup Options in the MATLAB Startup File”
- Preferences

**Purpose** Standard deviation

**Syntax**  
`s = std(X)`  
`s = std(X, flag)`  
`s = std(X, flag, dim)`

**Definitions** There are two common textbook definitions for the standard deviation `s` of a data vector `X`.

$$(1) s = \left( \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{\frac{1}{2}}$$

$$(2) s = \left( \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{\frac{1}{2}},$$

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

and  $n$  is the number of elements in the sample. The two forms of the equation differ only in  $n - 1$  versus  $n$  in the divisor.

**Description** `s = std(X)`, where `X` is a vector, returns the standard deviation using (1) above. The result `s` is the square root of an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples.

If `X` is a matrix, `std(X)` returns a row vector containing the standard deviation of the elements of each column of `X`. If `X` is a multidimensional array, `std(X)` is the standard deviation of the elements along the first nonsingleton dimension of `X`.

`s = std(X,flag)` for `flag = 0`, is the same as `std(X)`. For `flag = 1`, `std(X,1)` returns the standard deviation using (2) above, producing the second moment of the set of values about their mean.

`s = std(X,flag,dim)` computes the standard deviations along the dimension of `X` specified by scalar `dim`. Set `flag` to 0 to normalize `Y` by  $n-1$ ; set `flag` to 1 to normalize by  $n$ .

The input array, `X`, must be of type `double` or `single` for all syntaxes.

## Examples

For matrix `X`

```
X =
     1     5     9
     7    15    22
s = std(X,0,1)
s =
  4.2426    7.0711    9.1924
s = std(X,0,2)
s =
  4.000
  7.5056
```

## See Also

`corrcoef` | `cov` | `mean` | `median` | `var`

**Purpose** Plot discrete sequence data

**Syntax**

```
stem(Y)
stem(X,Y)
stem(__, 'fill')
stem(__, LineSpec)
stem(__, Name, Value)

stem(axes_handle, __)

h = stem(__)
```

**Description** `stem(Y)` plots the data sequence, `Y`, as stems that extend from a baseline along the  $x$ -axis. The data values are indicated by circles terminating each stem.

- If `Y` is a vector, then the  $x$ -axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stem` plots all elements in a row against the same  $x$  value, and the  $x$ -axis scale ranges from 1 to the number of rows in `Y`.

`stem(X,Y)` plots the data sequence, `Y`, at values specified by `X`. The `X` and `Y` inputs must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

- If `X` and `Y` are both vectors, then `stem` plots entries in `Y` against corresponding entries in `X`.
- If `X` is a vector and `Y` is a matrix, then `stem` plots each column of `Y` against the set of values specified by `X`, such that all elements in a row of `Y` are plotted against the same value.
- If `X` and `Y` are both matrices, then `stem` plots columns of `Y` against corresponding columns of `X`.

`stem(__, 'fill')` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

## stem

---

`stem( ___, LineSpec )` specifies the line style, marker symbol, and color.

`stem( ___, Name, Value )` specifies stemsseries properties using one or more `Name, Value` pair arguments.

`stem( axes_handle, ___ )` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle`, can precede any of the input argument combinations in the previous syntaxes.

`h = stem( ___ )` returns a vector of stemsseries object handles in `h`. When multiple stemsseries objects are present, you can make changes to properties of a specific stemsseries by specifying a particular handle.

### **Input Arguments**

#### **Y - Data sequence to display**

vector or matrix

Data sequence to display, specified as a vector or matrix. When `Y` is a vector, `stem` creates one stemsseries. When `Y` is a matrix, `stem` creates a separate stemsseries for each column.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

#### **X - Locations to plot data values in Y**

vector or matrix

Locations to plot data values in `Y`, specified as a vector or matrix. When `Y` is a vector, `X` must be a vector of the same size. When `Y` is a matrix, `X` must be a matrix of the same size, or a vector whose length equals the number of rows in `Y`.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**LineStyle - Line style, marker symbol, and color**

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

**Example:** `':*r'`

**Data Types**

char

**axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'LineStyle',':', 'MarkerFaceColor','red'` plots the stem as a dotted line and colors the marker face red.

For more information on these properties see `stemseries`.

**'LineStyle' - Line style**

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'_'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

**Example:** 'LineStyle','-.'

### 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the stem and marker edge.

**Example:** 'LineWidth',0.75

### 'Color' - Color

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'Color', [0 1 0]

**Example:** 'Color', 'green'

**Example:** 'Color', 'g'

### 'Marker' - Marker symbol

'o' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle

Specifier	Marker Symbol
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'Marker', '+'

**Example:** 'Marker', 'diamond'

### 'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector  
| string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerEdgeColor',[1 .8 .1]

### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

### 'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'MarkerSize',3.75

## Output Arguments

### h - Stemseries object handle

scalar or column vector

Stemseries object handle, returned as a scalar or column vector. This is a unique identifier, which you can use to query and modify the properties of a specific stemseries.

## Examples

### Plot Single Data Series

Plot 50 data values between  $-2\pi$  and  $2\pi$  with a vector input.

```
figure
Y = linspace(-2*pi,2*pi,50);
stem(Y)
```

Data values are plotted as stems extending from the baseline and terminating at the data value. The length of  $Y$  automatically determines the position of each stem on the  $x$ -axis.

### Plot Multiple Data Series

Plot two data series with a two-column matrix input.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
```

# stem

Each column of  $Y$  is plotted as a separate series, and entries in the same row of  $Y$  are plotted against the same  $x$  value. The number of rows in  $Y$  automatically generates the position of each stem on the  $x$ -axis.

## Plot Single Data Series at Specified $x$ values

Plot 50 data values of cosine evaluated between 0 and  $2\pi$  and specify the set of  $x$  values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = cos(X);
stem(X,Y)
```

The first vector input determines the position of each stem on the  $x$ -axis.

### Plot Multiple Data Series at Specified $x$ values

Plot 50 data values of sine and cosine evaluated between 0 and  $2\pi$  and specify the set of  $x$  values for the stem plot.

## stem

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
stem(X,Y)
```

The vector input determines the x-axis positions for both data series.

### **Plot Multiple Data Series at Unique Sets of x values**

Plot 50 data values of sine and cosine evaluated at different sets of  $x$  values. Specify the corresponding sets of  $x$  values for each series.

```
figure
x1 = linspace(0,2*pi,50)';
x2 = linspace(pi,3*pi,50)';
X = [x1, x2];
Y = [cos(x1), 0.5*sin(x2)];
stem(X,Y)
```

Each column of X is plotted against the corresponding column of Y.

# stem

---

## Fill in Plot Markers

Create a stem plot and fill the circles that terminate each stem.

```
figure  
X = linspace(0,10,20)';  
Y = (exp(0.25*X));  
stem(X,Y,'fill')
```

### Specify Stem and Marker Options

Create a stem plot and set the line style to a dotted line, the marker symbols to diamonds, and the color to red using the LineSpec option.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(X).*sin(X));
stem(X,Y,':diamondr')
```

To color the inside of the diamonds, use the 'fill' option.

## Specify Additional Stem and Marker Options

Create a stem plot and set the line style to a dot-dashed line, the marker face color to red, and the marker edge color to green using Name,Value pair arguments.

```
figure
X = linspace(0,2*pi,25)';
Y = (cos(2*X));
stem(X,Y,'LineStyle','-.-',...
     'MarkerFaceColor','red',...
     'MarkerEdgeColor','green')
```

The stem remains the default color.

### Specify Axes for Stem Plot

Create two subplots and return the handles to each axes, `s(1)` and `s(2)`.

```
figure  
s(1) = subplot(2,1,1);  
s(2) = subplot(2,1,2);
```

# stem

---

Create a stem plot in the lower subplot by referring to the axes handle, `s(2)`.

```
X = 0:25;  
Y = [exp(0.1*X); -exp(.05*X)]';  
stem(s(2),X,Y)
```

## Return Stemseries Handle

Create a stem plot with multiple series and return the handle to each stemseries.

```
figure
X = 0:25;
Y = [cos(X); exp(0.05*X)]';
h = stem(X,Y);
```

The `stem` function creates two `stemseries` objects, one for each column of data. The output argument, `h`, returns both `stemseries` handles.

Change the markers of the first series to blue circles and the second series to green squares using the handles.

```
set(h(1), 'MarkerFaceColor', 'blue')
set(h(2), 'MarkerFaceColor', 'green', 'Marker', 'square')
```

# stem

## Adjust Baseline Properties

Create a stem plot and change properties of the baseline.

Get the baseline handle.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(0.3*X).*sin(3*X));
h = stem(X,Y);
hbase = get(h,'Baseline');
```

Adjust the color and style of the baseline by specifying a line property and value.

```
set(hbase, 'LineStyle', '- -')
```

Make the baseline invisible by setting the visible property to 'off' .

```
set(hbase, 'Visible', 'off')
```

Delete the baseline using the delete command.

```
delete(hbase)
```

## **Change the Baseline Level**

Create a stem plot and change the baseline level to 2.

```
figure  
X = linspace(0,2*pi,50)';  
Y = (exp(0.3*X).*sin(3*X));  
h = stem(X,Y);  
hbase = get(h,'Baseline');  
set(hbase,'BaseValue',2)
```

**See Also**

[bar](#) | [plot](#) | [stairs](#) | [LineStyleStemseries](#) |

**Related Examples**

- [""](#)

# stem3

---

**Purpose** Plot 3-D discrete sequence data

**Syntax**

```
stem3(Z)
stem3(X,Y,Z)
stem3( __ , 'fill' )
stem3( __ ,LineStyle)
stem3( __ ,Name,Value)

stem3(axes_handle, __ )

h = stem3( __ )
```

**Description** `stem3(Z)` plots entries in *Z* as stems extending from the *xy*-plane and terminating with circles at the entry values. The stem locations in the *xy*-plane are automatically generated.

`stem3(X,Y,Z)` plots entries in *Z* as stems extending from the *xy*-plane where *X* and *Y* specify the stem locations in the *xy*-plane. The inputs *X*, *Y*, and *Z* must be vectors or matrices of the same size.

`stem3( __ , 'fill' )` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

`stem3( __ ,LineStyle)` specifies the line style, marker symbol, and color.

`stem3( __ ,Name,Value)` specifies stems series properties using one or more *Name,Value* pair arguments.

`stem3(axes_handle, __ )` plots into the axes specified by *axes\_handle* instead of into the current axes (*gca*). The option, *axes\_handle*, can precede any of the input argument combinations in the previous syntaxes.

`h = stem3( ___ )` returns the stemseries handle `h`.

## Input Arguments

### Z - Data sequence to display

vector or matrix

Data sequence to display, specified as a vector or matrix. `stem3` plots each element in `Z` as a stem extending from the  $xy$ -plane and terminating at the data value.

- If `Z` is a row vector, `stem3` plots all elements against the same  $y$  value at equally spaced  $x$  values.
- If `Z` is a column vector, `stem3` plots all elements against the same  $x$  value at equally spaced  $y$  values.
- If `Z` is a matrix, `stem3` plots each row of `Z` against the same  $y$  value at equally spaced  $x$  values.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### X - Locations to plot values of Z

vector or matrix

Locations to plot values of `Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### Y - Locations to plot values of Z

vector or matrix

Locations to plot values of `Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

## **LineStyle** - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

**Example:** `':*r'`

## **Data Types**

char

## **axes\_handle** - Axes handle

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'LineStyle',':', 'MarkerFaceColor','red'` plots the stem as a dotted line and sets the marker face color to red.

For more information on these properties see `stemseries`.

## **'LineStyle' - Line style**

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
'.'	Dotted line
'-.'	Dash-dot line
'none'	No line

Example: 'LineStyle', '-.'

#### 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the stem and marker edge.

Example: 'LineWidth', 0.75

#### 'Color' - Color

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'Color', [0 1 0]

Example: 'Color', 'green'

Example: 'Color', 'g'

### 'Marker' - Marker symbol

'o' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle

Specifier	Marker Symbol
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'Marker', '+'

**Example:** 'Marker', 'diamond'

### 'MarkerEdgeColor' - Marker edge color

[0 0 1] (blue) (default) | 'auto' | 'none' | three-element RGB vector  
| string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerEdgeColor',[1 .8 .1]

#### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

### 'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'Markersize',12

## Output Arguments

### h - Stemseries object handle

scalar

Stemseries object handle, specified as a scalar. This is a unique identifier, which you can use to query and modify the properties of the stemseries.

## Examples

### Row Vector Input

Create a 3-D stem plot of cosine values between  $-\pi/2$  and  $\pi/2$  with a row vector input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = cos(X);
```

# stem3

stem3(Z)

stem3 plots elements of Z against the same y value at equally space x values.

## Column Vector Input

Create a 3-D stem plot of cosine values between  $-\pi/2$  and  $\pi/2$  with a column vector input.

figure

```
X = linspace(-pi/2,pi/2,40)';  
Z = cos(X);  
stem3(Z)
```

`stem3` plots elements of `Z` against the same `x` value at equally spaced `y` values.

### Matrix Input

Create a 3-D stem plot of sine and cosine values between  $-\pi/2$  and  $\pi/2$  with a matrix input.

## stem3

```
figure
X = linspace(-pi/2,pi/2,40);
Z = [sin(X); cos(X)];
stem3(Z)
```

stem3 plots each row of Z against the same y value at equally space x values.

### Specify Stem Locations with Vector Inputs

Create a 3-D stem plot and specify the stem locations along a curve. Use `view` to adjust the angle of the axes in the figure.

```
figure
X = linspace(-5,5,60);
Y = cos(X);
Z = X.^2;
stem3(X,Y,Z)
view(-8,30)
```

## stem3

X and Y determine the stem locations. Z determines the marker heights.

### Specify Stem Locations with Matrix Inputs

Create a 3-D stem plot with matrix data and specify the stem locations in the  $xy$ -plane.

```
figure
[X,Y] = meshgrid(0:.1:1);
Z = exp(X+Y);
stem3(X,Y,Z)
```

X and Y determine the stem locations. Z determines the marker heights.

### Fill in the Circles

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Use 'fill' to fill in the circles.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'fill')
```

## stem3

### Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Set the stem to a dashed line style, the marker symbols to stars, and the color to magenta using `LineStyle`.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'--*m')
```

To specify only two of the three `LineStyleSpec` options, omit the third option from the string. For example, `'*m'` sets the marker symbol and the color and leaves the default line style.

### **Line Style, Marker Symbol, and Color Options**

Create a 3-D stem plot and specify the stem locations along a circle. Set the stem to a dashed line style, the marker symbols to stars, and the color to magenta using `LineStyleSpec`.

figure

## stem3

---

```
theta = linspace(0,2*pi);  
X = cos(theta);  
Y = sin(theta);  
Z = theta;  
stem3(X,Y,Z, 'm')
```

X and Y determine the stem locations. Z determines the marker heights.

### Additional Style Options

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Set the marker symbols to squares with green faces and magenta edges.

```
figure  
X = linspace(-pi,pi,40);  
Z = cos(X);  
stem3(Z,'Marker','s','MarkerEdgeColor','m','MarkerFaceColor','g')
```

## stem3

---

### Axes Handles

Specify an axes for the 3-D stem plot.

Create two subplots and return the handles to each axes, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);
```

Define vectors `X`, `Y` and `Z`.

```
X = linspace(-2,2,50);
Y = X.^3;
Z = exp(X);
```

Plot a 3-D stem plot in the lower subplot using the axes handle `s(2)`. Adjust the angle of the axes using `view`. For comparison, plot a 2-D stem plot in the upper subplot using `X` and `Z`.

```
stem(s(1),X,Z)
stem3(s(2),X,Y,Z)
view(-20,35)
```

### Stemseries Handle

Create a 3-D stem plot and use the stemseries handle to adjust properties of the plot.

Get the handle for the stemseries.

```
figure
X = linspace(0,2);
Y = X.^3;
Z = exp(X).*cos(Y);
```

## stem3

```
h = stem3(X,Y,Z,'fill');
```

Set the color to magenta and the marker face color to yellow. Use `view` to adjust the angle of the axes in the figure.

```
set(h,'Color','m','MarkerFaceColor','y');  
view(-10,35)
```

# Stemseries Properties

---

## Purpose

Define stemseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

Note that you cannot define default properties for stemseries objects.

See Plot Objects for information on stemseries objects.

## Stemseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of stemseries objects in legends.* Specifies whether this stemseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stemseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the stemseries object in a legend as one entry, but not its children objects
off	Do not include the stemseries or its children in a legend (default)
children	Include only the children of the stemseries as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BaseLine

handle

*Handle of the baseline object.* Handle of the line object used as the baseline. Set the properties of this line using its handle.

The following example makes the stem plot baseline a dashed, red line:

```
% Create stem plot  
stem_handle = stem(randn(10,1));  
% Obtain handle of baseline from stemseries object  
baseline_handle = get(stem_handle, 'BaseLine');  
% Set line properties  
set(baseline_handle, 'LineStyle', '- -', 'Color', 'red')
```

### BaseValue

y-axis value

*Y-axis value where baseline is drawn.* Specify the value along the y-axis at which the MATLAB software draws the baseline.

### BeingDeleted

on | {off} (read-only)

# Stemseries Properties

---

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the stemseries object.* An array containing the handles of all line objects parented to the stemseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

# Stemseries Properties

---

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

`ColorSpec`

*Color of stem lines.* A three-element RGB vector or one of the MATLAB predefined names, specifying the line color. See the `ColorSpec` reference page for more information on specifying color.

For example, the following statement creates a stem plot with red lines.

