`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a Surfaceplot graphics object.

## Tips

`surf` does not accept complex inputs.

## Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c}
 i-1, j \\
 | \\
 i, j-1 - i, j - i, j+1 \\
 | \\
 i+1, j
 \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way, `[X(:) Y(:) Z(:)]` returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The shading function sets the shading. If the shading is `interp`,  $C$  must be the same size as  $X$ ,  $Y$ , and  $Z$ ; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local

coordinates. If the shading is `faceted` (the default) or `flat`, `C(i,j)` specifies the constant color in the surface patch:

$$\begin{array}{ccc} (i,j) & - & (i,j+1) \\ | & C(i,j) & | \\ (i+1,j) & - & (i+1,j+1) \end{array}$$

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of `XLimMode`, `YLimMode`, and `ZLimMode` axes properties determines the axis labels. You can also set these properties using `axis` function.

The range of `C` or the current setting of the `CLim` and `CLimMode` axes properties determines the color scaling. You can also set the properties using `caxis` function. The scaled color values are indices into the current colormap.

## Examples

Color a sphere with the pattern of +1s and -1s in a Hadamard matrix.

```
k = 5;
n = 2^k-1;
[x,y,z] = sphere(n);
c = hadamard(2^k);
surf(x,y,z,c);
colormap([1 1 0; 0 1 1])
axis equal
```

# surf

---

## Purpose

Contour plot under a 3-D shaded surface plot

## Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

## Description

`surf(Z)` creates a contour plot under the three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface.

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses  $C$  to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a Surfaceplot graphics object.

## Tips

`surf` does not accept complex inputs.

## Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c}
 i-1, j \\
 | \\
 i, j-1 - i, j - i, j+1 \\
 | \\
 i+1, j
 \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way,  $[X(:) Y(:) Z(:)]$  returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The shading function sets the shading. If the shading is `interp`,  $C$  must be the same size as  $X$ ,  $Y$ , and  $Z$ ; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local

coordinates. If the shading is `faceted` (the default) or `flat`, `C(i,j)` specifies the constant color in the surface patch:

$$\begin{array}{ccc} (i,j) & - & (i,j+1) \\ | & C(i,j) & | \\ (i+1,j) & - & (i+1,j+1) \end{array}$$

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties (also set by the `axis` function) determines the axis labels.

The range of `C` or the current setting of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function) determines the color scaling. The scaled color values are used as indices into the current colormap.

## Examples

Display a surface plot and a contour plot of the peaks surface.

```
[X,Y,Z] = peaks(30);  
surf(X,Y,Z)  
colormap hsv
```

Properties

**How To**

- [Representing a Matrix as a Surface](#)
- [Coloring Mesh and Surface Plots](#)

# surf2patch

---

**Purpose** Convert surface data to patch data

**Syntax**

```
fvc = surf2patch(Z)
fvc = surf2patch(Z,C)
fvc = surf2patch(X,Y,Z)
fvc = surf2patch(X,Y,Z,C)
fvc = surf2patch(...,'triangles')
[f,v,c] = surf2patch(...)
```

**Description** `fvc = surf2patch(h)` converts the geometry and color data from the surface object identified by the handle `h` into patch format and returns the face, vertex, and color data in the struct `fvc`. You can pass this struct directly to the `patch` command.

`fvc = surf2patch(Z)` calculates the patch data from the surface's `ZData` matrix `Z`.

`fvc = surf2patch(Z,C)` calculates the patch data from the surface's `ZData` and `CData` matrices `Z` and `C`.

`fvc = surf2patch(X,Y,Z)` calculates the patch data from the surface's `XData`, `YData`, and `ZData` matrices `X`, `Y`, and `Z`.

`fvc = surf2patch(X,Y,Z,C)` calculates the patch data from the surface's `XData`, `YData`, `ZData`, and `CData` matrices `X`, `Y`, `Z`, and `C`.

`fvc = surf2patch(...,'triangles')` creates triangular faces instead of the quadrilaterals that compose surfaces.

`[f,v,c] = surf2patch(...)` returns the face, vertex, and color data in the three arrays `f`, `v`, and `c` instead of a struct.

**Examples** The first example uses the `sphere` command to generate the `XData`, `YData`, and `ZData` of a surface, which is then converted to a patch. Note that the `ZData` (`z`) is passed to `surf2patch` as both the third and fourth arguments — the third argument is the `ZData` and the fourth argument is taken as the `CData`. This is because the `patch` command does not

automatically use the  $z$ -coordinate data for the color data, as does the `surface` command.

Also, because `patch` is a low-level command, you must set the view to 3-D and shading to `faceted` to produce the same results produced by the `surf` command.

```
[x y z] = sphere;  
patch(surf2patch(x,y,z,z));  
shading faceted; view(3)
```

In the second example `surf2patch` calculates face, vertex, and color data from a surface whose handle has been passed as an argument.

```
s = surf(peaks);  
pause  
patch(surf2patch(s));  
delete(s)  
shading faceted; view(3)
```

## See Also

`patch` | `reducepatch` | `shrinkfaces` | `surface` | `surf`

# surface

---

**Purpose** Create surface object

**Syntax**

```
surface(Z)
surface(Z,C)
surface(X,Y,Z)
surface(X,Y,Z,C)
surface(x,y,Z)
surface(... 'PropertyName',PropertyValue,...)
h = surface(...)
```

**Properties** For a list of properties, see `Surface Properties`.

**Description** `surface` is the low-level function for creating surface graphics objects. Surfaces are plots of matrix data created using the row and column indices of each element as the  $x$ - and  $y$ -coordinates and the value of each element as the  $z$ -coordinate.

`surface(Z)` plots the surface specified by the matrix  $Z$ . Here,  $Z$  is a single-valued function, defined over a geometrically rectangular grid.

`surface(Z,C)` plots the surface specified by  $Z$  and colors it according to the data in  $C$  (see "Examples").

`surface(X,Y,Z)` uses  $C = Z$ , so color is proportional to surface height above the  $x$ - $y$  plane.

`surface(X,Y,Z,C)` plots the parametric surface specified by  $X$ ,  $Y$ , and  $Z$ , with color specified by  $C$ .

`surface(x,y,Z)`, `surface(x,y,Z,C)` replaces the first two matrix arguments with vectors and must have `length(x) = n` and `length(y) = m` where `[m,n] = size(Z)`. In this case, the vertices of the surface facets are the triples `(x(j),y(i),Z(i,j))`. Note that  $x$  corresponds to the columns of  $Z$  and  $y$  corresponds to the rows of  $Z$ . For a complete discussion of parametric surfaces, see the `surf` function.

`surface(... 'PropertyName',PropertyValue,...)` follows the  $X$ ,  $Y$ ,  $Z$ , and  $C$  arguments with property name/property value pairs to specify

additional surface properties. For a description of the properties, see `Surface Properties`.

`h = surface(...)` returns a handle to the created surface object.

## Tips

`surface` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds the surface object to the current axes.

If you do not specify separate color data (C), MATLAB uses the matrix (Z) to determine the coloring of the surface. In this case, color is proportional to values of Z. You can specify a separate matrix to color the surface independently of the data defining the area of the surface.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

`surface` provides convenience forms that allow you to omit the property name for the XData, YData, ZData, and CData properties. For example,

```
surface('XData',X,'YData',Y,'ZData',Z,'CData',C)
```

is equivalent to

```
surface(X,Y,Z,C)
```

When you specify only a single matrix input argument,

```
surface(Z)
```

MATLAB assigns the data properties as if you specified

```
surface('XData',[1:size(Z,2)],...  
       'YData',[1:size(Z,1)],...  
       'ZData',Z,...  
       'CData',Z)
```

The axis, `caxis`, `colormap`, `hold`, `shading`, and `view` commands set graphics properties that affect surfaces. You can also set and query

# surface

---

surface property values after creating them using the `set` and `get` commands.

## Examples

This example creates a surface using `peaks` to generate the data, and colors it using the `clown` image. The `ZData` is a 49-by-49 element matrix, while the `CData` is a 200-by-320 matrix. You must set the surface's `FaceColor` to `texturemap` to use `ZData` and `CData` of different dimensions.

```
load clown
surface(peaks,flipud(X),...
        'FaceColor','texturemap',...
        'EdgeColor','none',...
        'CDataMapping','direct')
colormap(map)
view(-35,45)
```

Note the use of the `surface(Z,C)` convenience form combined with property name/property value pairs.

Since the clown data (`X`) is typically viewed with the `image` command, which MATLAB normally displays with 'ij' axis numbering and `direct` `CDataMapping`, this example reverses the data in the vertical direction using `flipud` and sets the `CDataMapping` property to `direct`.

# surface

---

## Setting Default Properties

You can set default surface properties on the axes, figure, and root object levels:

```
set(0, 'DefaultSurfaceProperty', PropertyValue...)  
set(gcf, 'DefaultSurfaceProperty', PropertyValue...)  
set(gca, 'DefaultSurfaceProperty', PropertyValue...)
```

where *Property* is the name of the surface property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the surface properties.

## Tutorials

For examples, see [Representing a Matrix as a Surface](#).

## See Also

## Purpose

Surface properties

## Creating Surface Objects

Use `surface` to create surface objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see [Setting Default Property Values](#).

See “Core Graphics Objects” for general information about this type of object.

## Surface Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`AlphaData`

m-by-n matrix of `double` or `uint8`

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current `alphamap` (`AlphaDataMapping` set to `direct`)

# Surface Properties

---

- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

## `AlphaDataMapping`

`none` | `direct` | `{scaled}`

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data.

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range (the default).
- `scaled` — Transform the `AlphaData` to span the portion of the `alphamap` indicated by the axes `ALim` property, linearly mapping data values to alpha values.
- `direct` — Use the `AlphaData` as indices directly into the `alphamap`. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the `alphamap`, and values greater than `length(alphamap)` to the last alpha value in the `alphamap`. Values with a decimal portion are fixed to the nearest lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the `alphamap`).

## `AmbientStrength`

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the surface `DiffuseStrength` and `SpecularStrength` properties.

## Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this surface object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the surface object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
on	Represent this surface object in a legend (default)
off	Do not include this surface object in a legend
children	Same as on because surface objects do not have children

## Setting the IconDisplayStyle property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

# Surface Properties

---

## Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

`BackFaceLighting`  
`unlit | lit | {reverselit}`

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- `unlit` — Face not lit.
- `lit` — Face lit in normal way.
- `reverselit` — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

`BeingDeleted`  
`on | {off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

`BusyAction`  
`cancel | {queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the surface object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src, evnt)
% src - the object that is the source of the event
```

# Surface Properties

---

```
% evnt - empty for this property
sel_typ = get(gcf,'SelectionType')
switch sel_typ
    case 'normal'
        disp('User clicked left-mouse button')
        set(src,'Selected','on')
    case 'extend'
        disp('User did a shift-click')
        set(src,'Selected','on')
    case 'alt'
        disp('User did a control-click')
        set(src,'Selected','on')
        set(src,'SelectionHighlight','off')
end
end
```

Suppose `h` is the handle of a surface object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## CData

matrix (of type double)

*Vertex colors.* Values that specify the color at every point in `ZData`.

### Mapping CData to a Colormap

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see `caxis`) or interpreted directly as indices into the colormap, depending on the setting of the `CDataMapping` property.

## CData as True Color

True color defines an RGB value for each vertex. If the coordinate data (XData, for example) are contained in  $m$ -by- $n$  matrices, then CData must be an  $m$ -by- $n$ -by-3 array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

## Texturemapping the Surface FaceColor

If you set the FaceColor property to texturemap, CData does not need to be the same size as ZData, but must be of type double or uint8. In this case, MATLAB maps CData to conform to the surface defined by ZData.

CDataMapping  
{scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the surface. (If you use true color specification for CData, this property has no effect.)

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the caxis reference page for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to length(colormap). MATLAB maps values less than 1 to the first color in the colormap, and values greater than length(colormap) to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

Children  
matrix of handles

Always the empty matrix; surface objects have no children.

# Surface Properties

---

**Clipping**  
{on} | off

*Clipping to axes rectangle.* When **Clipping** is on, MATLAB does not display any portion of the surface that is outside the axes rectangle.

**CreateFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a surface object. You must define this property as a default value for surfaces or set the **CreateFcn** property during object creation.

For example, the following statement creates a surface (assuming *x*, *y*, *z*, and *c* are defined), and executes the function referenced by the function handle `@myCreateFcn`.

```
surface(x,y,z,c,'CreateFcn',@myCreateFcn)
```

MATLAB executes this routine after setting all surface properties. Setting this property on an existing surface object has no effect.

The handle of the object whose **CreateFcn** is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root **CallbackObject** property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DeleteFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete surface callback function.* Executes when you delete the surface object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    obj_tp = get(src, 'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src, 'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DiffuseStrength`

scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is 0.6.

# Surface Properties

---

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the surface object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EdgeAlpha`  
{scalar = 1} | flat | interp

*Transparency of the surface edges.*

- scalar — A single non-NaN scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.

- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

## EdgeColor

`{ColorSpec} | none | flat | interp`

*Color of the surface edge.* Determines how MATLAB colors the edges of the individual faces that make up the surface.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (black). See `ColorSpec` for more information on specifying color.
- `none` — Edges not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.

- `interp` — Linear interpolation of the `CData` values at the face vertices determines the edge color.

# Surface Properties

---

## EdgeLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on surface edges.

- none — Lights do not affect the edges of this object.
- flat — The effect of light objects is uniform across each edge of the surface.
- gouraud — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- phong — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase surface objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- normal — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- none — Do not erase the surface when it is moved or destroyed. While the object is still visible on the screen after erasing with EraseMode none, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the surface by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the surface does not damage the color of the objects behind it. However, surface color depends on the color of the screen behind it and is correctly colored only when over the axes background `Color`, or the figure background `Color` if the axes `Color` is none.
- `background` — Erase the surface by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is set to none. This damages objects that are behind the erased object, but surface objects are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### FaceAlpha

`{scalar = 1} | flat | interp | texturemap`

*Transparency of the surface faces.*

- `scalar` — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).

# Surface Properties

---

- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

## `FaceColor`

`ColorSpec` | `none` | `{flat}` | `interp` | `texturemap`

*Color of the surface face.*

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See the `ColorSpec` reference page for more information on specifying color.
- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example.)

## `FaceLighting`

`none` | `{flat}` | `gouraud` | `phong`

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on the surface.

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. This property is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching

# Surface Properties

---

the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the surface can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking on the surface selects the object below it (which might be the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is

the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

# Surface Properties

---

For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of surface edges.*

### Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Edge line width.* The width of the lines in points used to draw surface edges. The default width is 0.5 points. 1 point =  $\frac{1}{72}$  inch.

## Marker

character (see table)

*Marker symbol.* Specifies symbols that are displayed at vertices. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' 'h'	Six-pointed star (hexagram)
'none'	No marker (default)

### MarkerEdgeColor

none | {auto} | flat | ColorSpec

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the EdgeColor property.
- flat — Uses the CData value of the vertex to determine the color of the marker edge.

# Surface Properties

---

- `ColorSpec` — Defines color to use.

`MarkerFaceColor`

`{none} | auto | flat | ColorSpec`

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Uses the axes `Color` for the marker face color.
- `flat` — Uses the `CData` value of the vertex to determine the color of the face.
- `ColorSpec` — Defines a single color to use for all markers on the surface.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MeshStyle`

`{both} | row | column`

*Row and column lines.* Specifies whether to draw all edge lines or just row or column edge lines.

- `both` — Draws edges for both rows and columns.
- `row` — Draws row edges only.
- `column` — Draws column edges only.

## NormalMode

{auto} | manual

*MATLAB generated or user-specified normal vectors.*

- **auto** — MATLAB calculates vertex normals based on the coordinate data
- **manual** — If you specify your own vertex normals, MATLAB sets this property to **manual** and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of axes, hggroup, or hgtransform

*Parent of surface object.* Contains the handle of the surface object's parent. The parent of a surface object is the axes, hggroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays a dashed bounding box around the surface if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing a dashed bounding box around the surface. When `SelectionHighlight` is off, MATLAB does not draw the box.

# Surface Properties

---

**SpecularColorReflectance**  
scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

**SpecularExponent**  
scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

**SpecularStrength**  
scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the surface. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surface object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

**Type**  
string (read-only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For surface objects, Type is always 'surface'.

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the surface.* Assign this property the handle of a uicontextmenu object created in the same figure as the surface. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the surface.

## UserData

matrix

*User-specified data.* Data you want to associate with the surface object. The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## VertexNormals

vector | matrix

*Surface normal vectors.* The vertex normals for the surface. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

## Visible

{on} | off

*Surface object visibility.* By default, all surfaces are visible. When set to off, the surface is not visible, but still exists, and you can query and set its properties.

## XData

vector | matrix

# Surface Properties

---

*X-coordinates.* The  $x$ -position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of columns as `ZData`.

`YData`

vector | matrix

*Y-coordinates.* The  $y$ -position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of rows as `ZData`.

`ZData`

matrix

*Z-coordinates.* The  $z$ -position of the surface data points. See the `Description` section for more information.

## See Also

`surface`

## Purpose

Define surfaceplot properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

Note that you cannot define default properties for surfaceplot objects.

See Plot Objects for information on surfaceplot objects.

## Surfaceplot Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`AlphaData`

m-by-n matrix of `double` or `uint8`

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current `alphamap` (`AlphaDataMapping` set to `direct`)
- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

`AlphaDataMapping`

`none` | `direct` | `{scaled}`

# Surfaceplot Properties

---

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data. Values for this property are:

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range.
- `scaled` — Transform the `AlphaData` to span the portion of the `alphamap` indicated by the axes `ALim` property, linearly mapping data values to alpha values (the default).
- `direct` — Use the `AlphaData` as indices directly into the `alphamap`. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the `alphamap`, and values greater than `length(alphamap)` to the last alpha value in the `alphamap`. Values with a decimal portion are fixed to the nearest, lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the `alphamap`).

`AmbientStrength`

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the `surfaceplot` `DiffuseStrength` and `SpecularStrength` properties.

`Annotation`

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The Annotation property enables you to specify whether this surfaceplot object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the surfaceplot object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
on	Represent this surfaceplot object in a legend (default)
off	Do not include this surfaceplot object in a legend
children	Same as on because surfaceplot objects do not have children

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle hobj to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

# Surfaceplot Properties

---

## BackFaceLighting

unlit | lit | {reverselit}

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- unlit — Face not lit.
- lit — Face lit in normal way.
- reverselit — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

# Surfaceplot Properties

---

## CData

matrix

*Vertex colors.* A matrix containing values that specify the color at every point in ZData. If you set the FaceColor property to texturemap, CData does not need to be the same size as ZData. In this case, MATLAB maps CData to conform to the surfaceplot defined by ZData.

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see caxis) or interpreted directly as indices into the colormap, depending on the setting of the CDataMapping property. Note that any non-texture data passed as an input argument must be of type double.

True color defines an RGB value for each vertex. If the coordinate data (XData, for example) are contained in m-by-n matrices, then CData must be an m-by-n-by-3 array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

## CDataMapping

{scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the surfaceplot. (If you use true color specification for CData, this property has no effect.)

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the caxis reference page for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to length(colormap). MATLAB maps values less than

1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

**CDataMode**  
{auto} | manual

*Use automatic or user-specified color data values.* If you specify `CData`, MATLAB sets this property to `manual` and uses the `CData` values to color the surfaceplot.

If you set `CDataMode` to `auto` after having specified `CData`, MATLAB resets the color data of the surfaceplot to that defined by `ZData`, overwriting any previous values for `CData`.

**CDataSource**  
string (MATLAB variable)

*Link CData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `CData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `CData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

# Surfaceplot Properties

---

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Children**  
matrix of handles

Always the empty matrix; surfaceplot objects have no children.

**Clipping**  
{on} | off

*Clipping to axes rectangle.* When **Clipping** is on, MATLAB does not display any portion of the surfaceplot that is outside the axes rectangle.

**CreateFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where @*CallbackFcn* is a function handle that references the callback function and *graphicfcn* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DiffuseStrength

scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is 0.6.

# Surfaceplot Properties

---

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the surfaceplot object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EdgeAlpha`  
{scalar = 1} | flat | interp

*Transparency of the patch and surface edges.*

- scalar — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.

- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

## `EdgeColor`

`{ColorSpec} | none | flat | interp`

*Color of the surfaceplot edge.* This property determines how MATLAB colors the edges of the individual faces that make up the surface:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default `EdgeColor` is black. See `ColorSpec` for more information on specifying color.
- `none` — Edges are not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.

# Surfaceplot Properties

---

- `interp` — Linear interpolation of the CData values at the face vertices determines the edge color.

## EdgeLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on surfaceplot edges.

- `none` — Lights do not affect the edges of this object.
- `flat` — The effect of light objects is uniform across each edge of the surfaceplot.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

# Surfaceplot Properties

---

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## FaceAlpha

`{scalar = 1} | flat | interp | texturemap`

*Transparency of the surfaceplot faces.* This property can be any of the following:

- `scalar` — A single non-NaN scalar value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).
- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

## FaceColor

`ColorSpec | none | {flat} | interp`

*Color of the surfaceplot face.* This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See `ColorSpec` for more information on specifying color.

- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example for `surface`.)

## FaceLighting

`none` | `{flat}` | `gouraud` | `phong`

*Algorithm used for lighting calculations.* This property selects the algorithm used to calculate the effect of light objects on the surface. Choices are

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## HandleVisibility

`{on}` | `callback` | `off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility`

# Surfaceplot Properties

---

is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## Interruptible

off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

# Surfaceplot Properties

---

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`  
{-} | -- | : | -. | none

*Line style of surfaceplot object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`  
size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

`Marker`  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle

# Surfaceplot Properties

---

Specifier	Marker Type
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ''	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

none | {auto} | flat | ColorSpec

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the EdgeColor property.
- flat — Uses the CData value of the vertex to determine the color of the marker edge.
- ColorSpec — Defines color to use.

## MarkerFaceColor

{none} | auto | flat | ColorSpec

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Uses the axes `Color` for the marker face color.
- `flat` — Uses the `CData` value of the vertex to determine the color of the face.
- `ColorSpec` — Defines a single color to use for all markers on the surfaceplot.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MeshStyle`  
{both} | row | column

*Row and column lines.* Specifies whether to draw all edge lines or just row or column edge lines.

- `both` — Draws edges for both rows and columns.
- `row` — Draws row edges only.
- `column` — Draws column edges only.

`NormalMode`  
{auto} | manual

*MATLAB generated or user-specified normal vectors.*

# Surfaceplot Properties

---

- `auto` — MATLAB calculates vertex normals based on the coordinate data
- `manual` — If you specify your own vertex normals, MATLAB sets this property to `manual` and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of parent axes, `hggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hggroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

## SelectionHighlight

`{on}` | `off`

*Selected objects highlighted.*

- `on` — MATLAB indicates the selected state by drawing a dashed bounding box around the surface.
- `off` — MATLAB does not draw the bounding box except when in plot edit mode and objects are selected manually.

**SpecularColorReflectance**  
scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

**SpecularExponent**  
scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

**SpecularStrength**  
scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the surfaceplot. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surfaceplot object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

# Surfaceplot Properties

---

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For surfaceplot objects, `Type` is always the string `'surface'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## VertexNormals

vector | matrix

*Surfaceplot normal vectors.* Contains the vertex normals for the surfaceplot. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even

if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

vector | matrix

*X-coordinates.* The *x*-position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of columns as ZData.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the *x*-axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

# Surfaceplot Properties

---

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

vector | matrix

*Y-coordinates.* The *y*-position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of rows as `ZData`.

## YDataMode

{auto} | manual

*Use automatic or user-specified y-axis values.* If you specify `XData`, MATLAB sets this property to `manual`.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the *y*-axis ticks and *y*-tick labels to the row indices of the `ZData`, overwriting any previous values for `YData`.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

matrix

*Z-coordinates.* The *z*-position of the surfaceplot data points. See the Description section for more information.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the ZData. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's

# Surfaceplot Properties

---

ZDataSource does not change the object's ZData values, but you can use refreshdata to force an update of the object's data. refreshdata also lets you specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose**

Surface plot with colormap-based lighting

**Syntax**

```
surf1(Z)
surf1(...,'light')
surf1(...,s)
surf1(X,Y,Z,s,k)
h = surf1(...)
```

**Description**

The `surf1` function displays a shaded surface based on a combination of ambient, diffuse, and specular lighting models.

`surf1(Z)` and `surf1(X,Y,Z)` create three-dimensional shaded surfaces using the default direction for the light source and the default lighting coefficients for the shading model.  $X$ ,  $Y$ , and  $Z$  are vectors or matrices that define the  $x$ ,  $y$ , and  $z$  components of a surface.

`surf1(...,'light')` produces a colored, lighted surface using a MATLAB light object. This produces results different from the default lighting method, `surf1(...,'cdata')`, which changes the color data for the surface to be the reflectance of the surface.

`surf1(...,s)` specifies the direction of the light source.  $s$  is a two- or three-element vector that specifies the direction from a surface to a light source.  $s = [sx\ sy\ sz]$  or  $s = [azimuth\ elevation]$ . The default  $s$  is  $45^\circ$  counterclockwise from the current view direction.

`surf1(X,Y,Z,s,k)` specifies the reflectance constant.  $k$  is a four-element vector defining the relative contributions of ambient light, diffuse reflection, specular reflection, and the specular shine coefficient.  $k = [ka\ kd\ ks\ shine]$  and defaults to  $[.55, .6, .4, 10]$ .

`h = surf1(...)` returns a handle to a surface graphics object.

## Tips

surf1 does not accept complex inputs.

For smoother color transitions, use colormaps that have linear intensity variations (e.g., gray, copper, bone, pink).

The ordering of points in the X, Y, and Z matrices defines the inside and outside of parametric surfaces. If you want the opposite side of the surface to reflect the light source, use `surf1(X',Y',Z')`. Because of the way surface normal vectors are computed, surf1 requires matrices that are at least 3-by-3.

## Examples

View peaks using colormap-based lighting.

```
[x,y] = meshgrid(-3:1/8:3);  
z = peaks(x,y);  
surf1(x,y,z);  
shading interp  
colormap(gray);  
axis([-3,3,-3,3,-8,8])
```

To plot a lighted surface from a view direction other than the default,

```
view([10 10])  
grid on  
hold on  
surf(peaks)  
shading interp  
colormap copper  
hold off
```

# surfl

---

**See Also** [colormap](#) | [shading](#) | [light](#)

**Purpose** Compute and display 3-D surface normals

**Syntax**

```
surfnorm(Z)
surfnorm(X,Y,Z)
surfnorm(axes_handle, ___)
surfnorm( ___,Name,Value)
[Nx,Ny,Nz] = surfnorm( ___)
```

**Description**

`surfnorm(Z)` plots a surface of the matrix `Z` with `surf` and displays its surface normals as radiating vectors.

`surfnorm(X,Y,Z)` plots a surface and its surface normals from the vectors or matrices `X`, `Y`, and matrix `Z`. `X`, `Y`, and `Z` must be the same size.

`surfnorm(axes_handle, ___)` plots into `axes_handle` instead of `gca` and it can include any of the input arguments in previous syntaxes.

`surfnorm( ___,Name,Value)` can be used to set the value of the specified `Surface Properties`.

`[Nx,Ny,Nz] = surfnorm( ___)` returns the components of the 3-D surface normals for the surface without plotting the surface or surface normals.

- Tips**
- `surfnorm` does not accept complex inputs.
  - Reverse the direction of the normals by calling `surfnorm` with transposed arguments:  
  
`surfnorm(X',Y',Z')`
  - The surface normals represent conditions at vertices and are not normalized. Normals for surface elements that face away from the viewer do not display.
  - `surf1` uses `surfnorm` to compute surface normals when calculating the reflectance of a surface.

# surfnorm

---

## Input Arguments

### **Z**

2-D array of real numbers representing a surface

### **X**

2-D array of real numbers that defines the  $x$  component of the surface grid

### **Y**

2-D array of real numbers that defines the  $y$  component of the surface grid

### **axes\_handle**

Handle to the target axes in which to plot the surface

If you do not specify `axes_handle`, MATLAB uses current axes.

### **Name,Value**

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `'` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Property names and values of the surface object

See `Surface Properties` for description of property names and values.

## Output Arguments

### **[Nx,Ny,Nz]**

$x$ ,  $y$ , and  $z$  components of the three-dimensional surface normals for the surface

## Definitions

### **Surface Normal**

An imaginary line perpendicular to a flat surface or perpendicular to the tangent plane at a point on a non-flat surface

**Examples**

Plot the normal vectors for a truncated cone.

```
[x,y,z] = cylinder(1:10);  
surfnorm(x,y,z)  
axis([-12 12 -12 12 -0.1 1])
```

Get normal vectors of an expression representing a surface.

## surfnorm

---

```
[nx, ny, nz] = surfnorm(peaks);
```

Assign these normals to the `VertexNormals` property. MATLAB uses these normals to calculate the surface lighting. Set the surface `FaceLighting` to `gouraud`, using the `lighting` function:

```
b = reshape([nx ny nz], 49,49,3);  
% Create a plain surface of size equal to peaks.  
surf(ones(49), 'VertexNormals', b, 'EdgeColor', 'none')  
% Set lighting algorithm to gouraud  
lighting gouraud  
% Add a light  
camlight
```

## Algorithms

After performing a bicubic fit of the data in the  $x$ ,  $y$ , and  $z$  directions, diagonal vectors are computed and crossed to form the normal at each vertex.

`surf` | `quiver3` | `surface` | `isonormals` | `surf1`

# svd

---

**Purpose** Singular value decomposition

**Syntax**

```
s = svd(X)
[U,S,V] = svd(X)
[U,S,V] = svd(X,0)
[U,S,V] = svd(X,'econ')
```

**Description** The svd command computes the matrix singular value decomposition.

`s = svd(X)` returns a vector of singular values.

`[U,S,V] = svd(X)` produces a diagonal matrix **S** of the same dimension as **X**, with nonnegative diagonal elements in decreasing order, and unitary matrices **U** and **V** so that  $X = U*S*V'$ .

`[U,S,V] = svd(X,0)` produces the “economy size” decomposition. If **X** is *m*-by-*n* with  $m > n$ , then `svd` computes only the first *n* columns of **U** and **S** is *n*-by-*n*.

`[U,S,V] = svd(X,'econ')` also produces the “economy size” decomposition. If **X** is *m*-by-*n* with  $m \geq n$ , it is equivalent to `svd(X,0)`. For  $m < n$ , only the first *m* columns of **V** are computed and **S** is *m*-by-*m*.

## Examples

For the matrix

```
X =
     1     2
     3     4
     5     6
     7     8
```

the statement

```
[U,S,V] = svd(X)
```

produces

```
U =
-0.1525   -0.8226   -0.3945   -0.3800
```

```

-0.3499  -0.4214   0.2428   0.8007
-0.5474  -0.0201   0.6979  -0.4614
-0.7448   0.3812  -0.5462   0.0407

```

```

S =
  14.2691    0
         0   0.6268
         0    0
         0    0

```

```

V =
-0.6414   0.7672
-0.7672  -0.6414

```

The economy size decomposition generated by

```
[U,S,V] = svd(X,0)
```

produces

```

U =
-0.1525  -0.8226
-0.3499  -0.4214
-0.5474  -0.0201
-0.7448   0.3812

```

```

S =
  14.2691    0
         0   0.6268

```

```

V =
-0.6414   0.7672
-0.7672  -0.6414

```

## Diagnostics

If the limit of 75 QR step iterations is exhausted while seeking a singular value, this message appears:

```
Solution will not converge.
```

# svds

**Purpose** Find singular values and vectors

**Syntax**

```
s = svds(A)
s = svds(A,k)
s = svds(A,k,sigma)
s = svds(A,k,'L')
s = svds(A,k,sigma,options)
[U,S,V] = svds(A,...)
[U,S,V,flag] = svds(A,...)
```

**Description** `s = svds(A)` computes the six largest singular values and associated singular vectors of matrix A. If A is m-by-n, `svds(A)` manipulates eigenvalues and vectors returned by `eigs(B)`, where `B = [sparse(m,m) A; A' sparse(n,n)]`, to find a few singular values and vectors of A. The positive eigenvalues of the symmetric matrix B are the same as the singular values of A.

`s = svds(A,k)` computes the k largest singular values and associated singular vectors of matrix A.

`s = svds(A,k,sigma)` computes the k singular values closest to the scalar shift sigma. For example, `s = svds(A,k,0)` computes the k smallest singular values and associated singular vectors.

`s = svds(A,k,'L')` computes the k largest singular values (the default).

`s = svds(A,k,sigma,options)` sets some parameters (see `eigs`):

## Option Structure Fields and Descriptions

Field name	Parameter	Default
<code>options.tol</code>	Convergence tolerance: $\text{norm}(AV-US,1) \leq \text{tol} * \text{norm}(A,1)$	1e-10
<code>options.maxit</code>	Maximum number of iterations	300
<code>options.disp</code>	Number of values displayed each iteration	0

`svds` checks the accuracy of the computed singular vectors. If the vectors they are not accurate enough returns fewer singular values than requested. To obtain the requested number of singular values, try decreasing the error tolerance in the options structure.

`[U,S,V] = svds(A,...)` returns three output arguments, and if `A` is `m`-by-`n`:

- `U` is `m`-by-`k` with orthonormal columns
- `S` is `k`-by-`k` diagonal
- `V` is `n`-by-`k` with orthonormal columns
- `U*S*V'` is the closest rank `k` approximation to `A`

`[U,S,V,flag] = svds(A,...)` returns a convergence flag. If `eigs` converged, then `norm(A*V-U*S,1) <= tol*norm(A,1)` and `flag` is 0. If `eigs` did not converge, then `flag` is 1.

---

**Note** `svds` is best used to find a few singular values of a large, sparse matrix. To find all the singular values of such a matrix, `svd(full(A))` will usually perform better than `svds(A,min(size(A)))`.

---

## Algorithms

`svds(A,k)` uses `eigs` to find the `k` largest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`.

`svds(A,k,0)` uses `eigs` to find the `2k` smallest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`, and then selects the `k` positive eigenvalues and their eigenvectors.

## Examples

`west0479` is a real 479-by-479 sparse matrix. `svd` calculates all 479 singular values. `svds` picks out the largest and smallest singular values.