```
h = stem(randn(10,1),'Color','r');
```

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the stemseries object in the legend. The default is an empty string.

# Stemseries Properties

---

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### `HandleVisibility`

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

# Stemseries Properties

---

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

`{on} | off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stem plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

`on | {off}`

*Select the object by clicking stem lines or area of extent.* Select plot objects by:

- Clicking stem lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the stem lines to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the stem lines).

## Interruptible

`off | {on}`

# Stemseries Properties

---

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

**LineStyle**

{-} | -- | : | - . | none

*Line style of stemseries object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use **LineStyle** `none` when you want to place a marker at each point but do not want the points connected with a line (see the **Marker** property).

**LineWidth**

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

# Stemseries Properties

---

## Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' 'H'	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

`MarkerFaceColor`

`ColorSpec` | `{none}` | `auto`

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`

handle of parent axes, `hgggroup`, or `hgtransform`

# Stemseries Properties

---

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight

{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, create a stemseries object and set the Tag property:

```
Y = linspace(-2*pi,2*pi,10);  
t = stem(Y,'Tag','stem1')
```

To access the stemseries object, use `findobj` to find the object's handle. The following statement changes the `MarkerFaceColor` property of the object whose `Tag` is `stem1`.

```
set(findobj('Tag','stem1'),'MarkerFaceColor','red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stemseries objects, `Type` is `'hggroup'`. The following statement finds all `hggroup` objects in the current axes object.

```
t = findobj(gca,'Type','hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

# Stemseries Properties

---

## Visible

{on} | off

*Visibility of object and its children.*

- **on** — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

array

*X-axis location of stems.* The stem function draws an individual stem at each *x*-axis location in the `XData` array. `XData` can be either a matrix equal in size to `YData` or a vector equal in length to the number of rows in `YData`. That is, `length(XData) == size(YData,1)`. `XData` does not need to be monotonically increasing.

If you do not specify `XData` (which is the input argument `X`), the stem function uses the indices of `YData` to create the stem plot. See the `XDataMode` property for related information.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

scalar | vector | matrix

*Stem plot data.* YData contains the data plotted as stems. Each value in YData is represented by a marker in the stem plot. If YData is a matrix, MATLAB creates a series of stems for each column in the matrix.

The input argument Y in the `stem` function calling syntax assigns values to YData.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

# Stemseries Properties

---

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector

*Z-coordinates.* A data defining the stems for 3-D stem graphs. `XData` and `YData` (if specified) must be the same size.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable

be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# stopasync

---

<b>Purpose</b>	Stop asynchronous read and write operations
<b>Syntax</b>	<code>stopasync(obj)</code>
<b>Description</b>	<code>stopasync(obj)</code> stops any asynchronous read or write operation that is in progress for the serial port object, <code>obj</code> .
<b>Tips</b>	<p>You can write data asynchronously using the <code>fprintf</code> or <code>fwrite</code> function. You can read data asynchronously using the <code>readasync</code> function, or by configuring the <code>ReadAsyncMode</code> property to <code>continuous</code>. In-progress asynchronous operations are indicated by the <code>TransferStatus</code> property.</p> <p>If <code>obj</code> is an array of serial port objects and one of the objects cannot be stopped, the remaining objects in the array are stopped and a warning is returned. After an object stops:</p> <ul style="list-style-type: none"><li>• Its <code>TransferStatus</code> property is configured to <code>idle</code>.</li><li>• Its <code>ReadAsyncMode</code> property is configured to <code>manual</code>.</li><li>• The data in its output buffer is flushed.</li></ul> <p>Data in the input buffer is not flushed. You can return this data to the MATLAB workspace using any of the synchronous read functions. If you execute the <code>readasync</code> function, or configure the <code>ReadAsyncMode</code> property to <code>continuous</code>, then the new data is appended to the existing data in the input buffer.</p>
<b>See Also</b>	<code>fprintf</code>   <code>fwrite</code>   <code>readasync</code>   <code>ReadAsyncMode</code>   <code>TransferStatus</code>

**Purpose** Convert string to double-precision value

**Syntax**  
`X = str2double('str')`  
`X = str2double(C)`

**Description** `X = str2double('str')` converts the string `str`, which should be an ASCII character representation of a real or complex scalar value, to the MATLAB double-precision representation. The string can contain digits, a comma (thousands separator), a decimal point, a leading + or - sign, an `e` preceding a power of 10 scale factor, and an `i` for a complex unit.

If `str` does not represent a valid scalar value, `str2double` returns NaN.

`X = str2double(C)` converts the strings in the cell array of strings `C` to double precision. The matrix `X` returned will be the same size as `C`.

**Examples** Here are some valid `str2double` conversions.

```
str2double('123.45e7')
str2double('123 + 45i')
str2double('3.14159')
str2double('2.7i - 3.14')
str2double({'2.71' '3.1415'})
str2double('1,200.34')
```

**See Also** `char` | `hex2num` | `num2str` | `str2num` | `cast`

# str2func

---

**Purpose** Construct function handle from function name string

**Syntax** `str2func('str')`

**Description** `str2func('str')` constructs a function handle `fhandle` for the function named in the string `'str'`. The contents of `str` can be the name of a file that defines a MATLAB function, or the name of an anonymous function.

You can create a function handle `fh` using any of the following four methods:

- Create a handle to a named function:

```
fh = @functionName;  
fh = str2func(functionName);
```

- Create a handle to an anonymous function:

```
fh = @(x)functionDef(x);  
fh = str2func('@(x)functionDef(x)');
```

You can create an array of function handles from strings by creating the handles individually with `str2func`, and then storing these handles in a cell array.

**Tips** Nested functions are not accessible to `str2func`. To construct a function handle for a nested function, you must use the function handle constructor, `@`.

Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

## Examples **Example 1**

To convert the string, `'sin'`, into a handle for that function, type

```
fh = str2func('sin')
```

```
fh =  
    @sin
```

### Example 2

If you pass a function name string in a variable, the function that receives the variable can convert the function name to a function handle using `str2func`. The example below passes the variable, `funcname`, to function `makeHandle`, which then creates a function handle. Here is the function:

```
function fh = makeHandle(funcname)  
fh = str2func(funcname);
```

This is the code that calls `makeHandle` to construct the function handle:

```
makeHandle('sin')  
ans =  
    @sin
```

### Example 3

To call `str2func` on a cell array of strings, use the `cellfun` function. This returns a cell array of function handles:

```
fh_array = cellfun(@str2func, {'sin' 'cos' 'tan'}, ...  
                  'UniformOutput', false);
```

```
fh_array{2}(5)  
ans =  
    0.2837
```

### Example 4

In the following example, the `myminbnd` function expects to receive either a function handle or string in the first argument. If you pass a string, `myminbnd` constructs a function handle from it using `str2func`, and then uses that handle in a call to `fminbnd`:

```
function myminbnd(fhandle, lower, upper)  
if ischar(fhandle)
```

```
        disp 'converting function string to function handle ...'  
        fhandle = str2func(fhandle);  
    end  
    fminbnd(fhandle, lower, upper)
```

Whether you call `myminbnd` with a function handle or function name string, the function can handle the argument appropriately:

```
myminbnd('humps', 0.3, 1)  
converting function string to function handle ...  
ans =  
    0.6370
```

### Example 5

The `dirByType` function shown here creates an anonymous function called `dirCheck`. What the anonymous function does depends upon the value of the `dirType` argument passed in to the primary function. The example demonstrates one possible use of `str2func` with anonymous functions:

```
function dirByType(dirType)  
    switch(dirType)  
        case 'class', leadchar = '@';  
        case 'package', leadchar = '+';  
        otherwise disp('ERROR: Unrecognized type'), return;  
    end  
  
    dirfile = @(fs)isdir(fs.name);  
    dirCheckStr = ['@(fs)strcmp(fs.name(1,1),'', leadchar, '')'];  
    dirCheckFun = str2func(dirCheckStr);  
    s = dir;    filecount = length(s);  
  
    for k=1:filecount  
        fstruct = s(k);  
        if dirfile(fstruct) && dirCheckFun(fstruct)  
            fprintf('%s folder: %s\n', dirType, fstruct.name)  
        end  
    end  
end
```

Generate a list of class and package folders:

```
dirByType('class')
class folder: @Point
class folder: @asset
class folder: @bond

dirByType('package')
package folder: +containers
package folder: +event
package folder: +mypkg
```

# str2mat

---

**Purpose** Form blank-padded character matrix from strings

---

**Note** `str2mat` is not recommended. Use `char` instead.

---

**Syntax** `S = str2mat(T1, T2, T3, ...)`

**Description** `S = str2mat(T1, T2, T3, ...)` forms the matrix `S` containing the text strings `T1`, `T2`, `T3`, ... as rows. The function automatically pads each string with blanks in order to form a valid matrix. Each text parameter, `Ti`, can itself be a string matrix. This allows the creation of arbitrarily large string matrices. Empty strings are significant.

**Tips** `str2mat` differs from `strvcat` in that empty strings produce blank rows in the output. In `strvcat`, empty strings are ignored.

**Examples** `x = str2mat('36842', '39751', '38453', '90307');`

```
whos x
  Name      Size      Bytes  Class
  x         4x5         40    char array
```

```
x(2,3)
```

```
ans =
```

```
7
```

**See Also** `char`

**Purpose** Convert string to number

**Syntax**

```
x = str2num('str')
[x, status] = str2num('str')
```

## Description

---

**Note** str2num uses the eval function to convert the input argument. Side effects can occur if the string contains calls to functions. Using str2double can avoid some of these side effects.

---

`x = str2num('str')` converts the string `str`, which is an ASCII character representation of a numeric value, to numeric representation. `str2num` also converts string matrices to numeric matrices. If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

The input string can contain one or more numbers separated by spaces, commas, or semicolons, such as '5', '10,11,12', or '5,10;15,20'. In addition to numerical values and delimiters, the input string can also include a decimal point, leading + or - signs, the letter e or d preceding a power of 10 scale factor, or the letter i or j indicating a complex or imaginary number.

The following table shows several examples of valid inputs to `str2num`:

String Input	Numeric Output	Output Class
'500'	500	1-by-1 scalar double
'500 250 125 67'	500, 250, 125, 67	1-by-4 row vector of double
'500; 250; 125; 62.5'	500.0000 250.0000 125.0000 62.5000	4-by-1 column vector of double

# str2num

String Input	Numeric Output	Output Class
'1 23 6 21; 53:56'	1 23 6 21 53 54 55 56	2-by-5 matrix of double
'12e-3 5.9e-3'	0.0120 0.0059	vector of double
'uint16(500)'	500	16-bit unsigned integer

---

**Note** `str2num` does not operate on cell arrays. To convert a cell array of strings to a numeric value, use `str2double`.

---

If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

`[x, status] = str2num('str')` returns the status of the conversion in logical `status`, where `status` equals logical 1 (true) if the conversion succeeds, and logical 0 (false) otherwise.

Space characters can be significant. For instance, `str2num('1+2i')` and `str2num('1 + 2i')` produce `x = 1+2i`, while `str2num('1 +2i')` produces `x = [1 2i]`. You can avoid these problems by using the `str2double` function.

## Examples

Input a character string that contains a single number. The output is a scalar double:

```
A = str2num('500')
A =
    500

class(A)
ans =
    double
```

Repeat this operation, but this time using an unsigned 16-bit integer:

```
A = str2num('uint16(500)')
A =
    500

class(A)
ans =
    uint16
```

Try three different ways of specifying a row vector. Each returns the same answer:

```
str2num('2 4 6 8')           % Separate with spaces.
ans =
     2     4     6     8

str2num('2,4,6,8')          % Separate with commas.
ans =
     2     4     6     8

str2num('[2 4 6 8]')        % Enclose in brackets.
ans =
     2     4     6     8
```

Note that the first two of these commands do not need the MATLAB square bracket operator to create a matrix. The `str2num` function inserts the brackets for you if they are needed.

Use a column vector this time:

```
str2num('2; 4; 6; 8')
ans =
     2
     4
     6
     8
```

And now a 2-by-2 matrix:

# str2num

---

```
str2num('2 4; 6 8')
ans =
     2     4
     6     8
```

| [special characters](#)

<b>Purpose</b>	Concatenate strings horizontally
<b>Syntax</b>	<code>combinedStr = strcat(s1,s2,...,sN)</code>
<b>Description</b>	<p><code>combinedStr = strcat(s1,s2,...,sN)</code> horizontally concatenates strings in arrays. Inputs can be combinations of single strings, strings in scalar cells, character arrays with the same number of rows, and same-sized cell arrays of strings.</p> <ul style="list-style-type: none"><li>• If any input is a cell array, <code>combinedStr</code> is a cell array of strings. Otherwise, <code>combinedStr</code> is a character array.</li><li>• For character array inputs, <code>strcat</code> removes trailing ASCII white-space characters: space, tab, vertical tab, newline, carriage return, and form-feed. For cell array inputs, <code>strcat</code> does not remove trailing white space.</li></ul>

## Examples

### Concatenate Two Strings

```
str = strcat('Good', 'morning')
```

```
str =
```

```
Goodmorning
```

### Concatenate Two Cell Arrays

```
a = {'abcde', 'fghi'};
```

```
b = {'jkl', 'mn'};
```

```
ab = strcat(a, b)
```

```
ab =
```

```
    'abcdejkl'    'fghimn'
```

## Concatenate Two Cell Arrays with Scalar Cell

```
a = {'abcde', 'fgi'};
b = {'jkl', 'mn'};
c = {'Q'};

abc = strcat(a, b, c)

abc =

    'abcdejk1Q'    'fghimnQ'
```

## Input Arguments

### **s1,s2,...,sN** - Strings to horizontally concatenate

string | cell array of strings | character arrays

Strings to horizontally concatenate, specified as strings, cell arrays of strings, or character arrays with the same number of strings. When combining nonscalar cell arrays and multirow character arrays, cell arrays must be column vectors with the same number of rows as the character arrays.

### Data Types

char | cell

## Tips

- `strcat` strips trailing blank spaces. Adding a blank space at the end of the first string does not result in a blank space between the strings once concatenated.

```
str1 = strcat('Good ', 'morning')
```

```
str1 =
```

```
Goodmorning
```

Instead, add a blank space before the second string.

```
str2 = strcat('Good', ' morning')
```

```
str2 =
```

```
Good morning
```

- Strings can be horizontally concatenated using horizontal array concatenation. Horizontal array concatenation does not strip off trailing blank spaces from a string.

```
a = 'Good ';  
b = 'Morning';
```

```
using_strcat = strcat(a, b)  
using_arraycat = [a b]    % Equivalent to horzcat(a, b)
```

```
using_strcat =
```

```
GoodMorning
```

```
using_arraycat =
```

```
Good Morning
```

## See Also

# strcmp

---

**Purpose** Compare strings with case sensitivity

**Syntax** TF = strcmp(s1,s2)

**Description** TF = strcmp(s1,s2) compares two strings for equality. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or a scalar logical 0 for inequality. The comparison is case sensitive.

Inputs can be two strings, two same-sized cell arrays of strings, or a combination of a string and a cell array.

- If s1 , s2 are strings, TF is a logical scalar.
- If at least one input is a cell array of strings, TF is a logical array the same size as the cell array.

**Input Arguments** **s1,s2 - Strings or cell array of strings to compare**  
string | cell array of strings

Strings or cell array of strings to compare for equality, specified as two strings or a string and a cell array of strings or two equal-sized cell arrays of strings. The order of the inputs does not effect the comparison results.

**Data Types**  
char | cell

**Examples** **Compare Two Strings**

strcmp to compare two different strings.

```
strcmp('Yes' , 'No')
```

```
ans =
```

```
0
```

`strcmp` returns logical 0 (false) because the two strings are not equal. Use `strcmp` to compare two equal strings.

```
strcmp('Yes' , 'Yes')
```

```
ans =
```

```
1
```

The function `strcmp` returns logical 1 (true) because the two strings are equal.

### **Compare String and Cell Array of Strings**

Use `strcmp` to compare a string, 'upon', to each element of a cell array of strings.

```
a = 'upon';  
b = {'Once' 'upon';  
    'a' 'time'};  
strcmp(a, b)
```

```
ans =
```

```
0    1  
0    0
```

There is only one occurrence of string a in array b, and that occurs at element b{1, 2}.

### **Compare Two Cell Arrays of Strings**

Use `strcmp` to compare each element in a cell array of strings to the corresponding element in a second cell array of strings.