```
load west0479
s = svd(full(west0479))
s1 = svds(west0479,4)
ss = svds(west0479,6,0)
```

# svds

These plots show some of the singular values of west0479 as computed by svd and svds.

The largest singular value of west0479 can be computed a few different ways:

```
svds(west0479,1) =  
 3.189517598808622e+05  
max(svd(full(west0479))) =  
 3.18951759880862e+05  
norm(full(west0479)) =  
 3.189517598808623e+05
```

and estimated:

```
normest(west0479) =  
 3.189385666549991e+05
```

svd | eigs

**Purpose** Swap byte ordering

**Syntax** `Y = swapbytes(X)`

**Description** `Y = swapbytes(X)` reverses the byte ordering of each element in array `X`, converting little-endian values to big-endian (and vice versa). The input array must contain all full, noncomplex, numeric elements.

**Examples** **Example 1**

Reverse the byte order for a scalar 32-bit value, changing hexadecimal 12345678 to 78563412:

```
A = uint32(hex2dec('12345678'));
```

```
B = dec2hex(swapbytes(A))
```

```
B =
    78563412
```

**Example 2**

Reverse the byte order for each element of a 1-by-4 matrix:

```
X = uint16([0 1 128 65535])
```

```
X =
    0         1    128  65535
```

```
Y = swapbytes(X);
```

```
Y =
    0    256  32768  65535
```

Examining the output in hexadecimal notation shows the byte swapping:

```
format hex
```

```
X, Y
```

```
X =
    0000  0001  0080  ffff
```

# swapbytes

---

```
Y =  
    0000    0100    8000    ffff
```

## Example 3

Create a three-dimensional array A of 16-bit integers and then swap the bytes of each element:

```
format hex
```

```
A = uint16(magic(3) * 150);  
A(:,:,2) = A * 40;
```

```
A  
A(:,:,1) =  
    04b0    0096    0384  
    01c2    02ee    041a  
    0258    0546    012c  
A(:,:,2) =  
    bb80    1770    8ca0  
    4650    7530    a410  
    5dc0    d2f0    2ee0
```

```
swapbytes(A)  
ans(:,:,1) =  
    b004    9600    8403  
    c201    ee02    1a04  
    5802    4605    2c01  
ans(:,:,2) =  
    80bb    7017    a08c  
    5046    3075    10a4  
    c05d    f0d2    e02e
```

## See Also

`typecast`

**Purpose** Switch among several cases based on expression

**Syntax**

```
switch switch_expression
    case case_expression
        statements
    case case_expression
        statements
    ...
    otherwise
        statements
end
```

**Description** A switch block conditionally executes one set of statements from several choices. Each choice is a case.

An evaluated *switch\_expression* is a scalar or string. An evaluated *case\_expression* is a scalar, a string, or a cell array of scalars or strings. The switch block tests each case until one of the cases is true. A case is true when:

- For numbers, `eq(case_expression,switch_expression)`.
- For strings, `strcmp(case_expression,switch_expression)`.
- For objects that support the eq function, `eq(case_expression,switch_expression)`.
- For a cell array *case\_expression*, at least one of the elements of the cell array matches *switch\_expression*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the switch block.

*otherwise* is optional, and executes only when no case is true.

**Tips**

- Unlike the C language switch statement, the MATLAB switch does not fall through. If the first case statement is true, the other case

# switch/case/otherwise

---

statements do not execute. Do not use a `break` statement within a `switch` block.

- A *case\_expression* cannot include relational operators such as `<` or `>` to compare against the *switch\_expression*. To test for inequality, use `if-elseif` statements.
- Because MATLAB executes only one case of any `switch` statement, variables defined within one `case` are not available for other cases. For example, if your current workspace does not contain a variable `x`, only cases that define `x` can use it:

```
switch choice
    case 1
        x = -pi:0.01:pi;
    case 2
        % does not know anything about x
end
```

## Examples

Conditionally display different text depending on a value entered at the command line:

```
mynumber = input('Enter a number:');
```

```
switch mynumber
    case -1
        disp('negative one');
    case 0
        disp('zero');
    case 1
        disp('positive one');
    otherwise
        disp('other value');
end
```

---

Decide which plot to create based on the value of the string `plottype`:

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
    case 'bar'
        bar(x)
        title('Bar Graph')
    case {'pie', 'pie3'}
        pie3(x)
        title('Pie Chart')
        legend('First', 'Second', 'Third')
    otherwise
        warning('Unexpected plot type. No plot created.');
```

---

In MATLAB switch blocks, only the first matching case executes:

```
result = 52;

switch(result)
    case 52
        disp('result is 52')
    case {52, 78}
        disp('result is 52 or 78')
end
```

This code returns

```
result is 52
```

end | for | if | while

# symamd

---

**Purpose** Symmetric approximate minimum degree permutation

**Syntax**  
`p = symamd(S)`  
`p = symamd(S,knobs)`  
`[p,stats] = symamd(...)`

**Description** `p = symamd(S)` for a symmetric positive definite matrix `S`, returns the permutation vector `p` such that `S(p,p)` tends to have a sparser Cholesky factor than `S`. To find the ordering for `S`, `symamd` constructs a matrix `M` such that `spones(M'*M) = spones(S)`, and then computes `p = colamd(M)`. The `symamd` function may also work well for symmetric indefinite matrices.

`S` must be square; only the strictly lower triangular part is referenced.

`p = symamd(S,knobs)` where `knobs` is a scalar. If `S` is `n`-by-`n`, rows and columns with more than `knobs*n` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs = spparms('wh_frac')`.

`[p,stats] = symamd(...)` produces the optional vector `stats` that provides data about the ordering and the validity of the matrix `S`.

<code>stats(1)</code>	Number of dense or empty rows ignored by <code>symamd</code>
<code>stats(2)</code>	Number of dense or empty columns ignored by <code>symamd</code>
<code>stats(3)</code>	Number of garbage collections performed on the internal data structure used by <code>symamd</code> (roughly of size $8.4 * \text{nnz}(\text{tril}(S, -1)) + 9n$ integers)
<code>stats(4)</code>	0 if the matrix is valid, or 1 if invalid
<code>stats(5)</code>	Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists
<code>stats(6)</code>	Last seen duplicate or out-of-order row index in the column index given by <code>stats(5)</code> , or 0 if no such row index exists
<code>stats(7)</code>	Number of duplicate and out-of-order row indices

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `symamd`. For this reason, `symamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `symamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `symamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `symamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a symmetric elimination tree post-ordering.

## Examples

Here is a comparison of reverse Cuthill-McKee and minimum degree on the Bucky ball example mentioned in the `symrcm` reference page.

```
B = bucky+4*speye(60);
r = symrcm(B);
p = symamd(B);
R = B(r,r);
S = B(p,p);
subplot(2,2,1), spy(R,4), title('B(r,r)')
subplot(2,2,2), spy(S,4), title('B(s,s)')
subplot(2,2,3), spy(chol(R),4), title('chol(B(r,r))')
subplot(2,2,4), spy(chol(S),4), title('chol(B(s,s))')
```

Even though this is a very small problem, the behavior of both orderings is typical. RCM produces a matrix with a narrow bandwidth which fills in almost completely during the Cholesky factorization. Minimum degree produces a structure with large blocks of contiguous zeros which do not fill in during the factorization. Consequently, the minimum degree ordering requires less time and storage for the factorization.

## References

The authors of the code for `symamd` are Stefan I. Larimore and Timothy A. Davis ([davis@cise.ufl.edu](mailto:davis@cise.ufl.edu)), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National Laboratory.

`colamd` | `colperm` | `spparms` | `symrcm` | `amd`

# symbfact

---

**Purpose** Symbolic factorization analysis

**Syntax**

```
count = symbfact(A)
count = symbfact(A, 'sym')
count = symbfact(A, 'col')
count = symbfact(A, 'row')
count = symbfact(A, 'lo')
[count,h,parent,post,R] = symbfact(...)
[count,h,parent,post,L] = symbfact(A,type,'lower')
```

**Description**

`count = symbfact(A)` returns the vector of row counts of  $R=\text{chol}(A)$ . `symbfact` should be much faster than `chol(A)`.

`count = symbfact(A, 'sym')` is the same as `count = symbfact(A)`.

`count = symbfact(A, 'col')` returns row counts of  $R=\text{chol}(A'*A)$  (without forming it explicitly).

`count = symbfact(A, 'row')` returns row counts of  $R=\text{chol}(A*A')$ .

`count = symbfact(A, 'lo')` is the same as `count = symbfact(A)` and uses `tril(A)`.

`[count,h,parent,post,R] = symbfact(...)` has several optional return values.

The flop count for a subsequent Cholesky factorization is `sum(count.^2)`

Return Value	Description
h	Height of the elimination tree
parent	The elimination tree itself
post	Postordering of the elimination tree
R	0-1 matrix having the structure of <code>chol(A)</code> for the symmetric case, <code>chol(A'*A)</code> for the 'col' case, or <code>chol(A*A')</code> for the 'row' case.

`symbfact(A)` and `symbfact(A, 'sym')` use the upper triangular part of  $A$  (`triu(A)`) and assume the lower triangular part is the transpose of the upper triangular part. `symbfact(A, 'lo')` uses `tril(A)` instead.

`[count,h,parent,post,L] = symbfact(A,type,'lower')` where `type` is one of `'sym'`, `'col'`, `'row'`, or `'lo'` returns a lower triangular symbolic factor  $L=R'$ . This form is quicker and requires less memory.

# symmlq

---

## Purpose

Symmetric LQ method

## Syntax

```
x = symmlq(A,b)
symmlq(A,b,tol)
symmlq(A,b,tol,maxit)
symmlq(A,b,tol,maxit,M)
symmlq(A,b,tol,maxit,M1,M2)
symmlq(A,b,tol,maxit,M1,M2,x0)
[x,flag] = symmlq(A,b,...)
[x,flag,relres] = symmlq(A,b,...)
[x,flag,relres,iter] = symmlq(A,b,...)
[x,flag,relres,iter,resvec] = symmlq(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)
```

## Description

`x = symmlq(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should also be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `symmlq` converges, a message to that effect is displayed. If `symmlq` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`symmlq(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `symmlq` uses the default,  $1e-6$ .

`symmlq(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `symmlq` uses the default,  $\min(n,20)$ .

`symmlq(A,b,tol,maxit,M)` and `symmlq(A,b,tol,maxit,M1,M2)` use the symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(\text{sqrt}(M))*A*\text{inv}(\text{sqrt}(M))*y =$

$\text{inv}(\text{sqrt}(M)) * b$  for  $y$  and then return  $x = \text{in}(\text{sqrt}(M)) * y$ . If  $M$  is  $[]$  then `symmlq` applies no preconditioner.  $M$  can be a function handle `mfun` such that `mfun(x)` returns  $M \backslash x$ .

`symmlq(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is  $[]$ , then `symmlq` uses the default, an all-zero vector.

`[x,flag] = symmlq(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>symmlq</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>symmlq</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	<code>symmlq</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>symmlq</code> became too small or too large to continue computing.
5	Preconditioner $M$ was not symmetric positive definite.

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = symmlq(A,b,...)` also returns the relative residual  $\text{norm}(b - A * x) / \text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = symmlq(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = symmlq(A,b,...)` also returns a vector of estimates of the `symmlq` residual norms at each iteration, including  $\text{norm}(b - A * x_0)$ .

`[x,flag,relres,iter,resvec,resvecg] = symmlq(A,b,...)` also returns a vector of estimates of the conjugate gradients residual norms at each iteration.

## Examples

### Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50; M1 = spdiags(4*on,0,n,n);

x = symmlq(A,b,tol,maxit,M1);
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

### Example 2

This example replaces the matrix  $A$  in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in the function `run_symmlq` that:

- Calls `symmlq` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_symmlq` are available to `afun`.

The following shows the code for `run_symmlq`:

```
function x1 = run_symmlq
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = symmlq(@afun,b,tol,maxit,M1);

function y = afun(x)
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
```

```

        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
    end
end

```

When you enter

```
x1=run_symmlq;
```

MATLAB software displays the message

```

symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015

```

### Example 3

Use a symmetric indefinite matrix that fails with pcg.

```

A = diag([20:-1:1,-1:-1:-20]);
b = sum(A,2);           % The true solution is the vector of all ones.
x = pcg(A,b);          % Errors out at the first iteration.
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1

```

However, symmlq can handle the indefinite matrix A.

```

x = symmlq(A,b,1e-6,40);
symmlq converged at iteration 39 to a solution with relative
residual 1.3e-007

```

`function_handle` | `mldivide`

<b>Purpose</b>	Sparse reverse Cuthill-McKee ordering
<b>Syntax</b>	<code>r = symrcm(S)</code>
<b>Description</b>	<p><code>r = symrcm(S)</code> returns the symmetric reverse Cuthill-McKee ordering of <code>S</code>. This is a permutation <code>r</code> such that <code>S(r,r)</code> tends to have its nonzero elements closer to the diagonal. This is a good reordering for LU or Cholesky factorization of matrices that come from long, skinny problems. The ordering works for both symmetric and nonsymmetric <code>S</code>.</p> <p>For a real, symmetric sparse matrix, <code>S</code>, the eigenvalues of <code>S(r,r)</code> are the same as those of <code>S</code>, but <code>eig(S(r,r))</code> probably takes less time to compute than <code>eig(S)</code>.</p>
<b>Algorithms</b>	The algorithm first finds a pseudoperipheral vertex of the graph of the matrix. It then generates a level structure by breadth-first search and orders the vertices by decreasing distance from the pseudoperipheral vertex. The implementation is based closely on the SPARSPAK implementation described by George and Liu.
<b>Examples</b>	<p>The statement</p> <pre>B = bucky;</pre> <p>uses a function in the <code>demos</code> toolbox to generate the adjacency graph of a truncated icosahedron. This is better known as a soccer ball, a Buckminster Fuller geodesic dome (hence the name <code>bucky</code>), or, more recently, as a 60-atom carbon molecule. There are 60 vertices. The vertices have been ordered by numbering half of them from one hemisphere, pentagon by pentagon; then reflecting into the other hemisphere and gluing the two halves together. With this numbering, the matrix does not have a particularly narrow bandwidth, as the first spy plot shows</p> <pre>subplot(1,2,1),spy(B),title('B')</pre> <p>The reverse Cuthill-McKee ordering is obtained with</p>

```
p = symrcm(B);  
R = B(p,p);
```

The spy plot shows a much narrower bandwidth.

```
subplot(1,2,2), spy(R), title('B(p,p)')
```

This example is continued in the reference pages for `symamd`.

The bandwidth can also be computed with

```
[i,j] = find(B);  
bw = max(i-j) + 1;
```

The bandwidths of `B` and `R` are 35 and 12, respectively.

`colamd` | `colperm` | `symamd`

**Purpose** Determine symbolic variables in expression

**Syntax** `symvar 'expr'`  
`s = symvar('expr')`

**Description** `symvar 'expr'` searches the expression, `expr`, for identifiers other than `i`, `j`, `pi`, `inf`, `nan`, `eps`, and common functions. `symvar` displays those variables that it finds or, if no such variable exists, displays an empty cell array, `{}`.

`s = symvar('expr')` returns the variables in a cell array of strings, `s`. If no such variable exists, `s` is an empty cell array.

**Examples** `symvar` finds variables `beta1` and `x`, but skips `pi` and the `cos` function.

```
symvar 'cos(pi*x - beta1)'
```

```
ans =
```

```
    'beta1'
```

```
    'x'
```

**See Also** `strfind`

**Purpose** Two ways to call MATLAB functions

**Description** You can call MATLAB functions using either *command syntax* or *function syntax*, as described below.

## **Command Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by spaces:

```
functionname arg1 arg2 ... argn
```

Command syntax does not allow you to obtain any values that might be returned by the function. Attempting to assign output from the function to a variable using command syntax generates an error. Use function syntax instead.

Examples of command syntax:

```
save mydata.mat x y z
import java.awt.Button java.lang.String
```

Arguments are treated as string literals. See the examples below, under “Argument Passing” on page 1-6183.

## **Function Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by commas and enclosed in parentheses:

```
functionname(arg1, arg2, ..., argn)
```

You can assign the output of the function to one or more output values. When assigning to more than one output variable, separate the variables by commas or spaces and enclose them in square brackets ([ ]):

```
[out1,out2,...,outn] = functionname(arg1, arg2, ..., argn)
```

Examples of function syntax:

```
copyfile('srcfile', '..\mytests', 'writable')
[x1,x2,x3,x4] = deal(A{:})
```

Arguments are passed to the function by value. See the examples below, under “Argument Passing” on page 1-6183.

### Argument Passing

When calling a function using command syntax, MATLAB passes the arguments as string literals. When using function syntax, arguments are passed by value.

In the following example, assign a value to A and then call `disp` on the variable to display the value passed. Calling `disp` with command syntax passes the variable name, 'A':

```
A = pi;
disp A
    A
```

while function syntax passes the value assigned to A:

```
A = pi;
disp(A)
    3.1416
```

The next example passes two strings to `strcmp` for comparison. Calling the function with command syntax compares the variable names, 'str1' and 'str2':

```
str1 = 'one';    str2 = 'one';
strcmp str1 str2
ans =
    0           (unequal)
```

while function syntax compares the values assigned to the variables, 'one' and 'one':

```
str1 = 'one';    str2 = 'one';
strcmp(str1, str2)
```

```
ans =  
    1      (equal)
```

## Passing Strings

When using the function syntax to pass a string literal to a function, you must enclose the string in single quotes, ('string'). For example, to create a new folder called `myapptests`, use

```
mkdir('myapptests')
```

On the other hand, variables that contain strings do not need to be enclosed in quotes:

```
folder = 'myapptests';  
mkdir(folder)
```

`mlint`

## How To

- “Check Code for Errors and Warnings”

---

<b>Purpose</b>	Execute operating system command and return output
<b>Syntax</b>	<pre>status = system(command) [status,cmdout] = system(command) [status,cmdout] = system(command, '-echo')</pre>
<b>Description</b>	<p><code>status = system(command)</code> calls the operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the <code>status</code> variable.</p> <p><code>[status,cmdout] = system(command)</code> additionally returns the output of the command to <code>cmdout</code>. This syntax is most useful for commands that do not require user input, such as <code>dir</code>.</p> <p><code>[status,cmdout] = system(command, '-echo')</code> additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.</p>
<b>Input Arguments</b>	<p><b>command - Operating system command</b> string</p> <p>Operating system command, specified as a string. The command executes in a system shell, which might not be the shell from which you launched MATLAB.</p> <p><b>Example:</b> 'dir'</p> <p><b>Example:</b> 'ls'</p>
<b>Output Arguments</b>	<p><b>status - Command exit status</b> 0   nonzero integer</p> <p>Command exit status, returned as either 0 or a nonzero integer. When the command is successful, <code>status</code> is 0. Otherwise, <code>status</code> is a nonzero integer.</p>

- If command includes the ampersand character (&), then status is the exit status upon command launch.
- If command does not include the ampersand character (&), then status is the exit status upon command completion.

## **cmdout - Output of operating system command**

string

Output of the operating system command, returned as a string.

## **Examples**

### **Display Windows Operating System Command Status and Output**

On a Windows system, display the current folder using the cd command.

```
command = 'cd';  
[status,cmdout] = system(command)
```

```
status =  
    0  
cmdout =  
C:\matlab\myfiles
```

A status of zero indicates that the command completed successfully. MATLAB returns a string containing the current folder in cmdout.

### **Save UNIX Command Exit Status and Output**

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';  
[status,cmdout] = system(command);  
status
```

```
status =  
    0
```

---

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

## Limitations

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `system` with a DOS command that relies on the current folder fails. To work around this limitation, change the folder to a mapped drive before calling `system`.

## Algorithms

On UNIX, MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

## Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the command argument (for example, `'notepad &'` on a Windows platform, or `'emacs &'` on UNIX). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note** If command includes the trailing `&` character, `cmdout` is empty.

---

- On a UNIX system, the `system` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while the `system` function executes. This can lead to corrupted output when `system` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

## **Concepts**

- “Running External Commands, Scripts, and Programs”

---

<b>Purpose</b>	Create table from workspace variables
<b>Syntax</b>	<pre>T = table(var1,...,varN) T = table(var1,...,varN,Name,Value) T = table</pre>
<b>Description</b>	<p><code>T = table(var1,...,varN)</code> creates a table from the input variables, <code>var1,...,varN</code>. Variables can be of different sizes and data types, but all variables must have the same number of rows.</p> <p>If the inputs are workspace variables, <code>table</code> uses the workspace variable names as variable names for the table. Otherwise, <code>table</code> uses strings of the form <code>'Var1',...,'VarN'</code> where <code>N</code> is the number of variables.</p> <p>For more information on creating and using the <code>table</code> data type, see “Tables”.</p> <p><code>T = table(var1,...,varN,Name,Value)</code> includes additional options specified by one or more <code>Name,Value</code> pair arguments.</p> <p>For example, you can specify row names or variable names to include in the table.</p> <p><code>T = table</code> creates an empty 0-by-0 table.</p>
<b>Input Arguments</b>	<p><b>var1,...,varN - Input variables</b> arrays with the same number of rows</p> <p>Input variables, specified as arrays with the same number of rows. The input variables can be of different sizes and different data types.</p> <p>Common input variables are numeric arrays, logical arrays, character arrays, structure arrays, or cell arrays. Furthermore, input variables can be objects that are arrays that support indexing of the form <code>var(index1,...,indexN)</code>, where <code>index1</code> is a numeric or logical vector that corresponds to rows of the variable <code>var</code>. In addition, the array must implement a <code>vertcat</code> method and a <code>size</code> method with a <code>dim</code> argument.</p>

# table

---

**Example:** `table([1:4]', ones(4,3,2), eye(4,2))` creates a table from variables with 4 rows, but different sizes.

**Example:** `table([1:3]', {'one'; 'two'; 'three'}, ['A'; 'B'; 'C'])` creates a table from variables with 3 rows, but different data types.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** `'RowNames', {'row1', 'row2', 'row3'}` names the rows `row1`, `row2`, and `row3`.

### **'RowNames' - Row names**

`{}` (default) | cell array of nonempty, distinct strings

Row names, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows in the table.

### **'VariableNames' - Variable names**

cell array of nonempty, distinct strings

Variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables.

If the input variables, `var1`, ..., `varN`, are valid MATLAB identifiers, `table` uses the workspace variable names. Otherwise, `table` uses a cell array of `N` strings of the form `{'Var1', ..., 'VarN'}`, where `N` is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

**Output Arguments****T - Output table**

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

**Examples****Create Table from Workspace Variables**

Define workspace variables with the same number of rows.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

Create a table, T, as a container for the workspace variables.

```
T = table(Age,Height,Weight,BloodPressure,...
    'RowNames',LastName)
```

T =

	Age	Height	Weight	BloodPressure	
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

table names the variables with the workspace variable names.

**Create Table and Specify Variable Names**

Create a table from arrays with different data types.

# table

---

```
T = table(['M';'F';'M'],[45;32;34],...  
         {'NY';'CA';'MA'},logical([1;0;0]),...  
         'VariableNames',{'Gender' 'Age' 'State' 'Vote'})
```

T =

Gender	Age	State	Vote
M	45	'NY'	true
F	32	'CA'	false
M	34	'MA'	false

Each variable in T contains 3 rows.

**Gender** is a character array, **Age** is a double-precision array, **State** is a cell array of strings, and **Vote** is a logical array. You can use the function `summary` to print the data type and other information about the variables in the table.

## Related Examples

- “Create a Table”
- “Modify Units, Descriptions and Table Variable Names”
- “Access Data in a Table”

**Purpose** Convert table to homogenous array

**Syntax** `A = table2array(T)`

**Description** `A = table2array(T)` converts the table, `T`, to a homogeneous array, `A`.

**Input Arguments** **T - Input table**

table

Input table, specified as a table. All variables in `T` must have sizes and data types that are compatible for horizontal concatenation. Specifically, the size of all variable dimensions greater than 2 must match.

- If `T` is an `m`-by-`n` table with variables that each have one column, then each variable becomes one column in `A`, and `A` is an `m`-by-`n` array.
- If `T` contains variables that consist of more than one column, those variables become multiple columns in `A`, and the size of `A` is greater than the size of `T`.
- If `T` contains variables with more than two dimensions, the number of dimensions of `A` is the same as the number of variable dimensions.

**Examples** **Convert Table of Numeric Data to Array**

Create a table, `T`, consisting of numeric data.

```
T = table([1;2;3],[2 8; 4 10; 6 12],[3 12 21; 6 15 24; 9 18 27],...
    'VariableNames',{'One' 'Two' 'Three'})
```

`T =`

	One	Two		Three	
	—	—————		—————	
1	2	8	3	12	21
2	4	10	6	15	24
3	6	12	9	18	27

# table2array

---

Convert table, T, to an array.

```
A = table2array(T)
```

```
A =
```

```
     1     2     8     3    12    21
     2     4    10     6    15    24
     3     6    12     9    18    27
```

A contains two columns from variable Two and three columns from variable Three.

## Convert Numeric Subset of Table to Array

Define the numeric subset of a table to convert to an array.

Create a table with nonnumeric data in the first variable.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
         [71;69;64;67;64],[176;163;131;133;119],...
         'VariableNames',{'Gender' 'Age' 'Height' 'Weight'})
```

```
T =
```

Gender	Age	Height	Weight
M	38	71	176
M	43	69	163
F	38	64	131
F	40	67	133
F	49	64	119

Convert T(:,2:4) to an array.

```
A = table2array(T(:,2:4))
```

```
A =
```

```

38    71    176
43    69    163
38    64    131
40    67    133
49    64    119

```

A does not include data from the variable Gender.

## Convert Table with Three-Dimensional Variables to Array

Create a table, T, with two rows and three variables where each variable has three dimensions.

```
T = table(ones(2,1,3),2*ones(2,2,3),3*ones(2,3,3),'VariableNames',{'One','Two','Three'})
```

T =

One	Two	Three
[1x1x3 double]	[1x2x3 double]	[1x3x3 double]
[1x1x3 double]	[1x2x3 double]	[1x3x3 double]

The size of the table is 2-by-3.

Convert table T to an array.

```
A = table2array(T)
```

A(:, :, 1) =

```

1     2     2     3     3     3
1     2     2     3     3     3

```

A(:, :, 2) =

```

1     2     2     3     3     3
1     2     2     3     3     3

```

# table2array

---

`A(:, :, 3) =`

1	2	2	3	3	3
1	2	2	3	3	3

The size of A is 2-by-6-by-3.

## Algorithms

If T contains variables with different data types that are compatible for horizontal concatenation, `table2array` creates a homogeneous array, A, of the dominant data type. For example, if T contains `double` and `single` numeric data, `table2array(T)` returns an array with data type `single`.

## Tips

- `table2array` horizontally concatenates the variables in T to create A. If the variables in T are cell arrays, `table2array` does not concatenate their contents, and A is a cell array, equivalent to `table2cell(T)`. To create an array containing the contents of variables that are all cell arrays, use `cell2mat(table2cell(T))`.
- `table2array(T)` is equivalent to `T{:, :}`.

## Concepts

- “Concatenating Objects of Different Classes”

**Purpose** Convert table to cell array

**Syntax** `C = table2cell(T)`

**Description** `C = table2cell(T)` converts the table, `T`, to a cell array, `C`. Each variable in `T` becomes a column of cells in `C`.

**Input Arguments** **T - Input table**  
table

Input table, specified as a table.

If `T` is an `m`-by-`n` table, then `C` is an `m`-by-`n` cell array.

**Examples** **Convert Table to Cell Array**

Create a table, `T`, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
         [124 93;109 77; 125 83; 117 75; 122 80],...
         'VariableNames',{'Gender' 'Age' 'BloodPressure'},...
         'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

`T =`

	Gender	Age	BloodPressure	
	_____	_____	_____	_____
Smith	M	38	124	93
Johnson	M	43	109	77
Williams	F	38	125	83
Jones	F	40	117	75
Brown	F	49	122	80

Convert `T` to a cell array.

```
C = table2cell(T)
```

# table2cell

---

```
C =  
  
    'M'    [38]    [1x2 double]  
    'M'    [43]    [1x2 double]  
    'F'    [38]    [1x2 double]  
    'F'    [40]    [1x2 double]  
    'F'    [49]    [1x2 double]
```

C is a 5-by-3 cell array.

Vertically concatenate the table property, `T.Properties.VariableNames`, with C to include column headings for the cell array.

```
[T.Properties.VariableNames;C]
```

```
ans =  
  
    'Gender'    'Age'    'BloodPressure'  
    'M'         [ 38]    [1x2 double]  
    'M'         [ 43]    [1x2 double]  
    'F'         [ 38]    [1x2 double]  
    'F'         [ 40]    [1x2 double]  
    'F'         [ 49]    [1x2 double]
```

`T.Properties.VariableNames` is a cell array of strings.

## See Also

[cell2table](#) | [table2array](#) | [table2struct](#) | [table](#)

**Purpose** Convert table to structure array

**Syntax**

```
S = table2struct(T)
S = table2struct(T,'ToScalar',true)
```

**Description** `S = table2struct(T)` converts the table, `T`, to a structure array, `S`. Each variable of `T` becomes a field in `S`. If `T` is an `m`-by-`n` table, then `S` is a `m`-by-1 structure array with `n` fields.

`S = table2struct(T,'ToScalar',true)` converts the table, `T`, to a scalar structure `S`. Each variable of `T` becomes a field in `S`. If `T` is a `m`-by-`n` table, then `S` has `n` fields, each of which has `m` rows.

**Input Arguments**

**T - Input table**  
table

Input table, specified as a table.

**Examples**

**Convert Table to Structure Array**

Create a table, `T`, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
        [124 93;109 77; 125 83; 117 75; 122 80],...
        'VariableNames',{'Gender' 'Age' 'BloodPressure'})
```

`T =`

	Gender	Age	BloodPressure	
	M	38	124	93
	M	43	109	77
	F	38	125	83
	F	40	117	75
	F	49	122	80

# table2struct

---

Convert T to a structure array.

```
S = table2struct(T)
```

```
S =
```

```
5x1 struct array with fields:
```

```
    Gender  
    Age  
    BloodPressure
```

The structure is 5-by-1, corresponding to the five rows of the table, T. The three fields of S correspond to the three variables from T.

Display the field data for the first element of S.

```
S(1)
```

```
ans =
```

```
    Gender: 'M'  
    Age: 38  
    BloodPressure: [124 93]
```

The information corresponds to the first row of the table.

## Convert Table to Scalar Structure

Create a table, T, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...  
         [124 93;109 77; 125 83; 117 75; 122 80],...  
         'VariableNames',{'Gender' 'Age' 'BloodPressure'})
```

```
T =
```

```
    Gender    Age    BloodPressure  
    _____    _____    _____
```

M	38	124	93
M	43	109	77
F	38	125	83
F	40	117	75
F	49	122	80

Convert T to a scalar structure.

```
S = table2struct(T,'ToScalar',true)
```

```
S =
```

```
      Gender: [5x1 char]  
      Age: [5x1 double]  
  BloodPressure: [5x2 double]
```

The data in the fields of the scalar structure are 5-by-1, corresponding to the five rows in the table T.

Display the data for the field BloodPressure.

```
S.BloodPressure
```

```
ans =
```

124	93
109	77
125	83
117	75
122	80

The structure field BloodPressure contains all of the data that was in the variable of the same name from table T.

## Convert Table with Row Names to Structure

Create a table, T, that includes row names.

# table2struct

---

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],[124 93;109 77; 125 83;  
'VariableNames',{'Gender' 'Age' 'BloodPressure'},...  
'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

T =

	Gender	Age	BloodPressure	
Smith	M	38	124	93
Johnson	M	43	109	77
Williams	F	38	125	83
Jones	F	40	117	75
Brown	F	49	122	80

Convert T to a scalar structure.

```
S = table2struct(T,'ToScalar',true)
```

S =

```
Gender: [5x1 char]  
Age: [5x1 double]  
BloodPressure: [5x2 double]
```

Add a field for the row names from the table.

```
S.RowNames = T.Properties.RowNames
```

S =

```
Gender: [5x1 char]  
Age: [5x1 double]  
BloodPressure: [5x2 double]  
RowNames: {5x1 cell}
```

If `S` is a nonscalar structure, use `[S.RowNames] = T.Properties.RowNames{:}` to include a field with the row names from the table.

## See Also

[struct2table](#) | [table2cell](#) | [table2array](#) | [table](#)

# Table Properties

---

## Purpose

Modify table metadata properties

## Access and Modify Properties

A table, *T*, has properties that store metadata such as its variable names, row names, descriptions, and variable units. *T.Properties* returns a summary of all of the table properties.

You can access a property using *T.Properties.PropName*, where *T* is the name of the table and *PropName* is one of the table properties. For example, to access the *VariableDescriptions* property of a table named *Patients*, use *Patients.Properties.VariableDescriptions*.

You can modify a property value using *T.Properties.PropName = P* where *T* is the name of the table, *PropName* is one of the table properties, and *P* is the desired property value. For example, to modify the *VariableUnits* property of a table named *Patients*, use *Patients.Properties.VariableUnits = P* where *P* is a cell array of strings containing the specified information.

In contrast, you can access and modify variables within a table using *T.Variable* or *T.Variable = V*, where *T* is the name of the table, *Variable* is the name of the variable you want to access or modify, and *V* is the variable value you want.

## Properties

### **VariableNames - Variable names**

cell array of nonempty, distinct strings

Variable names, specified as a cell array of nonempty, distinct strings. The number of strings must equal the number of variables. MATLAB removes any leading or trailing white space from the strings.

If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of *N* strings of the form { 'Var1' ... 'Var*N*' } where *N* is the number of variables. You can determine valid MATLAB variable names using the function *isvarname*.

The variable names are visible when viewing the table and when using the summary function. Furthermore, you can use the variable names within parentheses, within curly braces, or with dot indexing to access table data.

## Example

```
%% Create a table
```

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...  
         [71;69;64;67;64],[176;163;131;133;119])

**RowNames - Row names**

`{}` (default) | cell array of nonempty, distinct strings

Row names, specified as a cell array of nonempty, distinct strings. This property can be empty, but if not empty, the number of strings must equal the number of rows in the table. MATLAB removes any leading or trailing white space from the strings. The default property value is an empty cell array.

The row names are visible when you view the table. Furthermore, you can use the row names within parentheses or curly braces to access the table data.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add row names
T.Properties.RowNames = LastName;

% Remove row names
T.Properties.RowNames = {};
```

## DimensionNames - Dimension names

`{'Row' `Variable'}` (default) | two-element cell array of strings

Dimension names, specified as a two-element cell array of strings.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic, ...
    'RowNames', LastName);

% Add dimension names
T.Properties.DimensionNames = {'Patient' 'Data'};
```

## Description - Table description

# Table Properties

---

'' (default) | string

Table description, specified as a string. This string is visible when using the summary function.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight);

% Add a table description
T.Properties.Description = 'Simulated patient data';

%View the summary
format compact
summary(T)
```

Description: Simulated patient data

Variables:

Gender: 100x1 char

Age: 100x1 double

Values:

min 25

median 39

max 50

Height: 100x1 double

Values:

min 60

median 67

max 72

Weight: 100x1 double

Values:

min 111

median 142.5

max 202

## VariableDescriptions - Variable descriptions

{ } (default) | cell array of strings

Variable descriptions, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have a description.

The variable descriptions are visible when using the summary function.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add variable descriptions
T.Properties.VariableDescriptions = {' ' ' ' ' ' ...
    'Has the patient ever been a smoker' ...
    'Systolic Pressure' 'Diastolic Pressure'};

% View the summary
format compact
summary(T)
```

```
Variables:
  Gender: 100x1 char
  Age: 100x1 double
  Values:
      min      25
      median   39
      max      50
  Height: 100x1 double
  Values:
      min      60
      median   67
      max      72
  Weight: 100x1 double
  Values:
```

# Table Properties

---

```
        min          111
        median       142.5
        max          202
Smoker: 100x1 logical
  Description: Has the patient ever been a smoker
  Values:
    true         34
    false        66
Systolic: 100x1 double
  Description: Systolic Pressure
  Values:
    min          109
    median       122
    max          138
Diastolic: 100x1 double
  Description: Diastolic Pressure
  Values:
    min          68
    median       81.5
    max          99
```

```
% Remove all the variable descriptions
T.Properties.VariableDescriptions = {};
```

## VariableUnits - Variable units

`{}` (default) | cell array of strings

Variable units, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have units.

The variable units are visible when using the summary function.