```
c = {'Time' 'flies' 'when';  
    'you're' 'having' 'fun.'};  
d = {'Time' 'drags' 'when';  
    'you're' 'anxiously' 'waiting.'};
```

# strcmp

---

```
strcmp(c, d)
```

```
ans =
```

```
    1    0    1  
    1    0    0
```

There are three instances of equal strings between `c` and `d`. These are 'Time' at indices {1, 1}, 'when' at indices {1, 3}, and 'you're' at indices {2, 1}.

## Tips

- The `strcmp` function is intended for comparison of character data. When you use it to compare numeric data, `strcmp` returns logical 0.
- For case insensitive string comparison, use `strcmpi` instead of `strcmp`.
- Any leading or trailing blanks are explicitly included in the comparison.
- The value returned by `strcmp` is not the same as the C language convention.
- `strcmp` supports international character sets.

## See Also

`regexp` | `regexp`i | `strcmp`i | `strfind` | `strncmp` | `strncmp`i

<b>Purpose</b>	Compare strings (case insensitive)
<b>Syntax</b>	TF = strcmpi(string,string) TF = strcmpi(string,cellstr) TF = strcmpi(cellstr,cellstr)
<b>Description</b>	<p>TF = strcmpi(string,string) compares two strings for equality, ignoring any differences in letter case. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.</p> <p>TF = strcmpi(string,cellstr) compares a string with each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the cellstr input in which logical 1 represents equality. The order of the input arguments is not important.</p> <p>TF = strcmpi(cellstr,cellstr) compares each element of one cell array of strings with the same element of the other, ignoring letter case. The function returns a logical array the same size as the input arrays.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• The strcmpi function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.</li><li>• Use strcmp for case-sensitive string comparisons.</li><li>• Any leading and trailing blanks in either of the strings are explicitly included in the comparison.</li><li>• The value returned by strcmpi is not the same as the C language convention.</li><li>• strcmpi supports international character sets.</li></ul>
<b>Input Arguments</b>	<p><b>string</b> A single character string or n-by-1 array of strings.</p> <p><b>cellstr</b> A cell array of strings.</p>

# strcmpi

---

## Output Arguments

### TF

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

## Examples

Perform a simple case-insensitive comparison of two strings:

```
strcmpi('Yes', 'No')
ans =
     0
strcmpi('Yes', 'yes')
ans =
     1
```

---

Create two cell arrays of strings and call strcmpi to compare them:

```
A = {'Handle Graphics', 'Statistics'; ...
     'Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing'; ...
     'Toolboxes', 'MATHWORKS'};

match = strcmpi(A, B)
match =
     1     0
     0     1
```

The result of comparing the two cell arrays is:

- `match{1,1}` is 1 because “Handle Graphics” in `A{1,1}` matches the same text in `B{1,1}`.

- `match{1,2}` is 0 because “Statistics” in `A{1,2}` does not match “Signal Processing” in `B{1,2}`.
- `match{2,1}` is 0 because “ Toolboxes”, in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
- `match{2,2}` is 1 because even though “MathWorks” in `A{2,2}` uses different letter case than “MATHWORKS” in `B{2,2}`, `strcmpi` performs the comparison without sensitivity to letter case.

# stream2

---

**Purpose** Compute 2-D streamline data

**Syntax**  
`XY = stream2(x,y,u,v,startx,starty)`  
`XY = stream2(u,v,startx,starty)`  
`XY = stream2(...,options)`

**Description** `XY = stream2(x,y,u,v,startx,starty)` computes streamlines from vector data `u` and `v`.

The arrays `x` and `y`, which define the coordinates for `u` and `v`, must be monotonic, but do not need to be uniformly spaced. `x` and `y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XY` contains a cell array of vertex arrays.

`XY = stream2(u,v,startx,starty)` assumes the arrays `x` and `y` are defined as `[x,y] = meshgrid(1:n,1:m)` where `[m,n] = size(u)`.

`XY = stream2(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

`[stepsize]`

or

`[stepsize, max_number_vertices]`

If you do not specify a value, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream2`.

**Examples**

This example draws 2-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx,sy] = meshgrid(80,20:10:50);
streamline(stream2(x(:,:,5),y(:,:,5),u(:,:,5),v(:,:,5),sx,sy));
```

# stream3

---

## Purpose

Compute 3-D streamline data

## Syntax

```
XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)
XYZ = stream3(U,V,W,startx,starty,startz)
XYZ = stream3(...,options)
```

## Description

`XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)` computes streamlines from vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XYZ` contains a cell array of vertex arrays.

`XYZ = stream3(U,V,W,startx,starty,startz)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)` where `[M,N,P] = size(U)`.

`XYZ = stream3(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream3`.

**Examples**

This example draws 3-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamline(stream3(x,y,z,u,v,w,sx,sy,sz))
view(3)
```

# streamline

---

## Purpose

Plot streamlines from 2-D or 3-D vector data

## Syntax

```
streamline(X,Y,Z,U,V,W,startx,starty,startz)
streamline(U,V,W,startx,starty,startz)
streamline(XYZ)
streamline(X,Y,U,V,startx,starty)
streamline(U,V,startx,starty)
streamline(XY)
streamline(...,options)
streamline(axes_handle,...)
h = streamline(...)
```

## Description

`streamline(X,Y,Z,U,V,W,startx,starty,startz)` draws streamlines from 3-D vector data  $U$ ,  $V$ ,  $W$ .

The arrays  $X$ ,  $Y$ , and  $Z$ , which define the coordinates for  $U$ ,  $V$ , and  $W$ , must be monotonic, but do not need to be uniformly spaced.  $X$ ,  $Y$ , and  $Z$  must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, `startz` define the starting positions of the streamlines. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

`streamline(U,V,W,startx,starty,startz)` assumes the arrays  $X$ ,  $Y$ , and  $Z$  are defined as  $[X,Y,Z] = \text{meshgrid}(1:N,1:M,1:P)$ , where  $[M,N,P] = \text{size}(U)$ .

`streamline(XYZ)` assumes  $XYZ$  is a precomputed cell array of vertex arrays (as produced by `stream3`).

`streamline(X,Y,U,V,startx,starty)` draws streamlines from 2-D vector data  $U$ ,  $V$ .

The arrays  $X$  and  $Y$ , which define the coordinates for  $U$  and  $V$ , must be monotonic, but do not need to be uniformly spaced.  $X$  and  $Y$  must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The output argument `h` contains a vector of line handles, one handle for each streamline.

`streamline(U,V,startx,starty)` assumes the arrays `X` and `Y` are defined as `[X,Y] = meshgrid(1:N,1:M)`, where `[M,N] = size(U)`.

`streamline(XY)` assumes `XY` is a precomputed cell array of vertex arrays (as produced by `stream2`).

`streamline(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 1000

`streamline(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of the into current axes object (`gca`).

`h = streamline(...)` returns a vector of line handles, one handle for each streamline.

## Examples

### Draw Streamlines

Define arrays `x`, `y`, `u`, and `v`.

```
[x,y] = meshgrid(0:0.1:1,0:0.1:1);  
u = x;  
v = -y;
```

# streamline

Create a quiver plot of the data. Plot streamlines that start at different points along the line  $y = 1$ .

```
figure
quiver(x,y,u,v)

startx = 0.1:0.1:1;
starty = ones(size(startx));
streamline(x,y,u,v,startx,starty);
```

`coneplot` | `stream2` | `stream3` | `streamparticles` | `meshgrid`

**How To**

- [Specifying Starting Points for Stream Plots](#)
- [Stream Line Plots of Vector Data](#)

# streamparticles

---

**Purpose** Plot stream particles

**Syntax**

```
streamparticles(vertices)
streamparticles(vertices,n)
streamparticles(...,'PropertyName',PropertyValue,...)
streamparticles(line_handle,...)
h = streamparticles(...)
```

**Description** `streamparticles(vertices)` draws stream particles of a vector field. Stream particles are usually represented by markers and can show the position and velocity of a streamline. `vertices` is a cell array of 2-D or 3-D vertices (as if produced by `stream2` or `stream3`).

`streamparticles(vertices,n)` uses `n` to determine how many stream particles to draw. The `ParticleAlignment` property controls how `n` is interpreted.

- If `ParticleAlignment` is set to `off` (the default) and `n` is greater than 1, approximately `n` particles are drawn evenly spaced over the streamline vertices.

If `n` is less than or equal to 1, `n` is interpreted as a fraction of the original stream vertices; for example, if `n` is 0.2, approximately 20% of the vertices are used.

`n` determines the upper bound for the number of particles drawn. The actual number of particles can deviate from `n` by as much as a factor of 2.

- If `ParticleAlignment` is `on`, `n` determines the number of particles on the streamline having the most vertices and sets the spacing on the other streamlines to this value. The default value is `n = 1`.

`streamparticles(...,'PropertyName',PropertyValue,...)` controls the stream particles using named properties and specified values. Any unspecified properties have default values. MATLAB ignores the case of property names.

## Stream Particle Properties

`Animate` — Stream particle motion [nonnegative integer]

The number of times to animate the stream particles. The default is 0, which does not animate. `Inf` animates until you enter **Ctrl+C**.

**FrameRate** — Animation frames per second [nonnegative integer]

This property specifies the number of frames per second for the animation. `Inf`, the default, draws the animation as fast as possible. Note that the speed of the animation might be limited by the speed of the computer. In such cases, the value of **FrameRate** cannot necessarily be achieved.

**ParticleAlignment** — Align particles with streamlines [on | {off}]

Set this property to `on` to draw particles at the beginning of each streamline. This property controls how `streamparticles` interprets the argument `n` (number of stream particles).

Stream particles are line objects. In addition to stream particle properties, you can specify any line object property, such as **Marker** and **EraseMode**. `streamparticles` sets the following line properties when called.

Line Property	Value Set by <code>streamparticles</code>
<code>EraseMode</code>	<code>xor</code>
<code>LineStyle</code>	<code>none</code>
<code>Marker</code>	<code>o</code>
<code>MarkerEdgeColor</code>	<code>none</code>
<code>MarkerFaceColor</code>	<code>red</code>

You can override any of these properties by specifying a property name and value as arguments to `streamparticles`. For example, this statement uses RGB values to set the `MarkerFaceColor` to medium gray:

```
streamparticles(vertices, 'MarkerFaceColor', [.5 .5 .5])
```

# streamparticles

---

`streamparticles(line_handle,...)` uses the line object identified by `line_handle` to draw the stream particles.

`h = streamparticles(...)` returns a vector of handles to the line objects it creates.

## Examples

This example combines streamlines with stream particle animation. The `interpstreamspeed` function determines the vertices along the streamlines where stream particles will be drawn during the animation, thereby controlling the speed of the animation. Setting the axes `DrawMode` property to `fast` provides faster rendering.

```
load wind
[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
sl = streamline(verts);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.025);
axis tight; view(30,30); daspect([1 1 .125])
camproj perspective; camva(8)
set(gca,'DrawMode','fast')
box on
streamparticles(iverts,35,'animate',10,'ParticleAlignment','on')
```

The following picture is a static view of the animation.

This example uses the streamlines in the  $z = 5$  plane to animate the flow along these lines with streamparticles.

```
load wind
daspect([1 1 1]); view(2)
[verts averts] = streamslice(x,y,z,u,v,w,[],[],[5]);
sl = streamline([verts averts]);
axis tight off;
set(sl,'Visible','off')
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.05);
set(gca,'DrawMode','fast','Position',[0 0 1 1],'ZLim',[4.9 5.1])
set(gcf,'Color','black')
streamparticles(iverts, 200, ...
    'Animate',100,'FrameRate',40, ...
    'MarkerSize',10,'MarkerFaceColor','yellow')
```

## How To

- [Creating Stream Particle Animations](#)
- [Specifying Starting Points for Stream Plots](#)

# streamribbon

---

**Purpose** 3-D stream ribbon plot from vector volume data

**Syntax**

```
streamribbon(X,Y,Z,U,V,W,startx,starty,startz)
streamribbon(U,V,W,startx,starty,startz)
streamribbon(vertices,X,Y,Z,cav,speed)
streamribbon(vertices,cav,speed)
streamribbon(vertices,twistangle)
streamribbon(...,width)
streamribbon(axes_handle,...)
h = streamribbon(...)
```

**Description** `streamribbon(X,Y,Z,U,V,W,startx,starty,startz)` draws stream ribbons from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the stream ribbons at the center of the ribbons. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The twist of the ribbons is proportional to the curl of the vector field. The width of the ribbons is calculated automatically.

`streamribbon(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamribbon(vertices,X,Y,Z,cav,speed)` assumes precomputed streamline vertices, curl angular velocity, and flow speed. `vertices` is a

cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, `cav`, and `speed` are 3-D arrays.

`streamribbon(vertices,cav,speed)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(cav)`.

`streamribbon(vertices,twistangle)` uses the cell array of vectors `twistangle` for the twist of the ribbons (in radians). The size of each corresponding element of `vertices` and `twistangle` must be equal.

`streamribbon(...,width)` sets the width of the ribbons to `width`.

`streamribbon(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamribbon(...)` returns a vector of handles (one per start point) to surface objects.

## Examples

This example uses stream ribbons to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream ribbons.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
axis tight
shading interp;
view(3);
camlight; lighting gouraud
```

# streamribbon

---

This example uses precalculated vertex data (`stream3`), curl average velocity (`curl1`), and speed  $\sqrt{u^2 + v^2 + w^2}$ . Using precalculated data enables you to use values other than those calculated from the single data source. In this case, the speed is reduced by a factor of 10 compared to the previous example.

figure

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
cav = curl(x,y,z,u,v,w);
spd = sqrt(u.^2 + v.^2 + w.^2).*0.1;
streamribbon(verts,x,y,z,cav,spd);
% Define viewing and lighting
axis tight
shading interp
view(3)
camlight; lighting gouraud
```

# streamribbon

---

This example specifies a twist angle for the stream ribbon.

```
figure
t = 0:.15:15;
verts = {[cos(t)' sin(t)' (t/3)']};
twistangle = {cos(t)'};
streamribbon(verts,twistangle);
% Define viewing and lighting
```

```
axis tight  
shading interp;  
view(3);  
camlight; lighting gouraud
```

This example combines cone plots (coneplot) and stream ribbon plots in one graph.

# streamribbon

---

```
figure
% Define 3-D arrays x, y, z, u, v, w
xmin = -7; xmax = 7;
ymin = -7; ymax = 7;
zmin = -7; zmax = 7;
x = linspace(xmin,xmax,30);
y = linspace(ymin,ymax,20);
z = linspace(zmin,zmax,20);
[x y z] = meshgrid(x,y,z);
u = y; v = -x; w = 0*x+1;
[cx cy cz] = meshgrid(linspace(xmin,xmax,30),...
    linspace(ymin,ymax,30),[-3 4]);
h = coneplot(x,y,z,u,v,w,cx,cy,cz,'quiver');
set(h,'Color','k');

% Plot two sets of streamribbons
[sx sy sz] = meshgrid([-1 0 1],[-1 0 1],[-6]);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
[sx sy sz] = meshgrid([1:6],[0],[-6]);
streamribbon(x,y,z,u,v,w,sx,sy,sz);

% Define viewing and lighting
shading interp
view(-30,10) ; axis off tight
camproj perspective; camva(66); camlookat;
camdolly(0,0,.5,'fixtarget')
camlight
```

# streamslice

---

## Purpose

Plot streamlines in slice planes

## Syntax

```
streamslice(X,Y,Z,U,V,W,startx,starty,startz)
streamslice(U,V,W,startx,starty,startz)
streamslice(X,Y,U,V)
streamslice(U,V)
streamslice(...,density)
streamslice(...,'arrowmode')
streamslice(...,'method')
streamslice(axes_handle,...)
h = streamslice(...)
[vertices arrowvertices] = streamslice(...)
```

## Description

`streamslice(X,Y,Z,U,V,W,startx,starty,startz)` draws well-spaced streamlines (with direction arrows) from vector data  $U$ ,  $V$ ,  $W$  in axis aligned  $x$ -,  $y$ -,  $z$ -planes starting at the points in the vectors `startx`, `starty`, `startz`. (The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.)

The arrays  $X$ ,  $Y$ , and  $Z$ , which define the coordinates for  $U$ ,  $V$ , and  $W$ , must be monotonic, but do not need to be uniformly spaced.  $X$ ,  $Y$ , and  $Z$  must have the same number of elements, as if produced by `meshgrid`.  $U$ ,  $V$ ,  $W$  must be  $m$ -by- $n$ -by- $p$  volume arrays.

Do not assume that the flow is parallel to the slice plane. For example, in a stream slice at a constant  $z$ , the  $z$  component of the vector field  $W$  is ignored when you are calculating the streamlines for that plane.

Stream slices are useful for determining where to start streamlines, stream tubes, and stream ribbons.

`streamslice(U,V,W,startx,starty,startz)` assumes  $X$ ,  $Y$ , and  $Z$  are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(X,Y,U,V)` draws well-spaced streamlines (with direction arrows) from vector volume data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`streamslice(U,V)` assumes `X, Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(...,density)` modifies the automatic spacing of the streamlines. `density` must be greater than 0. The default value is 1; higher values produce more streamlines on each plane. For example, 2 produces approximately twice as many streamlines, while 0.5 produces approximately half as many.

`streamslice(...,'arrowmode')` determines if direction arrows are present or not. `arrowmode` can be

- `arrows` — Draw direction arrows on the streamlines (default).
- `noarrows` — Do not draw direction arrows.

`streamslice(...,'method')` specifies the interpolation method to use. `method` can be

- `linear` — Linear interpolation (default)
- `cubic` — Cubic interpolation
- `nearest` — Nearest-neighbor interpolation

See `interp3` for more information on interpolation methods.

`streamslice(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

# streamslice

---

`h = streamslice(...)` returns a vector of handles to the line objects created.

`[vertices arrowvertices] = streamslice(...)` returns two cell arrays of vertices for drawing the streamlines and the arrows. You can pass these values to any of the streamline drawing functions (`streamline`, `streamribbon`, `streamtube`).

## Examples

### Create Stream Slice

Load the wind data set. Create a stream slice at  $z = 5$ .

```
load wind
```

```
figure  
streamslice(x,y,z,u,v,w,[],[],[5])  
axis tight
```

## See Also

[contourslice](#) | [slice](#) | [streamline](#) | [volumebounds](#) | [meshgrid](#) | [interp3](#) | [interp2](#) | [streamribbon](#) | [streamtube](#)

## How To

- [Specifying Starting Points for Stream Plots](#)

# streamtube

---

**Purpose** Create 3-D stream tube plot

**Syntax**

```
streamtube(X,Y,Z,U,V,W,startx,starty,startz)
streamtube(U,V,W,startx,starty,startz)
streamtube(vertices,X,Y,Z,divergence)
streamtube(vertices,divergence)
streamtube(vertices,width)
streamtube(vertices)
streamtube(...,[scale n])
streamtube(axes_handle,...)
h = streamtube(...z)
```

**Description** `streamtube(X,Y,Z,U,V,W,startx,starty,startz)` draws stream tubes from vector volume data `U, V, W`.

The arrays `X, Y, and Z`, which define the coordinates for `U, V, and W`, must be monotonic, but do not need to be uniformly spaced. `X, Y, and Z` must have the same number of elements, as if produced by `meshgrid`.

`startx, starty, and startz` define the starting positions of the streamlines at the center of the tubes. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The width of the tubes is proportional to the normalized divergence of the vector field.

`streamtube(U,V,W,startx,starty,startz)` assumes `X, Y, and Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamtube(vertices,X,Y,Z,divergence)` assumes precomputed streamline vertices and divergence. `vertices` is a cell array of

streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, and divergence are 3-D arrays.

`streamtube(vertices,divergence)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(divergence)`.

`streamtube(vertices,width)` specifies the width of the tubes in the cell array of vectors, `width`. The size of each corresponding element of `vertices` and `width` must be equal. `width` can also be a scalar, specifying a single value for the width of all stream tubes.

`streamtube(vertices)` selects the width automatically.

`streamtube(...,[scale n])` scales the width of the tubes by `scale`. The default is `scale = 1`. When the stream tubes are created, using start points or divergence, specifying `scale = 0` suppresses automatic scaling. `n` is the number of points along the circumference of the tube. The default is `n = 20`.

`streamtube(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamtube(...z)` returns a vector of handles (one per start point) to surface objects used to draw the stream tubes.

## Examples

This example uses stream tubes to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream tubes.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamtube(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
view(3)
axis tight
```

# streamtube

```
shading interp;  
camlight; lighting gouraud
```

This example uses precalculated vertex data (`stream3`) and divergence (`divergence`).

```
figure  
load wind
```

```
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
div = divergence(x,y,z,u,v,w);
streamtube(verts,x,y,z,-div);
% Define viewing and lighting
view(3)
axis tight
shading interp
camlight; lighting gouraud
```

# streamtube

# strfind

---

- If `str` is a cell array of strings, `k` is a cell array with each element being an array of type `double` corresponding to the indices of each occurrence of `pattern` in the corresponding element of `str`.

## Examples

### Find String Pattern

Define string `S` as follows:

```
S = 'Find the starting indices of the pattern string';
```

Find the pattern `in` in string `S`.

```
k = strfind(S, 'in')
```

```
k =
```

```
     2     15     19     45
```

There are four instances of the substring, `in`, found in `S`.

Find the pattern `In` in string `S`.

```
k = strfind(S, 'In')
```

```
k =
```

```
 []
```

Since `strfind` is case sensitive, the string, `In`, is not found in `S`, `k` is an empty array.

Find the blank spaces in string `S`.

```
k = strfind(S, ' ')
```

```
k =
```

```
     5     9    18    26    29    33    41
```

There are seven occurrences of blank spaces in the string S.

### Find String in Cell Array of Strings

Define the cell array of strings, `cstr`, as follows:

```
cstr = {'How much wood would a woodchuck chuck';  
       'if a woodchuck could chuck wood?'};
```

Find the pattern, `wood`, in cell array `cstr`.

```
idx = strfind(cstr, 'wood')
```

```
idx =
```

```
    [1x2 double]  
    [1x2 double]
```

Examine the output cell array to find the instances of `wood`.

```
idx{:,:}
```

```
ans =
```

```
    10    23
```

```
ans =
```

```
     6    28
```

The pattern, `wood`, occurs at indices 10 and 23 in the first string and at indices 6 and 28 in the second string.

### Tips

- The `strfind` function does not find a pattern of empty strings, `''`, within `str`.

# strfind

---

## See Also

strtok | strcmp | strncmp | strcmpi | strncmpi | regex |  
regexp | regexp\_i | regprep | strep | strsplit

**Purpose**

String handling

**Syntax**

```
S = 'Any Characters'  
S = [S1 S2 ...]  
C = {S1 S2 ...}  
S = strcat(S1, S2, ...)  
S = char(S1, S2, ...)  
S = char(X)  
X = double(S)
```

**Description**

`S = 'Any Characters'` creates a character array, or string. The string is actually a vector that contains the numeric codes for the characters (codes 0 to 127 are ASCII). The length of `S` is the number of characters. A quotation within the string is indicated by two quotation marks.

`S = [S1 S2 ...]` concatenates character arrays `S1`, `S2`, etc. into a new character array, `S`.

`C = {S1 S2 ...}` creates a cell array of strings. Separate each row of the cell array with a semicolon (;).

`S = strcat(S1, S2, ...)` horizontally concatenates `S1`, `S2`, etc., which can be character arrays or cell arrays of strings. If the inputs are character arrays, `strcat` removes trailing white space. For more information, see the `strcat` reference page.

`S = char(S1, S2, ...)` vertically concatenates character arrays `S1`, `S2`, etc., padding each input string as needed so that each row contains the same number of characters.

`S = char(X)` converts an array that contains positive integers representing numeric codes into a MATLAB character array.

`X = double(S)` converts the string to its equivalent integer numeric codes.

**Tips**

- To convert between character arrays and cell arrays of strings, use `char` and `cellstr`. Most string functions support both types.

# strings

---

- To determine whether S is a character array or cell array, call `ischar(S)` or `iscellstr(S)`.

## Examples

Create a simple string that includes a single quote.

```
msg = 'You're right!'
```

```
msg =  
You're right!
```

Create the string name using two methods of concatenation.

```
name = ['Thomas' ' R. ' 'Lee']  
name = strcat('Thomas', ' R.', ' Lee')
```

Create a character array of strings.

```
C = char('Hello', 'Goodbye', 'Yes', 'No')
```

```
C =  
Hello  
Goodbye  
Yes  
No
```

Create a cell array of strings.

```
S = {'Hello' 'Goodbye'; 'Yes' 'No'}
```

```
S =  
    'Hello'    'Goodbye'  
    'Yes'     'No'
```

## Concepts

- “Cell Arrays of Strings”

**Purpose** Join strings in cell array into single string

**Syntax** `str = strjoin(C)`  
`str = strjoin(C,delimiter)`

**Description** `str = strjoin(C)` constructs the string, `str`, by linking each string in the cell array, `C`, with a single space.

`str = strjoin(C,delimiter)` constructs the string, `str`, by linking each string of `C` with the elements in `delimiter`.

## Input Arguments

**C - Input text**  
1-by-n cell array of strings

Input text, specified as a 1-by-n cell array of strings. Each element in the cell array must contain a single string in a single row.

**Example:** `{'The', 'rain', 'in', 'Spain'}`

**Data Types**  
cell

**delimiter - Delimiting characters**  
string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings.

- If `delimiter` is a single string, then `strjoin` forms `str` by inserting `delimiter` between each element of `C`. The `delimiter` input can include any of these escape sequences:

<code>\\</code>	Backslash
<code>\0</code>	Null
<code>\a</code>	Alarm
<code>\b</code>	Backspace

# strjoin

---

<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab

- If `delimiter` is a cell array of strings, then it must contain one fewer element than `C`. Each element in the cell array must contain a single string in a single row. `strjoin` forms `str` by interleaving the elements of `delimiter` and `C`. All characters in `delimiter` are inserted as literal text, and escape sequences are not supported.

**Example:** `' , '`

**Example:** `{ ' , ' , ' ' }`

## Data Types

`char` | `cell`

## Examples

### Join List of Words with Whitespace

Join individual strings in a cell array of strings, `C`, with a single space.

```
C = {'one', 'two', 'three'};  
str = strjoin(C)
```

```
str =
```

```
one two three
```

### Join Cell Array of Strings

```
C = {'Newton', 'Gauss', 'Euclid', 'Lagrange'};  
str = strjoin(C, ', ')
```

```
str =
```

```
Newton, Gauss, Euclid, Lagrange
```

### **Join Strings with Multiple Different Delimiters**

Specify multiple different delimiters in a cell array of strings. The delimiter cell array must have one fewer element than C.

```
C = {'one', 'two', 'three'};  
str = strjoin(C, {' + ', ' = '})
```

```
str =
```

```
one + two = three
```

### **See Also**

[strsplit](#) | [strcat](#) | [cellstr](#) | [regexp](#)

# strjust

---

**Purpose** Justify character array

**Syntax**

```
T = strjust(S)
T = strjust(S, 'right')
T = strjust(S, 'left')
T = strjust(S, 'center')
```

**Description** T = strjust(S) or T = strjust(S, 'right') returns a right-justified version of the character array S.

T = strjust(S, 'left') returns a left-justified version of S.

T = strjust(S, 'center') returns a center-justified version of S.

**See Also** deblank | strtrim

**Purpose** Find possible matches for string

---

**Note** `strmatch` is not recommended. Use `strncmp` or `validatestring`, depending on your requirements, instead. `strncmp` returns the numeric index of all array elements that begin with the specified string, whereas `validatestring` returns a single string that represents the best match to the specified string. See Example 2, below.

To find an exact match for a string, use `strcmp`.

---

**Syntax**

```
x = strmatch(str, strarray)
x = strmatch(str, strarray, 'exact')
```

**Description**

`x = strmatch(str, strarray)` looks through the rows of the character array or cell array of strings `strarray` to find strings that begin with the text contained in `str`, and returns the matching row indices. If `strmatch` does not find `str` in `strarray`, `x` is an empty matrix (`[]`). Any trailing space characters in `str` or `strarray` are ignored when matching. `strmatch` is fastest when `strarray` is a character array.

`x = strmatch(str, strarray, 'exact')` compares `str` with each row of `strarray`, looking for an exact match of the entire strings. Any trailing space characters in `str` or `strarray` are ignored when matching.

**Examples** **Example 1**

The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'))
```

returns `x = [1; 3]` since rows 1 and 3 begin with 'max'. The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'),'exact')
```

returns `x = 1`, since only row 1 matches 'max' exactly.

## Example 2

This example shows how to replace use of the `strmatch` function with `validatestring` or `strncmp`.

To start with, use `strmatch` to return the index of those elements for which there is a match:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = strmatch('max',list)
x =
     1
     3
     4
```

`validatestring` returns the string representing the best match. If multiple or no matches exist, this statement would return an error:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = validatestring('max', list)
x =
    max
```

`strncmp` returns a logical array indicating which strings match the specified string:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = strncmp('max', list, 3)
x =
     1     0     1     1
```

If you prefer that MATLAB return the numeric indices of `list`, use `find` as follows:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = find(strncmp(list, 'max', 3))
```

If your input to `strmatch` is a character matrix, then first convert the matrix to a cell array using `cellstr`. Then, pass the output from `cellstr` to `strncmp` or `validatestring`

| `regexprep`

# strncmp

---

**Purpose** Compare first *n* characters of strings (case sensitive)

**Syntax**

```
TF = strncmp(string,string,n)
TF = strncmp(string,cellstr,n)
TF = strncmp(cellstr,cellstr,n)
```

**Description** `TF = strncmp(string,string,n)` compares the first *n* characters of two strings for equality. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strncmp(string,cellstr,n)` compares the first *n* characters of a string with the first *n* characters of each element of a cell array of strings. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the first two input arguments is not important.

`TF = strncmp(cellstr,cellstr,n)` compares each element of one cell array of strings with the same element of the other. `strncmp` attempts to match only the first *n* characters of these strings. The function returns a logical array the same size as either input array.

- Tips**
- The `strncmp` function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.
  - Use `strncmpi` for case-insensitive string comparisons.
  - Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
  - The value returned by `strncmp` is not the same as the C language convention.
  - `strncmp` supports international character sets.

**Input Arguments**

**string**  
Single character string or *n*-by-1 array of strings.

**cellstr**

Cell array of strings.

**n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

## **Output Arguments**

**TF**

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (**true**) if the size and content of both arrays are equal, and logical 0 (**false**) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (**true**) for those elements of the input arrays that are a match, and logical 0 (**false**) for those elements that are not.

## **Examples**

Before trying the `strncmp` function, use `strcmp` to perform a simple comparison of the two input strings. Because only the first 13 characters are the same, `strcmp` returns logical 0:

```
strcmp('Kansas City, KS', 'Kansas City, MO')
ans =
    0
```

Do the comparison again, but this time using `strncmp` and specifying the number of characters to compare:

```
chars2compare = length('Kansas City, KS') - 2
ans =
    13
strncmp('Kansas City, KS', 'Kansas City, MO', chars2compare)
ans =
    1
```

---

# strncmp

---

From a list of 10 MATLAB functions, find those that apply to using a camera:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...  
                'caxis' 'camtarget' 'cast' 'camorbit' ...  
                'callib' 'cart2sph'};
```

```
strncmp(function_list, 'cam', 3)  
ans =  
    0    0    1    0    0    1    0    1    0    0
```

```
function_list{strncmp(function_list, 'cam', 3)}  
ans =  
    camdolly  
ans =  
    camtarget  
ans =  
    camorbit
```

---

Create two 5-by-10 string arrays `str1` and `str2` that are equal, except for the element at row 4, column 3. Using linear indexing, this is element 14:

```
str1 = ['AAAAAAAAA'; 'BBBBBBBBBB'; 'CCCCCCCCC'; ...  
        'DDDDDDDDD'; 'EEEEEEEEEE']
```

```
str1 =  
    AAAAAAAAAA  
    BBBBBBBBBB  
    CCCCCCCCCC  
    DDDDDDDDDD  
    EEEEEEEEEE
```

```
str2 = str1;  
str2(4,3) = '-'  
str2 =  
    AAAAAAAAAA
```

```
BBBBBBBBBB  
CCCCCCCCCC  
DD-DDDDDD  
EEEEEEEEEE
```

Because MATLAB compares the arrays in linear order (that is, column by column rather than row by row), `strncmp` finds only the first 13 elements to be the same:

```
str1  A B C D E A B C D E A B C D E  
str2  A B C D E A B C D E A B C - E  
                                     |  
                                     element 14
```

```
strncmp(str1, str2, 13)  
ans =  
    1
```

```
strncmp(str1, str2, 14)  
ans =  
    0
```

## See Also

`strcmp` | `strncmpi` | `strcmpi` | `strfind` | `regexp` | `regexp` |

# strncmpi

---

**Purpose** Compare first *n* characters of strings (case insensitive)

**Syntax**  
TF = strncmpi(string,string,n)  
TF = strncmpi(string,cellstr,n)  
TF = strncmpi(cellstr,cellstr,n)

**Description** TF = strncmpi(string,string,n) compares the first *n* characters of two strings for equality, ignoring any differences in letter case. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

TF = strncmpi(string,cellstr,n) compares the first *n* characters of a string with the first *n* characters of each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the *cellstr* input in which logical 1 represents equality. The order of the input arguments is not important.

TF = strncmpi(cellstr,cellstr,n) compares each element of one cell array of strings with the same element of the other, ignoring letter case. strncmpi attempts to match only the first *n* characters of these strings. The function returns a logical array the same size as either input array.

- Tips**
- The strncmpi function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.
  - Use strcmp for case-sensitive string comparisons.
  - Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
  - The value returned by strncmpi is not the same as the C language convention.
  - strncmpi supports international character sets.

**Input Arguments** **string**  
A single character string or *n*-by-1 array of strings.

**cellstr**

A cell array of strings.

**n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

## Output Arguments

**TF**

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (**true**) if the size and content of both arrays are equal, and logical 0 (**false**) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (**true**) for those elements of the input arrays that are a match, and logical 0 (**false**) for those elements that are not.

## Examples

From a list of 10 MATLAB functions, find those that apply to using a camera. Do the comparison without sensitivity to letter case:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
                'caxis' 'Camtarget' 'cast' 'camorbit' ...
                'callib' 'cart2sph'};
```

```
strncmpi(function_list, 'CAM', 3)
```

```
ans =
```

```
    0    0    1    0    0    1    0    1    0    0
```

```
function_list{strncmpi(function_list, 'CAM', 3)}
```

```
ans =
```

```
    camdolly
```

```
ans =
```

```
    Camtarget
```

```
ans =
```

```
    camorbit
```

# strncmpi

---

## See Also

[strcmpi](#) | [strncmp](#) | [strcmp](#) | [strfind](#) | [regexpi](#) | [regexp](#) |

**Purpose** Read formatted data from string

---

**Note** `strread` is not recommended. Use `textscan` instead.

---

## Syntax

```
A = strread('str')
[A, B, ...] = strread('str')
[A, B, ...] = strread('str', 'format')
[A, B, ...] = strread('str', 'format', N)
[A, B, ...] = strread('str', 'format', N, param, value, ...)
```

## Description

`A = strread('str')` reads numeric data from input string `str` into a 1-by-`N` vector `A`, where `N` equals the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 1” on page 1-5993 below.