## Example

```
% Create a table
load patients
```

# Table Properties

```
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add variable units
T.Properties.VariableUnits = {' ' 'Yrs' 'In' 'Lbs' ' ' 'mm Hg' 'mm Hg'};

% View the summary
format compact
summary(T)
```

```
Variables:
  Gender: 100x1 char
  Age: 100x1 double
      Units: Yrs
      Values:
          min         25
          median      39
          max         50
  Height: 100x1 double
      Units: In
      Values:
          min         60
          median      67
          max         72
  Weight: 100x1 double
      Units: Lbs
      Values:
          min         111
          median     142.5
          max         202
  Smoker: 100x1 logical
      Values:
          true        34
          false      66
  Systolic: 100x1 double
      Units: mm Hg
      Values:
          min         109
```

# Table Properties

---

```
        median    122
        max       138
Diastolic: 100x1 double
Units: mm Hg
Values:
    min         68
    median     81.5
    max         99
```

```
% Remove all the variable units
T.Properties.VariableUnits = {};
```

## **UserData - Additional table information**

{ } (default) | variable containing information in any data type

Additional table information, specified as a variable containing information in any data type.

## **Example**

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add an anonymous function to the table metadata
formula = @(x) x.^2;
T.Properties.UserData = formula;
```

## **See Also**

## **Concepts**

- “Access Data in a Table”

**Purpose** Tangent of argument in radians

**Syntax**  $Y = \tan(X)$

**Description** The tan function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \tan(X)$  returns the circular tangent of each element of  $X$ .

**Examples** Graph the tangent function over the domain  $-\pi/2 < x < \pi/2$ .

```
x = (-pi/2)+0.01:0.01:(pi/2)-0.01;  
plot(x,tan(x)), grid on
```

The expression  $\tan(\pi/2)$  does not evaluate as infinite but as the reciprocal of the floating point accuracy `eps` since `pi` is only a floating-point approximation to the exact value of  $\pi$ .

# tan

---

## Tangent

The tangent of  $z$  is

$$\tan(z) = \frac{\sin(z)}{\cos(z)}.$$

<b>Purpose</b>	Tangent of argument in degrees
<b>Syntax</b>	$Y = \text{tand}(X)$
<b>Description</b>	$Y = \text{tand}(X)$ returns the tangent of the elements of $X$ , which are expressed in degrees.
<b>Input Arguments</b>	<p><b>X - Angle in degrees</b> scalar value   vector   matrix   N-D array</p> <p>Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The <code>tand</code> operation is element-wise when <math>X</math> is nonscalar.</p> <p><b>Data Types</b> single   double</p> <p><b>Complex Number Support:</b> Yes</p>
<b>Output Arguments</b>	<p><b>Y - Tangent of angle</b> scalar value   vector   matrix   N-D array</p> <p>Tangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as <math>X</math>.</p>
<b>Examples</b>	<p><b>Tangent of 90 degrees compared to tangent of <math>\pi/2</math> radians</b></p> <pre>tand(90)  ans =       Inf  tan(pi/2)  ans =      1.6331e+16  tand(90) is infinite, whereas tan(pi/2) is large but finite.</pre>

# tand

---

## Tangent of vector of complex angles, specified in degrees

```
z = [180+i 15+2i 10+3i];  
y = tand(z)
```

```
y =
```

```
0 + 0.0175i    0.2676 + 0.0374i    0.1758 + 0.0539i
```

## See Also

atand | tan | atan

**Purpose** Hyperbolic tangent

**Syntax**  $Y = \tanh(X)$

**Description** The tanh function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.  
 $Y = \tanh(X)$  returns the hyperbolic tangent of each element of  $X$ .

**Examples** Graph the hyperbolic tangent function over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;  
plot(x,tanh(x)), grid on
```

### Hyperbolic Tangent

The hyperbolic tangent of  $z$  is

# tanh

---

$$\tanh(z) = \frac{\sinh(z)}{\cosh(z)}.$$

---

<b>Purpose</b>	Compress files into tar file
<b>Syntax</b>	<code>tar(tarfilename,files)</code> <code>tar(tarfilename,files,rootfolder)</code> <code>entrynames = tar(...)</code>
<b>Description</b>	<p><code>tar(tarfilename,files)</code> creates a tar file named <i>tarfilename</i> from the list of files and folders specified in <i>files</i>. Folders recursively include all of their content. If <i>files</i> includes relative paths, the tar file also contains relative paths. The tar file does not include absolute paths.</p> <p><code>tar(tarfilename,files,rootfolder)</code> specifies the path for <i>files</i> relative to <i>rootfolder</i> rather than the current folder. Relative paths in the tar file reflect the relative paths in <i>files</i>, and do not include path information from <i>rootfolder</i>.</p> <p><code>entrynames = tar(...)</code> returns a string cell array of the names of the files contained in <i>tarfilename</i>. If <i>files</i> includes relative paths, <i>entrynames</i> also contains relative paths.</p>
<b>Tips</b>	tar cannot compress folders larger than 2 GB.
<b>Input Arguments</b>	<p><b>tarfilename</b></p> <p>String specifying the name of the tar file. If <i>tarfilename</i> has no extension, MATLAB appends the <code>.tar</code> extension. The <i>tarfilename</i> extension can end in <code>.tgz</code> or <code>.gz</code>. In this case, <i>tarfilename</i> is gzipped.</p> <p><b>files</b></p> <p>String or cell array of strings containing the list of files or folders included in <i>tarfilename</i>.</p> <p>Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.</p> <p>Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with <code>~/</code> or <code>~username/</code>,</p>

# tar

---

which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

## **rootfolder**

String specifying the path for *files*.

## **Examples**

Tar all files in the current folder to the file `backup.tgz`.

```
tar('backup.tgz','.');
```

## **See Also**

`gzip` | `gunzip` | `untar` | `unzip` | `zip`

<b>Purpose</b>	Name of system's temporary folder
<b>Syntax</b>	<code>tmp_folder = tempdir</code>
<b>Description</b>	<code>tmp_folder = tempdir</code> returns the name of the system's temporary folder, if one exists. This function does not create a new folder.
<b>See Also</b>	<code>delete</code>   <code>recycle</code>   <code>tempname</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Creating Temporary Files”</li></ul>

# tempname

---

**Purpose** Unique name for temporary file

**Syntax** `tmp_nam = tempname`

**Description** `tmp_nam = tempname` returns a unique string, `tmp_nam`, suitable for use as a temporary filename.

---

**Note** The filename that `tempname` generates is not guaranteed to be unique; however, it is likely to be so.

---

**See Also** `tempdir`

**How To**

- “Creating Temporary Files”

**Purpose**

Tetrahedron mesh plot

**Syntax**

```
tetramesh(T,X,c)
tetramesh(T,X)
tetramesh(TR)
h = tetramesh(...)
tetramesh(...,'param','value','param','value'...)
```

**Description**

`tetramesh(T,X,c)` displays the tetrahedrons defined in the  $m$ -by-4 matrix  $T$  as mesh.  $T$  is usually the output of a Delaunay triangulation of a 3-D set of points. A row of  $T$  contains indices into  $X$  of the vertices of a tetrahedron.  $X$  is an  $n$ -by-3 matrix, representing  $n$  points in 3 dimension. The tetrahedron colors are defined by the vector  $C$ , which is used as indices into the current colormap.

`tetramesh(T,X)` uses  $C = 1:m$  as the color for the  $m$  tetrahedra. Each tetrahedron has a different color (modulo the number of colors available in the current colormap).

`tetramesh(TR)` displays the tetrahedra in a triangulation representation.

`h = tetramesh(...)` returns a vector of tetrahedron handles. Each element of  $h$  is a handle to the set of patches forming one tetrahedron. You can use these handles to view a particular tetrahedron by turning the patch 'Visible' property 'on' or 'off'.

`tetramesh(...,'param','value','param','value'...)` allows additional patch property name/property value pairs to be used when displaying the tetrahedrons. For example, the default transparency parameter is set to 0.9. You can overwrite this value by using the property name/property value pair ('FaceAlpha',value) where value is a number between 0 and 1. See [Patch Properties](#) for information about the available properties.

**Examples**

Generate a 3-D Delaunay triangulation, then use `tetramesh` to visualize the tetrahedrons.

```
d = [-1 1];
```

# tetramesh

---

```
[x,y,z] = meshgrid(d,d,d); % a cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
DT = delaunayTriangulation(x,y,z);
tetramesh(DT);
camorbit(20,0)
```

# matlab.unittest.Test

---

**Superclasses**    TestSuite

**Purpose**            Specification of a single test method

**Description**      The matlab.unittest.Test class holds the information needed for the TestRunner object to be able to run a single Test method of a TestCase class. A scalar Test instance is the fundamental element contained in TestSuite arrays. A simple array of Test instances is a commonly used form of a TestSuite array.

**Properties**

**Name**

Name of the Test element.

**Attributes:**

Dependent	true
GetAccess	public
SetAccess	immutable

**Examples**

**Show Class of a TestSuite Array**

Create a suite of Test objects of all test methods in the BankAccountTest class.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?BankAccountTest);

whos suite
```

Name	Size	Bytes	Class	Attributes
suite	1x5	1636	matlab.unittest.Test	

Each test is a matlab.unittest.Test object.

Display test method names.

```
{suite.Name}'
```

```
ans =
```

```
'BankAccountTest/testConstructor'  
'BankAccountTest/testConstructorNotEnoughInputs'  
'BankAccountTest/testDesposit'  
'BankAccountTest/testWithdraw'  
'BankAccountTest/testNotifyInsufficientFunds'
```

## See Also

## Concepts

- [Property Attributes](#)

# matlab.unittest.TestCase

---

**Purpose** Superclass of all `matlab.unittest` test classes

**Description** The `TestCase` class is the means by which a test is written in the `matlab.unittest` framework. It provides the means to write and identify test content, as well as test fixture setup and teardown routines. Creating such a test requires deriving from `TestCase` to produce a `TestCase` subclass. Then, subclasses can leverage the metadata attributes to specify tests and test fixtures.

**Construction** The `TestCase` constructor is used to create `TestCase` instances intended for interactive, command line use. When tests are run in the framework, `TestCase` instances are constructed by the `matlab.unittest.TestRunner`.

## Methods

<code>addTeardown</code>	Dynamically add teardown routine
<code>applyFixture</code>	Use fixture with <code>TestCase</code>
<code>getSharedTestFixtures</code>	Provide access to shared test fixtures
<code>run</code>	Run <code>TestCase</code> test

## Inherited Methods

The `TestCase` class inherits methods from the following classes:

<code>matlab.unittest.qualifications.Assertion</code>	Qualification to validate preconditions of a test
<code>matlab.unittest.qualifications.Assumption</code>	Qualification to filter test content
<code>matlab.unittest.qualifications.FatalAssertion</code>	Qualification to abort test execution
<code>matlab.unittest.qualifications.Verification</code>	Qualification to produce soft-failure conditions

## Attributes

Classes that derive from `TestCase` can define methods blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

<code>Test</code>	Method block to contain test methods.
<code>TestMethodSetup</code>	Method block to contain setup code.
<code>TestMethodTeardown</code>	Method block to contain teardown code.
<code>TestClassSetup</code>	Method block to contain class level setup code.
<code>TestClassTeardown</code>	Method block to contain class level teardown code.

`TestCase` objects support the following class level attributes. Specify class-level attributes in the `classdef` block before the class name.

<code>SharedTestFixtures</code>	Class block to contain shared test fixtures. You must define <code>SharedTestFixtures</code> as a cell array of <code>matlab.unittest.fixtures.Fixture</code> instances.
---------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## Examples

### Create Test Case Class

Create a test case class, `FigurePropertiesTest`, with `TestMethodSetup` and `TestMethodTeardown` methods.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase
    properties
        TestFigure
    end
end
```

# matlab.unittest.TestCase

---

```
end

methods(TestMethodSetup)
    function createFigure(testCase)
        testCase.TestFigure = figure;
    end
end

methods(TestMethodTeardown)
    function closeFigure(testCase)
        close(testCase.TestFigure);
    end
end

methods(Test)

    function defaultCurrentPoint(testCase)

        cp = get(testCase.TestFigure, 'CurrentPoint');
        testCase.verifyEqual(cp, [0 0], ...
            'Default current point is incorrect')
    end

    function defaultCurrentObject(testCase)
        import matlab.unittest.constraints.IsEmpty;

        co = get(testCase.TestFigure, 'CurrentObject');
        testCase.verifyThat(co, IsEmpty, ...
            'Default current object should be empty');
    end
end

end

end
```

**See Also** TestRunner |

## Concepts

- “Method Attributes”
- “Class Attributes”

# matlab.unittest.TestCase.addTeardown

---

**Purpose** Dynamically add teardown routine

**Syntax** `addTeardown(testCase,tearDownFcn)`  
`addTeardown(testCase,tearDownFcn,arg1,...,argN)`

**Description** `addTeardown(testCase,tearDownFcn)` adds the `tearDownFcn` function handle that defines fixture teardown code to the `testCase` instance. The teardown code is executed in the reverse order to which it is added. This is known as LIFO (or Last-In-First-Out).  
`addTeardown(testCase,tearDownFcn,arg1,...,argN)`

## Input Arguments

### **testCase**

matlab.unittest.TestCase instance

### **tearDownFcn**

Function, specified as a function handle, that defines the fixture teardown code

### **arg1,...,argN**

Input arguments, 1 through N (if any), required by `tearDownFcn`, specified by any type. The argument type is specified by the function argument list.

## Examples

### **Call addTeardown in a TestMethodSetup Method**

```
classdef SomeTest < matlab.unittest.TestCase

    methods(TestMethodSetup)
        function createFixture(testCase)
            p = path;
            testCase.addTeardown(@path, p);
            addpath(fullfile(pwd, 'testHelpers'));
        end
    end
end
```

# matlab.unittest.TestCase.applyFixture

<b>Purpose</b>	Use fixture with TestCase
<b>Syntax</b>	<code>applyFixture(testCase, fixture)</code>
<b>Description</b>	<p><code>applyFixture(testCase, fixture)</code> prepares the specified fixture for use with the <code>TestCase</code>. This method enables the use of a fixture within the scope of a single <code>Test</code> method or <code>TestCase</code> class. The life cycle of the fixture is tied to the <code>TestCase</code>. When the <code>TestCase</code> goes out of scope, the test framework tears down the fixture.</p> <p>Call <code>applyFixture</code> within a <code>Test</code> method or <code>TestMethodSetup</code> method to use a fixture for the current test method alone. Use <code>applyFixture</code> within a <code>TestClassSetup</code> method to set up a fixture for the entire class.</p>

<b>Input Arguments</b>	<p><b>testCase</b> matlab.unittest.TestCase instance</p> <p><b>fixture</b> matlab.unittest.fixtures.Fixture instance</p>
------------------------	----------------------------------------------------------------------------------------------------------------------------------

## Examples **Apply Fixtures to TestCase Class**

Create a temporary folder and make it the current working folder.

```
classdef applyFixtureTest < matlab.unittest.TestCase
    methods(TestMethodSetup)
        function addHelpers(testCase)
            import matlab.unittest.fixtures.TemporaryFolderFixture;
            import matlab.unittest.fixtures.CurrentFolderFixture;

            % Create a temporary folder and make it the current working
            % folder.
            tempFolder = testCase.applyFixture(TemporaryFolderFixture);
            testCase.applyFixture(CurrentFolderFixture(tempFolder.Folder));
        end
    end
end
end
```

# matlab.unittest.TestCase.applyFixture

---

Each test method can write files to the current working folder, which is the temporary folder. After each test method runs, the test framework restores the working folder to its previous state and deletes the temporary folder.

**See Also** `matlab.unittest.fixtures`

# matlab.unittest.TestCase.getSharedTestFixtures

<b>Purpose</b>	Provide access to shared test fixtures
<b>Syntax</b>	<pre>fixtures = getSharedTestFixtures(testCase) fixtures = getSharedTestFixtures(testCase,fixtureClassName)</pre>
<b>Description</b>	<p><code>fixtures = getSharedTestFixtures(testCase)</code> provides access to the array of all shared test fixtures for <code>testCase</code>. <code>getSharedTestFixtures</code> returns an array of fixture objects, <code>fixtures</code>. Specify shared fixtures are using the <code>SharedTestFixtures</code> attribute for the <code>testCase</code> class.</p> <p><code>fixtures = getSharedTestFixtures(testCase,fixtureClassName)</code> returns only the shared fixtures that have the class name <code>fixtureClassName</code>.</p>
<b>Input Arguments</b>	<p><b>testCase</b> matlab.unittest.TestCase instance</p> <p><b>fixtureClassName</b> Name of test fixture class, specified as a string</p>
<b>Examples</b>	<p><b>Obtain Array of All Shared Fixtures</b></p> <p>Create the following class, <code>myTest</code>, on your MATLAB path. Two shared fixtures are used within the test method. This example assumes that the subfolder <code>helperFiles</code> exists in your working folder. Create the subfolder <code>helperFiles</code> in your working folder if it does not exist.</p> <pre>classdef (SharedTestFixtures={... matlab.unittest.fixtures.PathFixture('helperFiles'),...     matlab.unittest.fixtures.TemporaryFolderFixture}) ...     myTest &lt; matlab.unittest.TestCase methods(Test)     function accessFixtures(testCase)         myFixtures = testCase.getSharedTestFixtures     end end</pre>

# matlab.unittest.TestCase.getSharedTestFixtures

---

```
end
```

At the command prompt, run the test.

```
run(myTest);
```

```
Setting up PathFixture.
```

```
Description: Adds 'H:\Documents\doc_examples\helperFiles' to the path.
```

---

```
Setting up TemporaryFolderFixture.
```

```
Description: Creates a temporary folder.
```

---

```
Running myTest
```

```
myFixtures =
```

```
    1x2 heterogeneous Fixture (PathFixture, TemporaryFolderFixture) array with
```

```
.
```

```
Done myTest
```

---

```
Tearing down TemporaryFolderFixture.
```

```
Description: Deletes the temporary folder and all its contents.
```

---

```
Tearing down PathFixture.
```

```
Description: Restores the path to its previous state.
```

---

## Access Shared Fixtures of Particular Class

Create the class, `mySecondTest`, on your MATLAB path.

```
classdef (SharedTestFixtures={...  
    matlab.unittest.fixtures.TemporaryFolderFixture})...
```

# matlab.unittest.TestCase.getSharedTestFixtures

---

```
mySecondTest < matlab.unittest.TestCase
methods(Test)
function accessTemporaryFolderFixture(testCase)
    tempFolderFixture = testCase.getSharedTestFixtures...
        ('matlab.unittest.fixtures.TemporaryFolderFixture');
    temporaryFolder = tempFolderFixture.Folder
end
end
end
```

At the command prompt, run the test. The name of the temporary folder varies.

```
run(mySecondTest);
```

```
Setting up TemporaryFolderFixture.
Description: Creates a temporary folder.
```

---

```
Running mySecondTest
```

```
temporaryFolder =
```

```
C:\Temp\tpb92c9c67_02fa_4714_bfb0_b2127df0f31d
```

```
.
Done mySecondTest
```

---

```
Tearing down TemporaryFolderFixture.
Description: Deletes the temporary folder and all its contents.
```

## Concepts

- Class Attributes

# matlab.unittest.TestCase.run

---

**Purpose** Run TestCase test

**Syntax**  
`result = run(testCase)`  
`result = run(testCase, testMethod)`

**Description** `result = run(testCase)` uses `testCase` as a prototype to run a TestSuite array created from all test methods in the class defining `testCase`. This suite is run using a TestRunner object configured for text output.

`result = run(testCase, testMethod)` uses `testCase` as a prototype to run a TestSuite array created from `testMethod`. This test is run using a TestRunner object configured for text output.

This is a convenience method to allow interactive experimentation of TestCase classes in MATLAB, yet running the tests contained in them using a supported TestRunner object.

## Input Arguments

### **testCase**

matlab.unittest.TestCase instance

### **testMethod**

Name of desired test method, specified as one of the following:

- string
- `meta.method` instance

The method must correspond to a valid Test method of the `testCase` instance.

## Output Arguments

### **result**

A `matlab.unittest.TestResult` object containing the result of the test run.

## Examples

### Run Test Directly from Test Case

Add the `FigurePropertiesTest.m` test case file to a folder on your MATLAB path.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

    properties
        TestFigure
    end

    methods(TestMethodSetup)
        function createFigure(testCase)
            %comment
            testCase.TestFigure = figure;
        end
    end

    methods(TestMethodTeardown)
        function closeFigure(testCase)
            close(testCase.TestFigure);
        end
    end

    methods(Test)

        function defaultCurrentPoint(testCase)

            cp = get(testCase.TestFigure, 'CurrentPoint');
            testCase.verifyEqual(cp, [0 0], ...
                'Default current point is incorrect')
        end

        function defaultCurrentObject(testCase)
            import matlab.unittest.constraints.IsEmpty;

            co = get(testCase.TestFigure, 'CurrentObject');
```

# matlab.unittest.TestCase.run

---

```
        testCase.verifyThat(co, IsEmpty, ...  
            'Default current object should be empty');  
    end
```

```
end
```

```
end
```

Create a testcase object.

```
tc = FigurePropertiesTest;
```

Run the tests.

```
tc.run;
```

```
Running FigurePropertiesTest
```

```
..
```

```
Done FigurePropertiesTest
```

```
_____
```

All tests passed.

## See Also

[matlab.unittest.TestSuite.run](#) |  
[matlab.unittest.TestRunner.run](#) |

<b>Purpose</b>	Result of running test suite
<b>Description</b>	The <code>matlab.unittest.TestResult</code> class holds the information describing the result of running a test suite using the <code>matlab.unittest</code> framework. The results include information describing whether the test passed, failed, or ran to completion, as well as the duration of each test.
<b>Construction</b>	<code>TestResult</code> arrays are created and returned by the test runner, and are of the same size as the suite which was run.
<b>Properties</b>	<p><b>Duration</b></p> <p>Time elapsed running test.</p> <p>The <code>Duration</code> property indicates the amount of time taken to run a particular test, including the time taken setting up and tearing down any test fixtures.</p> <p>Fixture setup time is accounted for in the duration of the first test suite array element that uses the fixture. Fixture teardown time is accounted for in the duration of the last test suite array element that uses the fixture.</p> <p>The total run time for a suite of tests exceeds the sum of the durations for all the elements of the suite because the <code>Duration</code> property does not include all the overhead of the <code>TestRunner</code> object, nor any of the time consumed by test runner plugins.</p> <p><b>Failed</b></p> <p>Logical value showing if test failed.</p> <p>A <code>TRUE Failed</code> property indicates some form of test failure. When <code>Failed</code> is <code>FALSE</code>, then no failing conditions were encountered. A failing result can occur with a failure condition either in a test or in setting up and tearing down test fixtures. Failures can occur due to the following:</p> <ul style="list-style-type: none"><li>• Verification failures</li></ul>

- Assertion failures
- Uncaught MExceptions

Fatal assertions are also failing conditions, but in the event of a fatal assertion failure, the entire framework aborts and a `TestResult` object is never produced.

## **Incomplete**

Logical value showing if test did not run to completion.

A `TRUE` `Incomplete` property indicates a test did not run to completion. When it is `FALSE`, then no conditions were encountered that prevented the test from completing. In other words, when `FALSE` there were no stack disruptions out of the running test content. An incomplete result can occur with a stack disruption in either a test or when setting up and tearing down test fixtures. Incomplete tests can occur due to the following:

- Assertion failures
- Tests filtered through assumption
- Uncaught MExceptions

Fatal assertions are also conditions that prevent the completion of tests, but in the event of a fatal assertion failure the entire framework aborts and a `TestResult` object is never produced.

## **Name**

The name of the `TestSuite` object for the result.

The `Name` property is a string that holds the name of the test corresponding to this result.

## **Passed**

Logical value showing if the test passed.

When the `Passed` property is `TRUE`, then the test completed as expected without any failure. When it is `FALSE`, then the test did not run to completion and/or encountered a failure condition.

## Examples

### Use TestResult Object to Identify and Rerun Failed Tests

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

Result display method provides a summary of the results

```
suite = TestSuite.fromClass(?SomeTestClass)
results = run(suite)
```

```
results =
```

```
    matlab.unittest.TestResult
```

```
    Test Suite Summary:
```

```
    12 Passed, 4 Failed, 0 Not Run To Completion.
```

```
    5.5091 seconds testing time.
```

Rerun only the failed tests.

```
failedTests = suite([results.Failed]);
failedResults = run(failedTests)
```

```
failedResults =
```

```
    matlab.unittest.TestResult
```

```
    Test Suite Summary:
```

```
    0 Passed, 4 Failed, 0 Not Run To Completion.
```

```
    1.2894 seconds testing time.
```

Make the fix and rerun results.

# matlab.unittest.TestResult

---

```
newResults = run(failedTests)

newResults =

    matlab.unittest.TestResult

Test Suite Summary:
    4 Passed, 0 Failed, 0 Not Run To Completion.
    1.1607 seconds testing time.
```

## Concepts

- [Property Attributes](#)

<b>Purpose</b>	Class for running tests in matlab.unittest framework	
<b>Description</b>	<p>The matlab.unittest.TestRunner class is the fundamental API used to run a suite of tests in the matlab.unittest framework. It runs and operates on TestSuite arrays. Use this class to customize running tests.</p> <p>The TestRunner class is a sealed class; you cannot derive classes from the TestRunner class.</p>	
<b>Construction</b>	<p>To create a simple, silent TestRunner object, call the static withNoPlugins method.</p> <pre>runner = matlab.unittest.TestRunner.withNoPlugins</pre> <p>To create a TestRunner object to run tests from the MATLAB Command Window , call the static withTextOutput method.</p> <pre>runner = matlab.unittest.TestRunner.withTextOutput</pre> <p>To create a customized TestRunner object, call the addPlugin method.</p> <pre>runner = TestRunner.withNoPlugins; runner.addPlugin(SomePlugin())</pre>	
<b>Methods</b>	<pre>addPlugin run withNoPlugins withTextOutput</pre>	<pre>Add plugin to TestRunner object Run all tests in TestSuite array Create simplest runner possible Create TestRunner object for command window output</pre>
<b>Examples</b>	<b>Create TestRunner Object Configured for Text Output</b> <p>Add matlab.unittest classes to the current import list.</p> <pre>import matlab.unittest.TestRunner;</pre>	

# matlab.unittest.TestRunner

---

```
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create the TestRunner object and run the suite.

```
runner = TestRunner.withTextOutput;  
result = run(runner,suite);
```

## See Also

[TestSuite](#) | [TestResult](#) |

<b>Purpose</b>	Add plugin to TestRunner object
<b>Syntax</b>	<code>addPlugin(runner,plugin)</code>
<b>Description</b>	<code>addPlugin(runner,plugin)</code> adds plugin to runner.
<b>Input Arguments</b>	<b>runner</b> matlab.unittest.TestRunner object. <b>plugin</b> Mechanism provided to customize the manner in which a TestSuite array is run, specified as a TestRunnerPlugin object.

## Examples **Run Test with Custom Plugin**

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;  
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object.

```
runner = TestRunner.withNoPlugins;
```

Add a custom plugin.

```
import matlab.unittest.plugins.DiagnosticsValidationPlugin;  
runner.addPlugin(DiagnosticsValidationPlugin);
```

Run the test.

```
result = run(runner,suite);
```

# matlab.unittest.TestRunner.run

---

**Purpose** Run all tests in TestSuite array

**Syntax** `result = run(runner,suite)`

**Description** `result = run(runner,suite)` runs the TestSuite array defined by `suite` using the TestRunner object provided in `runner`, and returns the result in `result`.

This method runs all of the appropriate methods of the TestCase class to set up fixtures and run test content. It handles errors and qualification failures and records the information in `result`.

**Input Arguments**

**runner**  
matlab.unittest.TestRunner object.

**suite**  
Set of tests, specified as a matlab.unittest.TestSuite array.

**Output Arguments**

**result**  
A matlab.unittest.TestResult object containing the result of the test run. `result` is the same size as `suite` and each element is the result of the corresponding element in `suite`.

## Examples **Run All Tests in a Package**

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;  
import matlab.unittest.TestSuite;
```

Create a test suite, and a test runner that displays text.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);  
runner = TestRunner.withTextOutput;
```

Run the test suite.

```
result = runner.run(suite)
```

## See Also

```
matlab.unittest.TestSuite.run | matlab.unittest.TestCase.run  
|
```

# matlab.unittest.TestRunner.withNoPlugins

---

**Purpose** Create simplest runner possible

**Syntax** `runner = matlab.unittest.TestRunner.withNoPlugins`

**Description** `runner = matlab.unittest.TestRunner.withNoPlugins` creates a `TestRunner` that is guaranteed to have no plugins installed and returns it in `runner`. It is the method one can use to create the simplest runner possible without violating the guarantees a test writer has when writing `TestCase` classes. This runner is a silent runner, meaning that regardless of passing or failing tests, this runner produces no command window output, although the results returned after running a test suite are accurate.

This method can also be used when it is desirable to have complete control over which plugins are installed and in what order. It is the only method guaranteed to produce the minimal `TestRunner` with no plugins, so one can create it and add additional plugins as desired.

**Output Arguments** **runner**  
matlab.unittest.TestRunner object.

**Attributes** Static true

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

## **Examples** **Create a Silent TestRunner Object with no Plugins**

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;  
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object.

```
runner = TestRunner.withNoPlugins;  
  
% Run the suite silently  
result = run(runner,suite)
```

## Control Plugins

Using the TestRunner object created in the previous example, control which plugins are installed and in what order they are installed.

Add matlab.unittest class to the current import list.

```
import matlab.unittest.plugins;
```

Add specific plugins.

```
runner.addPlugin(DiagnosticsValidationPlugin);  
runner.addPlugin(TestSuiteProgressPlugin);
```

Rerun the tests.

```
result = run(runner,suite)
```

# matlab.unittest.TestRunner.withTextOutput

---

**Purpose** Create TestRunner object for command window output

**Syntax** `runner = matlab.unittest.TestRunner.withTextOutput`

**Description** `runner = matlab.unittest.TestRunner.withTextOutput` creates a TestRunner object that is configured for running tests from the MATLAB Command Window and returns it in `runner`. The output produced includes test progress as well as diagnostics in the event of test failures.

**Output Arguments** **runner**  
matlab.unittest.TestRunner object.

**Attributes**                      `Static`                                              `true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## **Examples**                      **Display Test Results in Command Window**

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;  
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object that produced output to the Command Window.

```
runner = TestRunner.withTextOutput;
```

```
% Run the suite
```

```
result = run(runner,suite)
```

**See Also** [run](#) |

# matlab.unittest.TestSuite

---

**Purpose** Class for grouping tests to run

**Description** The `matlab.unittest.TestSuite` class is the fundamental interface used to group and run a set of tests in the unit test framework. The `matlab.unittest.TestRunner` object can only run arrays of `TestSuite` objects.

**Construction** `TestSuite` arrays are created using static methods of the `TestSuite` class. These methods may return subclasses of the `TestSuite` class depending on the method call and context.

<b>Methods</b>	<code>fromClass</code>	Create suite from <code>TestCase</code> class
	<code>fromFile</code>	Create <code>TestSuite</code> array from test file
	<code>fromFolder</code>	Create <code>TestSuite</code> array from all tests in folder
	<code>fromMethod</code>	Create <code>TestSuite</code> array from single test method
	<code>fromPackage</code>	Create <code>TestSuite</code> array from all tests in package
	<code>run</code>	Run <code>TestSuite</code> array using <code>TestRunner</code> object configured for text output

## **Examples** Create Test Suite of Every Type of Test Set

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

Create test suites using a each method.

```
fileSuite = TestSuite.fromFile('SomeTestFile.m');
```

```
folderSuite = TestSuite.fromFolder(pwd);  
packageSuite = TestSuite.fromPackage('mypackage.subpackage');  
classSuite = TestSuite.fromClass(?mypackage.MyTestClass);  
methodSuite = TestSuite.fromMethod(?SomeTestClass,'testMethod');
```

Concatenate the suites.

```
largeSuite = [fileSuite, folderSuite, packageSuite, classSuite, methodSuite];
```

Run the full suite.

```
result = run(largeSuite)
```

# matlab.unittest.TestSuite.fromFile

---

<b>Purpose</b>	Create TestSuite array from test file
<b>Syntax</b>	<code>suite = matlab.unittest.TestSuite.fromFile(file)</code>
<b>Description</b>	<p><code>suite = matlab.unittest.TestSuite.fromFile(file)</code> creates a TestSuite array from all of the Test methods in <code>file</code>.</p> <p>When the test suite is run, MATLAB changes the current folder to the folder the suite was created from, and adds it to the path for the duration of the test run.</p>
<b>Input Arguments</b>	<p><b>file</b></p> <p>Class file derived from <code>matlab.unittest.TestCase</code> containing test methods, specified as a string.</p>
<b>Output Arguments</b>	<p><b>suite</b></p> <p>Set of tests, specified as a <code>matlab.unittest.TestSuite</code> array.</p>
<b>Attributes</b>	<p>Static <span style="float: right;">true</span></p> <p>To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.</p>

## Examples **Run Tests in Class File**

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.');
```

```
end
res = x + 5;
end
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput, 'double');
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'), 'add5:InputMustBeNumeri
        end
    end
end
```

Create a test suite from the Add5Test class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');
```

```
result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
```

---

## See Also

[TestRunner](#) | [fromFolder](#) |

# matlab.unittest.TestSuite.fromFolder

---

**Purpose** Create TestSuite array from all tests in folder

**Syntax**

```
suite = matlab.unittest.TestSuite.fromFolder(folder)
suite = matlab.unittest.TestSuite.fromFolder(folder,Name,
      Value)
```

**Description** `suite = matlab.unittest.TestSuite.fromFolder(folder)` creates a TestSuite array from all of the Test methods of all concrete TestCase classes contained in `folder` and returns that array in `suite`. If tests are function-based, a Test file is included in the TestSuite array if it follows the naming convention of starting or ending in the word 'test', which is case-insensitive. Class-based tests do not need to follow this naming convention. The method is not recursive, returning only those tests directly in the specified folder.

When the test suite is run, MATLAB changes the current folder to the folder the suite was created from, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFolder(folder,Name, Value)` creates a TestSuite array with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### **folder**

Folder containing test methods, specified as a string. `folder` can be either an absolute or relative path to the desired folder.

### **Name-Value Pair Arguments**

#### **'IncludingSubfolders'**

Include test methods from any `folder` subfolders, excluding package, class, and private folders.

## Output Arguments

### **suite**

Set of tests, specified as a `matlab.unittest.TestSuite` array.

## Attributes

Static true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## Examples

### Run Tests in Current Folder

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder(pwd);
result = run(suite);
```

### Run Tests in Subfolders

```
suite = TestSuite.fromFolder(pwd, 'IncludingSubfolders', true);
result = run(suite);
```

# texlabel

---

**Purpose** Format text into TeX string

**Syntax**  
`TeXString = texlabel(f)`  
`TeXString = texlabel(f, 'literal')`

**Description** `TeXString = texlabel(f)` converts the MATLAB expression `f` into the TeX equivalent for use in text strings. `texlabel` converts Greek variable names (for example, `lambda`, `delta`, and so on) into a string that is displayed as Greek letters. The TeXString output is useful as an argument to annotation functions such as `title`, `xlabel`, and `text`.

If TeXString is too long to fit into a figure window, then the center of the expression is replaced with a tilde ellipsis (~~~).

`TeXString = texlabel(f, 'literal')` interprets Greek variable names literally.

**Input Arguments** **f - Input MATLAB expression**  
string

Input MATLAB expression, specified as a string.

**Example:** `'theta (degrees)'`

**Data Types**  
char

**Examples** **Insert TeX String in Figure**

Create a figure and a TeX string for use in a text graphics object.