`[A, B, ...] = strread('str')` reads numeric data from the string input `str` into scalar output variables `A`, `B`, and so on. The number of output variables must equal the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 2” on page 1-5994 below.

`[A, B, ...] = strread('str', 'format')` reads data from `str` into variables `A`, `B`, and so on using the specified `format`. The number of output variables `A`, `B`, etc. must be equal to the number of format specifiers (e.g., `%s` or `%d`) in the `format` argument. You can read all of the data in `str` to a single output variable as long as you use only one format specifier in the command. See “Example 4” on page 1-5994 and “Example 5” on page 1-5995 below.

The table [Formats for strread](#) on page 1-5990 lists the valid format specifiers. More information on using formats is available under “Formats” on page 1-5993 in the “Tips” on page 1-5992 section below.

`[A, B, ...] = strread('str', 'format', N)` reads data from `str` using the format string `N` times, where `N` is an integer greater than zero. If `N` is -1, `strread` reads the entire string. When `str` contains

# strread

only numeric data, you can set `format` to the empty string ( `' '` ). See “Example 3” on page 1-5994 below.

`[A, B, ...] = strread('str', 'format', N, param, value, ...)` customizes `strread` using `param/value` pairs, as listed in the table Parameters and Values for `strread` on page 1-5991 below. When `str` contains only numeric data, you can set `format` to the empty string ( `' '` ). The `N` argument is optional and may be omitted entirely. See “Example 7” on page 1-5996 below.

## Formats for strread

Format	Action	Output
Literals (ordinary characters)	Ignore the matching characters. For example, in a string that has <code>Dept</code> followed by a number (for department number), to skip the <code>Dept</code> and read only the number, use <code>'Dept'</code> in the format string.	None
<code>%d</code>	Read a signed integer value.	Double array
<code>%u</code>	Read an integer value.	Double array
<code>%f</code>	Read a floating-point value.	Double array
<code>%s</code>	Read a white-space separated string.	Cell array of strings
<code>%q</code>	Read a double quoted string, ignoring the quotes.	Cell array of strings
<code>%c</code>	Read characters, including white space.	Character array
<code>%[...]</code>	Read the longest string containing characters specified in the brackets.	Cell array of strings

**Formats for stringstream (Continued)**

Format	Action	Output
%[ ^... ]	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
%*...	Ignore the characters following *. See “Example 8” on page 1-5996 below.	No output
%w...	Read field width specified by w. The %f format supports %w.pf, where w is the field width and p is the precision.	

**Parameters and Values for stringstream**

param	value	Action
whitespace	Any from the list below: \b Backspace \n New line \r Carriage return \t Horizontal tab \\ Backslash %% Percent sign ' Single quotation mark	Treats vector of characters, *, as white space. Default is \b\r\n\t.
delimiter	Delimiter character	Specifies delimiter character. Default is one or more whitespace characters.
expchars	Exponent characters	Default is eEdD.

# stream

## Parameters and Values for stream (Continued)

param	value	Action
bufsize	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
emptyvalue	Value to return for empty numeric fields in delimited files	Default is NaN.

### Tips

If you terminate the input string with a newline character (`\n`), `stream` returns arrays of equal size by padding arrays of lesser size with the `emptyvalue` character:

```
[A,B,C] = stream(sprintf('5,7,1,9\n'),'%d%d%d', ...  
                'delimiter', ',', 'emptyvalue',NaN)  
A =  
    5  
    9  
B =  
    7  
   NaN  
C =  
    1  
   NaN
```

If you remove the `\n` from the input string of this example, array `A` continues to be a 2-by-1 array, but `B` and `C` are now 1-by-1.

### Delimiters

If your data uses a character other than a space as a delimiter, you must use the `strread` parameter `'delimiter'` to specify the delimiter. For example, if the string `str` used a semicolon as a delimiter, you would use this command:

```
[names, types, x, y, answer] = strread(str, '%s %s %f ...
    %d %s', 'delimiter', ';');
```

### Formats

The format string determines the number and types of return arguments. The number of return arguments must match the number of conversion specifiers in the format string.

The `strread` function continues reading `str` until the entire string is read. If there are fewer format specifiers than there are entities in `str`, `strread` reapplies the format specifiers, starting over at the beginning. See “Example 5” on page 1-5995 below.

The format string supports a subset of the conversion specifiers and conventions of the C language `fscanf` routine. White-space characters in the format string are ignored.

### Preserving White-Space

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
str = '  An  example      of preserving      spaces      ';

strread(str, '%s', 'whitespace', '')
ans =
    '  An  example      of preserving      spaces      '
```

## Examples

### Example 1

Read numeric data into a 1-by-5 vector:

# strread

---

```
a = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100    8.2400    3.5700    6.2400    9.2700
```

## Example 2

Read numeric data into separate scalar variables:

```
[a b c d e] = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100
b =
    8.2400
c =
    3.5700
d =
    6.2400
e =
    9.2700
```

## Example 3

Read the only first three numbers in the string, also formatting as floating point:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%4.2f', 3)
a =
    0.4100
    8.2400
    3.5700
```

## Example 4

Truncate the data to one decimal digit by specifying format `%3.1f`. The second specifier, `%*1d`, tells `strread` not to read in the remaining decimal digit:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%3.1f %*1d')
a =
```

```
0.4000
8.2000
3.5000
6.2000
9.2000
```

## Example 5

Read six numbers into two variables, reusing the format specifiers:

```
[a b] = strread('0.41 8.24 3.57 6.24 9.27 3.29', '%f %f')
```

```
a =
    0.4100
    3.5700
    9.2700
b =
    8.2400
    6.2400
    3.2900
```

## Example 6

Read string and numeric data to two output variables. Ignore commas in the input string:

```
str = 'Section 4, Page 7, Line 26';

[name value] = strread(str, '%s %d,')
name =
    'Section'
    'Page'
    'Line'
value =
     4
     7
    26
```

## Example 7

Read the string used in the last example, but this time delimiting with commas instead of spaces:

```
str = 'Section 4, Page 7, Line 26';

[a b c] = strread(str, '%s %s %s', 'delimiter', ',')
a =
    'Section 4'
b =
    'Page 7'
c =
    'Line 26'
```

## Example 8

Read selected portions of the input string:

```
str = '<table border=5 width="100%" cellpadding=0>';

[border width space] = strread(str, ...
    '%*s*s %c %*s "%4s" %*s %c', 'delimiter', '= ')
border =
     5
width =
    '100%'
space =
     0
```

## Example 9

Read the string into two vectors, restricting the Answer values to T and F. Also note that two delimiters (comma and space) are used here:

```
str = 'Answer_1: T, Answer_2: F, Answer_3: F';

[a b] = strread(str, '%s %[TF]', 'delimiter', ', ', ' ')
a =
    'Answer_1:'
```

```
    'Answer_2: '  
    'Answer_3: '  
b =  
    'T'  
    'F'  
    'F'
```

**See Also**      textscan | sscanf

# strrep

---

**Purpose** Find and replace substring

**Syntax** `modifiedStr = strrep(origStr, oldSubstr, newSubstr)`

**Description** `modifiedStr = strrep(origStr, oldSubstr, newSubstr)` replaces all occurrences of the string `oldSubstr` within string `origStr` with the string `newSubstr`.

- Tips**
- `strrep` accepts input combinations of single strings, strings in scalar cells, and same-sized cell arrays of strings. If any inputs are cell arrays, `strrep` returns a cell array.
  - The `strrep` function does not find empty strings for replacement. That is, when `origStr` and `oldSubstr` both contain the empty string (''), `strrep` does not replace '' with the contents of `newSubstr`.
  - Before replacing strings, `strrep` finds all instances of `oldSubstr` in `origStr`, like the `strfind` function. For overlapping patterns, `strrep` performs multiple replacements. See the final example in the Examples section.

## Examples

Replace text in a character array:

```
claim = 'This is a good example.';
new_claim = strrep(claim, 'good', 'great')
```

MATLAB returns:

```
new_claim =
This is a great example.
```

---

Replace text in a cell array:

```
c_files = {'c:\cookies.m'; ...
           'c:\candy.m'; ...
           'c:\calories.m'};
d_files = strrep(c_files, 'c:', 'd:')
```

MATLAB returns:

```
d_files =  
    'd:\cookies.m'  
    'd:\candy.m'  
    'd:\calories.m'
```

---

Replace text in a cell array with values in a second cell array:

```
missing_info = {'Start: __'; ...  
               'End: __'};  
  
dates = {'01/01/2001'; ...  
         '12/12/2002'};
```

```
complete = strrep(missing_info, '__', dates)
```

MATLAB returns:

```
complete =  
    'Start: 01/01/2001'  
    'End: 12/12/2002'
```

---

Compare the use of `strrep` and `regexprep` to replace a string with a repeated pattern:

```
repeats = 'abc 2 def 22 ghi 222 jkl 2222';  
indices = strfind(repeats, '22')  
  
using_strrep = strrep(repeats, '22', '*')  
using_regexprep = regexprep(repeats, '22', '*')
```

MATLAB returns:

```
indices =  
    11    18    19    26    27    28
```

# strrep

---

```
using_strrep =  
abc 2 def * ghi ** jkl ***
```

```
using_regexprep =  
abc 2 def * ghi *2 jkl **
```

## See Also

[strfind](#) | [regexprep](#)

**Purpose** Split string at specified delimiter

**Syntax**

```
C = strsplit(str)
C = strsplit(str,delimiter)
C = strsplit(str,delimiter,Name,Value)

[C,matches] = strsplit( __ )
```

**Description** C = strsplit(str) splits the string, str, at whitespace into the cell array of strings, C. A whitespace character is equivalent to any sequence in the set {' ', '\f', '\n', '\r', '\t', '\v'}.

C = strsplit(str,delimiter) splits str at the delimiters specified by delimiter.

C = strsplit(str,delimiter,Name,Value) specifies additional delimiter options using one or more name-value pair arguments.

[C,matches] = strsplit( \_\_ ) additionally returns a cell array of strings, matches, using any of the input arguments in the previous syntaxes. matches contains all occurrences of delimiters upon which strsplit splits str.

## Input Arguments

**str - Input text**  
string

Input text, specified as a string.

**Data Types**  
char

**delimiter - Delimiting characters**  
string | 1-by-n cell array of strings

# strsplit

---

Delimiting characters, specified as a single string or a 1-by-n cell array of strings. Strings specified in `delimiter` do not appear in the string fragments of the output `C`.

Specify multiple delimiters in a cell array of strings. Each element of the cell array must contain a single string in a single row. The `strsplit` function splits `str` on the elements of `delimiter` in the order in which they appear in the cell array.

`delimiter` can include the following escape sequences:

<code>\\</code>	Backslash
<code>\0</code>	Null
<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab

**Example:** `' , '`

**Example:** `{ ' - ' , ' , ' }`

## Data Types

char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** 'DelimiterType', 'RegularExpression' instructs strsplit to treat delimiter as a regular expression.

### 'CollapseDelimiters' - Multiple delimiter handling

1 (true) (default) | 0 (false)

Multiple delimiter handling, specified as the comma-separated pair consisting of 'CollapseDelimiters' and either true or false. If true, then consecutive delimiters in str are treated as one. If false, then consecutive delimiters are treated as separate delimiters, resulting in empty string '' elements between matched delimiters.

**Example:** 'CollapseDelimiters', true

### 'DelimiterType' - Delimiter type

'Simple' (default) | 'RegularExpression'

Delimiter type, specified as the comma-separated pair consisting of 'DelimiterType' and one of the following strings.

'Simple'	Except for escape sequences, strsplit treats delimiter as a literal string.
'RegularExpression'	strsplit treats delimiter as a regular expression.

In both cases, delimiter can include escape sequences.

## Output Arguments

### C - Parts of original string

cell array of strings

Parts of the original string, returned as a cell array of strings. C always contains one more element than matches contains. Consequently, if the original string, str, ends with a delimiter, then the last cell in C contains an empty string.

### matches - Identified delimiters

cell array of strings

# strsplit

---

Identified delimiters, returned as a cell array of strings. `matches` always contains one fewer element than output `C` contains.

## Examples

### Split String on Whitespace

```
str = 'The rain in Spain.';
C = strsplit(str)
```

```
C =
    'The'    'rain'    'in'    'Spain.'
```

`C` is a cell array containing 4 strings.

### Split String of Values on Specific Delimiter

Split a string of comma-separated values.

```
data = '1.21, 1.985, 1.955, 2.015, 1.885';
C = strsplit(data,', ')
```

```
C =
    '1.21'    '1.985'    '1.955'    '2.015'    '1.885'
```

Split a string of values, `data`, which contains the units m/s with an arbitrary number of white-space on either side of the text. The regular expression, `\s*`, matches any white-space character appearing zero or more times.

```
data = '1.21m/s1.985m/s 1.955 m/s2.015 m/s 1.885m/s';
[C,matches] = strsplit(data,'\s*m/s\s*',...
    'DelimiterType','RegularExpression')
```

```
C =
    '1.21'    '1.985'    '1.955'    '2.015'    '1.885'    ''
```

```

matches =

    'm/s'    'm/s '    ' m/s'    ' m/s '    'm/s'

```

In this case, the last string in `C` is empty. This empty string is the string that follows the last matched delimiter.

## Split Path String on File Separator

```

myPath = 'C:\work\matlab';
C = strsplit(myPath,'\')

C =

    'C:'    'work'    'matlab'

```

## Split Text String with Multiple Delimiters

Split a string on ' ' and 'ain', treating multiple delimiters as one. Specify multiple delimiters in a cell array of strings.

```

str = 'The rain in Spain stays mainly in the plain.';
[C,matches] = strsplit(str,{' ','ain'},'CollapseDelimiters',true)

C =

    'The'    'r'    'in'    'Sp'    'stays'    'm'    'ly'    'in'

```

```

matches =

    ' '    'ain '    ' '    'ain '    ' '    'ain'    ' '    ' '

```

Split the same string on whitespace and on 'ain', using regular expressions and treating multiple delimiters separately.

```

[C,matches] = strsplit(str,{'\s','ain'},'CollapseDelimiters',...
    false, 'DelimiterType','RegularExpression')

C =

```

# strsplit

---

```
      'The'    'r'    ''    'in'    'Sp'    ''    'stays'    'm'    'ly'

matches =

      ''    'ain'    ''    ''    'ain'    ''    ''    'ain'    ''
```

In this case, `strsplit` treats the two delimiters separately, so empty strings appear in output `C` between the consecutively matched delimiters.

## Split Text with Multiple, Overlapping Delimiters

Split text on the strings `,` `'` and `'`, and `'`.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{'', ',', ' and '})
```

```
C =

    'bacon'    'lettuce'    'and tomato'
```

```
matches =

    ', '    ', '    '    ' and '    ' and '
```

Because the command lists `,` `'` first and `'`, and `'` contains `,` `'`, the `strsplit` function splits `str` on the first delimiter and never proceeds to the second delimiter.

If you reverse the order of delimiters, `'`, and `'` takes priority.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{'', ' and ', ','})
```

```
C =
```

```
'bacon' 'lettuce' 'tomato'
```

```
matches =
```

```
',' ' ' and '
```

[strjoin](#) | [strfind](#) | [regexp](#)

## Concepts

- “Regular Expressions”

# strtok

---

**Purpose** Selected parts of string

**Syntax**

```
token = strtok(str)
token = strtok(str, delimiter)
[token, remain] = strtok(str, ...)
```

**Description** `token = strtok(str)` parses input string `str` from left to right, returning part or all of that string in `token`. Using the white-space character as a delimiter, the `token` output begins at the start of `str`, skipping any delimiters that might appear at the start, and includes all characters up to either the next delimiter or the end of the string. White-space characters include space (ASCII 32), tab (ASCII 9), and carriage return (ASCII 13).

The `str` argument can be a string of characters enclosed in single quotation marks, a cell array of strings each enclosed in single quotation marks, or a variable representing either of the two. If `str` is a cell array of `N` strings, then `token` is a cell array of `N` tokens, with `token{1}` derived from `str{1}`, `token{2}` from `str{2}`, and so on.

`token = strtok(str, delimiter)` is the same as the above syntax except that you specify the delimiting character(s) yourself using the `delimiter` character vector input. White-space characters are not considered to be delimiters when using this syntax unless you include them in the `delimiter` argument. If the `delimiter` input specifies more than one character, MATLAB treats each character as a separate delimiter; it does not treat the multiple characters as a delimiting string. The number and order of characters in the `delimiter` argument is unimportant. Do not use escape sequences as delimiters. For example, use `char(9)` rather than `'\t'` for tab.

`[token, remain] = strtok(str, ...)` returns in `remain` that part of `str`, if any, that follows `token`. The delimiter is included in `remain`. If no delimiters are found in the body of the input string, then the entire string (excluding any leading delimiting characters) is returned in `token`, and `remain` is an empty string (`''`). If `str` is a cell array of strings, `token` is a cell array of tokens and `remain` is a cell array of string remainders.

## Examples

### Example 1

This example uses the default white-space delimiter. Note that space characters at the start of the string are not included in the token output, but the space character that follows token is included in remain:

```
s = ' This is a simple example.';
[token, remain] = strtok(s)
```

```
token =
This
remain =
 is a simple example.
```

### Example 2

Take a string of HTML code and break it down into segments delimited by the < and > characters. Write a while loop to parse the string and print each segment:

```
s = sprintf('%s%s%s%s', ...
'<ul class=continued><li class=continued>', ...
'<pre><a name="13474"></a>token = strtok', ...
(''str'', delimiter)<a name="13475"></a>', ...
'token = strtok(''str'')');

remain = s;

while true
    [str, remain] = strtok(remain, '<>');
    if isempty(str), break; end
    disp(sprintf('%s', str))
end
```

Here is the output:

```
ul class=continued
li class=continued
pre
```

```
a name="13474"  
/a  
token = strtok('str', delimiter)  
a name="13475"  
/a  
token = strtok('str')
```

### Example 3

Using `strtok` on a cell array of strings returns a cell array of strings in `token` and a character array in `remain`:

```
s = {'all in good time'; ...  
    'my dog has fleas'; ...  
    'leave no stone unturned'};  
  
remain = s;  
  
for k = 1:4  
    [token, remain] = strtok(remain);  
    token  
end
```

Here is the output:

```
token =  
    'all'  
    'my'  
    'leave'  
token =  
    'in'  
    'dog'  
    'no'  
token =  
    'good'  
    'has'  
    'stone'  
token =
```

```
'time'  
'fleas'  
'unturned'
```

## See Also

[strfind](#) | [strncmp](#) | [strcmp](#) | [textscan](#) | [strsplit](#)

# strtrim

---

**Purpose** Remove leading and trailing white space from string

**Syntax**  
S = strtrim(str)  
C = strtrim(cstr)

**Description** S = strtrim(str) returns a copy of string str with all leading and trailing white-space characters removed. A white-space character is one for which the isspace function returns logical 1 (true).

C = strtrim(cstr) returns a copy of the cell array of strings cstr with all leading and trailing white-space characters removed from each string in the cell array.

**Examples** Remove the leading white-space characters (spaces and tabs) from str:

```
str = sprintf(' \t Remove leading white-space')
str =
    Remove leading white-space
```

```
str = strtrim(str)
str =
Remove leading white-space
```

Remove leading and trailing white-space from the cell array of strings:

```
cstr = {' Trim leading white-space';
        'Trim trailing white-space '};

cstr = strtrim(cstr)
cstr =
    'Trim leading white-space'
    'Trim trailing white-space'
```

**See Also** isspace | cellstr | deblank | strjust

**Purpose**

Create structure array

**Syntax**

```
s = struct
s = struct(field,value)
s = struct(field1,value1,...,fieldN,valueN)
s = struct([])

s = struct(obj)
```

**Description**

`s = struct` creates a scalar (1-by-1) structure with no fields.

`s = struct(field,value)` creates a structure array with the specified field and values.

- If `value` is *not* a cell array, then `s` is a scalar structure, where `s.(field) = value`.
- If `value` is a cell array, then `s` is a structure array with the same dimensions as `value`. Each element of `s` contains the corresponding element of `value`. For example, `s = struct('f',{'a','b'})` returns `s(1).f = 'a'` and `s(2).f = 'b'`.
- If `value` is an empty cell array `{}`, then `s` is an empty (0-by-0) structure.

`s = struct(field1,value1,...,fieldN,valueN)` creates a structure array with multiple fields. Any nonscalar cell arrays in the set `value1,...,valueN` must have the same dimensions.

- If none of the `value` inputs is a cell array, or all are scalar cell arrays, then `s` is a scalar structure.
- If any of the `value` inputs are nonscalar cell arrays, then `s` has the same dimensions as the nonscalar cell arrays. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.
- If any `value` input is an empty cell array, `{}`, then output `s` is an empty (0-by-0) structure.

# struct

---

`s = struct([])` creates an empty (0-by-0) structure with no fields.

`s = struct(obj)` creates a structure with field names and values that correspond to properties of `obj`. MATLAB does not convert `obj`, but rather creates `s` as a new structure. This structure does not retain the class information, so private, protected, and hidden properties become public fields in `s`. The `struct` function issues a warning when you use this syntax.

## Input Arguments

### field - Field name

string

Field name, specified as a string. Valid field names begin with a letter, and can contain letters, digits, and underscores. The maximum length of a field name is the value that the `namelengthmax` function returns.

### value - Values within structure field

cell array | scalar | vector | multidimensional array

Values within structure field, specified as a cell array or as a scalar, vector, or multidimensional array of any other data type.

If none of the `value` inputs is a cell array, or all of the `value` inputs are scalar cell arrays, then output `s` is a scalar structure. Otherwise, `value` inputs that are nonscalar cell arrays must have the same dimensions, and output `s` also has those dimensions. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.

If any `value` input is an empty cell array, `{}`, then output `s` is an empty structure array.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | cell | function\_handle

**Complex Number Support:** Yes

### obj - Object

any nonfundamental class

Object of any class, except the fundamental data types such as double or char.

## Examples

### Structure with One Field

Create a nonscalar structure with one field, `f`.

```
field = 'f';
value = {'some text';
        [10, 20, 30];
        magic(5)};
s = struct(field,value)

s =
3x1 struct array with fields:
    f
```

View the contents each element.

```
s.f

ans =
some text

ans =
    10    20    30

ans =
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

When you access a field of a nonscalar structure, such as `s.f`, MATLAB returns a comma-separated list. In this case, `s.f` is equivalent to `s(1).f`, `s(2).f`, `s(3).f`.

## Structure with Multiple Fields

Create a nonscalar structure with several fields.

```
field1 = 'f1'; value1 = zeros(1,10);  
field2 = 'f2'; value2 = {'a', 'b'};  
field3 = 'f3'; value3 = {pi, pi.^2};  
field4 = 'f4'; value4 = {'fourth'};
```

```
s = struct(field1,value1,field2,value2,field3,value3,field4,value4)
```

```
s =  
1x2 struct array with fields:  
    f1  
    f2  
    f3  
    f4
```

The cell arrays for `value2` and `value3` are 1-by-2, so `s` is also 1-by-2. Because `value1` is a numeric array and not a cell array, both `s(1).f1` and `s(2).f1` have the same contents. Similarly, because the cell array for `value4` has a single element, `s(1).f4` and `s(2).f4` have the same contents.

```
s(1)
```

```
ans =  
    f1: [0 0 0 0 0 0 0 0 0 0]  
    f2: 'a'  
    f3: 3.1416  
    f4: 'fourth'
```

```
s(2)
```

```
ans =  
    f1: [0 0 0 0 0 0 0 0 0 0]  
    f2: 'b'  
    f3: 9.8696  
    f4: 'fourth'
```

### Fields that Contain Cell Arrays

Create a structure with a field that contains a cell array.

```
field = 'mycell';
value = {'a','b','c'};
s = struct(field,value)

s =
    mycell: {'a' 'b' 'c'}
```

### Empty Structure Array

Create an empty structure with several fields.

```
s = struct('a', {}, 'b', {}, 'c', {})

s =
0x0 struct array with fields:
    a
    b
    c
```

### Nested Structure Array

Create a nested structure: a contains field b, which in turn contains fields c and d.

```
a.b = struct('c', {}, 'd', {})

a =
    b: [0x0 struct]
```

View the names of the fields of nested structure a.b.

```
fieldnames(a.b)

ans =
    'c'
    'd'
```

# struct

---

## Related Examples

- “Create a Structure Array”
- “Access Data in a Structure Array”
- “Generate Field Names from Variables”

**Purpose** Convert structure to cell array

**Syntax** `c = struct2cell(s)`

**Description** `c = struct2cell(s)` converts the  $m$ -by- $n$  structure `s` (with  $p$  fields) into a  $p$ -by- $m$ -by- $n$  cell array `c`.

If structure `s` is multidimensional, cell array `c` has size `[p size(s)]`.

- Use `fieldnames` to obtain structure field names in the same order as `struct2cell` returns structure values.

**Examples** The commands

```
clear s, s.category = 'tree';  
s.height = 37.4; s.name = 'birch';
```

create the structure

```
s =  
    category: 'tree'  
    height: 37.4000  
    name: 'birch'
```

Converting the structure to a cell array,

```
c = struct2cell(s)
```

```
c =  
    'tree'  
    [37.4000]  
    'birch'
```

**See Also** `cell2struct` | `cell` | `iscell` | `struct` | `isstruct` | `fieldnames`

**How To** • dynamic field names

# struct2table

---

**Purpose** Convert structure array to table

**Syntax**  
`T = struct2table(S)`  
`T = struct2table(S,Name,Value)`

**Description** `T = struct2table(S)` converts the structure array, `S`, to a table, `T`. Each field of `S` becomes a variable in `T`.

`T = struct2table(S,Name,Value)` creates a table from a structure array, `S`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify row names to include in the table.

## Input Arguments

### **S** - Structure array

structure array

Structure array, specified as a scalar structure array.

- If `S` is a scalar structure with `n` fields, all of which have `m` rows, then `T` is an `m`-by-`n` table.
- If `S` is a nonscalar `m`-by-1 structure array with `n` fields, then `T` is an `m`-by-`n` table.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `RowNames','{' row1',' row2',' row3' }` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

### **'RowNames'** - Row names for `T`

`{}` (default) | cell array of nonempty, distinct strings

Row names for T, specified as the comma-separated pair consisting of 'RowNames' and a cell array of nonempty, distinct strings.

### 'AsArray' - Indicator for how to treat scalar structure

false (default) | true | 0 | 1

Indicator for how to treat scalar structure, specified as the comma-separated pair consisting of 'AsArray' and either false, true, 0, or 1.

true	struct2table converts S to a table with one row and n variables. The variables can be different sizes.
false	struct2table converts a scalar structure array with n fields into an m-by-n table. Each field must have m rows. This is the default behavior

## Output Arguments

### T - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Convert Scalar Structure to Table

Convert a scalar structure to a table using the default options.

Create a structure array, S.

```
S.Name = {'CLARK'; 'BROWN'; 'MARTIN'};
S.Gender = {'M'; 'F'; 'M'};
S.SystolicBP = [124; 122; 130];
S.DiastolicBP = [93; 80; 92];
```

S

S =

# struct2table

---

```
        Name: {3x1 cell}
        Gender: {3x1 cell}
        SystolicBP: [3x1 double]
        DiastolicBP: [3x1 double]
```

The scalar structure, **S**, has four fields, each with three rows.

Convert the structure array to a table.

```
T = struct2table(S)
```

```
T =
```

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93
'BROWN'	'F'	122	80
'MARTIN'	'M'	130	92

The structure field names in **S** become the variable names in the output table. The size of **T** is 3-by-4.

Change **Name** from a variable to row names by modifying the table property, **T.Properties.RowNames**, and then deleting the variable **Name**.

```
T.Properties.RowNames = T.Name;
T.Name = [];
```

```
T
```

```
T =
```

	Gender	SystolicBP	DiastolicBP
CLARK	'M'	124	93

```
BROWN      'F'      122      80
MARTIN     'M'      130      92
```

## Convert Nonscalar Structure Array to Table

Create a nonscalar structure array, S.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
S
```

```
S =
```

```
3x1 struct array with fields:
```

```
Name
Gender
SystolicBP
DiastolicBP
```

S is a 3-by-1 structure array with four fields.

Convert the structure array to a table.

```
T = struct2table(S)
```

# struct2table

---

```
T =
```

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93
'BROWN'	'F'	122	80
'MARTIN'	'M'	130	92

The structure field names in `S` become the variable names in the output table. The size of `T` is 3-by-4.

## Treat Scalar Structure As Array

Use `'AsArray'`, `true` to create a table from a scalar structure whose fields have different numbers of rows.

Create a scalar structure, `S`, with fields `name`, `billing`, and `test`.

```
S.name = 'John Doe';  
S.billing = 127.00;  
S.test = [79, 75, 73; 180, 178, 177.5; 220, 210, 205];  
S
```

```
S =
```

```
    name: 'John Doe'  
  billing: 127  
    test: [3x3 double]
```

The fields have a different number of rows. Therefore, you cannot use `struct2table(S)`, which uses `'AsArray'`, `false` by default.

Treat the scalar structure as an array and convert it to a table.

```
T = struct2table(S, 'AsArray', true)
```

```
T =
```

<u>name</u>	<u>billing</u>	<u>test</u>
'John Doe'	127	[3x3 double]

T contains one row.

# structfun

---

**Purpose** Apply function to each field of scalar structure

**Syntax**  
`[A1,...,An] = structfun(func,S)`  
`[A1,...,An] = structfun(func,S,Name,Value)`

**Description** `[A1,...,An] = structfun(func,S)` applies the function specified by function handle `func` to each field of scalar structure `S`. Output arrays `A1,...,An`, where `n` is the number of outputs from function `func`, contain the outputs from the function calls.

`[A1,...,An] = structfun(func,S,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

## Input Arguments

### **func**

Handle to a function that accepts a single input argument and returns `n` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

### **S**

Scalar structure.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'UniformOutput'**

Logical value, as follows:

- `true` (1) Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type and size. The `structfun` function combines the outputs in arrays  $A_1, \dots, A_n$ , where  $n$  is the number of function outputs. Each output array is of the same type as the individual function outputs.
- `false` (0) Requests that the `structfun` function combine the outputs into scalar structures  $A_1, \dots, A_n$ , with the same fields as input structure `S`. The outputs of function `func` can be of any size or type.

**Default:** `true`

### 'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

## Output Arguments

### $A_1, \dots, A_n$

Arrays that collect the  $n$  outputs from function `func`.

If `UniformOutput` is `true` (the default):

# structfun

---

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each input. The class of the corresponding output array is the same as the class of the individual outputs from function `func`.
- Each array `A` is a column vector whose length equals the number of fields in `S`. The `structfun` function applies function `func` to the fields of `S` in the same order as that returned by the `fieldnames` function.

If `UniformOutput` is `false`, each array `A` is a scalar structure with the same fields as input `S`.

## Examples

Create a scalar structure, and count the number of characters in each field.

```
s.f1 = 'Sunday';  
s.f2 = 'Monday';  
s.f3 = 'Tuesday';  
s.f4 = 'Wednesday';  
s.f5 = 'Thursday';  
s.f6 = 'Friday';  
s.f7 = 'Saturday';
```

```
lengths = structfun(@numel, s)
```

---

Shorten the text in each field of `s`, created in the previous example. Because the output is nonscalar, set `UniformOutput` to `false`.

```
shortNames = structfun(@(x) ( x(1:3) ), s, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function.

---

Define and call a custom error handling function.

```
function result = errorfun(errorinfo, field)
```

```
        warning(errorinfo.identifier, errorinfo.message);
        result = NaN;
    end

    mystruct.f1 = 'text';
    myresult = structfun(@(x) x^2, mystruct, 'ErrorHandler', @errorfun)
```

## Tutorials

- “Anonymous Functions”

# strvcat

---

**Purpose** Concatenate strings vertically

---

**Note** `strvcat` is not recommended. Use `char` instead. Unlike `strvcat`, the `char` function does not ignore empty strings.

---

**Syntax** `S = strvcat(t1, t2, t3, ...)`  
`S = strvcat(c)`

**Description** `S = strvcat(t1, t2, t3, ...)` forms the character array `S` containing the text strings (or string matrices) `t1, t2, t3, ...` as rows. Spaces are appended to each string as necessary to form a valid matrix. Empty arguments are ignored.