```
figure
plot((1:10).^2)
TeXString = texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)');
```

Add a text object containing the TeX string to the figure.

```
text(3,90,TeXString)
```

If you include the 'literal' argument, `texlabel` interprets Greek variable names literally. Add a text object containing the literal string.

```
text(4,60,texlabel('\lambda_{12}^{3/2}/\pi - \pi*\delta^{2/3}','literal'))
```

# texlabel

---

**See Also**      text | title | xlabel | ylabel | zlabelString |

**Purpose**

Create text object in current axes

**Syntax**

```
text(x,y,'string')  
text(x,y,z,'string')  
text(x,y,z,'string','PropertyName',PropertyValue....)  
text('PropertyName',PropertyValue....)  
h = text(...)
```

**Properties**

For a list of properties, see [Text Properties](#).

**Description**

`text` is the low-level function for creating text graphics objects. Use `text` to place character strings at specified locations.

`text(x,y,'string')` adds the string in quotes to the location specified by the point  $(x,y)$   $x$  and  $y$  must be numbers of class `double`.

`text(x,y,z,'string')` adds the string in 3-D coordinates.  $x$ ,  $y$  and  $z$  must be numbers of class `double`.

`text(x,y,z,'string','PropertyName',PropertyValue....)` adds the string in quotes to the location defined by the coordinates and uses the values for the specified text properties. For a description of the properties, see [Text Properties](#).

`text('PropertyName',PropertyValue....)` omits the coordinates entirely and specifies all properties using property name/property value pairs.

`h = text(...)` returns a column vector of handles to text objects, one handle per object. All forms of the `text` function optionally return this output argument.

See the [String](#) property for a list of symbols, including Greek letters.

**Tips****Position Text Within the Axes**

The default text units are the units used to plot data in the graph. Specify the text location coordinates (the  $x$ ,  $y$ , and  $z$  arguments) in the data units of the current graph (see “Examples” on page 1-6273). You can use other units to position the text by setting the `text Units`

property to normalized or one of the nonrelative units (pixels, inches, centimeters, points, or characters).

Note that the Axes Units property controls the positioning of the Axes within the figure and is not related to the axes data units used for graphing.

The Extent, VerticalAlignment, and HorizontalAlignment properties control the positioning of the character string with regard to the text location point.

If the coordinates are vectors, text writes the string at all locations defined by the list of points. If the character string is an array the same length as x, y, and z, text writes the corresponding row of the string array at each point specified.

## **Multiline Text**

When specifying strings for multiple text objects, the string can be:

- A cell array of strings
- A padded string matrix

Each element of the specified string array creates a different text object.

When specifying the string for a single text object, cell arrays of strings and padded string matrices result in a text object with a multiline string, while vertical slash characters are not interpreted as separators and result in a single line string containing vertical slashes.

## **Behavior of the Text Function**

text is a low-level function that accepts property name/property value pairs as input arguments. However, the convenience form:

```
text(x,y,z,'string')
```

is equivalent to:

```
text('Position',[x,y,z],'String','string')
```

---

You can specify other properties only as property name/property value pairs. For a description of each property, see `Text Properties`. You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

`text` does not respect the setting of the figure or axes `NextPlot` property. This allows you to add text objects to an existing axes without setting `hold` to `on`.

## Examples

Annotate the point  $(\pi, 0)$  with the string  $\sin(\pi)$  on the following graph:

```
plot(0:pi/20:2*pi,sin(0:pi/20:2*pi))
text(pi,0,' \leftarrow \sin(\pi)', 'FontSize', 18)
```

Use embedded TeX sequences to display an equation:

```
axes
text(0.5,0.5,'\ite^{i\omega\tau} = \cos(\omega\tau) + i \sin(\omega\tau)')
```

MATLAB displays:

$$e^{i\omega\tau} = \cos(\omega\tau) + i \sin(\omega\tau)$$

## Setting Default Properties

You can set default text properties on the axes, figure, and root object levels:

```
set(0, 'DefaulttextProperty', PropertyValue...)  
set(gcf, 'DefaulttextProperty', PropertyValue...)  
set(gca, 'DefaulttextProperty', PropertyValue...)
```

Where *Property* is the name of the text property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access text properties.

# Text Properties

---

**Purpose** Text properties

**Creating Text Objects** Use text to create text objects.

**Modifying Properties** You can set and query graphics object properties using the property editor or the set and get commands.

- Property Editor is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see [Setting Default Property Values](#).

See [Core Objects](#) for general information about this type of object.

**Text Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation  
hg.Annotation object (read-only)

*Handle of Annotation object.* The Annotation property enables you to specify whether this text object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the text object is displayed in a figure legend:

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Represent this text object in a legend (default)
off	Do not include this text object in a legend
children	Same as on because text objects do not have children

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

`BackgroundColor`  
`ColorSpec | {none}`

*Color of text extent rectangle.* Defines a color for the rectangle that encloses the text Extent plus the text Margin. For example, the following code creates a text object that labels a plot and sets the background color to light green.

```
text(3*pi/4, sin(3*pi/4), ...  
 ['sin(3*pi/4) = ', num2str(sin(3*pi/4))], ...  
 'HorizontalAlignment', 'center', ...  
 'BackgroundColor', [.7 .9 .7]);
```

# Text Properties

---

For additional features, see the following properties:

- **EdgeColor** — Color of the rectangle's edge (none by default).
- **LineStyle** — Style of the rectangle's edge line (first set **EdgeColor**)
- **LineWidth** — Width of the rectangle's edge line (first set **EdgeColor**)
- **Margin** — Increase the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the **EdgeColor** rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the **EdgeColor** property and the area defined by the **BackgroundColor** change.

See also [Drawing Text in a Box](#) in the MATLAB Graphics documentation for an example using background color with contour labels.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

# Text Properties

---

## ButtonDownFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the text object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    sel_typ = get(gcf, 'SelectionType')
    switch sel_typ
        case 'normal'
            disp('User clicked left-mouse button')
            set(src, 'Selected', 'on')
        case 'extend'
            disp('User did a shift-click')
            set(src, 'Selected', 'on')
        case 'alt'
            disp('User did a control-click')
            set(src, 'Selected', 'on')
            set(src, 'SelectionHighlight', 'off')
    end
end
```

Suppose `h` is the handle of a text object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h, 'ButtonDownFcn', @button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

matrix (read-only)

The empty matrix; text objects have no children.

## Clipping

on | {off}

*Clipping mode.* When `Clipping` is on, MATLAB does not display any portion of the text that is outside the axes.

## Color

ColorSpec

*Text color.* A three-element RGB vector or one of the predefined names, specifying the text color. The default value is `[0 0 0]` (black). See the [ColorSpec](#) reference page for more information on specifying color.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a text object. You must define this property as a default value for `text` or in a call to the `text` function that creates a new text object. For example, the statement:

```
set(0, 'DefaultTextCreateFcn', @text_create)
```

# Text Properties

---

defines a default value on the root level that sets the figure Pointer property to crosshairs whenever you create a text object. The callback function must be on your MATLAB path when you execute the above statement.

```
function text_create(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    set(gcf, 'Pointer', 'crosshair')
end
```

MATLAB executes this function after setting all text properties. Setting this property on an existing text object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete text callback function.* Executes when you delete the text object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src, evnt)
% src - the object that is the source of the event
```

```
% evt - empty for this property
    obj_tp = get(src,'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DisplayName**  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the text object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where  $n$  is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

# Text Properties

---

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EdgeColor

ColorSpec | {none}

*Color of edge drawn around text extent rectangle plus margin.*  
Specifies the color of a box drawn around the text `Extent` plus the text `Margin`. For example, the following code draws a red rectangle around text that labels a plot.

```
text(3*pi/4,sin(3*pi/4),...  
'\leftarrow sin(t) = .707',...  
'EdgeColor','red');
```

For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (none by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increases the size of the rectangle by adding a margin to the area defined by the text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

## Editing

`on` | `{off}`

*Enable or disable editing mode.* When this property is `off` (the default), you cannot edit the text string interactively (i.e., you must change the `String` property to change the text). When you set this property to `on`, MATLAB enables editing and places an insert cursor wherever the mouse is within the text. To apply the new text string, do any one of the following:

- Press the **Esc** key.
- Click anywhere away from the text string.
- Reset the `Editing` property to `off`.

MATLAB updates the `String` property to contain the new text and resets the `Editing` property to `off`. You must reset the `Editing` property to `on` to resume editing.

## EraseMode

`{normal}` | `none` | `xor` | `background`

# Text Properties

---

*Erase mode.* Controls the technique MATLAB uses to draw and erase text objects. Alternative erase modes are useful for creating animated sequences where controlling the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the text when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the text by performing an exclusive OR (XOR) with each pixel index of the screen beneath it. When the text is erased, it does not damage the objects beneath it. However, when text is drawn in `xor` mode, its color depends on the color of the screen beneath it. It is correctly colored only when it is over axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.
- **background** — Erase the text by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`. This damages objects that are behind the erased text, but text is always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Extent

position rectangle (read-only)

*Position and size of text.* A four-element vector that defines the size and position of the text string:

```
[left,bottom,width,height]
```

If the `Units` property is `data` (the default), `left` and `bottom` are the  $x$ - and  $y$ -coordinates of the lower left corner of the text `Extent`.

For all other values of `Units`, `left` and `bottom` are the distance from the lower left corner of the axes `Position` rectangle to the lower left corner of the text `Extent`. `width` and `height` are the dimensions of the `Extent` rectangle. All measurements are in units specified by the `Units` property.

## FontAngle

```
{normal} | italic | oblique
```

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

## FontName

```
name (such as Courier) | FixedWidth
```

*Font family.* Specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports. The default font is `Helvetica`.

# Text Properties

---

## Specifying a Fixed-Width Font

If you want text to use a fixed-width font that looks good in any locale, you should set `FontName` to the string `FixedWidth`:

```
set(text_handle, 'FontName', 'FixedWidth')
```

This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan where multibyte character sets are used). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` (note that this string is case sensitive) and rely on `FixedWidthFontName` to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`.

Note that setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

### FontSize

size in `FontUnits`

*Font size.* Specifies the font size to use for text in units determined by the `FontUnits` property. The default is 10 points. 1 point =  $1/72$  inch.

### FontWeight

{normal} | bold | light | demi

*Weight of text characters.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `bold` or `demi` causes MATLAB to use a bold font.

## FontUnits

{points} | normalized | inches | centimeters | pixels

*Font size units.* MATLAB uses this property to determine the units used by the `FontSize` property.

- `normalized` — Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.

Note that if you are setting both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

# Text Properties

---

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`,

- The object's handle does not appear in its parent's `Children` property.
- Figures do not appear in the root's `CurrentFigure` property.
- Objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property.
- Axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

## HitTest

`{on} | off`

*Selectable by mouse click.* Determines if the text can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the text. If `HitTest` is `off`, clicking the text selects the object below it (which is usually the axes containing it).

For example, suppose you define the button down function of an image (see the `ButtonDownFcn` property) to display text at the location you click with the mouse.

First define the callback routine.

```
function bd_function
pt = get(gca,'CurrentPoint');
text(pt(1,1),pt(1,2),pt(1,3),...
'\fontsize{20}\oplus} The spot to label',...
'HitTest','off')
```

Now display an image, setting its `ButtonDownFcn` property to the callback routine.

```
load earth
image(X,'ButtonDownFcn','bd_function'); colormap(map)
```

When you click the image, MATLAB displays the text string at that location. With `HitTest` set to `off`, existing text cannot intercept any subsequent button down events that occur over the text. This enables the image's button down function to execute.

`HorizontalAlignment`  
{left} | center | right

*Horizontal alignment of text.* Specifies the horizontal justification of the text string. It determines where MATLAB places the string with regard to the point specified by the `Position` property. The following picture illustrates the alignment options.

`HorizontalAlignment` viewed with the `VerticalAlignment` set to `middle` (the default).

See the `Extent` property for related information.

See “Text Alignment” for more information and examples.

# Text Properties

---

## Interpreter

latex | {tex} | none

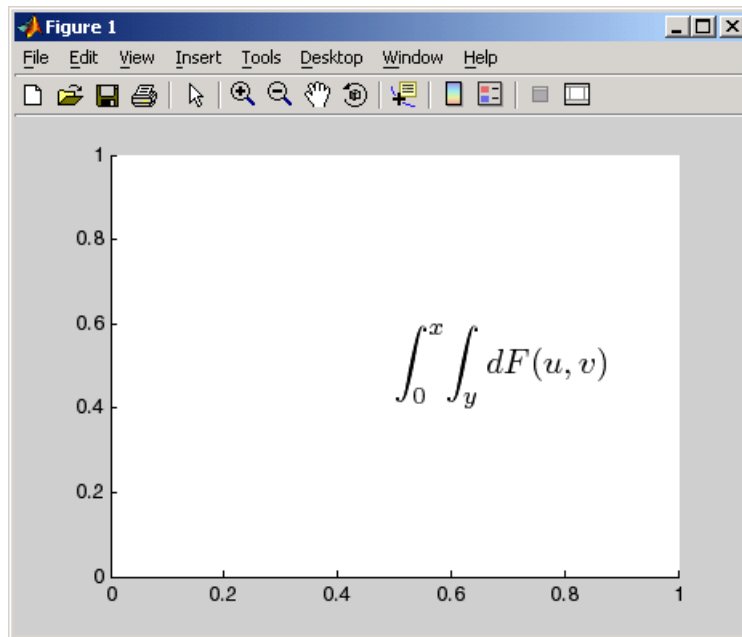

*Interpret TeXinstructions.* Controls whether MATLAB interprets certain characters in the **String** property as TeX instructions (default) or displays all characters literally.

- **latex** — Supports a basic subset of the LaTeX markup language.
- **tex** — Supports a subset of plain TeX markup language. See the **String** property for a list of supported TeX instructions.
- **none** — Displays literal characters.

## LaTeX Interpreter

To enable the LaTeX interpreter for text objects, set the **Interpreter** property to **latex**. For example, the following statement displays an equation in a figure at the point [.5 .5], and enlarges the font to 16 points.

```
text('Interpreter','latex',...  
    'String','$$\int_0^x \! \int_y dF(u,v)$$',...  
    'Position',[.5 .5],...  
    'FontSize',16)
```

---

**Note** The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, reduce this amount by about 10 characters per line.

---

## Information About Using TeX

The following references may be useful to people who are not familiar with TeX.

- Donald E. Knuth, *The TeXbook*, Addison Wesley, 1986.
- The TeX Users Group home page: <http://www.tug.org>

Interruptible  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Edge line type.* Specifies the line style used to draw the edges of the text `Extent`.

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

For example, the following code draws a red rectangle with a dotted line style around text that labels a plot.

```
text(3*pi/4,sin(3*pi/4),...  
     '\leftarrow sin(t) = .707',...  
     'EdgeColor','red',...  
     'LineWidth',2,...  
     'LineStyle',':');
```

# Text Properties

---

For additional features, see the following properties:

- **BackgroundColor** — Color of the rectangle's interior (none by default)
- **EdgeColor** — Color of the rectangle's edge (none by default)
- **LineWidth** — Width of the rectangle's edge line (first set EdgeColor)
- **Margin** — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the EdgeColor rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the EdgeColor property and the area defined by the BackgroundColor change.

**LineWidth**  
scalar (points)

*Width of line used to draw text extent rectangle.* When you set the text `EdgeColor` property to a color (the default is none), MATLAB displays a rectangle around the text `Extent`. Use the `LineWidth` property to specify the width of the rectangle edge. For example, the following code draws a red rectangle around text that labels a plot and specifies a line width of 3 points:

```
text(3*pi/4,sin(3*pi/4),...  
'\leftarrow sin(t) = .707',...  
'EdgeColor','red',...  
'LineWidth',3);
```

For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (none by default)
- `EdgeColor` — Color of the rectangle's edge (none by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)

# Text Properties

---

- **Margin** — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

## Margin

scalar (pixels)

*Distance between the text extent and the rectangle edge.* When you specify a color for the `BackgroundColor` or `EdgeColor` text properties, MATLAB draws a rectangle around the area defined by the text `Extent` plus the value specified by the `Margin`. For example, the following code displays a light green rectangle with a 10-pixel margin.

```
text(5*pi/4,sin(5*pi/4),...  
    ['sin(5*pi/4) = ',num2str(sin(5*pi/4))],...  
    'HorizontalAlignment','center',...  
    'BackgroundColor',[.7 .9 .7],...  
    'Margin',10);
```

For additional features, see the following properties:

- **BackgroundColor** — Color of the rectangle's interior (none by default)
- **EdgeColor** — Color of the rectangle's edge (none by default)
- **LineStyle** — Style of the rectangle's edge line (first set **EdgeColor**)
- **LineWidth** — Width of the rectangle's edge line (first set **EdgeColor**)

## See how margin affects text extent properties

This example enables you to change the values of the **Margin** property and observe the effects on the **BackgroundColor** area and the **EdgeColor** rectangle.

[Click to view in editor](#) — This link opens the MATLAB editor with the following example.

[Click to run example](#) — Use your scroll wheel to vary the **Margin**.

# Text Properties

---

## Parent

handle of axes, hggroup, or hgtransform

*Parent of text object.* Handle of the text object's parent. The parent of a text object is the axes, hggroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Position

[x,y,[z]]

*Location of text.* A two- or three-element vector, [x y [z]], that specifies the location of the text in three dimensions. If you omit the z value, it defaults to 0. All measurements are in units specified by the Units property. Initial value is [0 0 0].

## Rotation

scalar (default = 0)

*Text orientation.* Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation).

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also set to on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by

drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

String  
string

*Text string.* Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See *Mathematical Symbols*, *Greek Letters*, and *TeX Characters* for an example.

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

When the text `Interpreter` property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

**TeX Character Sequence Table**

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	$\alpha$	<code>\upsilon</code>	$\upsilon$	<code>\sim</code>	$\sim$
<code>\angle</code>	$\angle$	<code>\phi</code>	$\Phi$	<code>\leq</code>	$\leq$
<code>\ast</code>	$*$	<code>\chi</code>	$\chi$	<code>\infty</code>	$\infty$
<code>\beta</code>	$\beta$	<code>\psi</code>	$\psi$	<code>\clubsuit</code>	$\clubsuit$

# Text Properties

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\gamma</code>	$\Upsilon$	<code>\omega</code>	$\omega$	<code>\diamondsuit</code>	$\blacklozenge$
<code>\delta</code>	$\delta$	<code>\Gamma</code>	$\Gamma$	<code>\heartsuit</code>	$\heartsuit$

<code>\rceil</code>	$\rceil$	<code>\rangle</code>	$\rangle$	<code>\mid</code>	$\mid$
<code>\vee</code>	$\vee$			<code>\copyright</code>	$\copyright$
<code>\langle</code>	$\langle$				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers:

- `\bf` — Bold font
- `\it` — Italic font
- `\sl` — Oblique font (rarely available)
- `\rm` — Normal font
- `\fontname{fontname}` — Specify the name of the font family to use.
- `\fontsize{fontsize}` — Specify the font size in FontUnits.

# Text Properties

---

- `\color{colorSpec}` — Specify color for succeeding characters

Stream modifiers remain in effect until the end of the string or only within the context defined by braces `{ }`.

## Specifying Text Color in TeX Strings

Use the `\color` modifier to change the color of characters following it from the previous color (which is black by default). Syntax is:

- `\color{colorname}` — Use for the eight basic named colors (red, green, yellow, magenta, blue, black, white), and plus the four Simulink colors (gray, darkGreen, orange, and lightBlue).

Note that short names (one-letter abbreviations) for colors are not supported by the `\color` modifier.

- `\color[rgb]{r g b}` — Use to specify an RGB triplet with values between 0 and 1 as a cell array

For example:

```
text(.1,.5,['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0 .5 .5}teal \color{red}red} black again'])
```

## Specifying Subscript and Superscript Characters

The subscript character “`_`” and the superscript character “`^`” modify the character or substring defined in braces immediately following.

To print the special characters used to define the TeX strings when `Interpreter` is `tex`, prefix them with the backslash “`\`” character: `\\`, `\{`, `\}`, `\_`, `\^`.

See the “Examples” on page 1-6273 in the text reference page for more information.

When `Interpreter` is `none`, no characters in the `String` are interpreted, and all are displayed when the text is drawn.

When `Interpreter` is `latex`, MATLAB provides a complete LaTeX interpreter for text objects. See the `Interpreter` property for more information.

# Text Properties

---

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

## Type

string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For text objects, `Type` is always 'text'.

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the text.* The handle of a `uicontextmenu` object created in the same figure as the text. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the text.

## Units

pixels | normalized | inches |  
| characters | centimeters | points | {data}

*Units of measurement.* Specifies the units MATLAB uses to interpret the `Extent` and `Position` properties. All units are measured from the lower left corner of the axes plot box.

- `normalized` — Units map the lower left corner of the rectangle defined by the axes to (0,0) and the upper right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.

- **characters** — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.
- **data** — Data units of the parent axes as determined by the data graphed (not the axes Units property, which controls the positioning of the axes within the figure window).

If you change the value of Units, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume Units is set to the default value.

## UserData

matrix

*User-specified data.* Data you want to associate with the text object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## VerticalAlignment

top | cap | {middle} | baseline |  
bottom

*Vertical alignment of text.* Specifies the vertical justification of the text string. It determines where MATLAB places the string vertically with regard to the points specified by the Position property.

- **top** — Place the top of the string's Extent rectangle at the specified y-position.
- **cap** — Place the string so that the top of a capital letter is at the specified y-position.
- **middle** — Place the middle of the string at the specified y-position.
- **baseline** — Place font baseline at the specified y-position.

# Text Properties

---

- **bottom** — Place the bottom of the string’s Extent rectangle at the specified *y*-position.

The following picture illustrates the alignment options.

**Text VerticalAlignment property viewed with the HorizontalAlignment property set to left (the default).**

See “Text Alignment” for more information and examples.

**Visible**  
{on} | off

*Text visibility.* By default, all text is visible. When set to **off**, the text is not visible, but still exists, and you can query and set its properties.

**See Also**      text

**Purpose** Read data from text file; write to multiple outputs

---

**Note** textread is not recommended. Use textscan instead.

---

**Syntax**

```
[A,B,C,...] = textread(filename,format)
[A,B,C,...] = textread(filename,format,N)
[...] = textread(...,param,value,...)
```

**Description** [A,B,C,...] = textread(filename,format) reads data from the file filename into the variables A,B,C, and so on, using the specified format, until the entire file is read. The filename and format inputs are strings, each enclosed in single quotes. textread is useful for reading text files with a known format. textread handles both fixed and free format files.

---

**Note** When reading large text files, reading from a specific point in a file, or reading file data into a cell array rather than multiple outputs, you might prefer to use the textscan function.

---

textread matches and converts groups of characters from the input. Each input field is defined as a string of non-white-space characters that extends to the next white-space or delimiter character, or to the maximum field width. Repeated delimiter characters are significant, while repeated white-space characters are treated as one.

The format string determines the number and types of return arguments. The number of return arguments is the number of items in the format string. The format string supports a subset of the conversion specifiers and conventions of the C language fscanf routine. Values for the format string are listed in the table below. White-space characters in the format string are ignored.

# textread

<b>format</b>	<b>Action</b>	<b>Output</b>
Literals (ordinary characters)	Ignore the matching characters. For example, in a file that has Dept followed by a number (for department number), to skip the Dept and read only the number, use 'Dept' in the format string.	None
%d	Read a signed integer value.	Double array
%u	Read an integer value.	Double array
%f	Read a floating-point value.	Double array
%s	Read a white-space or delimiter-separated string.	Cell array of strings
%q	Read a double quoted string, ignoring the quotes.	Cell array of strings
%c	Read characters, including white space.	Character array
%[...]	Read the longest string containing characters specified in the brackets.	Cell array of strings
%[^...]	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
%*... instead of %	Ignore the matching characters specified by *.	No output
%w... instead of %	Read field width specified by w. The %f format supports %w.pf, where w is the field width and p is the precision.	

[A,B,C,...] = textread(filename,format,N) reads the data, reusing the format string N times, where N is an integer greater than zero. If N is smaller than zero, textread reads the entire file.

[...] = textread(...,param,value,...) customizes textread using param/value pairs, as listed in the table below.

param	value	Action
bufsize	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
delimiter	One or more characters	Act as delimiters between elements. Default is none.
emptyvalue	Scalar double	Value given to empty cells when reading delimited files. Default is 0.
endofline	Single character or '\r\n'	Character that denotes the end of a line. Default is determined from file
expchars	Exponent characters	Default is eEDD.
headerlines	Positive integer	Ignores the specified number of lines at the beginning of the file.
whitespace	Any from the list below: ' '           Space \b            Backspace \n            Newline \r            Carriage return \t            Horizontal tab	Treats vector of characters as white space. Default is '\b\t'.

---

**Note** When `textread` reads a consecutive series of `whitespace` values, it treats them as one white space. When it reads a consecutive series of `delimiter` values, it treats each as a separate delimiter.

---

# textread

---

## Tips

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
textread('myfile.txt', '%s', 'whitespace', '')
ans =
    '  An example      of preserving  spaces  '
```

## Examples

### Example 1 – Read All Fields in Free Format File Using %

The first line of `mydata.dat` is

```
Sally   Level1 12.34 45 Yes
```

Read the first line of the file as a free format file using the % format.

```
[names, types, x, y, answer] = textread('mydata.dat', ...
    '%s %s %f %d %s', 1)
```

returns

```
names =
    'Sally'
types =
    'Level1'
x =
    12.340000000000000
y =
    45
answer =
    'Yes'
```

### Example 2 – Read as Fixed Format File, Ignoring the Floating Point Value

The first line of `mydata.dat` is

```
Sally   Level1 12.34 45 Yes
```

Read the first line of the file as a fixed format file, ignoring the floating-point value.

```
[names, types, y, answer] = textread('mydata.dat', ...  
'%9c %6s %*f %2d %3s', 1)
```

returns

```
names =  
Sally  
types =  
    'Level1'  
y =  
    45  
answer =  
    'Yes'
```

`%*f` in the format string causes `textread` to ignore the floating point value, in this case, 12.34.

### Example 3 – Read Using Literal to Ignore Matching Characters

The first line of `mydata.dat` is

```
Sally    Type1 12.34 45 Yes
```

Read the first line of the file, ignoring the characters `Type` in the second field.

```
[names, typenum, x, y, answer] = textread('mydata.dat', ...  
'%s Type%d %f %d %s', 1)
```

returns

```
names =  
    'Sally'  
typenum =  
    1  
x =  
    12.340000000000000  
y =  
    45
```

```
answer =  
    'Yes'
```

Type%d in the format string causes the characters Type in the second field to be ignored, while the rest of the second field is read as a signed integer, in this case, 1.

## Example 4 – Specify Value to Fill Empty Cells

For files with empty cells, use the emptyvalue parameter. Suppose the file data.csv contains:

```
1,2,3,4,,6  
7,8,9,,11,12
```

Read the file using NaN to fill any empty cells:

```
data = textread('data.csv', '', 'delimiter', ',', ...  
    'emptyvalue', NaN);
```

## Example 5 – Read File into a Cell Array of Strings

Read the file fft.m into cell array of strings.

```
file = textread('fft.m', '%s', 'delimiter', '\n', ...  
    'whitespace', '');
```

## See Also

textscan | dlmread | fscanf

**Purpose**

Read formatted data from text file or string

**Syntax**

```
C = textscan(fileID,formatSpec)
C = textscan(fileID,formatSpec,N)

C = textscan(str,formatSpec)
C = textscan(str,formatSpec,N)

C = textscan( ___,Name,Value)

[C,position] = textscan( ___ )
```

**Description**

`C = textscan(fileID,formatSpec)` reads data from an open text file into cell array `C`. The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading from a file, close the file by calling `fclose(fileID)`.

`textscan` attempts to match the data in the file to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(fileID,formatSpec,N)` reads file data, using the `formatSpec` `N` times, where `N` is a positive integer. To read additional data from the file after `N` cycles, call `textscan` again using the original `fileID`. If you resume a text scan of a file by calling `textscan` with the same file identifier (`fileID`), then `textscan` automatically resumes reading at the point where it terminated the last read.

`C = textscan(str,formatSpec)` reads data from a string, `str` into cell array `C`. For strings, repeated calls to `textscan` restart the scan from the beginning each time. To restart a scan from the last position, request a `position` output.

`textscan` attempts to match the data in the string, `str`, to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(str,formatSpec,N)` reads string data, using the `formatSpec` `N` times, where `N` is a positive integer.

`C = textscan( ___,Name,Value)` specifies options using one or more `Name,Value` pair arguments, in addition to any of the input arguments in the previous syntaxes.

`[C,position] = textscan( ___)` returns the file or string position at the end of the scan as the second output argument, using any of the input arguments in the previous syntaxes. For a file, this is the value that `ftell(fileID)` would return after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

## Input Arguments

### **fileID - File identifier**

numeric scalar

File identifier of an open text file, specified as a number. Before reading a file with `textscan`, you must use `fopen` to open the file and obtain the `fileID`.

### **Data Types**

double

### **formatSpec - Format of the data fields**

string

Format of the data fields, specified as a string of one or more conversion specifiers. When `textscan` reads a file or string, it attempts to match the data to the `formatSpec` string. If `textscan` fails to match a data field, it stops reading and returns all fields read before the failure.

The number of conversion specifiers determines the number of cells in output array, `C`.

### **Numeric Fields**

This table lists available conversion specifiers for numeric inputs.

<b>Numeric Input Type</b>	<b>Conversion Specifier</b>	<b>Output Class</b>
Integer, signed	%d	int32
	%d8	int8
	%d16	int16
	%d32	int32
	%d64	int64
Integer, unsigned	%u	uint32
	%u8	uint8
	%u16	uint16
	%u32	uint32
	%u64	uint64
Floating-point number	%f	double
	%f32	single
	%f64	double
	%n	double

### Character Fields

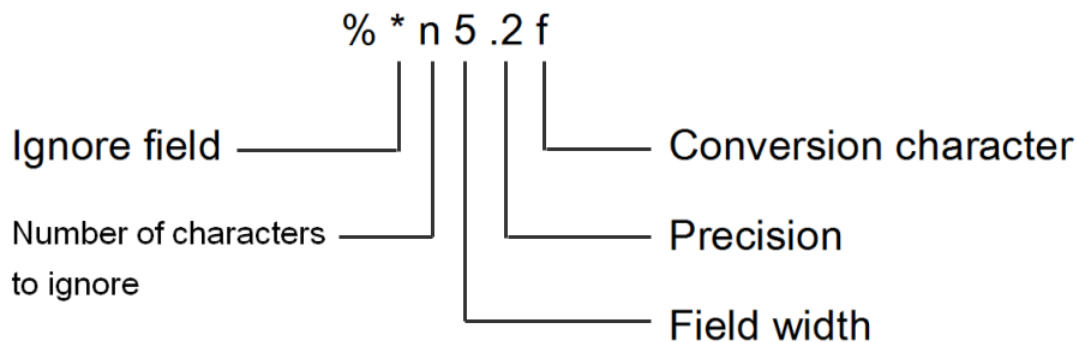

This table lists available conversion specifiers for character inputs.

<b>Character Strings</b>	<b>Conversion Specifier</b>	<b>Details</b>
Characters	%s	String
	%q	String, where double quotation marks indicate text to keep together
	%c	Any single character, including a delimiter

Character Strings	Conversion Specifier	Details
Pattern-matching strings	<code>%[...]</code>	Read only the characters inside the brackets up to the first nonmatching character. To include <code>]</code> in the set, specify it first: <code>%[ ]...</code> .  Example: <code>%[mus]</code> reads 'summer ' as 'summ'.
	<code>%[^...]</code>	Exclude characters inside the brackets, reading until the first matching character. To exclude <code>]</code> , specify it first: <code>%[^ ]...</code> .  Example: <code>%[^xrg]</code> reads 'summer ' as 'summe'.

## Optional Operators

Conversion specifiers in `formatSpec` can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Fields and Characters to Ignore

`textscan` reads all characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field.

Use the following operators to skip or read portions of fields.

Operator	Action Taken
<code>%*</code>	<p>Skip the field. <code>textscan</code> does not create an output cell for any field that it skips.</p> <p>Example: <code>'%s %*s %s %s %*s %*s %s'</code> (spaces are optional) converts the string <code>'Blackbird singing in the dead of night'</code> to four output cells with the strings <code>'Blackbird'</code> <code>'in'</code> <code>'the'</code> <code>'night'</code></p>
<code>%*n</code>	<p>Ignore <math>n</math> characters of the field, where <math>n</math> is an integer less than or equal to the number of characters in the field.</p> <p>Example: <code>%*4s</code> ignores 4 characters, so <code>'%*4s %s'</code> reads <code>'summer'</code> as <code>'er'</code>.</p>

- Field Width

`textscan` reads the number of characters or digits specified by the field width or precision, or up to the first delimiter, whichever comes first. A decimal point is counted as a digit. Specify the field width by inserting a number after the percent character (%) in the conversion specifier.

Example: `%5f` reads `'123.456'` as `123.4`.

---

**Note** When the field width operator is used with single characters (`%c`), `textscan` also reads delimiter characters.  
 Example: `%7c` reads 7 characters, including white-space, so `'Day and night'` reads as `'Day and'`.

---

- Precision

For floating-point numbers (`%n`, `%f`, `%f32`, `%f64`), you can specify the number of decimal digits to read.

Example: `%7.2f` reads `'123.456'` as `123.45`.

- Literal Text to Ignore

`textscan` ignores specified text appended to the `formatSpec` string.

Example: `Level%u8` reads `'Level1'` as `1`.

Example: `%u8Step` reads `'2Step'` as `2`.

## **N - Number of times to apply formatSpec**

integer

Number of times to apply `formatSpec`, specified as an integer.

### **Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |  
`uint16` | `uint32` | `uint64`

### **str - Input string**

string

Input string to read.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Names are not case sensitive.

**Example:** `C =`

```
textscan(fileID,formatSpec,'HeaderLines',3,'Delimiter','(',')')
skips the first three lines of the data, and then reads the remaining
data, treating commas as a delimiter.
```

**'CollectOutput' - Logical indicator determining data concatenation**`false (default) | true`

Logical indicator determining data concatenation, specified as the comma-separated pair consisting of 'CollectOutput' and either `true` or `false`. If `true`, then `textscan` concatenates consecutive output cells of the same fundamental MATLAB class into a single array.

**'CommentStyle' - Symbols designating text to ignore**`string | cell array of strings`

Symbols designating text to ignore, specified as the comma-separated pair consisting of 'CommentStyle' and a string or cell array of strings.

For example, specify a string such as `'%'` to ignore characters following the string on the same line. Specify a cell array of two strings, such as `{'/*', '*/'}`, to ignore characters between the strings.

`textscan` checks for comments only at the start of each field, not within a field.

**Example:** `'CommentStyle',{'/*', '*/'}`

**'Delimiter' - Field delimiter characters**`{' ', '\b', '\t'} (default) | string | cell array of strings`

Field delimiter characters, specified as the comma-separated pair consisting of 'Delimiter' and a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

**Example:** `'delimiter',{';', '*'}`

`textscan` interprets repeated delimiter characters as separate delimiters, and returns an empty value to the output cell.

Within each row of data, the default field delimiter is white space. White space can be any combination of space (`' '`), backspace (`'\b'`), or tab (`'\t'`) characters. If you do not specify a delimiter, `textscan` interprets repeated white-space characters as a single delimiter.

When you specify one of the following escape sequences as a delimiter, `textscan` converts that sequence to the corresponding control character:

<code>\b</code>	Backspace
<code>\n</code>	Newline
<code>\r</code>	Carriage return
<code>\t</code>	Tab
<code>\\</code>	Backslash ( <code>\</code> )

## **'EmptyValue' - Returned value for empty numeric fields**

`NaN` (default) | scalar

Returned value for empty numeric fields in delimited text files, specified as the comma-separated pair consisting of `'EmptyValue'` and a scalar.

## **'EndOfLine' - End-of-line characters**

string

End-of-line characters, specified as the comma-separated pair consisting of `'EndOfLine'` and a string. The default end-of-line sequence depends on the format of your file and can include a newline character (`'\n'`), a carriage return (`'\r'`), or a combination of the two (`'\r\n'`).

If there are missing values and an end-of-line sequence at the end of the last line in a file, then `textscan` returns empty values for those fields. This ensures that individual cells in output cell array, `C`, are the same size.

## **'ExpChars' - Exponent characters**

`'eEdD'` (default) | string

Exponent characters, specified as the comma-separated pair consisting of `'ExpChars'` and a string. The default exponent characters are `e`, `E`, `d`, and `D`.

## **'HeaderLines' - Number of header lines**

`0` (default) | positive integer

Number of header lines, specified as the comma-separated pair consisting of 'HeaderLines' and a positive integer. textscan skips the header lines, including the remainder of the current line.

#### **'MultipleDelimsAsOne' - Multiple delimiter handling**

0 (false) (default) | 1 (true)

Multiple delimiter handling, specified as the comma-separated pair consisting of 'MultipleDelimsAsOne' and either true or false. If true, textscan treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter. You must also specify the Delimiter option.

**Example:** 'MultipleDelimsAsOne',1

#### **'ReturnOnError' - Behavior when textscan fails to read or convert**

1 (true) (default) | 0 (false)

Behavior when textscan fails to read or convert, specified as the comma-separated pair consisting of 'ReturnOnError' and either true or false. If true, textscan terminates without an error and returns all fields read. If false, textscan terminates with an error and does not return an output cell array.

#### **'TreatAsEmpty' - Strings to treat as empty value**

string | cell array of strings

Strings to treat as empty values, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a single string or cell array of strings. This option only applies to numeric fields.

#### **'Whitespace' - White-space characters**

' \b\t' (default) | string

White-space characters, specified as the comma-separated pair consisting of 'Whitespace' and a string of one or more characters. textscan adds a space character, char(32), to any specified

Whitespace, unless Whitespace is empty ( ' ') and formatSpec includes any string conversion specifier.

When you specify one of the following escape sequences as any white-space character, textscan converts that sequence to the corresponding control character:

\b	Backspace
\n	Newline
\r	Carriage return
\t	Tab
\\	Backslash (\)

## Output Arguments

### **C** - File or string data

cell array

File or string data, returned as a cell array.

For each numeric conversion specifier in formatSpec, the textscan function returns a K-by-1 MATLAB numeric vector to the output cell array, C, where K is the number of times that textscan finds a field matching the specifier.

For each string conversion specifier in formatSpec, the textscan function returns a K-by-1 cell vector of strings, where K is the number of times that textscan finds a field matching the specifier. For each character conversion that includes a field width operator, textscan returns a K-by-M character array, where M is the field width.

### **position** - File or string position

integer

File or string position at the end of the scan, returned as an integer of class double. For a file, ftell(fileID) would return the same value after calling textscan. For a string, position indicates how many characters textscan read.

## Examples

### Read a String

Read a string of floating-point numbers.

```
str = '0.41 8.24 3.57 6.24 9.27';
```

```
C = textscan(str,'%f');
```

The formatSpec string '%f' tells textscan to match each field in str to a double-precision floating-point number.

Display the contents of cell array C.

```
celldisp(C)
```

```
C{1} =  
  
    0.4100  
    8.2400  
    3.5700  
    6.2400  
    9.2700
```

Read the same string, truncating each value to one decimal digit.

```
C = textscan(str,'%3.1f %*1d');
```

The specifier %3.1f indicates a field width of 3 digits and a precision of 1. textscan reads a total of 3 digits, including the decimal point and the 1 digit after the decimal point. The specifier, %\*1d, tells textscan to skip the remaining digit.

Display the contents of cell array C.

```
celldisp(C)
```

```
C{1} =  
  
    0.4000
```

```
8.2000
3.5000
6.2000
9.2000
```

## Read Different Types of Data

Using a text editor, create a file `scan1.dat` that contains data in the following form:

```
09/12/2005 Level1 12.34 45 1.23e10 inf Nan Yes 5.1+3i
10/12/2005 Level2 23.54 60 9e19 -inf 0.001 No 2.2-.5i
11/12/2005 Level3 34.90 12 2e5 10 100 No 3.1+.1i
```

Open the file, and read each column with the appropriate conversion specifier.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s %s %f32 %d8 %u %f %f %s %f');
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =
```

```
09/12/2005
```

```
C{1}{2} =
```

```
10/12/2005
```

```
C{1}{3} =
```

```
11/12/2005
```

```
C{2}{1} =
```

Level1

C{2}{2} =

Level2

C{2}{3} =

Level3

C{3} =

12.3400

23.5400

34.9000

C{4} =

45

60

12

C{5} =

4294967295

4294967295

200000

C{6} =

Inf  
-Inf  
10

C{7} =

NaN  
0.0010  
100.0000

C{8}{1} =

Yes

C{8}{2} =

No

C{8}{3} =

No

C{9} =

5.1000 + 3.0000i  
2.2000 - 0.5000i  
3.1000 + 0.1000i

textscan returns a 1-by-9 cell array C.

View the MATLAB data type of each of the cells in C.

C

C =

Columns 1 through 5

{3x1 cell} {3x1 cell} [3x1 single] [3x1 int8] [3x1 ui

Columns 6 through 9

[3x1 double] [3x1 double] {3x1 cell} [3x1 double]

For example, C{1} and C{2} are cell arrays. C{5} is of data type uint32, so the first two elements of C{5} are the maximum values for a 32-bit unsigned integer, or intmax('uint32').

### Remove a Literal String

Remove the text 'Level' from each field in the second column of the data from the previous example.

Match the literal string in the formatSpec input.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s Level%d %f32 %d8 %u %f %f %s %f');
fclose(fileID);
C{2}
```

ans =

```
1
2
3
```

View the MATLAB data type of the second cell in C.

```
class(C{2})
```

```
ans =
```

```
int32
```

The second cell of the 1-by-9 cell array, C, is now of data type int32.

## Skip the Remainder of a Line

Read the first column of the file in the previous example into a cell array, skipping the rest of the line.

```
fileID = fopen('scan1.dat');  
dates = textscan(fileID, '%s %*[^\\n]');  
fclose(fileID);  
dates{1}
```

```
ans =
```

```
    '09/12/2005'
```

```
    '10/12/2005'
```

```
    '11/12/2005'
```

textscan returns a 1-by-1 cell array dates.

## Specify Delimiter and Empty Value Conversion

Using a text editor, create a comma-delimited file, data.csv, that contains

```
1, 2, 3, 4, , 6  
7, 8, 9, , 11, 12
```

Read the file, converting empty cells to -Inf.

```
fileID = fopen('data.csv');  
C = textscan(fileID, '%f %f %f %f %u8 %f', ...  
    'delimiter', ',', 'EmptyValue', -Inf);  
fclose(fileID);
```

```
column4 = C{4}, column5 = C{5}
```

```
column4 =
```

```
    4  
 -Inf
```

```
column5 =
```

```
    0  
   11
```

textscan returns a 1-by-6 cell array, `C`. The `textscan` function converts the empty value in `C{4}` to `-Inf`, where `C{4}` is associated with a floating-point format. Because MATLAB represents unsigned integer `-Inf` as 0, `textscan` converts the empty value in `C{5}` to 0, and not `-Inf`.

### Read Custom Empty Value Strings and Comments

Using a text editor, create a comma-delimited file, `data2.csv`, that contains the lines

```
abc, 2, NA, 3, 4  
// Comment Here  
def, na, 5, 6, 7
```

Designate the input that `textscan` should treat as comments or empty values.

```
fileID = fopen('data2.csv');  
C = textscan(fileID,'%s %n %n %n %n','delimiter',' ','...  
'treatAsEmpty',{'NA','na'},'commentStyle','//');  
fclose(fileID);  
celldisp(C)
```

```
C{1}{1} =  
abc
```

```
C{1}{2} =
def

C{2} =
    2
    NaN

C{3} =
    NaN
    5

C{4} =
    3
    6

C{5} =
    4
    7
```

## Treat Repeated Delimiters as One

Using a text editor, create a file, `data3.csv`, that contains

```
1,2,3,,4
5,6,7,,8
```

To treat the repeated commas as a single delimiter, use the `MultipleDelimsAsOne` parameter, and set the value to 1 (`true`).

```
fileID = fopen('data3.csv');
C = textscan(fileID,'%f %f %f %f','delimiter',' ','...',
'MultipleDelimsAsOne',1);
fclose(fileID);
celldisp(C)
```

```
C{1} =
    1
    5
```

```
C{2} =
     2
     6
```

```
C{3} =
     3
     7
```

```
C{4} =
     4
     8
```

### Collect Numeric Data

Using a text editor, create a file, `grades.txt`, that contains:

Student_ID	Test1	Test2	Test3
1	91.5	89.2	77.3
2	88.0	67.8	91.0
3	76.3	78.1	92.5
4	96.4	81.2	84.6

Read the column headers using the format `'%s'` four times.

```
fileID = fopen('grades.txt');

formatSpec = '%s';
N = 4;
C_text = textscan(fileID,formatSpec,N,'delimiter','|');
```

Read the numeric data in the file.

```
C_data0 = textscan(fileID,'%d %f %f %f')

C_data0 =
    [4x1 int32]    [4x1 double]    [4x1 double]    [4x1 double]
```

The default value for `CollectOutput` is 0 (`false`), so `textscan` returns each column of the numeric data in a separate array.

Set `CollectOutput` to 1 (`true`) to collect the consecutive columns of the same class into a single array.

```
frewind(fileID);

C_text = textscan(fileID, '%s', N, 'delimiter', '|');

C_data1 = textscan(fileID, '%d %f %f %f', 'CollectOutput', 1)

C_data1 =
    [4x1 int32]    [4x3 double]
```

The test scores, which are all `double`, are collected into a single 4-by-3 array.

Close the file, `grades.txt`.

```
fclose(fileID);
```

### Read Nondefault Control Characters

Use `sprintf` to convert nondefault escape sequences in your data.

Create a string that includes a form feed character, `\f`. Then, to read the string using `textscan`, call `sprintf` to explicitly convert the form feed.

```
lyric = sprintf('Blackbird\fsinging\nin\nfthe\fof\nfnight');
C = textscan(lyric, '%s', 'delimiter', sprintf('\f'));
C{1}
```

```
ans =

    'Blackbird'
    'singing'
    'in'
    'the'
```

```
'dead'
'of'
'night'
```

textscan returns a 1-by-1 cell array, C.

### Resume a Text Scan of a String

Resume a scan of a string from a position other than the beginning.

If you resume a text scan of a string, textscan reads from the beginning of the string each time. To resume a scan from any other position in the string, use the two-output argument syntax in your initial call to textscan.

For example, create a string called lyric. Read the first word of the string, and then resume the scan.

```
lyric = 'Blackbird singing in the dead of night';
[firstword,pos] = textscan(lyric,'%9c',1);
lastpart = textscan(lyric(pos+1:end),'%s');
```

## Algorithms

textscan converts numeric fields to the specified output type according to MATLAB rules regarding overflow, truncation, and the use of NaN, Inf, and -Inf. For example, MATLAB represents an integer NaN as zero. If textscan finds an empty field associated with an integer format specifier (such as %d or %u), it returns the empty value as zero and not NaN.

textscan does not include leading white-space characters in the processing of any data fields. When processing numeric data, textscan also ignores trailing white space.

textscan imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type (such as %d or %f). Valid forms for a complex number are:

$\pm\langle\text{real}\rangle\pm\langle\text{imag}\rangle i j$	Example: 5.7-3.1i
$\pm\langle\text{imag}\rangle i j$	Example: -7j

# textscan

---

Do not include embedded white space in a complex number. `textscan` interprets embedded white space as a field delimiter.

<b>Purpose</b>	Wrapped string matrix for given uicontrol
<b>Syntax</b>	<pre>outstring = textwrap(h,instring) outstring = textwrap(h,instring,columns) [outstring,position] = textwrap(...)</pre>
<b>Description</b>	<p><code>outstring = textwrap(h,instring)</code> returns a wrapped string cell array, <code>outstring</code>, that fits inside the uicontrol with handle <code>h</code>. <code>instring</code> is a cell array, with each cell containing a single line of text. <code>outstring</code> is the wrapped string matrix in cell array format. Each cell of the input string is considered a paragraph.</p> <p><code>outstring = textwrap(h,instring,columns)</code> returns an <code>outstring</code> with each line wrapped at <code>columns</code> characters. Spaces are included in the character count.</p> <p><code>[outstring,position] = textwrap(...)</code> returns the recommended position of the uicontrol in the units of the uicontrol. <code>position</code> considers the extent of the multiline text in the <code>x</code> and <code>y</code> directions.</p> <p><code>textwrap</code> maintains the original line breaks in the input cell array and adds new ones. It can calculate uicontrol positions with any type of Units, including normalized units.</p>
<b>Tips</b>	When programming a GUI, do not call <code>copyobj</code> or <code>textwrap</code> (which calls <code>copyobj</code> ) inside a <code>CreateFcn</code> . The act of copying the uicontrol object fires the <code>CreateFcn</code> repeatedly, which raises a series of error messages after exceeding the root object's <code>RecursionLimit</code> property.
<b>Examples</b>	<p>Place two text-wrapped strings in text uicontrols. The left one has a <code>Position</code> calculated by <code>textwrap</code> in Units of pixels; the right one's <code>Position</code> is calculated manually in Units of characters:</p> <pre>figure('Position',[560 528 350 250]); % Make a text uicontrol to wrap in Units of Pixels % Create it in Units of Pixels, 100 wide, 10 high pos = [10 100 100 10]; ht = uicontrol('Style','Text','Position',pos);</pre>

# textwrap

---

```
string = {'This is a string for the left text uicontrol.',...
          'to be wrapped in Units of Pixels,',...
          'with a position determined by TEXTWRAP.'};
% Wrap string, also returning a new position for ht
[outstring,newpos] = textwrap(ht,string) %#ok<NOPRT>

newpos1 =
    29.8000    7.6154    15.0000    10.0000

set(ht1,'String',outstring1,'Position',newpos1)
```

**See Also**

[align](#) | [uicontrol](#)

**Purpose** Transpose-free quasi-minimal residual method

**Syntax**

```
x = tfqmr(A,b)
x = tfqmr(afun,b)
x = tfqmr(a,b,tol)
x = tfqmr(a,b,tol,maxit)
x = tfqmr(a,b,tol,maxit,m)
x = tfqmr(a,b,tol,maxit,m1,m2,x0)
[x,flag] = tfqmr(A,B,...)
[x,flag,relres] = tfqmr(A,b,...)
[x,flag,relres,y]y(A,b,...)
[x,flag,relres,iter,resvec] = tfqmr(A,b,...)
```

**Description** `x = tfqmr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and the right-hand side column vector  $b$  must have length  $n$ .

`x = tfqmr(afun,b)` accepts a function handle, `afun`, instead of the matrix  $A$ . The function, `afun(x)`, accepts a vector input  $x$  and returns the matrix-vector product  $A*x$ . In all of the following syntaxes, you can replace  $A$  by `afun`. “Parameterizing Functions” explains how to provide additional parameters to the function `afun`.

`x = tfqmr(a,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `tfqmr` uses the default,  $1e-6$ .

`x = tfqmr(a,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `tfqmr` uses the default,  $\min(N,20)$ .

`x = tfqmr(a,b,tol,maxit,m)` and `x = tfqmr(a,b,tol,maxit,m1,m2)` use preconditioners  $m$  or  $m=m1*m2$  and effectively solve the system  $A*inv(M)*x = B$  for  $x$ . If  $M$  is `[]` then a preconditioner is not applied.  $M$  may be a function handle `mfun` such that `mfun(x)` returns  $m\backslash x$ .

`x = tfqmr(a,b,tol,maxit,m1,m2,x0)` specifies the initial guess. If `x0` is `[]` then `tfqmr` uses the default, an all zero vector.

`[x,flag] = tfqmr(A,B,...)` also returns a convergence flag:

Flag	Convergence
0	tfqmr converged to the desired tolerance tol within maxit iterations.
1	tfqmr iterated maxit times but did not converge.
2	Preconditioner m was ill-conditioned.
3	tfqmr stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during tfqmr became too small or too large to continue computing.

`[x,flag,relres] = tfqmr(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If flag is 0, then  $\text{relres} \leq \text{tol}$ .

`[x,flag,relres,y]y(A,b,...)` also returns the iteration number at which x was computed:  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = tfqmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Example 1

This example shows how to use tfqmr with a matrix input and with a function input.

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = tfqmr(A,b,tol,maxit,M1,M2,[]);
```

You can also use a matrix-vector product function as input:

```
function y = afun(x,n)
```

```
y = 4 * x;  
y(2:n) = y(2:n) - 2 * x(1:n-1);  
y(1:n-1) = y(1:n-1) - x(2:n);  
x1 = tfqmr(@(x)afun(x,n),b,tol,maxit,M1,M2);
```

If `applyOp` is a function suitable for use with `qmr`, it may be used with `tfqmr` by wrapping it in an anonymous function:

```
x1 = tfqmr(@(x)applyOp(x,'notransp'),b,tol,maxit,M1,M2);
```

## Example 2

This example demonstrates the use of a preconditioner.

**1**

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;  
A = west0479;
```

**2**

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

**3**

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

**4**

Use `tfqmr` to find a solution at the requested tolerance and number of iterations:

```
[x0,f10,rr0,it0,rv0] = tfqmr(A,b,tol,maxit);
```

`f10` is 1 because `tfqmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the

best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

## 5

Plot the behavior of `tfqmr`:

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

Note that like `bicgstab`, `tfqmr` keeps track of half iterations. The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

## 6

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));  
Error using ilu  
There is a pivot equal to zero. Consider decreasing  
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = tfqmr(A,b,tol,maxit,L,U);
```

`f11` is 0 because `tfqmr` drives the relative residual to  $4.1410e-014$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

## 8

You can follow the progress of `tfqmr` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

# throw (MException)

---

**Purpose** Issue exception and terminate function

**Syntax** `throw(exception)`

**Description** `throw(exception)` issues an exception based on the information contained in *exception*. The exception terminates the currently running function and returns control to its caller. The *exception* argument is scalar object of the MException class that contains information on the cause of the error and where it occurred. The `throw` function passes *exception* back to the caller of the currently running function, and eventually back to the Command Window when the program terminates. The exception is made available to any calling function by means of the `catch` function, and to the Command Window by means of the `MException.last` function.

Unlike `throwAsCaller` and `rethrow`, the `throw` function also sets the *stack* field of the *exception* to the location from which `throw` was called.

**Tips** There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

- 1** Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.
- 2** Reissue the original exception by throwing the initial exception unmodified. Use the `MException.rethrow` method to do this.
- 3** Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the `MException.addCause` and `throw` methods to do this.

- 4 Make it appear that the error originated in the caller of the currently running function. Use the MException throwAsCaller method to do this.

## Examples

### Example 1

This example tests the output of function `evaluate_plots` and throws an exception if it is not acceptable:

```
[minval, maxval] = evaluate_plots(p24, p28, p41);
if minval < lower_bound || maxval > upper_bound
    exception = MException('VerifyOutput:OutOfBounds', ...
        'Results are outside the allowable limits');
    throw(exception);
end
```

### Example 2

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested try-catch block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second using `addCause`:

```
function data = read_it(filename);
try
    % Attempt to open and read from a file.
    fid = fopen(filename, 'r');
    data = fread(fid);
catch exception1
    % If the error was caused by an invalid file ID, try
    % reading from another location.
    if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
        msg = sprintf( ...
            '\nCannot open file %s. Try another location? ', ...
            filename);
        reply = input(msg, 's')
        if reply(1) == 'y'
            newFolder = input('Enter folder name: ', 's');
```

## throw (MException)

---

```
        else
            throw(exception1);
        end
        oldpath = addpath(newFolder);
        try
            fid = fopen(filename, 'r');
            data = fread(fid);
        catch exception2
            exception3 = addCause(exception2, exception1)
            path(oldpath);
            throw(exception3);
        end
        path(oldpath);
    end
end
fclose(fid);

try
    d = read_it('anytextfile.txt');
catch exception
end

exception
exception =
    MException object with properties:

        identifier: 'MATLAB:FileIO:InvalidFid'
        message: 'Invalid file identifier. Use fopen
                to generate a valid file identifier.'
        stack: [1x1 struct]
        cause: {[1x1 MException]}

    Cannot open file anytextfile.txt. Try another location?y
Enter folder name: xxxxxxx
Warning: Name is nonexistent or not a directory: xxxxxxx.
> In path at 110
    In addpath at 89
```

last(MException)

# throwAsCaller (MException)

---

**Purpose** Throw exception as if from calling function

**Syntax** `throwAsCaller(exception)`

**Description** `throwAsCaller(exception)` throws an exception from the currently running function based on the *exception* input, a scalar object of the `MException` class. The MATLAB software exits the currently running function and returns control to either the keyboard or an enclosing catch block in a calling function. Unlike the `throw` function, MATLAB omits the current stack frame from the `stack` field of the `MException`, thus making the exception look as if it is being thrown by the caller of the function.

In some cases, it is not relevant to show the person running your program the true location that generated an exception, but is better to point to the calling function where the problem really lies. You might also find `throwAsCaller` useful when you want to simplify the error display, or when you have code that you do not want made public.

**Tips** There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

- 1** Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.
- 2** Reissue the original exception by throwing the initial exception unmodified. Use the `MException` `rethrow` method to do this.
- 3** Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the `MException` `addCause` and `throw` methods to do this.

- 4 Make it appear that the error originated in the caller of the currently running function. Use the MException throwAsCaller method to do this.

## Examples

The function `klein_bottle`, in this example, generates a Klein Bottle figure by revolving the figure-eight curve defined by `XYKLEIN`. It defines a few variables and calls the function `draw_klein`, which executes three functions in a try-catch block. If there is an error, the catch block issues an exception using either `throw` or `throwAsCaller`:

```
function klein_bottle(pq)
ab = [0 2*pi];
rtr = [2 0.5 1];
box = [-3 3 -3 3 -2 2];
vue = [55 60];
draw_klein(ab, rtr, pq, box, vue)

function draw_klein(ab, rtr, pq, box, vue)
clf
try
    tube('xyklein',ab, rtr, pq, box, vue);
    shading interp
    colormap(pink);
catch exception
    throw(exception)
%    throwAsCaller(exception)
end
```

Call the `klein_bottle` function, passing a vector, and the function completes normally by drawing the figure.

```
klein_bottle([40 40])
```

Call the function again, this time passing a scalar value. Because the catch block issues the exception using `throw`, MATLAB displays error messages for line 16 of function `draw_klein`, and for line 6 of function `klein_bottle`:

## throwAsCaller (MException)

---

```
klein_bottle(40)
Error using klein_bottle>draw_klein (line 16)
Attempted to access pq(2); index out of bounds because numel(pq)=1.

Error in klein_bottle (line 6)
draw_klein(ab, rtr, pq, box, vue)
```

Run the function again, this time changing the `klein_bottle.m` file so that the catch block uses `throwAsCaller` instead of `throw`. This time, MATLAB only displays the error at line 6 of the main program:

```
klein_bottle(40)
Error using klein_bottle (line 6)
Attempted to access pq(2); index out of bounds because numel(pq)=1.
```

<b>Purpose</b>	Start stopwatch timer
<b>Syntax</b>	<pre>tic timerVal = tic</pre>
<b>Description</b>	<p><code>tic</code> starts a stopwatch timer to measure performance. The function records the internal time at execution of the <code>tic</code> command. Display the elapsed time with the <code>toc</code> function.</p> <p><code>timerVal = tic</code> returns the value of the internal timer at the execution of the <code>tic</code> command, so that you can record time for simultaneous time spans.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• Consecutive <code>tic</code> commands overwrite the internally recorded starting time.</li><li>• The <code>clear</code> function does not reset the starting time recorded by a <code>tic</code> command.</li><li>• The following actions result in unexpected output:<ul style="list-style-type: none"><li>▪ Using <code>tic</code> and <code>toc</code> to time <code>timeit</code></li><li>▪ Using <code>tic</code> and <code>toc</code> within a function timed by <code>timeit</code></li></ul></li></ul>
<b>Output Arguments</b>	<p><b>timerVal</b></p> <p>Value of the internal timer at the execution of the <code>tic</code> command. This value is used as an input argument for a subsequent call to <code>toc</code>. You should not rely on the meaning of this value.</p>
<b>Examples</b>	<p>Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.</p> <pre>tic A = rand(12000, 4400); B = rand(12000, 4400); toc C = A' .* B';</pre>

```
toc
```

---

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
    A = rand(n,n);
    b = rand(n,1);
    tic;
    x = A\b;
    t(n) = toc;
end
plot(t)
```

---

Measure multiple time spans simultaneously using two pairs of `tic/toc` calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000;    minTime = Inf;    nsum = 10;
tic; % TIC, pair 1

for i=1:REPS
    tStart = tic; % TIC, pair 2
    total = 0;
    for j=1:nsum
        total = total + besselj(j,REPS);
    end

    tElapsed = toc(tStart); % TOC, pair 2
    minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS; % TOC, pair 1
```

**See Also**

`clock` | `cputime` | `etime` | `profile` | `timeit` | `toc`

---

<b>Purpose</b>	Measure time required to run function
<b>Syntax</b>	<pre>t = timeit(f) t = timeit(f,numOutputs)</pre>
<b>Description</b>	<p><code>t = timeit(f)</code> measures the typical time (in seconds) required to run the function specified by the function handle <code>f</code>.</p> <p><code>t = timeit(f,numOutputs)</code> calls <code>f</code> with the desired number of outputs, <code>numOutputs</code>. By default, <code>timeit</code> calls the function <code>f</code> with one output (or no outputs, if the function does not return any outputs).</p>
<b>Input Arguments</b>	<p><b>f - function to be measured</b> function handle</p> <p>Function to be measured, specified as a function handle. <code>f</code> is either a handle to a function that takes no input, or a handle to an anonymous function with an empty argument list.</p> <p><b>numOutputs - Number of desired outputs from f</b> integer</p> <p>Number of desired outputs from <code>f</code>, specified as an integer. If the function specified by <code>f</code> has a variable number of outputs, <code>numOutputs</code> specifies which syntax <code>timeit</code> uses to call the function. For example, the <code>svd</code> function returns a single output, <code>s</code>, or three outputs, <code>[U,S,V]</code>. Set <code>numOutputs</code> to 1 to time the <code>s = svd(X)</code> syntax, or set it to 3 to time the <code>[U,S,V] = svd(X)</code> syntax.</p>
<b>Algorithms</b>	<code>timeit</code> calls the specified function multiple times, and computes the median of the measurements.
<b>Examples</b>	<p><b>Determine Time to Obtain Current Date</b></p> <p>Use <code>timeit</code> to time a function call to <code>date</code>. This example uses a handle to a function that accepts no input.</p>

```
f = @date;  
t = timeit(f)
```

```
t =
```

```
1.3481e-04
```

## Determine Time to Compute Matrix Summation

Time the combination of several mathematical matrix operations: matrix transposition, element-by-element multiplication, and summation of columns.

```
A = rand(12000, 400);  
B = rand(400, 12000);  
f = @() sum(A.' .* B, 1);  
timeit(f)
```

```
ans =
```

```
0.0427
```

## Compare Time to Run svd with Multiple Outputs

Determine how long it takes to run svd with one output argument, `s=svd(X)`.

```
X = [1 2; 3 4; 5 6; 7 8];  
f = @() svd(X);  
t1 = timeit(f)
```

```
t1 =
```

```
1.5427e-05
```

Compare the results to svd with three output arguments, `[U,S,V]=svd(X)`.

```
t2 = timeit(f,3)
```

```
t2 =  
  
2.6695e-05
```

### Compare Time to Execute Custom Preallocation to Calling zeros

Create a short function to allocate a matrix using nested loops. Preallocating an array using a nested loop is inefficient, but is shown here for illustrative purposes.

```
function mArr = preAllocFcn(x,y)  
for m = 1:x  
    for n = 1:y  
        mArr(m,n) = 0;  
    end  
end  
end
```

Compare the time to allocate zeros to a matrix using nested loops and using the zeros function.

```
x = 1000;  
y = 500;  
g = @() preAllocFcn(x,y);  
h = @() zeros(x,y);  
diffRunTime = timeit(g)-timeit(h)  
  
diffRunTime =  
  
0.2004
```

### Tips

- The following actions result in unexpected output:
  - Using `timeit` between `tic` and `toc`
  - Using `timeit` to time a function that includes calls to `tic` and `toc`
  - Using `timeit` recursively

# timeit

---

---

<b>Purpose</b>	Read elapsed time from stopwatch
<b>Syntax</b>	<pre>toc elapsedTime = toc toc(timerVal) elapsedTime = toc(timerVal)</pre>
<b>Description</b>	<p><code>toc</code> reads the elapsed time from the stopwatch timer started by the <code>tic</code> function. The function reads the internal time at the execution of the <code>toc</code> command, and displays the elapsed time since the most recent call to the <code>tic</code> function that had no output, in seconds.</p> <p><code>elapsedTime = toc</code> returns the elapsed time in a variable.</p> <p><code>toc(timerVal)</code> displays the time elapsed since the <code>tic</code> command corresponding to <code>timerVal</code>.</p> <p><code>elapsedTime = toc(timerVal)</code> returns the elapsed time since the <code>tic</code> command corresponding to <code>timerVal</code>.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• Consecutive calls to the <code>toc</code> function with no input return the elapsed since the most recent <code>tic</code>. Therefore, you can take multiple measurements from a single point in time.  Consecutive calls to the <code>toc</code> function with the same <code>timerVal</code> input return the elapsed time since the <code>tic</code> function call that corresponds to that input.</li><li>• The following actions result in unexpected output:<ul style="list-style-type: none"><li>▪ Using <code>tic</code> and <code>toc</code> to time <code>timeit</code></li><li>▪ Using <code>tic</code> and <code>toc</code> within a function timed by <code>timeit</code></li></ul></li></ul>
<b>Input Arguments</b>	<p><b>timerVal</b></p> <p>Value of the internal timer saved from a previous call to the <code>tic</code> command.</p>

## Output Arguments

### **elapsedTime**

Scalar double representing the time elapsed between `tic` and `toc` commands, in seconds.

## Examples

Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.

```
tic
A = rand(12000, 4400);
B = rand(12000, 4400);
toc
C = A' .* B';
toc
```

---

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
    A = rand(n,n);
    b = rand(n,1);
    tic;
    x = A\b;
    t(n) = toc;
end
plot(t)
```

---

Measure multiple time spans simultaneously using two pairs of `tic/toc` calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000;    minTime = Inf;    nsum = 10;
tic; % TIC, pair 1
```

---

```
for i=1:REPS
    tStart = tic; % TIC, pair 2
    total = 0;
    for j=1:nsum
        total = total + besselj(j,REPS);
    end

    tElapsed = toc(tStart); % TOC, pair 2
    minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS; % TOC, pair 1
```

**Purpose** MATLAB Gateway to LibTIFF library routines

**Description** The `Tiff` class represents a connection to a Tagged Image File Format (TIFF) file and provides access to many of the capabilities of the LibTIFF library. Use the methods of the `Tiff` object to call routines in the LibTIFF library. While you can use the `imread` and `imwrite` functions to read and write TIFF files, the `Tiff` class offers capabilities that these functions don't provide, such as reading subimages, writing tiles and strips of image data, and modifying individual TIFF tags.

In most cases, the syntax of the `Tiff` method is similar to the syntax of the corresponding LibTIFF library function. To get the most out of the `Tiff` object, you must be familiar with the LibTIFF API, as well as the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

MATLAB supports LibTIFF version 4.0.0.

For copyright information, see the `libtiffcopyright.txt` file.

**Construction** `obj = Tiff(filename,mode)` creates a `Tiff` object associated with the TIFF file `filename`. `mode` specifies the type of access to the file.

A TIFF file is made up of one or more image file directories (IFDs). An IFD contains image data and associated metadata. IFDs can also contain subIFDs which also contain image data and metadata. When you open a TIFF file for reading, the `Tiff` object makes the first IFD in the file the *current* IFD. `Tiff` methods operate on the current IFD. You can use `Tiff` object methods to navigate among the IFDs and the subIFDs in a TIFF file.

When you open a TIFF file for writing or appending, the `Tiff` object automatically creates a IFD in the file for writing subsequent data. This IFD has all the default values specified in TIFF Revision 6.0.

When creating a new TIFF file, before writing any image to the file, you must create certain required fields (tags) in the file. These tags include `ImageWidth`, `ImageHeight`, `BitsPerSample`, `SamplesPerPixel`, `Compression`, `PlanarConfiguration`, and `Photometric`. If the image data has a striped layout, the IFD contains the `RowsPerStrip` tag. If

the image data has a tiled layout, the IFD contains the `TileWidth` and `TileHeight` tags. Use the `setTag` method to define values for these tags.

## Input Arguments

### filename

Text string specifying name of file.

### mode

One of the following text strings specifying the type of access to the TIFF file.

## Supported Values

Parameter	Description
'r'	Open file for reading (default)
'w'	Open file for writing; discard existing contents
'w8'	Open file for writing a BigTIFF file; discard existing contents
'a'	Open or create file for writing; append data to end of file.
'r+'	Open (do not create) file for reading and writing

## Properties

### Compression

Specify scheme used to compress image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

None
CCITTRLE (Read-only)
CCITTFax3
CCITTFax4
LZW
JPEG
CCITTRLEW (Read-only)
PackBits
SGILog
SGILog24
Deflate
AdobeDeflate (Same as deflate)

Example: Set the Compression tag to the value JPEG. Note how you use the property to specify the value.

```
tiffobj.setTag('Compression', Tiff.Compression.JPEG);
```

## ExtraSamples

Describe extra components

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This field is required if there are extra channels in addition to the usual colormetric channels.

### Supported Values

Value of ExtraSamples	Description
Unspecified	Unspecified data
AssociatedAlpha	Associated alpha (pre-multiplied)
UnassociatedAlpha	Unassociated alpha data

Example: Set the ExtraSamples tag to the value AssociatedAlpha. Note how you use the property to specify the value.

```
tiffobj.setTag('ExtraSamples', Tiff.ExtraSamples.AssociatedAlpha)
```

See Also “Specify Tiff object properties and describe alpha channel” on page 1-6376

### Group3Options

Options for Group 3 Fax Compression

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property is also referred to as Fax3 and T4Options. This value is a bit mask controlled by the first three bits.

### Supported Values

Supported values include the following.