`S = strvcat(c)` when `c` is a cell array of strings, passes each element of `c` as an input to `strvcat`. Empty strings in the input are ignored.

**Tips** If each text parameter, `ti`, is itself a character array, `strvcat` appends them vertically to create arbitrarily large string matrices.

**Examples** The command `strvcat('Hello', 'Yes')` is the same as `['Hello'; 'Yes']`, except that `strvcat` performs the padding automatically.

```
t1 = 'first'; t2 = 'string'; t3 = 'matrix'; t4 = 'second';
```

```
S1 = strvcat(t1, t2, t3)          S2 = strvcat(t4, t2, t3)
```

```
S1 =                               S2 =
```

```
first                               second  
string                              string  
matrix                              matrix
```

```
S3 = strvcat(S1, S2)
```

```
S3 =
```

first  
string  
matrix  
second  
string  
matrix

# sub2ind

---

**Purpose** Convert subscripts to linear indices

**Syntax** `linearInd = sub2ind(matrixSize, rowSub, colSub)`  
`linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)`

**Description** `linearInd = sub2ind(matrixSize, rowSub, colSub)` returns the linear index equivalent to the row and column subscripts `rowSub` and `colSub` for a matrix of size `matrixSize`. The `matrixSize` input is a 2-element vector that specifies the number of rows and columns in the matrix as `[nRows, nCols]`. The `rowSub` and `colSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscript pairs for the matrix. Example 3 demonstrates the use of vectors for the `rowSub` and `colSub` inputs.

`linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)` returns the linear index equivalent to the specified subscripts for each dimension of an N-dimensional array of size `arraySize`. The `arraySize` input is an n-element vector that specifies the number of dimensions in the array. The `dimNSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscripts for the matrix.

The `rowSub` and `colSub` inputs must belong to the same class. The `linearInd` output is the same class as the subscript inputs.

If needed, `sub2ind` assumes that unspecified trailing subscripts are 1. See Example 2, below.

## Examples

### Example 1

This example converts the subscripts (2, 1, 2) for three-dimensional array A to a single linear index. Start by creating a 3-by-4-by-2 array A:

```
rng(0,'twister'); % Initialize random number generator.  
A = rand(3, 4, 2)
```

```
A(:, :, 1) =  
    0.8147    0.9134    0.2785    0.9649
```

```

    0.9058    0.6324    0.5469    0.1576
    0.1270    0.0975    0.9575    0.9706
A(:, :, 2) =
    0.9572    0.1419    0.7922    0.0357
    0.4854    0.4218    0.9595    0.8491
    0.8003    0.9157    0.6557    0.9340

```

Find the linear index corresponding to (2, 1, 2):

```

linearInd = sub2ind(size(A), 2, 1, 2)
linearInd =
    14

```

Make sure that these agree:

```

A(2, 1, 2)          A(14)
ans =              and =
    0.4854          0.4854

```

## Example 2

Using the 3-dimensional array A defined in the previous example, specify only 2 of the 3 subscript arguments in the call to sub2ind. The third subscript argument defaults to 1.

The command

```

linearInd = sub2ind(size(A), 2, 4)
ans =
    11

```

is the same as

```

linearInd = sub2ind(size(A), 2, 4, 1)
ans =
    11

```

## Example 3

Using the same 3-dimensional input array A as in Example 1, accomplish the work of five separate `sub2ind` commands with just one.

Replace the following commands:

```
sub2ind(size(A), 3, 3, 2);
sub2ind(size(A), 2, 4, 1);
sub2ind(size(A), 3, 1, 2);
sub2ind(size(A), 1, 3, 2);
sub2ind(size(A), 2, 4, 1);
```

with a single command:

```
sub2ind(size(A), [3 2 3 1 2], [3 4 1 3 4], [2 1 2 2 1])
ans =
    21     11     15     19     11
```

Verify that these linear indices access the same array elements as their subscripted counterparts:

```
[A(3,3,2), A(2,4,1), A(3,1,2), A(1,3,2), A(2,4,1)]
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576
```

```
A([21, 11, 15, 19, 11])
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576
```

## See Also

`ind2sub` | `find` | `size`

**Purpose** Create axes in tiled positions

**Syntax**

```
subplot(m,n,p)
subplot(m,n,p,'replace')
subplot(m,n,p,'align')
subplot('Position',positionVector)
subplot( __ ,Name,Value)
```

```
h = subplot( __ )
```

```
subplot(h)
```

**Description** `subplot(m,n,p)` divides the current figure into an m-by-n grid and creates an axes in the grid position specified by p. MATLAB numbers its grids by row, such that the first grid is the first column of the first row, the second grid is the second column of the first row, and so on.

`subplot(m,n,p,'replace')` deletes any existing axes in grid location p and creates a new axes.

`subplot(m,n,p,'align')` creates a new axes so that the plot boxes are aligned. This is the default behavior.

`subplot('Position',positionVector)` creates a new axes at the position specified by positionVector. The positionVector is a four-element vector of the form [left,bottom,width,height], such that the entries are normalized values between 0.0 to 1.0. If the position vector specifies an axes that overlaps any previous axes, then the new axes replaces the existing ones.

`subplot( __ ,Name,Value)` specifies properties for the axes using any of the input argument combinations in the previous syntaxes and one or more Name,Value pair arguments.

# subplot

---

`h = subplot( __ )` returns the handle to the axes created by the `subplot` function.

`subplot(h)` makes the axes with handle `h` the current axes for subsequent plotting commands.

## Input Arguments

### **m - Number of grid rows**

1 (default) | positive integer

Number of grid rows, specified as a positive integer.

### **Data Types**

single | double

### **n - Number of grid columns**

1 (default) | positive integer

Number of grid columns, specified as a positive integer.

### **Data Types**

single | double

### **p - Grid position for new axes**

positive integer | vector

Grid position for the new axes, specified as a positive integer or a vector of positive integers.

- If `p` is a positive integer, then `subplot` creates a new axes in grid location `p`.
- If `p` is a vector of positive integers, then `subplot` creates a new axes that spans the grid locations listed in `p`. For example, `subplot(2,3,[2,5])` creates one axes spanning positions 2 and 5. Use `subplot(2,3,[2,6])` to create one axes spanning positions 2, 3, 5, and 6.

### **Data Types**

single | double

**positionVector - Normalized position for new axes**

four-element vector of values between 0.0 and 1.0

Normalized position for the new axes, specified as a four-element vector of values between 0.0 and 1.0 with the form `[left,bottom,width,height]`. The values are normalized with respect to the interior of the figure. The first two elements specify the position of the bottom-left corner of the axes in relation to the bottom-left corner of the figure. The last two elements specify the width and height of the new axes. Use this syntax to position an axes that does not align with grid positions.

**Example:** `[0.1, 0.1, 0.35, 0.35]`

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

You can set any axes properties for a subplot. Some plotting functions override existing axes property settings. Execute plotting functions before specifying axes properties to avoid overriding them. For a list of axes properties see [Axes Properties](#).

**Example:** `'XGrid','on'`

**Output Arguments****h - Handle to axes object**

scalar

Handle to axes object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific axes object.

# subplot

---

## Examples

### Upper and Lower Subplots

Create a figure with two stacked subplots. Plot a sine wave in each axes.

```
x = linspace(0,10);  
y1 = sin(x);  
y2 = sin(5*x);
```

```
figure  
subplot(2,1,1);  
plot(x,y1)
```

```
subplot(2,1,2);  
plot(x,y2)
```

### Quadrant of Subplots

Create a figure divided into four subplots.

Set up four vectors to store sine values of different frequencies.

```
x = linspace(0,10);  
y1 = sin(x);  
y2 = sin(2*x);  
y3 = sin(4*x);  
y4 = sin(8*x);
```

# subplot

---

Plot the four sine waves and title each subplot.

```
figure
subplot(2,2,1);
plot(x,y1);
title('Subplot 1: sin(x)')

subplot(2,2,2);
plot(x,y2);
title('Subplot 2: sin(2x)')

subplot(2,2,3);
plot(x,y3);
title('Subplot 3: sin(4x)')

subplot(2,2,4);
plot(x,y4);
title('Subplot 4: sin(8x)')
```

### Subplots with Different Sizes

Create a figure with subplots of different sizes.

Set up a vector of sine values and a vector of polynomial values.

```
x = linspace(-3.8,3.8);  
y_cos = cos(x);  
y_poly = 1 - x.^2./2 + x.^4./24;
```

# subplot

---

Plot the sine wave in the first subplot and the polynomial in the second subplot. Create a third subplot that spans the lower half of the figure and plot both vectors together. Add titles to each subplot.

```
figure
subplot(2,2,1);
plot(x,y_cos);
title('Subplot 1: Cosine')

subplot(2,2,2);
plot(x,y_poly,'g');
title('Subplot 2: Polynomial')

subplot(2,2,[3,4]);
plot(x,y_cos,'b',x,y_poly,'g');
title('Subplot 3 and 4: Both')
```

### Replacing Subplots

Replace a subplot with an empty axes.

Initialize the random number generator. Use a loop to create a figure with four stem plots of random data.

```
rng(0,'twister');  
figure  
for k = 1:4  
    data = rand(1,10);
```

# subplot

```
subplot(2, 2, k)  
stem(data);  
end
```

Replace the second subplot with an empty axes.

```
subplot(2,2,2,'replace')
```

## Subplots at Specified Positions

Specify position vectors to create two subplots that are not aligned.

Store the data from the magic function in vector y.

```
y = magic(4);
```

Plot the vector in one subplot. Create a bar graph in a second subplot.

```
y = magic(4);  
figure  
positionVector1 = [0.1, 0.2, 0.3, 0.3];  
subplot('Position',positionVector1)  
plot(y)  
  
positionVector2 = [0.5, 0.1, 0.4, 0.7];  
subplot('Position',positionVector2)  
bar(y)
```

# subplot

## Return Subplot Axes Handle

Create a figure with two subplots and store the handle to each subplot.

```
figure  
h1 = subplot(2,1,1);  
h2 = subplot(2,1,2);
```

Store the data from the peaks function in matrix Z. Use the axes handle to plot the first 20 rows of Z in the upper subplot. Plot the entire data set in the lower subplot.

```
Z = peaks;  
plot(h1,Z(1:20,:))  
plot(h2,Z);
```

Change the tick marks for the lower subplot using axes properties.  
Execute plotting functions before specifying axes properties to avoid  
overriding existing axes property settings.

```
set(h2,'XTick',[0,10,25,40,50])
```

## Specify Axes Properties

Use the Parent axes property to specify the figure for a subplot.

Create two figures and store the handle to each figure.

```
f1 = figure;  
f2 = figure;
```

Create an axes in the lower subplot of the first figure by setting the Parent axes property value to f1. Save the handle to the subplot axes as h.

```
h = subplot(2,1,2, 'Parent', f1);
```

Set up a vector of random data and create a stem plot. Use axes handle h to specify the axes for the plotting function.

```
rng(0, 'twister');  
data = rand(1,10);  
stem(h,data)  
title(h, 'Lower Subplot of First Figure')
```

### Make Axes the Current Axes

Use a subplot axes handle to make it the current axes.

Create a figure with multiple subplots. Store the handle to each subplot in vector `h`.

```
figure;  
for k = 1:4  
    h(k) = subplot(2,2,k);  
end
```

# subplot

---

Make the second subplot the current axes. Plot a sine wave and change the axis limits.

```
x = linspace(1,50);  
y = sin(x);  
  
subplot(h(2));  
plot(x,y,'Color',[0.1, 0.5, 0.1]);  
title('Second Subplot')  
axis([0,50,-1,1])
```

## Tips

- If the axes already exists, then the command `subplot(m,n,p)` makes the subplot in position `p` the current axes.
- `subplot(111)` is an exception and not identical in behavior to `subplot(1,1,1)`. For reasons of backwards compatibility, `subplot(111)` is a special case of `subplot` that does not immediately create an axes, but sets up the figure so that the next graphics command executes `clf reset`. The next graphics command deletes all the figure children and creates a new axes in the default position.

# subplot

---

`subplot(111)` does not return a handle and an error occurs if code specifies a return argument.

- If a new subplot axes overlaps an existing axes, then MATLAB deletes the existing axes. To overlay a new axes on top of existing subplots, use the `axes` command. For example, `subplot('Position',[.35 .35 .3 .3])` deletes any underlying subplots, but `axes('Position',[.35 .35 .3 .3])` positions a new axes in the middle of the figure without deleting any underlying axes.
- When using a script to create subplots, MATLAB does not finalize the `Position` property value until either a `drawnow` command is issued or MATLAB returns to await a user command. The `Position` property value for a subplot is subject to change until the script either refreshes the plot or exits.

<b>Input Arguments</b>	<p><b>A</b> Object</p> <p><b>S</b> struct array with two fields, <code>type</code> and <code>subs</code>.</p> <ul style="list-style-type: none"> <li><code>type</code> is a string containing <code>'()''</code>, <code>'{}''</code>, or <code>'.'</code>, where <code>'()''</code> specifies integer subscripts, <code>'{}''</code> specifies cell array subscripts, and <code>'.'</code> specifies subscripted structure fields.</li> <li><code>subs</code> is a cell array or string containing the actual subscripts.</li> </ul> <p><b>B</b></p>

# subsasgn

---

Assignment value (right-hand side)

## Output Arguments

**A**  
Result of evaluating assignment.

## Examples

See how MATLAB calls `subsasgn` for the expression:

```
A(1:2,:) = B;
```

The syntax `A(1:2,:) = B` calls `A = subsasgn(A,S,B)` where `S` is a 1-by-1 structure with `S.type = '()'` and `S.subs = {1:2, ':'}`. The string `':'` indicates a colon used as a subscript.

---

See how MATLAB calls `subsasgn` for the expression:

```
A{1:2} = B;
```

The syntax `A{1:2} = B` calls `A = subsasgn(A,S,B)` where `S.type = '{}'` and `S.subs = {[1 2]}`.

---

See how MATLAB calls `subsasgn` for the expression:

```
A.field = B;
```

The syntax `A.field = B` calls `A = subsasgn(A,S,B)` where `S.type = '.'` and `S.subs = 'field'`.

---

See how MATLAB calls `subsasgn` for the expression:

```
A(1,2).name(3:5)=B;
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscripting levels. For instance, `A(1,2).name(3:5)=B` calls `A=subsasgn(A,S,B)` where `S` is a 3-by-1 structure array with the following values:

```
S(1).type = '()'    S(2).type = '.'    S(3).type = '()'
S(1).subs = {1,2}  S(2).subs = 'name'  S(3).subs = {[3 4
                    5]}
```

## Algorithms

In the assignment  $A(J,K,\dots) = B(M,N,\dots)$ , subscripts  $J, K, M, N$ , and so on, can be scalar, vector, or arrays, when all the following are true:

- The number of subscripts specified for  $B$ , excluding trailing subscripts equal to 1, does not exceed the value returned by `ndims(B)`.
- The number of nonscalar subscripts specified for  $A$  equals the number of nonscalar subscripts specified for  $B$ . For example,  $A(5, 1:4, 1, 2) = B(5:8)$  is valid because both sides of the equation use one nonscalar subscript.
- The order and length of all nonscalar subscripts specified for  $A$  matches the order and length of nonscalar subscripts specified for  $B$ . For example,  $A(1:4, 3, 3:9) = B(5:8, 1:7)$  is valid because both sides of the equation (ignoring the one scalar subscript 3) use a 4-element subscript followed by a 7-element subscript.

See `numel` for information concerning the use of `numel` with regards to the overloaded `subsasgn` function.

# subsindex

---

**Purpose** Subscript indexing with object

**Syntax** `ind = subsindex(A)`

**Description** `ind = subsindex(A)` called by MATLAB for the expression `X(A)` when `A` is an object, unless such an expression results in a call to an overloaded `subsref` or `subsasgn` method for `X`. `subsindex` must return the value of the object as a zero-based integer index. (`ind` must contain integer values in the range 0 to `prod(size(X))-1`.) Call `subsindex` directly from an overloaded `subsref` or `subsasgn` method.

MATLAB invokes `subsindex` separately on all the subscripts in an expression, such as `X(A,B)`.

**See Also** `subsasgn` | `subsasgn`

**Tutorials**

- “Using Objects as Indices”

<b>Purpose</b>	Angle between two subspaces
<b>Syntax</b>	<code>theta = subspace(A,B)</code>
<b>Description</b>	<code>theta = subspace(A,B)</code> finds the angle between two subspaces specified by the columns of A and B. If A and B are column vectors of unit length, this is the same as <code>acos(abs(A'*B))</code> .
<b>Tips</b>	If the angle between the two subspaces is small, the two spaces are nearly linearly dependent. In a physical experiment described by some observations A, and a second realization of the experiment described by B, <code>subspace(A,B)</code> gives a measure of the amount of new information afforded by the second experiment not associated with statistical errors of fluctuations.
<b>Examples</b>	<p>Consider two subspaces of a Hadamard matrix, whose columns are orthogonal.</p> <pre>H = hadamard(8); A = H(:,2:4); B = H(:,5:8);</pre> <p>Note that matrices A and B are different sizes — A has three columns and B four. It is not necessary that two subspaces be the same size in order to find the angle between them. Geometrically, this is the angle between two hyperplanes embedded in a higher dimensional space.</p> <pre>theta = subspace(A,B) theta =     1.5708</pre> <p>That A and B are orthogonal is shown by the fact that theta is equal to <math>\pi/2</math>.</p> <pre>theta - pi/2 ans =     0</pre>

# subsref

---

**Purpose** Redefine subscripted reference for objects

**Syntax** `B = subsref(A,S)`

**Description** `B = subsref(A,S)` is called by MATLAB for the syntax `A(i)`, `A{i}`, or `A.i` when `A` is an object. `S` is a struct array with two fields, `type` and `subs`.

The `type` field is string containing `'()'`, `'{}'`, or `','`, where `'()'` specifies integer subscripts, `'{}'` specifies cell array subscripts, and `','` specifies subscripted structure fields. The `subs` field is a cell array or a string containing the actual subscripts.

`B` is the result of the indexed expression.

MATLAB uses the built-in `subsref` function to interpret indexed references to objects. To modify the indexed reference behavior of objects, overload `subsref` in the class.

If `A` is a fundamental class (see “Fundamental MATLAB Classes”), then an indexed reference to `A` calls the built-in `subsref` function. It does not call a `subsref` method that you have overloaded for that class. Therefore, if `A` is an array of class `double`, and there is an `@double/subsref` method on your MATLAB path, the statement `A(I)` calls the MATLAB built-in `subsref` function.

**Tips** Within a class’s own methods, MATLAB calls the built-in `subsref`, not the class defined `subsref`. This behavior enables to use the default `subsref` behavior when defining specialized indexing for your class. See “`subsref` and `subsasgn` Within Class Methods — Built-In Called” for more information.

**Examples** See how MATLAB calls `subsref` for the expression:

```
A(1:2,:)
```

The syntax `A(1:2,:)` calls `B = subsref(A,S)` where `S` is a 1-by-1 structure with `S.type='()'` and `S.subs={1:2,','}`. The string `','` indicates a colon used as a subscript.

See how MATLAB calls `subsref` for the expression:

```
A{1:2}
```

The syntax `A{1:2}` calls `B = subsref(A,S)` where `S.type='{}'` and `S.subs={1 2}`.

See how MATLAB calls `subsref` for the expression:

```
A.field
```

The syntax `A.field` calls `B = subsref(A,S)` where `S.type='.'` and `S.subs='field'`.

See how MATLAB calls `subsref` for the expression:

```
A(1,2).name(3:5)
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscript levels. For instance, `A(1,2).name(3:5)` calls `subsref(A,S)` where `S` is a 3-by-1 structure array with the following values:

<code>S(1).type='()'</code>	<code>S(2).type='.'</code>	<code>S(3).type='()'</code>
<code>S(1).subs={1,2}</code>	<code>S(2).subs='name'</code>	<code>S(3).subs={[3 4 5]}</code>

## See Also

`numel` | `subsasgn` | `substruct`

## Tutorials

- “Indexed Reference and Assignment”

# substruct

---

**Purpose** Create structure argument for subsasgn or subsref

**Syntax** `S = substruct(type1, subs1, type2, subs2, ...)`

**Description** `S = substruct(type1, subs1, type2, subs2, ...)` creates a structure with the fields required by an overloaded `subsref` or `subsasgn` method. Each `type` string must be one of `.'`, `'()`, or `'{'`. The corresponding `subs` argument must be either a field name (for the `.'` type) or a cell array containing the index vectors (for the `'()` or `'{'` types).

**Output Arguments** **S**  
struct with these fields:

- `type`: one of `.'`, `'()`, or `'{'`
- `subs`: subscript values (field name or cell array of index vectors)

**Examples** Call `subsref` with arguments equivalent to the syntax:

```
B = A(3,5).field;
```

where `A` is an object of a class that implements a `subsref` method

Use `substruct` to form the input struct, `S`:

```
S = substruct('()', {3,5}, '.', 'field');
```

Call the class method:

```
B = subsref(A,S);
```

The struct created by `substruct` in this example contains:

```
S(1)
```

```
ans =
```

```
type: '()'  
subs: {[3] [5]}
```

S(2)

ans =

```
type: '.'  
subs: 'field'
```

- “Indexed Reference and Assignment”

# subvolume

---

**Purpose** Extract subset of volume data set

**Syntax**

```
[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)
[Nx,Ny,Nz,Nv] = subvolume(V,limits)
Nv = subvolume(...)
```

**Description** `[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)` extracts a subset of the volume data set `V` using the specified axis-aligned `limits`. `limits = [xmin,xmax,ymin, ymax,zmin,zmax]` (Any NaNs in the limits indicate that the volume should not be cropped along that axis.)

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The subvolume is returned in `NV` and the coordinates of the subvolume are given in `NX`, `NY`, and `NZ`.

`[Nx,Ny,Nz,Nv] = subvolume(V,limits)` assumes the arrays `X`, `Y`, and `Z` are defined as

```
[X,Y,Z] = meshgrid(1:N,1:M,1:P)
```

where `[M,N,P] = size(V)`.

`Nv = subvolume(...)` returns only the subvolume.

## Examples

This example uses a data set that is a collection of MRI slices of a human skull. The data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then a subset of the data is extracted (`subvolume`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with interpolated face color draws the end caps (`FaceColor`, `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).
- A 100-element grayscale colormap provides coloring for the end caps (`colormap`).

- Adding lights to the right and left of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = subvolume(D,[60,80,nan,80,nan,nan]);
p1 = patch(isosurface(x,y,z,D, 5),...
           'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
           'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight right; camlight left; lighting gouraud
```

# subvolume

---

**Purpose**

Sum of array elements

**Syntax**

```
S = sum(A)
S = sum(A,dim)
S = sum( __ , type)
```

**Description**

`S = sum(A)` returns the sum of the elements of `A` along the first array dimension whose size does not equal 1:

- If `A` is a vector, then `sum(A)` returns the sum of the elements.
- If `A` is a nonempty, nonvector matrix, then `sum(A)` treats the columns of `A` as vectors and returns a row vector whose elements are the sums of each column.
- If `A` is an empty 0-by-0 matrix, then `sum(A)` returns 0, a 1-by-1 matrix.
- If `A` is a multidimensional array, then `sum(A)` treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of row vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`S = sum(A,dim)` sums the elements of `A` along dimension `dim`. The `dim` input is a positive integer scalar.

`S = sum( __ , type)` accumulates in and returns an array in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be 'double' or 'native'.

**Input Arguments****A - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**dim - Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `sum(A, 1)` works on successive elements in the columns of A and returns a row vector of the sums of each column.
- `sum(A, 2)` works on successive elements in the rows of A and returns a column vector of the sums of each row.

`sum` returns A if `dim` is greater than `ndims(A)`.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**type - Output class**

'double' | 'native'

Output class, specified as 'double' or 'native', defines the data type that the operation is performed in and returned in.

- If `type` is 'double', then `sum` computes and returns a double-precision array, regardless of the input data type. For example, if A is single,

then `sum` accumulates in and returns in `double`. This is the default behavior for integer data types when `type` is not specified.

- If `type` is `'native'`, `sum` accumulates natively and returns an array with the same data type as the input array `A`. For example, if `A` has data type `int8`, then `sum(A, 'native')` accumulates in and returns in `int8`. This is the default behavior for `single` and `double` data types when `type` is not specified.

### Data Types

`char`

## Output Arguments

### S - Sum array

`scalar` | `vector` | `matrix` | `multidimensional array`

Sum array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of `A` acted on by `sum` has size 1 in `S`.

The class of `S` is as follows:

- If the `type` argument is not used and the input is not `single`, then the output is `double`.
- If the `type` argument is not used and the input is `single`, then the output is `single`.
- If the `type` argument specifies `'double'`, then the output is `double` regardless of the input data type.
- If the `type` argument specifies `'native'`, then the output is the same data type as the input.

## Examples

### Sum of Vector Elements

Create a vector and compute the sum of the elements.

```
A = 1:10;  
S = sum(A)
```

```
S =
```

55

## Sum of Elements in Each Column

Create a 3-by-3 matrix.

A = [1 3 2; 4 2 5; 6 1 4]

A =

1	3	2
4	2	5
6	1	4

Compute the sum of the elements in each column.

S = sum(A)

S =

11	6	11
----	---	----

## Sum of Elements in Each Row

Create a 3-by-3 matrix.

A = [1 3 2; 4 2 5; 6 1 4]

A =

1	3	2
4	2	5
6	1	4

Compute the sum of the elements in each row.

S = sum(A,2)

S =

---

```
6
11
11
```

### Sum of Elements in Each Plane

Create a 4-by-2-by-3 multidimensional array of ones.

```
A = ones(4,2,3)
```

```
A(:,:,1) =
```

```
1 1
1 1
1 1
1 1
```

```
A(:,:,2) =
```

```
1 1
1 1
1 1
1 1
```

```
A(:,:,3) =
```

```
1 1
1 1
1 1
1 1
```

Compute the sum along the third (`dim = 3`) dimension.

```
S = sum(A,3)
```

```
S =
```

## sum

---

```
3 3
3 3
3 3
3 3
```

The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is 1.

### Integer Overflow Due to Output Data Type

Create a vector of signed 8-bit integers and compute the sum of the elements.

```
A = int8(1:20);
S = sum(A)
```

```
S =
```

```
210
```

The output has data type `double` because of default behavior.

```
class(S)
```

```
ans =
```

```
double
```

To keep the same data type in the output as in the input, specify `type` as `'native'`.

```
S = sum(A, 'native')
```

```
S =
```

```
127
```

This disagrees with the double-precision value of 210 because the output has data type `int8` and is saturated.

```
class(S)
```

```
ans =
```

```
int8
```

**See Also**

```
cumsum | diff | isfloat | prod
```

# summary

---

**Purpose** Print summary of table or categorical array

**Syntax** `summary(T)`  
`summary(A)`  
`summary(A,dim)`

**Description** `summary(T)` prints a summary of the table, `T`. The table summary displays the table description from `T.Properties.Description` followed by a summary of the table variables.

`summary(A)` prints a summary of the categorical array, `A`.

- If `A` is a vector, then `summary(A)` displays the category names along with the number of elements in each category (the category counts). Furthermore, the summary contains the number of elements that are undefined.
- If `A` is a matrix, then `summary` treats the columns of `A` as vectors and displays the category counts for each column of `A`.
- If `A` is a multidimensional array, then `summary` acts along the first array dimension whose size does not equal 1.

`summary(A,dim)` prints the category counts of the categorical array, `A`, along dimension `dim`.

For example, you can display the counts of each row in a categorical array using `counts(A,2)`.

## Input Arguments

### **T - Input table**

table

Input table, specified as a table.

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

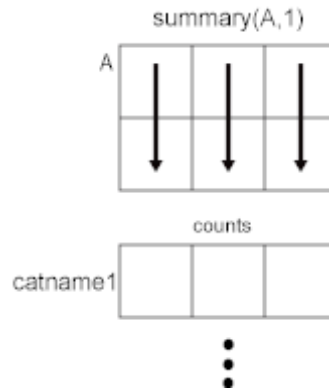

**dim - Dimension of A to operate along**

positive integer scalar

Dimension of A to operate to along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional categorical array, A:

If  $\text{dim} = 1$ , then  $\text{summary}(A, 1)$  displays the category counts for each column of A.

If  $\text{dim} = 2$ , then  $\text{summary}(A, 2)$  returns the category counts of each row of A.

# summary

---

If `dim` is greater than `ndims(A)`, then `summary(A)` returns an array the same size as `A` for each category. `summary` returns 1 for elements in the corresponding category and 0 otherwise.

## Examples

### Summary of Table

Create a table.

```
load patients
BloodPressure = [Systolic Diastolic];
T = table(Gender, Age, Smoker, BloodPressure, 'RowNames', LastName);
```

Add descriptions and units to table T.

```
T.Properties.Description = 'Simulated patient data';
T.Properties.VariableUnits = {'' 'Yrs' '' 'mm Hg'};
T.Properties.VariableDescriptions{4} = 'Systolic/Diastolic';
```

Print a summary of table T.

```
format compact
```

```
summary(T)
```

```
Description: Simulated patient data
Variables:
  Gender: 100x1 cell string
  Age: 100x1 double
      Units: Yrs
      Values:
          min      25
          median   39
          max      50
  Smoker: 100x1 logical
      Values:
          true     34
          false    66
  BloodPressure: 100x2 double
```

```

Units: mm Hg
Description: Systolic/Diastolic
Values:

```

	BloodPressure_1	BloodPressure_2
min	109	68
median	122	81.5
max	138	99

summary displays the minimum, median, and maximum values for each column of the variable BloodPressure.

### Summary of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```

    plane    car    train    car    plane

```

A has three categories, car, plane, and train.

Print a summary of A.

```
summary(A)
```

```

    car    plane    train
     2         2         1

```

car appears in two elements of A, plane appears in two elements, and train appears in one element.

Since A is a row vector, summary lists the occurrences of each category horizontally.

### Summary of Each Column in Categorical Array

Create a 3-by-2 categorical array, A, from a numeric array.

# summary

---

```
X = [1 3; 2 1; 3 1; 4 2];
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical(X,valueset,catnames)
```

```
A =

    red         blue
    green      red
    blue       red
    <undefined> green
```

A has three categories, red, green, and blue. The value, 4, was not included in the valueset input to the categorical function. Therefore, the corresponding element, A(4,1), does not have a corresponding category and is undefined.

Print a summary of A.

```
summary(A)

    red         1     2
    green      1     1
    blue       1     1
    <undefined> 1     0
```

red appears in one element in the first column of A and two in the second column.

green appears in one element in the first column of A and none in the second column.

blue appears in one element in the first column of A and one in the second column.

A contains only one undefined element. It occurs in the first column.

**Category Counts of Each Row in Categorical Array**

Create a 3-by-2 categorical array, A, from a numeric array.

```
A = categorical([1 3; 2 1; 3 1],1:3,{'red' 'green' 'blue'})
```

A =

```

      red      blue
      green    red
      blue     red

```

A has three categories, red, green, and blue.

Print a summary of A along the second dimension.

```
summary(A,2)
```

```

      red      green      blue
      1         0         1
      1         1         0
      1         0         1

```

red appears in one element in the first row of A, one in the second row, and one in the third row.

green appears in only one element. It occurs in the second row of A.

blue appears in one element in the first row of A and one in the third column.

**Definitions****Table Summary**

The table summary displays the table description from `T.Properties.Description` followed by information on the variables of T.

The summary contains the following information on the variables:

## summary

---

- Name: Size and Data Type — variable name from `T.Properties.VariableNames`, the size of the variable, and the data type of the variable.
- Units — variable's units from `T.Properties.VariableUnits`.
- Description — variable's description from `T.Properties.VariableDescriptions`.
- Values — only included for numeric variables, logical variables, or categorical variables.
  - numeric variables — minimum, median, and maximum values.
  - logical variables — number of values that are true and the number of values that are false.
  - categorical variables — number of elements from each category.

**Purpose**

Superclass names

**Syntax**

```
superclasses('ClassName')  
superclasses(obj)  
s = superclasses(...)
```

**Description**

`superclasses('ClassName')` displays the names of all visible superclasses of the MATLAB class with the name *ClassName*. Visible classes have a `Hidden` attribute value of `false` (the default).

`superclasses(obj)` `obj` is an instance of a MATLAB class. `obj` can be either a scalar object or an array of objects.

`s = superclasses(...)` returns the superclass names in a cell array of strings.

**Examples**

Get the name of the `hgsetget` class superclass:

```
superclasses('hgsetget')
```

Superclasses for class `hgsetget`:

```
handle
```

# superiorto

---

**Purpose** Establish superior class relationship

**Syntax** `superiorto('class1', 'class2', ...)`

**Description** `superiorto('class1', 'class2', ...)` establishes that the class invoking this function in its constructor has higher precedence than the classes in the argument list.

The `superiorto` function establishes a precedence that determines which object method MATLAB calls. Use this function only from a constructor that calls the `class` function to create an object. For classes defined with `classdef` statements, see “Class Precedence”.

**Examples** Show function dispatching:

`a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. The constructor method for `class_c` contains the statement `superiorto('class_a')`. Then, either of the following two statements:

```
e = fun(a,c);  
e = fun(c,a);
```

invokes `class_c/fun`.

If you call a function with two objects having an unspecified relationship, MATLAB considers the two objects to have equal precedence. In this case, MATLAB calls the left-most object method. So `fun(b,c)` calls `class_b/fun`, while `fun(c,b)` calls `class_c/fun`.

# surf

---

## Purpose

3-D shaded surface plot

## Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

## Description

`surf(Z)` creates a three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface.

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses  $C$  to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.