Encoding2D	Bit 0 is 1. This specifies two-dimensional coding. If more than one strip is specified, each strip must begin with a one-dimensionally coded line. That is, RowsPerStrip should be a multiple of Parameter K, as documented in the CCITT specification.
Uncompressed	Bit 1 is 1. This specifies an uncompressed mode when encoding.
FillBits	Bit 2 is 1. Fill bits are added as necessary before EOL codes such that EOL always ends on a byte boundary. This ensures an EOL-sequence of 1 byte preceded by a zero nibble, for example, xxxx-0000 0000-0001.

Example:

```
mask = bitor(Tiff.Group3Options.Encoding2D,Tiff.Group3Options.Uncompressed);  
tiffobj.setTag('Group3Options',mask);
```

## InkSet

Specify set of inks used in separated image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

In this context, separated refers to photometric interpretation, not the planar configuration.

### Supported Values

CMYK	Order of components: cyan, magenta, yellow, black. Usually, a value of 0 represents 0% ink coverage and a value of 255 represents 100% ink coverage for that component, but consult the TIFF specification for <code>DotRange</code> . When you specify CMYK, do not set the <code>InkNames</code> tag.
MultiInk	Any ordering other than CMYK. Consult the TIFF specification for <code>InkNames</code> field for a description of the inks used.

Example:

```
tiffobj.setTag('InkSet', Tiff.InkSet.CMYK);
```

### JPEGColorMode

Specify control of YCbCr/RGB conversion

Use these values only when the photometric interpretation is YCbCr.

This property should not be used for the purpose of reading YCbCr imagery as RGB. In this case, use the RGBA interface provided by the `readRGBAImage`, `readRGBAStrip`, and `readRGBATile` methods.

### Supported Values

Raw (default)	Keep input as separate Y, Cb, and Cr matrices.
RGB	Convert RGB input to YCbCr.

Example:

```
tiffobj.setTag('JPEGColorMode', Tiff/JPEGColorMode.RGB);
```

See also “Create YCbCr/JPEG image from RGB data” on page 1-6376

## Orientation

Specify visual orientation of the image data.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

The first row represents the top of the image, and the first column represents the left side. Support for this tag is for informational purposes only, and it does not affect how MATLAB reads or writes the image data.

## Supported Values

TopLeft
TopRight
BottomRight
BottomLeft
LeftTop
RightTop
RightBottom
LeftBottom

Example:

```
tiffobj.setTag('Orientation', Tiff.Orientation.TopRight);
```

## Photometric

Specify color space of image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

MinIsWhite
MinIsBlack
RGB
Palette
Mask
Separated (CMYK)
YCbCr
CIELab
ICCLab
ITULab
LogL
LogLUV
CFA
LinearRaw

Example:

```
tiffobj.setTag('Photometric', Tiff.Photometric.RGB);
```

## PlanarConfiguration

Specifies how image data components are stored on disk

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

Chunky	Store component values for each pixel contiguously. For example, in the case of RGB data, the first three pixels would be stored in the file as RGBRGBRGB etc. Almost all TIFF images have contiguous planar configurations.
Separate	Store component values for each pixel separately. For example, in the case of RGB data, the red component would be stored separately in the file from the green and blue components.

Example:

```
tiffobj.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.Chunky)
```

## ResolutionUnit

Specify unit of measure used to interpret the XResolution and YResolution tags.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

None (default)
Inch
Centimeter

Example: Set ResolutionUnit tag to the value Inch. Then, setting XResolution tag to 300 means pixels per inch.

```
tiffObj.setTag('ResolutionUnit', Tiff.ResolutionUnit.Inch);  
tiffObj.setTag('XResolution', 300);
```

```
tiffObj.setTag('YResolution', 300);
```

### SampleFormat

Specify how to interpret each pixel sample

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the examples.

### Supported Values

UInt (default)
Int
IEEEFP

Void, ComplexInt, and ComplexIEEEFP are not supported.

Example:

```
tiffobj.setTag('SampleFormat', Tiff.SampleFormat.IEEFFP);
```

### SGILogDataFmt

Specify control of client data for SGILog codec

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

These enumerated values should only be used when the photometric interpretation value is `LogL` or `LogLUV`. The `BitsPerSample`, `SamplesPerPixel`, and `SampleFormat` tags should not be set if the image type is `LogL` or `LogLuv`. The choice of `SGILogDataFmt` will set these tags automatically. The `Float` and `Bits8` settings imply a `SamplesPerPixel` value of 3 for `LogLUV` images, but only 1 for `LogL` images.

## Supported Values

Float	Single precision samples
Bits8	uint8 samples (read only)

This tag can be set only once per instance of a LogL/LogLuv Tiff image object instance.

Example:

```
tiffobj = Tiff('example.tif', 'r');  
tiffobj.setDirectory(3); % image three is a LogLuv image  
tiffobj.setTag('SGILogDataFmt', Tiff.SGILogDataFmt.Float);  
imdata = tiffobj.read();
```

## SubFileType

Specify type of image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

SubFileType is a bitmask that indicates the type of the image.

## Supported Values

Default	Default value for single image file or first image.
ReducedImage	The current image is a thumbnail or reduced-resolution image that typically would be found in a sub-IFD.
Page	The image is a single image of a multi-image (or multipage) file.
Mask	The image is a transparency mask for another image in the file. The photometric interpretation value must be Photometric.Mask.

Example:

```
tiffobj.setTag('SubFileType', Tiff.SubFileType.Mask);
```

### **TagID**

List of recognized TIFF tag names with their ID numbers

This property identifies all the supported TIFF tags with their ID numbers. Use this property to specify a tag when using the `setTag` method. For example, `Tiff.TagID.ImageWidth` returns the ID of the `ImageWidth` tag. To get a list of the names of supported tags, use the `getTagNames` method.

Example:

```
tiffobj.setTag(Tiff.TagID.ImageWidth, 300);
```

### **Thresholding**

Specifies technique used to convert from gray to black and white pixels.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

#### **Supported Values**

BiLevel (default)
HalfTone
ErrorDiffuse

Example:

```
tiffobj.setTag('Thresholding', Tiff.Thresholding.HalfTone);
```

### **YCbCrPositioning**

Specify relative positioning of chrominance samples

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property identifies all supported values for the `YCbCrPositioning` tag.

## Supported Values

Centered	Specify for compatibility with industry standards such as PostScript Level 2
Cosited	Specify for compatibility with most digital video standards such as CCIR Recommendation 601-1.

Example:

```
tiffobj.setTag('YCbCrPositioning', Tiff.YCbCrPositioning.Centered);
```

## Methods

<code>close</code>	Close Tiff object
<code>computeStrip</code>	Index number of strip containing specified coordinate
<code>computeTile</code>	Index number of tile containing specified coordinates
<code>currentDirectory</code>	Index of current IFD
<code>getTag</code>	Value of specified tag
<code>getTagNames</code>	List of recognized TIFF tags
<code>getVersion</code>	LibTIFF library version
<code>isTiled</code>	Determine if tiled image
<code>lastDirectory</code>	Determine if current IFD is last in file
<code>nextDirectory</code>	Make next IFD current IFD

<code>numberOfStrips</code>	Total number of strips in image
<code>numberOfTiles</code>	Total number of tiles in image
<code>read</code>	Read entire image
<code>readEncodedStrip</code>	Read data from specified strip
<code>readEncodedTile</code>	Read data from specified tile
<code>readRGBImage</code>	Read image using RGBA interface
<code>readRGBAStrip</code>	Read strip data using RGBA interface
<code>readRGBATile</code>	Read tile data using RGBA interface
<code>rewriteDirectory</code>	Write modified metadata to existing IFD
<code>setDirectory</code>	Make specified IFD current IFD
<code>setSubDirectory</code>	Make subIFD specified by byte offset current IFD
<code>setTag</code>	Set value of tag
<code>write</code>	Write entire image
<code>writeDirectory</code>	Create new IFD and make it current IFD
<code>writeEncodedStrip</code>	Write data to specified strip
<code>writeEncodedTile</code>	Write data to specified tile

## Examples

### Create New TIFF File Using Tiff object

Create a new file called `myfile.tif`. To run this example, your directory must be writable.

```
t = Tiff('myfile.tif', 'w');
```

Close the Tiff object.

```
t.close();
```

## **Specify Tiff object properties and describe alpha channel**

Create an array of data, `data`, that contains colormetric channels and an alpha channel.

```
rgb = imread('example.tif');
numrows = size(rgb,1);
numcols = size(rgb,2);
alpha = 255*ones([numrows numcols], 'uint8');
data = cat(3,rgb,alpha);
```

Create a Tiff object, `t`, and set the object properties. Set the value of the `ExtraSamples` tag because the data contains the alpha channel in addition to the colormetric channels.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.RGB);
t.setTag('Compression',Tiff.Compression.None);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',4);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ExtraSamples',Tiff.ExtraSamples.Unspecified);
t.setTag('ImageLength',numrows);
t.setTag('ImageWidth',numcols);
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write the data to the Tiff object.

```
t.write(data);
t.close();
```

## **Create YCbCr/JPEG image from RGB data**

Get RGB data.

```
rgb = imread('example.tif');
```

Create a Tiff object, `t`, and set the object properties. Specify RGB input data using the `JPEGColorMode` property.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.YCbCr);
t.setTag('Compression',Tiff.Compression.JPEG);
t.setTag('YCbCrSubSampling',[2 2]);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',3);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ImageLength',size(rgb,1));
t.setTag('ImageWidth',size(rgb,2));
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
t.setTag('JPEGColorMode',Tiff.JPEGColorMode.RGB);
t.setTag('JPEGQuality',75);
```

Write the data to the Tiff object.

```
t.write(rgb);
t.close();
```

# timer

---

**Purpose** Create object to schedule execution of MATLAB commands

**Description** Use a `timer` object to schedule the execution of MATLAB commands one or multiple times. If you schedule the timer to execute multiple times, you can define the time between executions and how to handle queuing conflicts.

The `timer` object uses callback functions to execute commands. Callback functions execute code during some event. For the `timer` object, you can specify the callback function as a function handle or as a string. If the callback function is a string, MATLAB evaluates it as executable code. The timer object supports callback functions when a timer starts (`StartFcn`), executes (`TimerFcn`), stops (`StopFcn`), or encounters an error (`ErrorFcn`).

---

**Note** The `timer` object is subject to the limitations of your hardware, operating system, and software. Avoid using timer objects for real-time applications.

---

**Construction** `t = timer` creates an empty timer object to schedule execution of MATLAB commands. An error occurs if the timer starts and `TimerFcn` is not defined.

`t = timer(Name,Value)` creates a timer object with additional options that you specify using one or more `Name,Value` pair arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

The argument name, `Name`, corresponds to a timer property name. In the constructor, the property values are specified using `Name, Value` pair arguments.

### BusyMode

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code>
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

### ErrorFcn

# timer

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

## ExecutionMode

String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

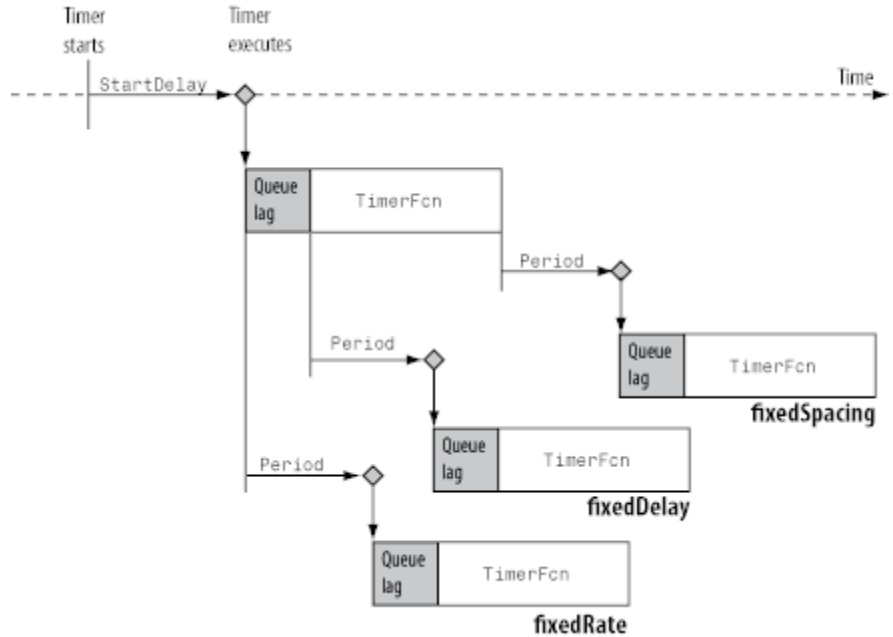

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the `timer` class, and is the default value.

### singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the Period property. The Period property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

## Name

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

## **ObjectVisibility**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

## **Period**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

## **StartDelay**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

## **StartFcn**

String, function handle, or cell array defining the function that executes when the timer starts.

## **StopFcn**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

**Tag**

String that represents a label for the object.

**TasksToExecute**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

**TimerFcn**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

**UserData**

Generic field for data that you want to add to the object.

**Properties****AveragePeriod**

Average time in seconds between `TimerFcn` executions since the timer started. Value is `NaN` until timer executes two timer callbacks.

# timer

---

## InstantPeriod

The time in seconds between the last two executions of `TimerFcn`. Value is NaN until timer executes two timer callbacks.

## Running

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

## TasksExecuted

The number of times the timer called `TimerFcn` since the timer started.

## Type

String that identifies the object type.

## Methods

<code>delete</code>	Remove timer object from memory
<code>get</code>	Query property values for timer object
<code>isvalid</code>	Determine timer object validity
<code>set</code>	Set property values for timer object
<code>start</code>	Start timer object
<code>startat</code>	Schedule timer to fire at specified time
<code>stop</code>	Stop timer object
<code>timerfind</code>	Find timer object
<code>timerfindall</code>	Find timer object, regardless of visibility
<code>wait</code>	Block command prompt until timer stops running

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Display Message Using Timer

Display a message using an anonymous function as a callback function. It is important to note that the first two arguments the callback function passes are a handle to the timer object and an event structure. Even if the function doesn't use these arguments, the function definition requires them.

Wait 3 seconds, and then display the message '3 seconds have elapsed'.

```
t = timer;
t.StartDelay = 3;
t.TimerFcn = @(myTimerObj, thisEvent)disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Suppose the function does not require the timer or event object. Use the tilde (~) operator to ignore the inputs.

```
t.TimerFcn = @(~,~) disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Delete the timer object.

```
delete(t)
```

### Execute Callback Function Multiple Times

Display the event and date/time output when the timer starts, fires, and stops. The timer callback function will be executed 3 times with 2 seconds between calls. The first two arguments the callback function passes are a handle to the timer object and an event structure. The event structure contains two fields: Type is a string that identifies the

type of event that caused the callback, and Data is a structure that contains a date time vector of when the event occurred.

```
t = timer;
t.StartFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
    datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.TimerFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
    datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.StopFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
    datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.Period = 2;
t.TasksToExecute = 3;
t.ExecutionMode = 'fixedRate';
start(t)
```

```
StartFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:52.865
TimerFcn executed 14-Mar-2013 09:08:54.866
StopFcn executed 14-Mar-2013 09:08:54.869
```

Delete the timer object.

```
delete(t)
```

## Define Custom Callback Functions

Create a timer object to remind yourself to take 30-second ergonomic breaks every 10 minutes over the course of 8 hours.

Create a function in a file named `createErgoTimer.m` that returns a timer object. Have this file include three local functions to handle timer start, execute, and stop tasks.

```
function t = createErgoTimer()
secondsBreak = 30;
secondsBreakInterval = 600;
```

```

secondsPerHour = 60^2;
secondsWorkTime = 8*secondsPerHour;

t = timer;
t.UserData = secondsBreak;
t.StartFcn = @ergoTimerStart;
t.TimerFcn = @takeBreak;
t.StopFcn = @ergoTimerCleanup;
t.Period = secondsBreakInterval+secondsBreak;
t.StartDelay = t.Period-secondsBreak;
t.TasksToExecute = ceil(secondsWorkTime/t.Period);
t.ExecutionMode = 'fixedSpacing';
end

```

Using `StartDelay` allows the timer to start without directing you to take a break immediately. Set the execution mode to `'fixedSpacing'` so that 10 minutes and 30 seconds (`t.Period`) elapses after the completion of a `TimerFcn` execution. This allows you to stretch for 30 seconds before the start of the next 10 minute interval.

In the `createErgoTimer.m` file, add a local function to handle the tasks associated with starting the timer. By default, the `timer` object passes itself and event data to the callback function. The function disregards the event data.

```

function ergoTimerStart(mTimer,~)
secondsPerMinute = 60;
secondsPerHour = 60*secondsPerMinute;
str1 = 'Starting Ergonomic Break Timer.  ';
str2 = sprintf('For the next %d hours you will be notified',...
    round(mTimer.TasksToExecute*(mTimer.Period + ...
    mTimer.UserData)/secondsPerHour));
str3 = sprintf(' to take a %d second break every %d minutes.',...
    mTimer.UserData, (mTimer.Period - ...
    mTimer.UserData)/secondsPerMinute);
disp([str1 str2 str3]);
end

```

## timer

---

Add a local function to handle the tasks associated with executing the timer. The `TimerFcn` callback should tell you to take a 30 second break.

```
function takeBreak(mTimer,~)
disp('Take a 30 second break.')
end
```

Add a local function to handle the tasks associated with stopping the timer.

```
function ergoTimerCleanup(mTimer,~)
disp('Stopping Ergonomic Break Timer. ');
delete(mTimer)
end
```

Deleting the timer object removes it from memory.

From the command line, call the `createErgoTimer` function to create and start a timer.

```
t = createErgoTimer;
start(t)
```

```
Starting Ergonomic Break Timer. For the next 8 hours you will be notified
```

```
Every 10 minutes, you will be reminded to take a 30 second break.
```

```
Take a break.
```

You can leave the timer running for 8 hours or stop it manually. Recall that you included the task of deleting the timer from memory in the `StopFcn` callback.

```
stop(t)
```

```
Stopping Ergonomic Break Timer.
```

## Tips

- To force the execution of the callback functions in the event queue, include a call to the `drawnow` function in your code. The `drawnow` function flushes the event queue.

**See Also** `function_handle`

## Concepts

- Timer Callback Functions
- “Handling Timer Queuing Conflicts”
- “Ignore Function Outputs”
- Property Attributes

# timer.delete

---

**Purpose** Remove timer object from memory

**Syntax** `delete(t)`

**Description** `delete(t)` removes the timer object, `t`, from memory. If `t` is an array of timer objects, `delete` removes all the objects from memory.

When you delete a timer object, it becomes invalid and you cannot reuse it. If multiple references to a timer object exist in the workspace, deleting the timer object invalidates the remaining references. To remove invalid timer objects references from the workspace, use the `clear` command.

- Tips**
- Use the `isvalid` method to determine if a timer object exists in memory, but is not cleared from the workspace.
  - Use the `timerfind` and `timerfindall` methods to return timer objects currently existing in memory. This approach is useful if the reference to the timer object is cleared from the workspace (using the `clear` command), but not deleted from memory.

**Input Arguments**

**t**  
Object of class `timer`.

## Examples Delete a Timer

Create and start a timer that generates a 10-by-10 array of random numbers.

```
t = timer('TimerFcn','rand(10);');  
start(t)
```

Delete the timer from memory.

```
delete(t)
```

Call the `whos` function to see if a reference still exists in the workspace.

whos

Name	Size	Bytes	Class	Attributes
ans	10x10	800	double	
t	1x1	104	timer	

Try to restart the timer.

```
start(t)
```

```
Error using timer/start (line 27)  
Invalid timer object. This object has been deleted and should be removed.
```

The timer cannot be restarted.

Clear the timer object reference from the workspace.

```
clear t
```

## Delete Multiple Timers Using timerfind

Use `delete` with the `timerfind` method to remove all visible timers from memory. This is an alternative to deleting individual timers by variable name.

Create and start three timers that compute the sine, cosine and tangent of  $\pi/4$ .

```
t1 = timer('TimerFcn','sin(pi/4);');  
t2 = timer('TimerFcn','cos(pi/4);');  
t3 = timer('TimerFcn','tan(pi/4);');
```

Delete the timers from memory using `timerfind`. This removes all visible timer objects from memory.

```
delete(timerfind);
```

## See Also

[timer](#) | [isvalid](#) | [timerfind](#) | [timerfindall](#) |

# timer.get

---

**Purpose** Query property values for timer object

**Syntax**

```
get(t)
V = get(t)
V = get(t,propName)
```

**Description** `get(t)` queries property values for timer object, `t`, and displays all property names and current values. `t` must be a scalar timer object.

`V = get(t)` queries property values for timer object, `t` and returns a structure, `V`, where each field name is the name of a property of `t` and each field contains the value of that property. If `t` is an `M`-by-1 vector of timer objects, `V` is an `M`-by-1 array of structures.

`V = get(t,propName)` returns the value, `V`, of the timer object property specified in `propName`. If `propNames` is a vector cell array of `N` property names, and `t` is a vector of `M` timer objects, `v` is an `M`-by-`N` cell array of property values.

**Input Arguments**

**t**  
Object of class `timer`.

**propName**  
String enclosed in single quotation marks that specifies a `timer` property.

**Examples**      **Display All Properties of Timer**

```
t = timer;
get(t)

AveragePeriod: NaN
BusyMode: 'drop'
ErrorFcn: ''
ExecutionMode: 'singleShot'
```

```
InstantPeriod: NaN
      Name: 'timer-1'
ObjectVisibility: 'on'
      Period: 1
      Running: 'off'
StartDelay: 0
StartFcn: ''
StopFcn: ''
      Tag: ''
TasksExecuted: 0
TasksToExecute: Inf
TimerFcn: ''
      Type: 'timer'
      UserData: []
```

Delete the timer from memory.

```
delete(t)
```

### **Obtain Properties for Array of Timers**

Create three timers.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Get properties of an array of timers.

```
V = get([t1,t2,t3])
```

```
V =
```

3x1 struct array with fields:

```
AveragePeriod
BusyMode
ErrorFcn
ExecutionMode
```

```
InstantPeriod  
Name  
ObjectVisibility  
Period  
Running  
StartDelay  
StartFcn  
StopFcn  
Tag  
TasksExecuted  
TasksToExecute  
TimerFcn  
Type  
UserData
```

Delete the timers from memory.

```
delete([t1,t2,t3])
```

## **Obtain Single Property for Timer**

Create a timer and determine if it is running.

```
t = timer;  
get(t,'Running')
```

```
ans =
```

```
off
```

Delete the timer from memory.

```
delete(t)
```

## **Obtain Specified Properties for Array of Timers**

Create three timers.

```
t1 = timer;  
t2 = timer;
```

```
t3 = timer;
```

Obtain name, period, and running property values from the array of timers.

```
V = get([t1,t2,t3],{'Name','Running','Period'})
```

```
V =
```

```
    'timer-1'    'off'    [1]
    'timer-2'    'off'    [1]
    'timer-3'    'off'    [1]
```

## Alternatives

You can also use dot notation can also be used to query timer object properties. For example, `t.Running` returns the same value as `get(t, 'Running')`.

## See Also

[timer | set |](#)

# timer.isvalid

---

**Purpose** Determine timer object validity

**Syntax** `validCheck = isvalid(t)`

**Description** `validCheck = isvalid(t)` determines timer object validity and returns a logical array, `validCheck`, that contains a 0 where the elements of `t` are invalid timer objects and a 1 where the elements of `t` are valid timer objects.

An invalid timer object is an object that is deleted from memory using `delete` and cannot be reused. Use the `clear` command to remove an invalid timer object from the workspace.

**Tips**

- To return timer objects existing in memory, use the `timerfind` and `timerfindall` methods. This practice is useful if the reference to the timer object is cleared from the workspace (using the `clear` function), but the object has not been deleted from memory.

**Input Arguments**

**t**  
Object or array of objects of class `timer`

## Examples **Check Timer Object Validity**

Create a timer object. While this timer object is valid, it cannot start because a `TimerFcn` is not defined.

```
t = timer;  
out = isvalid(t)
```

```
out =
```

```
1
```

Delete the timer object, making it invalid.

```
delete(t)  
out1 = isvalid(t)
```

```
out1 =  
    0
```

## See Also

[timer](#) | [delete](#) | [timerfind](#) | [timerfindall](#) |

# timer.set

---

**Purpose** Set property values for timer object

**Syntax**

```
set(t)
propStruct = set(t)

set(t,Name)
propCell = set(t,Name)
set(t,Name,Value)
set(t,S)
set(t,PN,PV)
```

**Description** `set(t)` displays the property names and their possible values for all configurable properties of timer object `t`.

`propStruct = set(t)` returns the values in a struct.

`set(t,Name)` displays the possible values for the specified property, `Name`, of timer object, `t`.

`propCell = set(t,Name)` returns the values in a cell.

`set(t,Name,Value)` sets the properties specified by one or more `Name, Value` pair arguments. `t` can be a single timer object or a vector of timer objects, in which case `set` configures the property values for all timer objects, `t`.

`set(t,S)` configures the properties of `t`, with the values specified in `S`, where `S` is a structure whose field names are object property names.

`set(t,PN,PV)` configures the properties specified in the cell array of strings, `PN`, to the corresponding values in the cell array `PV`, for the timer object `t`.

**Input Arguments****t**Object of class `timer`.**S**Structure whose field names are `timer` property names.**PN,PV**

Cell array of strings, `PN`, and corresponding cell array of values, `PV`. The cell array of `PN` must be a 1-by-`N` or `N`-by-1 array. If `t` is an array of `timer` objects, `PV` can be an `M`-by-`N` cell array, where `M` is equal to the length of `t` and `N` is equal to the length of `PN`. In this case, each `timer` object is updated with a different set of values for the list of property names contained in `PN`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'BusyMode'**

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

<b>BusyMode Values</b>	<b>Behavior if Queue Empty</b>	<b>Behavior if Queue Not Empty</b>	<b>Notes</b>
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code>
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

### **'ErrorFcn'**

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

### **'ExecutionMode'**

String that defines how the timer object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

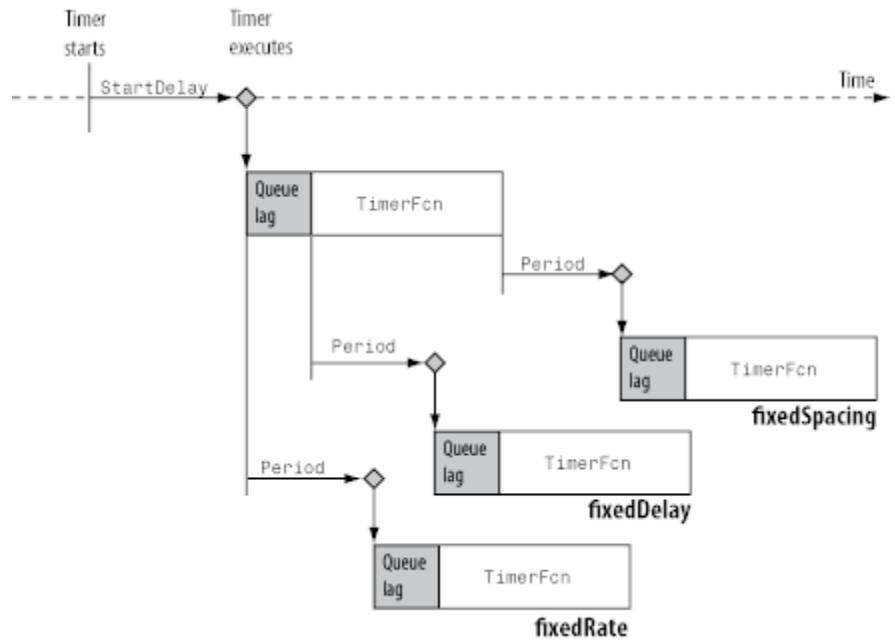

- 'singleShot' is the single execution mode for the timer class, and is the default value.

**singleShot**

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

# timer.set

**Default:** 'singleShot'

## 'Name'

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

## 'ObjectVisibility'

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the

timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

#### **'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

#### **'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

#### **'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

#### **'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer stop method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.

- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **'Tag'**

String that represents a label for the object.

## **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

## **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

## **'UserData'**

Generic field for data that you want to add to the object.

## **Output Arguments**

### **propStruct**

Configurable properties of `t`, returned as a structure. The field names of `propStruct` are the property names of `t`, and the associated values of `propStruct` are cell arrays of the possible property values. If the property in `t` does not have a finite set of possible values, the property value in `propStruct` is an empty cell array.

### **propCell**

Possible values of a given property name, returned as cell array of strings. If the property does not have a finite set of possible string values, set returns an empty cell array.

## Examples **Display Configurable Timer Object Properties**

Instantiate a timer object and call the `set` method.

```
t = timer;
set(t)
```

```

BusyMode: [ {drop} | queue | error ]
ErrorFcn: string -or- function handle -or- cell array
ExecutionMode: [ {singleShot} | fixedSpacing | fixedDelay | fixedD
Name
ObjectVisibility: [ {on} | off ]
Period
StartDelay
StartFcn: string -or- function handle -or- cell array
StopFcn: string -or- function handle -or- cell array
Tag
TasksToExecute
TimerFcn: string -or- function handle -or- cell array
UserData
```

Some of the timer properties, such as `Running`, are not displayed because they are read only.

Use the `set` method to output a structure.

```
out = set(t)
```

```
out =
```

```

    BusyMode: {3x1 cell}
    ErrorFcn: {}
 ExecutionMode: {4x1 cell}
    Name: {}
```

```
ObjectVisibility: {2x1 cell}
    Period: {}
    StartDelay: {}
    StartFcn: {}
    StopFcn: {}
    Tag: {}
    TasksToExecute: {}
    TimerFcn: {}
    UserData: {}
```

Delete the timer object from memory.

```
delete(t)
```

## Display Possible Property Values

Instantiate a timer object and display possible values for the `BusyMode` property.

```
t = timer;
set(t, 'BusyMode')
```

```
[ {drop} | queue | error ]
```

The output shows the three possible values for `BusyMode`. The default value, `drop`, is indicated by curly braces.

Display the possible values for `ErrorFcn`.

```
set(t, 'ErrorFcn')
```

```
string -or- function handle -or- cell array
```

A description of the possible values is displayed since `ErrorFcn` does not have a set list of possible values.

Output the possible property values.

```
out1 = set(t, 'BusyMode')
out2 = set(t, 'ErrorFcn')
```

```
out1 =  
  
    'drop'  
    'queue'  
    'error'
```

```
out2 =  
  
    {}
```

While `set(t, 'ErrorFcn')` displays a description of the possible values, `out2 = set(t, 'ErrorFcn')` returns an empty cell.

Delete the timer from memory.

```
delete(t)
```

### **Set Timer Object Property**

Instantiate a timer object and make the object invisible. Display the object's visibility and delete the object.

```
t = timer;  
set(t, 'ObjectVisibility', 'off');  
get(t, 'ObjectVisibility')  
delete(t)
```

```
ans =
```

```
off
```

### **Set Timer Object Properties Using Structure**

Construct a structure to modify several timer object properties.

```
s.BusyMode = 'queue';  
s.ExecutionMode = 'fixedDelay';  
s.ObjectVisibility = 'off'
```

```
s =  
  
    BusyMode: 'queue'  
    ExecutionMode: 'fixedDelay'  
    ObjectVisibility: 'off'
```

Create a timer, display the properties in `s`, modify the timer, display the new values of the properties, and delete the timer.

```
t = timer;  
get(t,{'BusyMode','ExecutionMode','ObjectVisibility'})  
set(t,s);  
get(t,{'BusyMode','ExecutionMode','ObjectVisibility'})  
delete(t)
```

```
ans =  
  
    'drop'    'singleShot'    'on'
```

```
ans =  
  
    'queue'    'fixedDelay'    'off'
```

### Set Timer Objects Using Cell Arrays

Create a cell array of properties to modify, and a cell array of the values of the corresponding properties. Instantiate a timer, and display the initial values of the properties in the property name cell array, `nameArr`.

```
nameArr = {'BusyMode','ExecutionMode','Period'};  
valArr = {'queue','fixedDelay',3};  
t = timer;  
get(t,nameArr)
```

```
ans =  
  
    'drop'    'singleShot'    [1]
```

Modify the timer object and display the new property values. Delete the timer.

```
set(t,nameArr,valArr)
get(t,nameArr)
delete(t)

ans =

    'queue'    'fixedDelay'    [3]
```

Instantiate an array of three timers. Create a new property name cell array to modify the BusyMode, ExecutionMode, and UserData properties. Display the initial values of the properties for each timer.

```
tArr = [timer timer timer];
nameArr = {'BusyMode','ExecutionMode','UserData'};
get(tArr,nameArr)

ans =

    'drop'    'singleShot'    []
    'drop'    'singleShot'    []
    'drop'    'singleShot'    []
```

Assign each property a different value in each timer. Create a cell array containing the new values. Each row indicates the values for the properties in the corresponding timer.

```
valArr = {'queue','fixedDelay',3;...
          'error','fixedSpacing',42;...
          'drop','fixedRate','hello'};
```

Modify the timer object properties and display the updated values.

```
set(tArr,nameArr,valArr)
get(tArr,nameArr)

ans =
```

## timer.set

---

```
'queue'      'fixedDelay'    [ 3]
'error'      'fixedSpacing'  [ 42]
'drop'       'fixedRate'     'hello'
```

Delete the timers from memory.

```
delete(tArr)
```

### Alternatives

You can also use dot notation to set timer object properties. For example, `t.ObjectVisibility = 'off'` sets the property to the same value as `set(t, 'ObjectVisibility', 'off')`.

**Purpose** Schedule timer to fire at specified time

**Syntax**  
`startat(t, firingTime)`  
`startat(t, Y, M, D)`  
`startat(t, Y, M, D, H, MI, S)`

**Description** `startat(t, firingTime)` schedules timer, `t`, to fire at specified time, `firingTime`. A timer fires by executing the callback function, `timerFcn`. `firingTime` must be within 25 days of the current time.

- If `t` is an array of timer objects and `firingTime` is a scalar, `startat` sets all the timers to fire at the specified time.
- If `t` is an array of timer objects and `firingTime` is an array of the same size as `t`, `startat` sets each timer to fire at the corresponding time.

`startat(t, Y, M, D)` starts the timer and schedules execution of `TimerFcn` at the year (Y), month (M), and day (D) specified.

`startat(t, Y, M, D, H, MI, S)` also specifies the hour (H), minute (MI), and second (S) specified.

## Algorithms

- The `startat` method specifies when the timer object executes the `TimerFcn` callback, not when the timer starts running. The timer starts running with the call to the `startat` method.
- Based on the specified time, `startat` computes and sets the required `StartDelay` property of the timer object, `t`. Additionally, it sets the `Running` property of the timer object to 'on', and executes the `StartFcn` callback.
- `startat` modifies the timer object's `startDelay` property. As such, `startat` overrides specified values of the timer's `startDelay` property.

## Input Arguments

**t**  
Object of class `timer`.

### **firingTime**

Time at which the timer object is to fire, specified as a serial date number, date string, or a date vector. `firingTime` can be a single date or an array of dates with the same number of rows as timer objects in `t`.

- A serial date number indicates the number of days that have elapsed since 1-Jan-0000 (starting at 1). See `datenum` for additional information about serial date numbers.
- To specify date strings, use the following date formats defined by the `datestr` function: 0, 1, 2, 6, 13, 14, 15, 16, or 23. These numeric identifiers correspond to formats defined by the `formatOut` property of the `datestr` function. Date strings with two-character years are interpreted to be within the 100 years centered on the current year.
- Date vectors are specified as an `m`-by-6 or `m`-by-3 matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements indicating year, month, day, hour, minute, and second, in that order. A partial date vector has three elements indicating year, month, and day, in that order.

### **Y,M,D**

Time at which the timer object is to fire, specified as numbers indicating the year (Y), month (M), and day (D). Month values less than 1 are set to 1; other arguments can wrap and have negative values.

### **Y,M,D,H,MI,S**

Time at which the timer object is to fire, specified as numbers indicating the year (Y), month (M), day (D), hour (H), minute (MI), and second (S) specified. Month values less than 1 are set to 1; other arguments can wrap and have negative values.

**Examples****Start Timer in 2Seconds**

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
         'StartFcn', @(~,~)disp('Started.'));
```

Set the timer to fire 2 seconds from the present time using a serial date. A serial date is specified in days.

```
two = 2/(60^2*24); % two seconds in serial time
fTime = now + two
startat(t,fTime);
```

```
fTime =
```

```
7.3527e+05
```

```
Started.
```

```
Fired.
```

Wait for the timer to fire, and then delete the timer.

```
delete(t)
```

**Start Timer Using Year, Month, Day**

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
         'StartFcn', @(~,~)disp('Started.'));
```

Schedule the timer to start 2 days from present at 00:00:00

```
[Y, M, D, H, MI, S] = datevec(now+2);
startat(t,Y,M,D)
```

```
Started.
```

Manually stop and delete the timer.

## timer.startat

---

stop(t)  
delete(t)

### Concepts

- “Carryover in Date Vectors and Strings”

<b>Purpose</b>	Stop timer object
<b>Syntax</b>	<code>stop(t)</code>
<b>Description</b>	<p><code>stop(t)</code> stops the timer object, <code>t</code>. If <code>t</code> is an array of timer objects, the <code>stop</code> method stops each timer.</p> <p>The <code>stop</code> method sets the <code>Running</code> property of the timer object to 'off' and executes the <code>StopFcn</code> callback .</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• Use the <code>stop</code> method to stop a timer manually. The timer automatically stops when the <code>TimerFcn</code> callback executes the number of times specified by the <code>ExecutionMode</code> and <code>TasksToExecute</code> properties or when an error occurs while executing a <code>TimerFcn</code> callback.</li></ul>
<b>Input Arguments</b>	<p><b>t</b></p> <p>Object of class <code>timer</code>.</p>
<b>Examples</b>	<p><b>Stop Timer</b></p> <p>Create a timer object that generates 100 random numbers and executes one million times. Define a <code>StopFcn</code> callback that displays the message 'Timer has stopped.' Start the timer and verify the timer is running</p> <pre>t = timer('TimerFcn','rand(100,1);',...          'ExecutionMode','fixedSpacing','TasksToExecute',1e6,...          'StopFcn','disp(''Timer has stopped.'')'); start(t) t.Running  ans =  on</pre> <p>Manually stop the timer and verify it is no longer running. Delete the timer.</p>

# timer.stop

---

```
stop(t)
t.Running
delete(t)
```

```
Timer has stopped.
```

```
ans =
```

```
off
```

```

## Purpose

Find timer object

## Syntax

```
out = timerfind
out = timerfind(Name,Value)
out = timerfind(t,Name,Value)
out = timerfind(S)
```

## Description

`out = timerfind` finds the “visible timer objects” on page 1-6425 and returns an array, `out`.

`out = timerfind(Name,Value)` finds “visible timer objects” on page 1-6425 with property values matching those passed as `Name, Value` pair arguments and returns an array, `out`.

`out = timerfind(t,Name,Value)` matches `Name, Value` pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfind(S)` matches property values defined in the structure, `S`, and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

## Tips

- `timerfind` only finds “visible timer objects” on page 1-6425. Visible timer objects are those that are in memory and have the `ObjectVisibility` property set to 'on'. To find objects that are hidden, but still valid, use `timerfindall`.

## Input Arguments

**t**

Array of objects of class `timer`

**S**

Structure with field names corresponding to timer object property names. Field values are the corresponding property values.

# timer.timerfind

---

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1, Value1, . . . , NameN, ValueN**.

## 'BusyMode'

String that indicates action taken when a timer has to execute **TimerFcn** before the completion of previous execution of the **TimerFcn**. When **Running='on'**, **BusyMode** is read only. This table summarizes the busy modes.

<b>BusyMode Values</b>	<b>Behavior if Queue Empty</b>	<b>Behavior if Queue Not Empty</b>	<b>Notes</b>
'drop'	Adds task to queue	Drops task	Possible skipping of <b>TimerFcn</b>
'error'	Adds task to queue	Completes task; throws error specified by <b>ErrorFcn</b> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <b>Period</b> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

## 'ErrorFcn'

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

## 'ExecutionMode'

String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

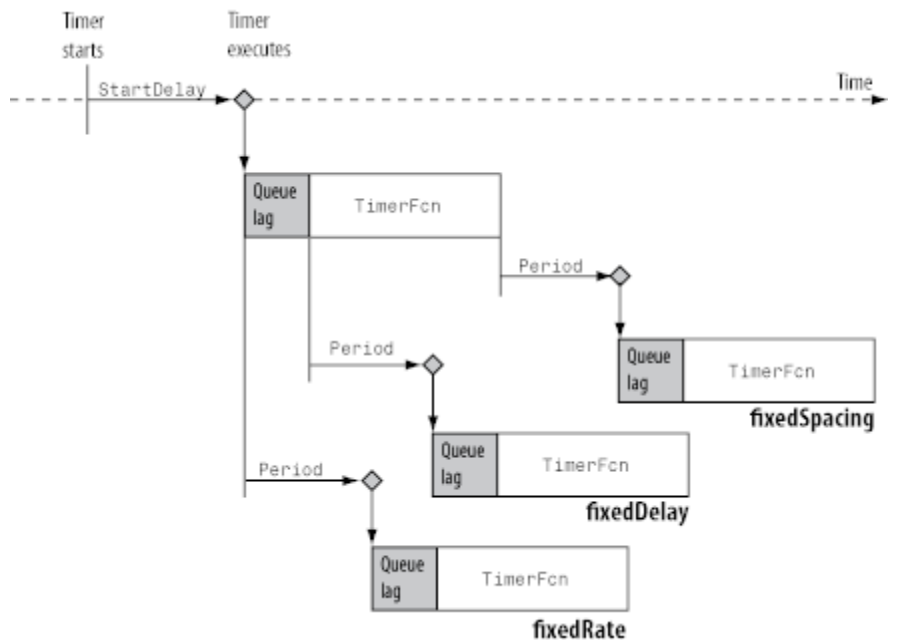

- 'singleShot' is the single execution mode for the timer class, and is the default value.

# timer.timerfind

## singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the Period property. The Period property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

## **'Name'**

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

## **'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

## **'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

## **'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

## **'StartFcn'**

# timer.timerfind

---

String, function handle, or cell array defining the function that executes when the timer starts.

## **'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer stop method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **'Tag'**

String that represents a label for the object.

## **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

## **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

## **'UserData'**

Generic field for data that you want to add to the object.

## Read Only Name-Value Pair Arguments

### AveragePeriod

Average time in seconds between `TimerFcn` executions since the timer started. Value is NaN until timer executes two timer callbacks.

### InstantPeriod

The time in seconds between the last two executions of `TimerFcn`. Value is NaN until timer executes two timer callbacks.

### Running

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

### TasksExecuted

The number of times the timer called `TimerFcn` since the timer started.

### Type

String that identifies the object type.

## Definitions

### visible timer objects

*Visible timer objects* are timer objects that are in memory and have the `ObjectVisibility` property set to 'on'.

## Examples

### Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag', 'broadcastProgress','UserData','Monday');
t2 = timer('Tag', 'displayProgress','UserData','Monday');
timerArr = [timer('Tag', 'broadcastProgress','UserData','Tuesday');
            timer('Tag', 'displayProgress','UserData','Tuesday');
            timer('Tag', 'displayProgress','UserData','Wednesday');];
```

# timer.timerfind

---

Find all the timers in memory.

```
out1 = timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3
4	singleShot	1	''	timer-4
5	singleShot	1	''	timer-5

Find only those timers in memory that have the string value, 'displayProgress', as the Tag property.

```
out2 = timerfind('Tag','displayProgress')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-2
2	singleShot	1	''	timer-4
3	singleShot	1	''	timer-5

Limit the search for timers with the string value, 'displayProgress', as the Tag property to timer objects in timerArr.

```
out3 = timerfind(timerArr,'Tag','displayProgress')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-4
2	singleShot	1	''	timer-5

Define a struct containing the Tag and UserData properties of interest.

```
searchStruct = struct('Tag','broadcastProgress','UserData','Monday')

searchStruct =

    Tag: 'broadcastProgress'
  UserData: 'Monday'
```

Use the struct as the search criteria to find timer objects in memory.

```
out4 = timerfind(searchStruct)
```

```
Timer Object: timer-1

Timer Settings
  ExecutionMode: singleShot
    Period: 1
  BusyMode: drop
  Running: off

Callbacks
  TimerFcn: ''
  ErrorFcn: ''
  StartFcn: ''
  StopFcn: ''
```

Delete the timer objects.

```
delete(t1); delete(t2); delete(timerArr)
```

## Delete Timer by Name

Simulate having existing timers in memory by creating an array of timers. Create a new timer with a custom name. List all visible timers.

```
existingTimers = [timer timer timer];

myTimerName = 'myTimer';
anotherTimer = timer('Name',myTimerName);
```

# timer.timerfind

---

```
timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3
4	singleShot	1	''	myTimer

Delete the specified timer and list all visible timers.

```
delete(timerfind('Name',myTimerName));  
timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3

Delete all visible timers from memory.

```
delete(timerfind)
```

## Find Valid Timer Objects Cleared from Workspace

Use `timerfind` to find 'lost' timer object references. References are lost when you clear the timer object from the workspace, but do not delete it from memory.

Create two timer objects. Since the callback function does not require the timer or event object, you can use the tilde (~) operator to ignore the inputs in the function handle.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));  
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));  
whos
```

Name	Size	Bytes	Class	Attributes
t1	1x1	104	timer	
t2	1x1	104	timer	

Clear one of the timer objects from the workspace. To actually remove the timer from memory, you need to both clear it and delete it.

```
clear t1
whos
```

Name	Size	Bytes	Class	Attributes
t2	1x1	104	timer	

Try to delete the timer, t1.

```
delete(t1)
```

```
Undefined function or variable 't1'.
```

The timer, t1, can not be removed from memory using delete because its reference has been cleared.

Find valid timer objects in memory.

```
out = timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-1
2	singleShot	1	1x1 function_handle	arraytimer-2

Since two timers were found, determine which timer does not exist in the workspace.

```
out ~= t2
```

# timer.timerfind

---

```
ans =  
  
     1     0
```

The first timer object in `out` is not equal to `t2`. This was previously `t1`. It is reassigned to `t1`. Since it is still valid, the timer can be started.

```
t1 = out(1);  
start(t1);
```

```
Timer 1 Fired!
```

Delete timer objects. `timerfind` provides a way of accessing timer objects in memory. It does not copy the objects; therefore you do not need to delete `out` from memory. To verify, use `timerfind`.

```
delete(t1); delete(t2);  
timerfind
```

```
ans =  
  
     []
```

## Delete All Timer Objects in Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));  
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));  
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));  
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Clear two timers from the workspace.

```
clear t2 t3
```

Pass `timerfind` to `delete` to remove all timer objects from memory, whether or not they exist in the workspace.

```
delete(timerfind)
timerfind
```

```
ans =
```

```
    []
```

## See Also

[timer](#) | [delete](#) | [timerfindall](#) |

# timer.timerfindall

---

**Purpose** Find timer object, regardless of visibility

**Syntax**

```
out = timerfindall
out = timerfindall(Name,Value)
out = timerfindall(t,Name,Value)
out = timerfindall(S)
```

**Description** `out = timerfindall` finds timer objects existing in memory, regardless of visibility and returns an array, `out`. Use the `ObjectVisibility` property to set the object's visibility.

`out = timerfindall(Name,Value)` finds timer objects existing in memory, regardless of visibility whose property values match those passed as `Name,Value` pair arguments and returns an array, `out`.

`out = timerfindall(t,Name,Value)` matches `Name,Value` pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfindall(S)` matches property values defined in the structure, `S` and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

**Tips**

- `timerfindall` finds timer objects in memory, regardless of the value of the `ObjectVisibility` property. To limit the search to objects with `ObjectVisibility` set to 'on', use `timerfind`.

**Input Arguments**

**t**  
Array of objects of class `timer`.

**S**  
Structure with field names corresponding to `timer` object property names. Field values are the corresponding property values.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'BusyMode'

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code>
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

# timer.timerfindall

---

## 'ErrorFcn'

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

## 'ExecutionMode'

String that defines how the timer object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

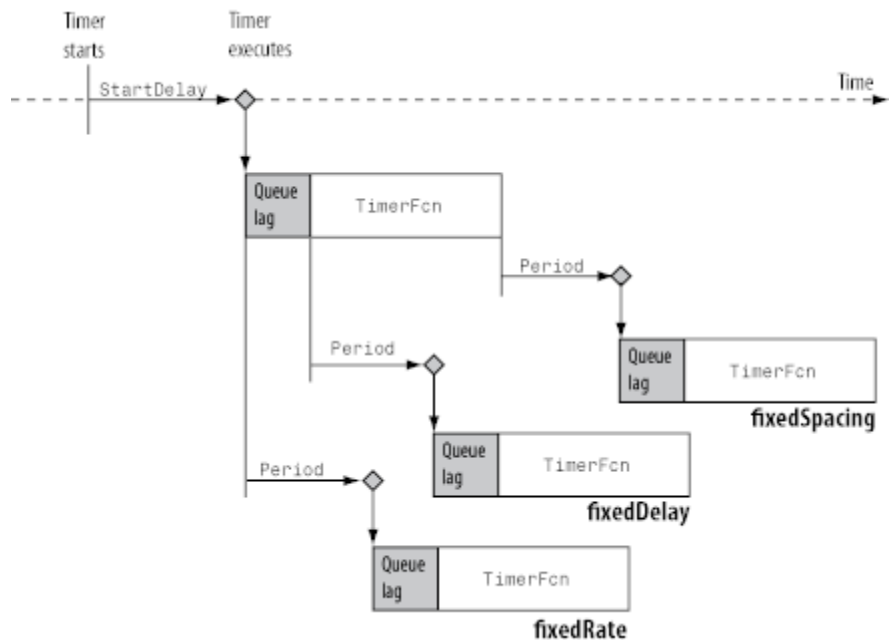

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the timer class, and is the default value.

## singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the Period property. The Period property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

# timer.timerfindall

---

## **'Name'**

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

## **'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

## **'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

## **'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

## **'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

## **'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **'Tag'**

String that represents a label for the object.

## **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

## **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

## **'UserData'**

# timer.timerfindall

---

Generic field for data that you want to add to the object.

## Read Only Name-Value Pair Arguments

### AveragePeriod

Average time in seconds between TimerFcn executions since the timer started. Value is NaN until timer executes two timer callbacks.

### InstantPeriod

The time in seconds between the last two executions of TimerFcn. Value is NaN until timer executes two timer callbacks.

### Running

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

### TasksExecuted

The number of times the timer called TimerFcn since the timer started.

### Type

String that identifies the object type.

## Examples

### Find and Delete All Timers From Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));  
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));  
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));  
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers t2 and t4 to be invisible.

```
t2.ObjectVisibility = 'off';  
t4.ObjectVisibility = 'off';
```

Clear timers t1 and t2 from the workspace.

```
clear t1 t2
whos
```

Name	Size	Bytes	Class	Attributes
t3	1x1	104	timer	
t4	1x1	104	timer	

Find all visible timers in memory.

```
timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-1
2	singleShot	1	1x1 function_handle	arraytimer-3

timerfind finds only timers t1 and t2, since they are visible. Timer t2 is still valid and in memory even though it was cleared from the workspace

Find all timers in memory.

```
timerfindall
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-1
2	singleShot	1	1x1 function_handle	arraytimer-2
3	singleShot	1	1x1 function_handle	arraytimer-3
4	singleShot	1	1x1 function_handle	arraytimer-4

timerfindall finds all four valid timers in memory even though t2 and t4 are invisible and t1 and t2 were cleared from the workspace.

# timer.timerfindall

---

Delete all timers from memory.

```
delete(timerfindall)
```

## Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag', 'broadcastProgress','UserData','Monday');
t2 = timer('Tag', 'displayProgress','UserData','Monday');
timerArr = [timer('Tag', 'broadcastProgress','UserData','Tuesday');
            timer('Tag', 'displayProgress','UserData','Tuesday');
            timer('Tag', 'displayProgress','UserData','Wednesday');];
```

Make timer t1 and timerArr(2) invisible.

```
t1.ObjectVisibility = 'off';
timerArr(2).ObjectVisibility = 'off';
```

Find all the timers in memory using timerfind.

```
out1 = timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-2
2	singleShot	1	''	timer-3
3	singleShot	1	''	timer-5

timerfind does not find the hidden timers.

Find all the timers in memory using timerfindall.

```
out2 = timerfindall
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1

```
2      singleShot      1      ''      timer-2
3      singleShot      1      ''      timer-3
4      singleShot      1      ''      timer-4
5      singleShot      1      ''      timer-5
```

timerfindall finds all timers, even the invisible ones.

Find only those timers in memory that have the string value, 'displayProgress', as the Tag property.

```
out3 = timerfindall('Tag','displayProgress')
```

Timer Object Array

```
Index:  ExecutionMode:  Period:  TimerFcn:      Name:
1      singleShot      1      ''      timer-2
2      singleShot      1      ''      timer-4
3      singleShot      1      ''      timer-5
```

Limit the search for timers that have the string value, 'displayProgress', as the Tag property to timer objects in timerArr.

```
out4 = timerfindall(timerArr,'Tag','displayProgress')
```

Timer Object Array

```
Index:  ExecutionMode:  Period:  TimerFcn:      Name:
1      singleShot      1      ''      timer-4
2      singleShot      1      ''      timer-5
```

Define a struct containing the Tag and UserData properties of interest.

```
searchStruct = struct('Tag','broadcastProgress','UserData','Monday')
```

```
searchStruct =
```

```
Tag: 'broadcastProgress'
UserData: 'Monday'
```

# timer.timerfindall

---

Use the struct as the search criteria to find timer objects in memory.

```
out5 = timerfindall(searchStruct)
```

```
Timer Object: timer-1
```

```
Timer Settings
```

```
ExecutionMode: singleShot
```

```
Period: 1
```

```
BusyMode: drop
```

```
Running: off
```

```
Callbacks
```

```
TimerFcn: ''
```

```
ErrorFcn: ''
```

```
StartFcn: ''
```

```
StopFcn: ''
```

Delete the timer objects.

```
delete(timerfindall)
```

## Find Invisible Timers

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
```

```
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
```

```
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
```

```
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers t2 and t4 to be invisible, and clear timers t1 and t2 from the workspace.

```
t2.ObjectVisibility = 'off';
```

```
t4.ObjectVisibility = 'off';
```

```
clear t1 t2;
```

```
whos
```

Name	Size	Bytes	Class	Attributes
t3	1x1	104	timer	
t4	1x1	104	timer	

Find all valid invisible timers.

```
out = timerfindall('ObjectVisibility','off')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-2
2	singleShot	1	1x1 function_handle	arraytimer-4

Both valid invisible timers were found by `timerfindall`, regardless of whether they were in the workspace.

## See Also

[timer](#) | [delete](#) | [timerfind](#) |

# timer.wait

---

**Purpose** Block command prompt until timer stops running

**Syntax** `wait(t)`

**Description** `wait(t)` blocks the command prompt until timer, `t`, stops running. If `t` is an array of timer objects, `wait` blocks the MATLAB command line until each timer in `t` has stopped running.

To block the command line, the timer object must first start via `start` or `startat` before calling the `wait` method. If the timer is not running, `wait` returns immediately.

**Input Arguments** `t`  
Array of timer objects

## Examples **Block Command Prompt While Timer Runs**

Create a timer that waits 10 seconds, and then displays a message. Start the timer and wait for it to finish.

```
T = timer('TimerFcn',@(~,~)disp('Fired.'), 'StartDelay',10);  
start(T);
```

```
Fired.
```

Notice that after the timer starts, the MATLAB prompt returns.

Start the timer and use the `wait` method to block anyone from entering commands at the MATLAB command line. You must start the timer before calling the `wait` command.

```
start(T);  
wait(T);
```

```
Fired.
```

Notice that after the timer starts, the MATLAB prompt disappears until the timer stops.

Delete the timer.

```
delete(T)
```

## See Also

[timer | start |](#)

# times, .\*

---

**Purpose** Element-wise multiplication

**Syntax**  
`C = A.*B`  
`C = times(A,B)`

**Description** `C = A.*B` multiplies arrays A and B element by element and returns the result in C.

`C = times(A,B)` is an alternate way to execute `A.*B`, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Left array

scalar | vector | matrix | multidimensional array

Left array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### B - Right array

scalar | vector | matrix | multidimensional array

Right array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Multiply Two Vectors

Create two vectors, A and B, and multiply them element by element.

```
A = [1 0 3];  
B = [2 3 7];  
C = A.*B
```

```
C =
```

```
     2     0    21
```

### Multiply Two Arrays

Create two 3-by-3 arrays, A and B, and multiply them element by element.

```
A = [1 0 3; 5 3 8; 2 4 6];  
B = [2 3 7; 9 1 5; 8 8 3];  
C = A.*B
```

```
C =
```

```
     2     0    21  
    45     3    40  
    16    32    18
```

mtimes

# title

---

**Purpose** Add title to current axes

**Syntax**

```
title(str)
title(str,Name,Value)

title(axes_handle, ___ )

h = title( ___ )
```

**Description** `title(str)` adds the title consisting of a string, `str`, at the top and in the center of the current axes. Each axes graphics object has one predefined title.

`title(str,Name,Value)` additionally specifies the title properties using one or more `Name,Value` pair arguments.

`title(axes_handle, ___ )` adds the title to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a title. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = title( ___ )` returns the handle to the text object used as the title. The handle is useful when making future modifications to the title.

## Input Arguments

### **str - Text to display as title**

string

Text to display as a title, specified as a string. You also can specify the name of a function that returns a string.

**Example:** 'myTitle'

**Example:** date

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a title when quoted as a normal string. To display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

### **axes\_handle - Axes handle**

`handle`

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Color', 'red', 'FontSize', 14` adds a title with red, 14-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

### **'Color' - Text color**

`[0 0 0]` (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

**Example:** 'Color',[0 1 0]

**Example:** 'Color','green'

### **'FontAngle' - Character slant**

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

**Example:** 'FontAngle','italic'

### **'FontName' - Font name**

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to

hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName', 'Courier'

### **'FontSize' - Font size**

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize', 12.5

### **'FontUnits' - Font size units**

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $\frac{1}{72}$  inch

---

**Note** When setting both the `FontSize` and the `FontUnits`, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`. For example, to set the font size to 0.3 inches, call `'FontUnits','inches','FontSize',0.3` in the argument list.

---

## **'FontWeight' - Weight of text characters**

`'normal'` (default) | `'bold'` | `'light'` | `'demi'`

Weight of text characters, specified as the comma-separated pair consisting of `'FontWeight'` and one of the following strings:

- `'normal'`
- `'bold'`
- `'light'`
- `'demi'`

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to `'bold'` or `'demi'` causes MATLAB to use a bold font.

**Example:** `'FontWeight','bold'`

## **'Interpreter' - Character interpretation**

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of `'Interpreter'` and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** 'Interpreter', 'latex'

## Output Arguments

### **h** - Handle to text object

scalar

Handle to the text object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the title.

## Examples

### **Add Title to Current Figure**

Create a figure and display a title in the current axes.

```
figure
plot((1:10).^2)
title('My Title')
```

You also can call `title` with a function that returns a string. For example, the `date` function returns a string containing today's date.

```
title(date)
```

MATLAB sets the output of `date` as the axes title.

### **Include Variable's Value in Title**

Include the value of variable `c` in a title.

```
figure
plot((1:10).^2)
f = 70;
c = (f-32)/1.8;
title(['Temperature is ',num2str(c),' C'])
```

## Create Multicolored Title Using TeX Markup

In a TeX string, use the color modifier `\color` to change the color of characters following it from the previous color.

```
figure
plot((1:10).^2)
title(['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0.5.5}teal \color{red}red} black again'])
```

## Create Colored Title Using Name,Value Pair Argument

Include the value of variable `n` in a title, and set the color of the title.

Use the Name,Value pair `'Color', 'y'` to set the color of the title to yellow.

```
figure
plot((1:10).^2)
title('Case number # 3','Color', 'y')
```

## Include Greek Symbols in Title

Use a TeX string to include Greek symbols in a title.

```
t = (0:0.01:0.2);
y = exp(-25*t);
figure
plot(t,y)
title('y = \ite^{\lambda t}','Color','b')
```

The text object `String` property lists the available symbols. The `'Interpreter'` property must be `'tex'` (the default).

### Include Superscript or Subscript Character in Title

```
figure
plot((1:10).^2)
title('\alpha^2 and X_1')
```

The superscript character “^” and the subscript character “\_” modify the character or substring defined in braces immediately following.

### Create Multiline Title

Create a multiline title using a multiline cell array.

```
figure
plot((1:10).^2)
title({'First line'; 'Second line'})
```

### Display Text As Typed

Set the Interpreter property as 'none' so that the string X\_1 is displayed in the figure as typed, without making 1 a subscript of X.

```
figure
plot((1:10).^2)
title('X_1', 'Interpreter', 'none')
```

MATLAB displays the string X\_1 in the title of the figure.

### Add Title to Specific Axes

Create two subplots and return the handles to the axes objects, s(1) and s(2).

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Add a title to each subplot by referring to its axes handle, s(1), or s(2).

# title

---

```
title(s(1), 'Top Plot')
title(s(2), 'Bottom Plot')
```

## Add Title and Return Object Handle

Add a title to a plot and return the handle to the text object used as the title.

```
figure
plot((1:10).^2)
```

```
h = title('My Title');
```

MATLAB returns the object handle in the output variable, h.

Set the color of the title to red, using the object handle.

```
set(h, 'Color', 'red')
```

**Concepts**

- [Adding Titles to Graphs](#)  
[Text Properties](#)

# todatenum

---

**Purpose** Convert CDF epoch object to MATLAB datenum

**Syntax** `n = todatenum(obj)`

**Description** `n = todatenum(obj)` converts the CDF epoch object `ep_obj` into a MATLAB serial date number. Note that a CDF epoch is the number of milliseconds since 01-Jan-0000 whereas a MATLAB datenum is the number of days since 00-Jan-0000.

**Examples** Construct a CDF epoch object from a date string, and then convert the object back into a MATLAB date string:

```
dstr = datestr(today)
dstr =
    08-Oct-2003

obj = cdfepoch(dstr)
obj =
    cdfepoch object:
    08-Oct-2003 00:00:00

dstr2 = datestr(todatenum(obj))
dstr2 =
    08-Oct-2003
```

**See Also** `cdfepoch` | `cdfinfo` | `cdfread` | `datenum`

**Purpose** Toeplitz matrix

**Syntax** `T = toeplitz(c,r)`  
`T = toeplitz(r)`

**Description** A *Toeplitz* matrix is defined by one row and one column. A *symmetric Toeplitz* matrix is defined by just one row. `toeplitz` generates Toeplitz matrices given just the row or row and column description.

`T = toeplitz(c,r)` returns a nonsymmetric Toeplitz matrix `T` having `c` as its first column and `r` as its first row. If the first elements of `c` and `r` are different, a message is printed and the column element is used.

For a real vector `r`, `T = toeplitz(r)` returns the symmetric Toeplitz matrix formed from vector `r`, where `r` defines the first row of the matrix. For a complex vector `r` with a real first element, `T = toeplitz(r)` returns the Hermitian Toeplitz matrix formed from `r`, where `r` defines the first row of the matrix and `r'` defines the first column. When the first element of `r` is not real, the resulting matrix is Hermitian off the main diagonal, i.e.,  $T_{ij} = \text{conj}(T_{ji})$  for  $i \neq j$ .

**Examples** A Toeplitz matrix with diagonal disagreement is

```
c = [1 2 3 4 5];
r = [1.5 2.5 3.5 4.5 5.5];
toeplitz(c,r)
Column wins diagonal conflict:
ans =
    1.000    2.500    3.500    4.500    5.500
    2.000    1.000    2.500    3.500    4.500
    3.000    2.000    1.000    2.500    3.500
    4.000    3.000    2.000    1.000    2.500
    5.000    4.000    3.000    2.000    1.000
```

**See Also** `hankel` | `kron`

# toolboxdir

---

**Purpose** Root folder for specified toolbox

**Syntax**

```
toolboxdir('tbxFolderName')
s = toolboxdir('tbxFolderName')
s = toolboxdir tbxFolderName
```

**Description** `toolboxdir('tbxFolderName')` returns a string that is the absolute path to the specified toolbox, `tbxFolderName`, where `tbxFolderName` is the folder name for the toolbox.

`s = toolboxdir('tbxFolderName')` returns the absolute path to the specified toolbox to the output argument, `s`.

`s = toolboxdir tbxFolderName` is the command form of the syntax.

**Tips** `toolboxdir` is particularly useful for MATLAB Compiler software. The base folder of all toolboxes installed with MATLAB software is:

```
matlabroot/toolbox/tbxFolderName
```

However, in deployed mode, the base folders of the toolboxes are different. `toolboxdir` returns the correct root folder, whether running from MATLAB or from an application deployed with the MATLAB Compiler software.

To determine the folder name for a given toolbox, run the following code, substituting the name of a product function for *toolboxfcn*:

```
n = 'toolboxfcn';
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\\/]+';
regexp(which(n), pat, 'match', 'once')
```

For example, to determine the product name for Control System Toolbox set `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss'
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\\/]+'
regexp(which(n), pat, 'match', 'once')
```

control

## Examples

Obtain the path for the Control System Toolbox software:

```
s = toolboxdir('control')
```

MATLAB returns:

```
s = C:\Program Files\MATLAB\R2012a\toolbox\control
```

## See Also

# trace

---

<b>Purpose</b>	Sum of diagonal elements
<b>Syntax</b>	<code>b = trace(A)</code>
<b>Description</b>	<code>b = trace(A)</code> is the sum of the diagonal elements of the matrix A.
<b>Algorithms</b>	<code>t = sum(diag(A));</code>
<b>See Also</b>	<code>det</code>   <code>eig</code>

**Purpose**

Transpose

**Syntax**

```
b = a.'  
b = transpose(a)
```

**Description**

`b = a.'` computes the non-conjugate transpose of matrix `a` and returns the result in `b`.

`b = transpose(a)` is called for the syntax `a.'` when `a` is an object.

**See Also**

`ctranspose` | `permute`

# trapz

---

**Purpose** Trapezoidal numerical integration

**Syntax**  
`Z = trapz(Y)`  
`Z = trapz(X,Y)`  
`Z = trapz(...,dim)`

**Description** `Z = trapz(Y)` computes an approximation of the integral of `Y` via the trapezoidal method (with unit spacing). To compute the integral for spacing other than one, multiply `Z` by the spacing increment. Input `Y` can be complex.

If `Y` is a vector, `trapz(Y)` is the integral of `Y`.

If `Y` is a matrix, `trapz(Y)` is a row vector with the integral over each column.

If `Y` is a multidimensional array, `trapz(Y)` works across the first nonsingleton dimension.

`Z = trapz(X,Y)` computes the integral of `Y` with respect to `X` using trapezoidal integration. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `trapz(X,Y)` operates across this dimension.

`Z = trapz(...,dim)` integrates across the dimension of `Y` specified by scalar `dim`. The length of `X`, if given, must be the same as `size(Y,dim)`.

## Examples

### Example 1

The exact value of  $\int_0^{\pi} \sin(x) dx$  is 2.

To approximate this numerically on a uniformly spaced grid, use

```
X = 0:pi/100:pi;  
Y = sin(X);
```

Then both

```
Z = trapz(X,Y)
```

and

```
Z = pi/100*trapz(Y)
```

produce

```
Z =  
    1.9998
```

### Example 2

A nonuniformly spaced example is generated by

```
X = sort(rand(1,101)*pi);  
Y = sin(X);  
Z = trapz(X,Y);
```

The result is not as accurate as the uniformly spaced grid. One random sample produced

```
Z =  
    1.9984
```

### Example 3

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);  
  
trapz(z, 1./z)  
ans =  
    0.0000 + 3.1411i
```

### See Also

# treelayout

---

**Purpose** Lay out tree or forest

**Syntax** `[x,y] = treelayout(parent,post)`  
`[x,y,h,s] = treelayout(parent,post)`

**Description** `[x,y] = treelayout(parent,post)` lays out a tree or a forest. `parent` is the vector of parent pointers, with 0 for a root. `post` is an optional postorder permutation on the tree nodes. If you omit `post`, `treelayout` computes it. `x` and `y` are vectors of coordinates in the unit square at which to lay out the nodes of the tree to make a nice picture.

`[x,y,h,s] = treelayout(parent,post)` also returns the height of the tree `h` and the number of vertices `s` in the top-level separator.

**See Also** `etree` | `treepplot` | `etreeplot` | `symbfact`

**Purpose**

Plot picture of tree

**Syntax**

```
treeplot(p)
treeplot(p,nodeSpec,edgeSpec)
```

**Description**

`treeplot(p)` plots a picture of a tree given a vector of parent pointers, with  $p(i) = 0$  for a root.

`treeplot(p,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `' '` to omit one or both.

**Examples**

To plot a tree with 12 nodes, call `treeplot` with a 12-element input vector. The index of each element in the vector is shown adjacent to each node in the figure below. (These indices are shown only for the point of illustrating the example; they are not part of the `treeplot` output.)

To generate this plot, set the value of each element in the nodes vector to the index of its parent, (setting the parent of the root node to zero).

# treeplot

---

The node marked 1 in the figure is represented by `nodes(1)` in the input vector, and because this is the root node which has a parent of zero, you set its value to zero:

```
nodes(1) = 0;    % Root node
```

`nodes(2)` and `nodes(8)` are children of `nodes(1)`, so set these elements of the input vector to 1:

```
nodes(2) = 1;    nodes(8) = 1;
```

`nodes(5:7)` are children of `nodes(4)`, so set these elements to 4:

```
nodes(5) = 4;    nodes(6) = 4;    nodes(7) = 4;
```

Continue in this manner until each element of the vector identifies its parent. For the plot shown above, the `nodes` vector now looks like this:

```
nodes = [0 1 2 2 4 4 4 1 8 8 10 10];
```

Now call `treeplot` to generate the plot:

```
treeplot(nodes)
```

## See Also

[etree](#) | [etreeplot](#) | [treelayout](#)

**Purpose** Lower triangular part of matrix

**Syntax**  
 $L = \text{tril}(X)$   
 $L = \text{tril}(X,k)$

**Description**  $L = \text{tril}(X)$  returns the lower triangular part of  $X$ .  
 $L = \text{tril}(X,k)$  returns the elements on and below the  $k$ th diagonal of  $X$ .  $k = 0$  is the main diagonal,  $k > 0$  is above the main diagonal, and  $k < 0$  is below the main diagonal.

**Examples** `tril(ones(4,4),-1)`

ans =

```

0  0  0  0
1  0  0  0
1  1  0  0
1  1  1  0
```

**See Also** `diag` | `triu`

# trimesh

---

## Purpose

Triangular mesh plot

## Syntax

```
trimesh(Tri,X,Y,Z,C)
trimesh(Tri,X,Y,Z)
trimesh(Tri,X,Y)
trimesh(TR)
trimesh(...'PropertyName',PropertyValue...)
h = trimesh(...)
```

## Description

`trimesh(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a mesh. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the  $X$ ,  $Y$ , and  $Z$  vertices. The edge color is defined by the vector `C`.

`trimesh(Tri,X,Y,Z)` uses `C = Z` so color is proportional to surface height.

`trimesh(Tri,X,Y)` displays the triangles in a 2-D plot.

`trimesh(TR)` displays the triangles in a triangulation representation.

`trimesh(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trimesh(...)` returns a handle to the displayed triangles.

## Examples

Create vertex vectors and a face matrix, then create a triangular mesh plot.

```
[x,y]=meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trimesh(tri,x,y,z)
```

If the surface is already a triangulation representation, then you can pass the triangulation to `trimesh`:

```
tr = triangulation(tri,x(:),y(:),z(:));  
trimesh(tr)
```

### See Also

# triplequad

---

## Purpose

Numerically evaluate triple integral

`triplequad` will be removed in a future release. Use `integral3` instead.

## Syntax

```
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)
```

## Description

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)` evaluates the triple integral  $\text{fun}(x,y,z)$  over the three dimensional rectangular region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min} \leq y \leq y_{\max}$ ,  $z_{\min} \leq z \leq z_{\max}$ . The first input, `fun`, is a function handle. `fun(x,y,z)` must accept a vector `x` and scalars `y` and `z`, and return a vector of values of the integrand.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)` uses a tolerance `tol` instead of the default, which is  $1.0e-6$ .

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quad1` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quad1`.

## Examples

Pass function handle `@integrnd` to `triplequad`:

```
Q = triplequad(@integrnd,0,pi,0,1,-1,1);
```

where the file `integrnd.m` is

```
function f = integrnd(x,y,z)
f = y*sin(x)+z*cos(x);
```

Pass anonymous function handle `F` to `triplequad`:

```
F = @(x,y,z)y*sin(x)+z*cos(x);  
Q = triplequad(F,0,pi,0,1,-1,1);
```

This example integrates  $y\sin(x)+z\cos(x)$  over the region  $0 \leq x \leq \pi$ ,  $0 \leq y \leq 1$ ,  $-1 \leq z \leq 1$ . Note that the integrand can be evaluated with a vector  $x$  and scalars  $y$  and  $z$ .

## See Also

[dblquad](#) | [quad2d](#) | [quad](#) | [quadgk](#) | [quadl](#) | [function\\_handle](#) | [integral](#) | [integral2](#) | [integral3](#)

## How To

- “Anonymous Functions”

# triplot

---

**Purpose** 2-D triangular plot

**Syntax**

```
triplot(TRI,x,y)
triplot(TRI,x,y,color)
triplot(TR)
h = triplot(...)
triplot(...,'param','value','param','value'...)
```

**Description** `triplot(TRI,x,y)` displays the triangles defined in the  $m$ -by-3 matrix `TRI`. A row of `TRI` contains indices into the vectors `x` and `y` that define a single triangle. The default line color is blue.

`triplot(TRI,x,y,color)` uses the string `color` as the line color. `color` can also be a line specification. See `ColorSpec` for a list of valid color strings. See `LineStyle` for information about line specifications.

`triplot(TR)` displays the triangles in a triangulation representation.

`h = triplot(...)` returns a vector of handles to the displayed triangles.

`triplot(...,'param','value','param','value'...)` allows additional line property name/property value pairs to be used when creating the plot. See `Line Properties` for information about the available properties.

**Examples** Plot a Delaunay triangulation for 10 randomly generated points.

```
P = gallery('uniformdata',10,2,2);
DT = delaunayTriangulation(P);
triplot(DT)
```

| [trisurf](#)

# TriRep

---

**Purpose** (Will be removed) Triangulation representation

---

**Note** TriRep will be removed in a future release. Use `triangulation` instead.

---

**Description** TriRep provides topological and geometric queries for triangulations in 2-D and 3-D space. For example, for triangular meshes you can query triangles attached to a vertex, triangles that share an edge, neighbor information, circumcenters, or other features. You can create a `TriRep` directly using existing triangulation data. Alternatively, you can create a Delaunay triangulation, via `DelaunayTri`, which provides access to the `TriRep` functionality.

**Construction** `TriRep` (Will be removed) Triangulation representation

**Methods**

<code>baryToCart</code>	(Will be removed) Convert point coordinates from barycentric to Cartesian
<code>cartToBary</code>	(Will be removed) Convert point coordinates from cartesian to barycentric
<code>circumcenters</code>	(Will be removed) Circumcenters of specified simplices
<code>edgeAttachments</code>	(Will be removed) Simplices attached to specified edges
<code>edges</code>	(Will be removed) Triangulation edges

faceNormals	(Will be removed) Unit normals to specified triangles
featureEdges	(Will be removed) Sharp edges of surface triangulation
freeBoundary	(Will be removed) Facets referenced by only one simplex
incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information
size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

## Properties

X	Coordinates of the points in the triangulation
Triangulation	Triangulation data structure

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Indexing

TriRep objects support indexing into the triangulation using parentheses (). The syntax is the same as for arrays.

## Examples

Load a 2-D triangulation and use the TriRep constructor to build an array of the free boundary edges:

```
load trimesh2d
```

This loads triangulation `tri` and vertex coordinates `x, y`:

```
trep = TriRep(tri, x,y);  
fe = freeBoundary(trep)';  
triplot(trep);
```

You can add the free edges `fe` to the plot:

```
hold on;  
plot(x(fe), y(fe), 'r', 'LineWidth', 2);  
hold off;
```

```
axis([-50 350 -50 350]);  
axis equal;
```

**See Also**

[delaunayTriangulation](#) | [triangulation](#) | [scatteredInterpolant](#)

# TriRep

---

**Purpose** (Will be removed) Triangulation representation

---

**Note** TriRep will be removed in a future release. Use `triangulation` instead.

---

**Syntax**

```
TR = TriRep(TRI, X, Y)
TR = TriRep(TRI, X, Y, Z)
TR = TriRep(TRI, X)
```

**Description** `TR = TriRep(TRI, X, Y)` creates a 2-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y)`. `TRI` is an  $m$ -by-3 matrix that defines the triangulation in face-vertex format, where  $m$  is the number of triangles. Each row of `TRI` is a triangle defined by indices into the column vector of vertex coordinates `(X, Y)`.

`TR = TriRep(TRI, X, Y, Z)` creates a 3-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y, Z)`. `TRI` is an  $m$ -by-3 or  $m$ -by-4 matrix that defines the triangulation in simplex-vertex format, where where  $m$  is the number of simplices; triangles or tetrahedra in this case. Each row of `TRI` is a simplex defined by indices into the column vector of vertex coordinates `(X, Y, Z)`.

`TR = TriRep(TRI, X)` creates a triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `X`. `TRI` is an  $m$ -by- $n$  matrix that defines the triangulation in simplex-vertex format, where  $m$  is the number of simplices and  $n$  is the number of vertices per simplex. Each row of `TRI` is a simplex defined by indices into the array of vertex coordinates `X`. `X` is an  $mpts$ -by- $ndim$  matrix where  $mpts$  is the number of points and  $ndim$  is the dimension of the space where the points reside, where  $2 \leq ndim \leq 3$ .

**Examples** Load a 3-D tetrahedral triangulation compute the free boundary. First, load triangulation `tet` and vertex coordinates `X`.

```
load tetmesh
```

Create the triangulation representation and compute the free boundary.

```
trep = TriRep(tet, X);  
[tri, Xb] = freeBoundary(trep);
```

## See Also

[scatteredInterpolant](#) | [delaunayTriangulation](#)

# TriScatteredInterp

---

**Purpose** (Will be removed) Interpolate scattered data

---

**Note** TriScatteredInterp will be removed in a future release. Use scatteredInterpolant instead.

---

**Description** TriScatteredInterp is used to perform interpolation on a scattered dataset that resides in 2-D or 3-D space. A scattered data set defined by locations  $X$  and corresponding values  $V$  can be interpolated using a Delaunay triangulation of  $X$ . This produces a surface of the form  $V = F(X)$ . The surface can be evaluated at any query location  $QX$ , using  $QV = F(QX)$ , where  $QX$  lies within the convex hull of  $X$ . The interpolant  $F$  always goes through the data points specified by the sample.

**Definitions** The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set. The *convex hull* of a set of points is the smallest convex set containing all points of the original set. These definitions extend naturally to higher dimensions.

**Construction** TriScatteredInterp (Will be removed) Interpolate scattered data

<b>Properties</b>	$X$	Defines locations of scattered data points in 2-D or 3-D space.
	$V$	Defines value associated with each data point.

Method	Defines method used to interpolate the data .	
	natural	Natural neighbor interpolation
	linear	Linear interpolation (default)
	nearest	Nearest neighbor interpolation

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Create a data set:

```
x = rand(100,1)*4-2;  
y = rand(100,1)*4-2;  
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz:

```
ti = -2:.25:2;  
[qx,qy] = meshgrid(ti,ti);  
qz = F(qx,qy);  
mesh(qx,qy,qz);  
hold on;  
plot3(x,y,z, 'o');
```

# TriScatteredInterp

---

## See Also

[delaunayTriangulation](#) | [interp1](#) | [interp2](#) | [interp3](#) | [meshgrid](#)

**Purpose** (Will be removed) Interpolate scattered data

---

**Note** TriScatteredInterp will be removed in a future release. Use scatteredInterpolant instead.

---

**Syntax**

```
F = TriScatteredInterp()  
F = TriScatteredInterp(X, V)  
F = TriScatteredInterp(X, Y, V)  
F = TriScatteredInterp(X, Y, Z, V)  
F = TriScatteredInterp(DT, V)  
F = TriScatteredInterp(..., method)
```

**Description**

F = TriScatteredInterp() creates an empty scattered data interpolant. This can subsequently be initialized with sample data points and values (Xdata, Vdata) via F.X = Xdata and F.V = Vdata.

F = TriScatteredInterp(X, V) creates an interpolant that fits a surface of the form  $V = F(X)$  to the scattered data in (X, V). X is a matrix of size mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside (ndim is 2 or 3). The column vector V defines the values at X, where the length of V equals mpts.

F = TriScatteredInterp(X, Y, V) and F = TriScatteredInterp(X, Y, Z, V) allow the data point locations to be specified in alternative column vector format when working in 2-D and 3-D.

F = TriScatteredInterp(DT, V) uses the specified DelaunayTri object DT as a basis for computing the interpolant. DT is a Delaunay triangulation of the scattered data locations, DT.X. The matrix DT.X is of size mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . V is a column vector that defines the values at DT.X, where the length of V equals mpts.

F = TriScatteredInterp(..., method) allows selection of the technique method used to interpolate the data.

# TriScatteredInterp

---

## Input Arguments

X	Matrix of size <code>mpts-by-ndim</code> , where <code>mpts</code> is the number of points and <code>ndim</code> is the dimension of the space where the points reside. Input may also be specified as column vectors (X, Y) or (X, Y, Z)	
V	Column vector that defines the values at X, where the length of V equals <code>mpts</code> .	
DT	Delaunay triangulation of the scattered data locations	
method	natural	Natural neighbor interpolation
	linear	Linear interpolation (default)
	nearest	Nearest-neighbor interpolation

## Output Arguments

F	Creates an interpolant that fits a surface of the form $V = F(X)$ to the scattered data.
---	------------------------------------------------------------------------------------------

## Evaluation

To evaluate the interpolant, express the statement in Monge's form  $V_q = F(X_q)$ ,  $V_q = F(X_q, Y_q)$ , or  $V_q = F(X_q, Y_q, Z_q)$  where  $V_q$  is the value of the interpolant at the query location and  $X_q$ ,  $Y_q$ , and  $Z_q$  are the vectors of point locations.

## Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set.

## Examples

Create a data set:

```
x = rand(100,1)*4-2;  
y = rand(100,1)*4-2;  
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz .

```
ti = -2:.25:2;  
[qx,qy] = meshgrid(ti,ti);  
qz = F(qx,qy);  
mesh(qx,qy,qz);  
hold on;  
plot3(x,y,z, 'o');
```

## See Also

[delaunayTriangulation](#) | [interp1](#) | [interp2](#) | [interp3](#) | [meshgrid](#)

# trisurf

---

**Purpose** Triangular surface plot

**Syntax**

```
trisurf(Tri,X,Y,Z,C)
trisurf(Tri,X,Y,Z)
trisurf(TR)
trisurf(...'PropertyName',PropertyValue...)
h = trisurf(...)
```

**Description** `trisurf(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a surface. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the  $X$ ,  $Y$ , and  $Z$  vertices. The color is defined by the vector `C`.

`trisurf(Tri,X,Y,Z)` uses `C=Z` so color is proportional to surface height.

`trisurf(TR)` displays the triangles in a triangulation representation. It uses `C = TR.Points(:,3)` to make the the surface color is proportional to height.

`trisurf(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trisurf(...)` returns a patch handle.

**Examples** Create vertex vectors and a face matrix, then create a triangular surface plot.

```
[x,y] = meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trisurf(tri,x,y,z)
```

If the surface is in the form of a triangulation representation, you can pass it to `trisurf` alone:

```
tr = triangulation(tri,x(:),y(:),z(:));  
trisurf(tr)
```

# triu

**Purpose** Upper triangular part of matrix

**Syntax**  
`U = triu(X)`  
`U = triu(X,k)`

**Description** `U = triu(X)` returns the upper triangular part of `X`.  
`U = triu(X,k)` returns the element on and above the `k`th diagonal of `X`.  
`k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.

**Examples** `triu(ones(4,4), -1)`

```
ans =  
  
    1    1    1    1  
    1    1    1    1  
    0    1    1    1  
    0    0    1    1
```

**See Also** `diag` | `tril`

**Purpose** Logical 1 (true)

**Syntax**

```
true
true(n)
true(m, n)
true(m, n, p, ...)
true(size(A))
true(..., 'like', p)
```

**Description** `true` is shorthand for logical (1).  
`true(n)` is an n-by-n matrix of logical ones.  
`true(m, n)` or `true([m, n])` is an m-by-n matrix of logical ones.  
`true(m, n, p, ...)` or `true([m n p ...])` is an m-by-n-by-p-by-... array of logical ones.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

`true(size(A))` is an array of logical ones that is the same size as array `A`.

`true(..., 'like', p)` is an array of logical ones of the same data type and sparsity as the logical array `p`.

**Tips** `true(n)` is much faster and more memory efficient than `logical(ones(n))`.

**See Also** `false` | `logical`

# try/catch

---

**Purpose** Execute statements and catch resulting errors

**Syntax**

```
try
    statements
catch exception
    statements
end
```

**Description** try and catch blocks allow you to override the default error behavior for a set of program statements. If any statement in a try block generates an error, program control goes immediately to the catch block, which contains your error handling statements.

*exception* is an optional MException object input to the catch block that allows you to identify the error.

Both try and catch blocks can contain nested try/catch statements.

**Examples** Provide more information about a dimension mismatch error:

```
A = rand(3);
B = ones(5);

try
    C = [A; B];
catch err

    % Give more information for mismatch.
    if (strcmp(err.identifier, 'MATLAB:catenate:dimensionMismatch'))

        msg = sprintf('%s', ...
            'Dimension mismatch occurred: First argument has ', ...
            num2str(size(A,2)), ' columns while second has ', ...
            num2str(size(B,2)), ' columns. ');
        error('MATLAB:myCode:dimensions', msg);

    % Display any other errors as usual.
    else
```

```
        rethrow(err);
    end

end % end try/catch
```

---

Catch an error when reading an image file, and try adjusting the file extension to resolve the error (.jpg and .jpeg are similar, as are .tif and .tiff):

```
function imageData = readImage(filename)
try
    imageData = imread(filename);
catch exception

    % Is the error because MATLAB could not find the file?
    if ~exist(filename, 'file')

        % Check for common typos in the extension.
        [~, ~, extension] = fileparts(filename);
        switch extension
            case '.jpg'
                altFilename = strrep(filename, '.jpg', '.jpeg');
            case '.jpeg'
                altFilename = strrep(filename, '.jpeg', '.jpg');
            case '.tif'
                altFilename = strrep(filename, '.tif', '.tiff');
            case '.tiff'
                altFilename = strrep(filename, '.tiff', '.tif');
            otherwise
                rethrow(exception);
        end

        % Try again, with modified filename.
        try
            imageData = imread(altFilename);
        catch exception2
```

# try/catch

---

```
        % Rethrow original error.  
        rethrow(exception)  
    end  
  
    else  
        rethrow(exception)  
    end  
  
end
```

error | assert | MException

**Purpose** Create tscollection object

**Syntax**

```
tsc = tscollection(TimeSeries)
tsc = tscollection(Time)
tsc = tscollection(...,'Parameter',Value,...)
```

**Description** `tsc = tscollection(TimeSeries)` creates a `tscollection` object `tsc` with one or more `timeseries` objects already in the MATLAB workspace. The argument `TimeSeries` can be a

- Single `timeseries` object
- Cell array of `timeseries` objects

`tsc = tscollection(Time)` creates an empty `tscollection` object with the time vector `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.

`tsc = tscollection(...,'Parameter',Value,...)` creates a `tscollection` object with optional parameter-value pairs you enter after specifying either a time vector or a `timeseries` object. You can specify the following parameter:

- `Name` — String that specifies the name of this `tscollection` object

## Tips

### Definition: Time Series Collection

A time series collection object is a MATLAB variable that groups several time series with a common time vector. The time series that you include in the collection are called members of this collection.

### Properties of Time Series Collection Objects

This table lists the properties of the `tscollection` object. You can specify the `Time`, `TimeSeries`, and `Name` properties as input arguments in the constructor.

# tscollection

---

Property	Description
Name	tscollection name as a string. This can differ from the tscollection name in the MATLAB workspace.
Time	<p>When TimeInfo.StartDate is empty, values are measured relative to 0 . When TimeInfo.StartDate is defined, values represent date strings measured relative to the StartDate.</p> <p>The length of Time must be the same as the first or the last dimension of Data for each collection .</p>
TimeInfo	<p>Contains fields for contextual information about Time:</p> <ul style="list-style-type: none"><li>• Units — Time units with any of the following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', 'nanoseconds'</li><li>• Start — Start time</li><li>• End — End time (read only)</li><li>• Increment — Interval between subsequent time values. NaN when times are not uniformly sampled.</li><li>• Length — Length of the time vector (read only)</li><li>• Format — String defining the date string display format. See datestr.</li><li>• StartDate — Date string defining the reference date. See setabstime (tscollection).</li><li>• UserData — Any additional user-defined information</li></ul>

## Examples

The following example shows how to create a tscollection object.

1 Import the sample data.

```
load count.dat
```

**2** Create three `timeseries` objects to store each set of data:

```
count1 = timeseries(count(:,1),1:24,'name', 'ts1');  
count2 = timeseries(count(:,2),1:24,'name', 'ts2');  
count3 = timeseries(count(:,3),1:24,'name', 'ts3');
```

**3** Create a `tscollection` object named `tsc` and add to it two out of three time series already in the MATLAB workspace, by using the following syntax:

```
tsc = tscollection({count1 count2},'name','tsc')
```

## See Also

`addts` | `datestr` | `setabstime` (`tscollection`) | `timeseries`

# tsdata.event

---

**Purpose** Construct event object for timeseries object

**Syntax**  
`e = tsdata.event(Name,Time)`  
`e = tsdata.event(Name,Time,'Datenum')`

**Description** `e = tsdata.event(Name,Time)` creates an event object with the specified Name that occurs at the time Time. Time can either be a real value or a date string.

`e = tsdata.event(Name,Time,'Datenum')` uses 'Datenum' to indicate that the Time value is a serial date number generated by the datenum function. The Time value is converted to a date string after the event is created.

**Tips** You add events by using the addevent method.

Fields of the `tsdata.event` object include the following:

- **EventData** — MATLAB array that stores any user-defined information about the event
- **Name** — String that specifies the name of the event
- **Time** — Time value when this event occurs, specified as a real number
- **Units** — Time units
- **StartDate** — A reference date, specified in MATLAB datestr format. StartDate is empty when you have a numerical (non-date-string) time vector.

**Purpose** N-D closest simplex search

**Syntax** `t = tsearchn(X,TRI,XI)`  
`[t,P] = tsearchn(X,TRI,XI)`

**Description** `t = tsearchn(X,TRI,XI)` returns the indices `t` of the enclosing simplex of the Delaunay triangulation `TRI` for each point in `XI`. `X` is an `m`-by-`n` matrix, representing `m` points in `N`-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in `N`-dimensional space. `tsearchn` returns `NaN` for all points outside the convex hull of `X`. `tsearchn` requires a triangulation `TRI` of the points `X` obtained from `delaunayn`.

`[t,P] = tsearchn(X,TRI,XI)` also returns the barycentric coordinate `P` of `XI` in the simplex `TRI`. `P` is a `p`-by-`n+1` matrix. Each row of `P` is the barycentric coordinate of the corresponding point in `XI`. It is useful for interpolation.

**See Also** `delaunayTriangulation`

# tstool

---

**Purpose** Open Time Series Tools GUI

**Compatibility** `tstool` will be removed in a future release.

- To create a time series object, use `timeseries`.
- To create a time series collection with one or more `timeseries` objects, use `tscollection`.
- To open a time series object or collection in the Variables editor, use `openvar`.
- To plot a time series object, use `plot`.

`tstool(sldata)` and `tstool(ModelDataLogs, 'replace')` have been removed. To view logged signal data, use the Simulink Simulation Data Inspector instead.

**Syntax**

```
tstool
tstool(ts)
tstool(tsc)
```

**Description** `tstool` starts the Time Series Tools GUI without loading any data.

`tstool(ts)` starts the Time Series Tools GUI and loads the time-series object `ts` from the MATLAB workspace.

`tstool(tsc)` starts the Time Series Tools GUI and loads the time-series collection object `tsc` from the MATLAB workspace.

**See Also** `timeseries` | `tscollection`

**How To**

- “View Logged Signal Data with the Simulation Data Inspector”

**Purpose**

Display contents of file

**Syntax**

```
type('filename')  
type filename
```

**Description**

`type('filename')` displays the contents of the specified file in the MATLAB Command Window. Use the full path for `filename`, or use a MATLAB relative partial path.

If you do not specify a file extension and there is no `filename` file without an extension, the `type` function adds the `.m` extension by default. The `type` function checks the folders specified in the MATLAB search path, which makes it convenient for listing the contents of files on the screen. Use `type` with `more` on to see the listing one screen at a time.

`type filename` is the command form of the syntax.

**Examples**

`type('foo.bar')` lists the contents of the file `foo.bar`.

`type foo` lists the contents of the file `foo`. If `foo` does not exist, `type foo` lists the contents of the file `foo.m`.

**See Also**

`cd` | `dbtype` | `delete` | `dir` | `more` | `path` | `what` | `who`

# typecast

---

**Purpose** Convert data types without changing underlying data

**Syntax** `Y = typecast(X, type)`

**Description** `Y = typecast(X, type)` converts a numeric value in `X` to the data type specified by `type`. Input `X` must be a full, noncomplex, numeric scalar or vector. The `type` input is a string set to one of the following: 'uint8', 'int8', 'uint16', 'int16', 'uint32', 'int32', 'uint64', 'int64', 'single', or 'double'.

`typecast` is different from the MATLAB `cast` function in that it does not alter the input data. `typecast` always returns the same number of bytes in the output `Y` as were in the input `X`. For example, casting the 16-bit integer 1000 to `uint8` with `typecast` returns the full 16 bits in two 8-bit segments (3 and 232) thus keeping its original value ( $3 \times 256 + 232 = 1000$ ). The `cast` function, on the other hand, truncates the input value to 255.

The output of `typecast` can be formatted differently depending on what system you use it on. Some computer systems store data starting with its most significant byte (an ordering called *big-endian*), while others start with the least significant byte (called *little-endian*).

---

**Note** MATLAB issues an error if `X` contains fewer values than are needed to make an output value.

---

## Examples

### Example 1

This example converts between data types of the same size:

```
typecast(uint8(255), 'int8')
ans =
    -1
```

```
typecast(int16(-1), 'uint16')
ans =
```

65535

### Example 2

Set X to a 1-by-3 vector of 32-bit integers, then cast it to an 8-bit integer type:

```
X = uint32([1 255 256])
X =
         1         255         256
```

Running this on a little-endian system produces the following results. Each 32-bit value is divided up into four 8-bit segments:

```
Y = typecast(X, 'uint8')
Y =
     1     0     0     0 255     0     0     0     0     1     0     0
```

The third element of X, 256, exceeds the 8 bits that it is being converted to in Y(9) and thus overflows to Y(10):

```
Y(9:12)
ans =
     0     1     0     0
```

Note that `length(Y)` is equal to `4.*length(X)`. Also note the difference between the output of `typecast` versus that of `cast`:

```
Z = cast(X, 'uint8')
Z =
     1  255  255
```

### Example 3

This example casts a smaller data type (`uint8`) into a larger one (`uint16`). Displaying the numbers in hexadecimal format makes it easier to see just how the data is being rearranged:

```
format hex
X = uint8([44 55 66 77])
X =
```

# typecast

---

```
2c 37 42 4d
```

The first `typecast` is done on a big-endian system. The four 8-bit segments of the input data are combined to produce two 16-bit segments:

```
Y = typecast(X, 'uint16')
Y =
    2c37    424d
```

The second is done on a little-endian system. Note the difference in byte ordering:

```
Y = typecast(X, 'uint16')
Y =
    372c    4d42
```

You can format the little-endian output into big-endian (and vice versa) using the `swapbytes` function:

```
Y = swapbytes(typecast(X, 'uint16'))
Y =
    2c37    424d
```

## Example 4

This example attempts to make a 32-bit value from a vector of three 8-bit values. MATLAB issues an error because there are an insufficient number of bytes in the input:

```
format hex
typecast(uint8([120 86 52]), 'uint32')
```

```
Error using typecast
Too few input values to make output type.
```

Repeat the example, but with a vector of four 8-bit values, and it returns the expected answer:

```
typecast(uint8([120 86 52 18]), 'uint32')
ans =
```

12345678

cast | class | swapbytes

# uibuttongroup

---

**Purpose** Create container object to exclusively manage radio buttons and toggle buttons

**Syntax** `uibuttongroup('PropertyName1',Value1,'PropertyName2',Value2, ...)`  
`handle = uibuttongroup(...)`

**Description** A `uibuttongroup` groups components and manages exclusive selection behavior for radio buttons and toggle buttons that it contains. It can also contain other user interface controls, axes, `uipanel`s, and `uibuttongroup`s. It cannot contain ActiveX controls.

`uibuttongroup('PropertyName1',Value1,'PropertyName2',Value2, ...)` creates a visible container component in the current figure window. This component manages exclusive selection behavior for `uicontrol`s of style `radiobutton` and `togglebutton`.

`handle = uibuttongroup(...)` creates a `uibuttongroup` object and returns a handle to it in `handle`.

A `uibuttongroup` object can have axes, `uicontrol`, `uipanel`, and `uibuttongroup` objects as children. However, only `uicontrol`s of style `radiobutton` and `togglebutton` are managed by the component.

When programming a button group, you do not code callbacks for the individual buttons; instead, use its `SelectionChangeFcn` callback to manage responses to selections. The following example illustrates how you use `uibuttongroup` event data to do this.

For the children of a `uibuttongroup` object, the `Position` property is interpreted relative to the button group. If you move the button group, the children automatically move with it and maintain their positions in the button group.

If you have a button group that contains a set of radio buttons and toggle buttons and you want:

- An immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's `SelectionChangeFcn` callback function,

not in the individual toggle button `Callback` functions. See the `SelectionChangeFcn` property and the example on this reference page for more information.

- Another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

Use the `Parent` property to specify the parent as a figure, `uipanel`, or `uibuttongroup`. If you do not specify a parent, `uibuttongroup` adds the button group to the current figure. If no figure exists, one is created.

See the `Uibuttongroup Properties` reference page for more information.

After creating a `uibuttongroup`, you can set and query its property values using `set` and `get`. Run `get(handle)` to see a list of properties and their current values. Run `set(handle)` to see a list of object properties you can set and their legal values.

## Tips

If you set the `Visible` property of a `uibuttongroup` object to `'off'`, any child objects it contains (buttons, button groups, etc.) become invisible along with the `uibuttongroup` panel itself. However, doing this does *not* affect the settings of the `Visible` property of any of its child objects, even though all of them remain invisible until the button group's visibility is set to `'on'`. `uipanel` components also behave in this manner.

Do not use the `CreateFcn` of a button group to create the buttons it contains. You can toggle buttons created in the button group `CreateFcn` on and off, but clicking them does not trigger the button group `SelectionChangeCallback` and the buttons do not display the expected mutually-exclusive behavior.

## Examples

This example creates a `uibuttongroup` with three radio buttons. It manages the radio buttons with the `SelectionChangeFcn` callback, `selcbk`.

When you select a new radio button, `selcbk` displays the `uibuttongroup` handle on one line, the `EventName`, `OldValue`, and `NewValue` fields

of the event data structure on a second line, and the value of the SelectedObject property on a third line.

```
% Create the button group.
h = uibuttongroup('visible','off','Position',[0 0 .2 1]);
% Create three radio buttons in the button group.
u0 = uicontrol('Style','radiobutton','String','Option 1',...
    'pos',[10 350 100 30],'parent',h,'HandleVisibility','off');
u1 = uicontrol('Style','radiobutton','String','Option 2',...
    'pos',[10 250 100 30],'parent',h,'HandleVisibility','off');
u2 = uicontrol('Style','radiobutton','String','Option 3',...
    'pos',[10 150 100 30],'parent',h,'HandleVisibility','off');
% Initialize some button group properties.
set(h,'SelectionChangeFcn',@selcbk);
set(h,'SelectedObject',[]); % No selection
set(h,'Visible','on');
```

For the SelectionChangeFcn callback, selcbk, the source and event data structure arguments are available only if selcbk is called using a function handle. See SelectionChangeFcn for more information.

```
function selcbk(source,eventdata)
disp(source);
disp([ eventdata.EventName, ' ',...
    get(eventdata.OldValue,'String'),' ', ...
    get(eventdata.NewValue,'String')]);
disp(get(get(source,'SelectedObject'),'String'));
```

If you click Option 2 with no option selected, the `SelectionChangeFcn` callback, `selcbk`, displays:

```
3.0011
```

```
SelectionChanged    Option 2  
Option 2
```

If you then click Option 1, the `SelectionChangeFcn` callback, `selcbk`, displays:

```
3.0011
```

```
SelectionChanged  Option 2  Option 1  
Option 1
```

# uibuttongroup

---

## See Also

[uicontrol](#) | [uipanel](#)

**Purpose** Describe button group properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

Uibuttongroup takes its default property values from `uipanel`. To set a `uibuttongroup` default property value, set the default for the corresponding `uipanel` property. Note that you can set no default values for the `uibuttongroup` `SelectedObject` and `SelectionChangeFcn` properties.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

**Uibuttongroup Properties** This section describes all properties useful to `uibuttongroup` objects and lists valid values. Curly braces `{ }` enclose default values.

Property Name	Description
<code>BackgroundColor</code>	Color of the button group background
<code>BeingDeleted</code>	This object is being deleted
<code>BorderType</code>	Type of border around the button group
<code>BorderWidth</code>	Width of the button group border in pixels
<code>BusyAction</code>	Interruption of other callback routines
<code>ButtonDownFcn</code>	Button-press callback routine
<code>Children</code>	All children of the button group

# Uibuttongroup Properties

---

Property Name	Description
Clipping	Clipping of child axes, panels, and button groups to the button group. Does not affect child user interface controls (uicontrol)
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
FontAngle	Title font angle
FontName	Title font name
FontSize	Title font size
FontUnits	Title font units
FontWeight	Title font weight
ForegroundColor	Title font color and color of 2-D border line
HandleVisibility	Handle accessibility from command line and GUIs
HighlightColor	3-D frame highlight color
Interruptible	Callback routine interruption mode
Parent	uibuttongroup object's parent
Position	Button group position relative to parent figure, panel, or button group
ResizeFcn	User-specified resize routine
Selected	Whether object is selected
SelectedObject	Currently selected uicontrol of style radiobutton or togglebutton
SelectionChangeFcn	Callback routine executed when the selected radio button or toggle button changes
SelectionHighlight	Object highlighted when selected

# Uibuttongroup Properties

Property Name	Description
ShadowColor	3-D frame shadow color
Tag	User-specified object identifier
Title	Title string
TitlePosition	Location of title string in relation to the button group
Type	Object class
UIContextMenu	Associate context menu with the button group
Units	Units used to interpret the position vector
UserData	User-specified data
Visible	Button group visibility  <b>Note</b> Controls the visibility of a uibuttongroup and of its child axes, uibuttongroups, uipanel, and child uicontrols. Setting it does not change their Visible property.

BackgroundColor  
ColorSpec

*Color of the uibuttongroup background.* A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the ColorSpec reference page for more information on specifying color.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the BeingDeleted property to on when the object's delete function callback is called

# Uibuttongroup Properties

---

(see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BorderType

`none` | `{etchedin}` | `etchedout` |  
`beveledin` | `beveledout` | `line`

*Border of the uibuttongroup area.* Used to define the button group area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders. A line border is 2-D. Use the `ForegroundColor` property to specify its color.

## BorderWidth

integer

*Width of the button group border.* The width of the button group borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

## BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string or function handle

*Button-press callback routine.* A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the `uibuttongroup`. This is useful for implementing actions to interactively modify object properties, such as size and position, when they are clicked on (using the `selectmoveresize` function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

## `Children`

vector of handles

*Children of the `uibuttongroup`.* A vector containing the handles of all children of the `uibuttongroup`. Although a `uibuttongroup` manages only `uicontrols` of style `radiobutton` and `togglebutton`, its children can be axes, `uipanel`s, `uibuttongroup`s, and other `uicontrol`s. You can use this property to reorder the children.

## `Clipping`

{on} | off

*Clipping mode.* By default, MATLAB clips a `uibuttongroup`'s child axes, `uipanel`s, and `uibuttongroup`s to the `uibuttongroup` rectangle. If you set `Clipping` to `off`, the axis, `uipanel`, or

# Uibuttongroup Properties

---

`uibuttongroup` is displayed outside the button group rectangle. This property does not affect child `uicontrols` which, by default, can display outside the button group rectangle.

**CreateFcn**  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uibuttongroup` object. MATLAB sets all property values for the `uibuttongroup` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the `uibuttongroup` being created.

Setting this property on an existing `uibuttongroup` object has no effect.

To define a default `CreateFcn` callback for all new `uibuttongroups` you must define the same default for all `uipanel`s. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uibuttongroup`. For example, the code

```
set(0, 'DefaultUipanelCreateFcn', 'set(gcb0, ...  
    ' 'FontName', 'arial', 'FontSize', 12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel or button group. It sets the default font name and font size of the `uipanel` or `uibuttongroup` title.

To override this default and create a button group whose `FontName` and `FontSize` properties are set to different values, call `uibuttongroup` with code similar to

```
hpt = uibuttongroup(..., 'CreateFcn', 'set(gcb0, ...  
    ' 'FontName', 'times', 'FontSize', 14)')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uibuttongroup` call. In the example above, if instead of redefining the `CreateFcn` property for this `uibuttongroup`, you had explicitly set `FontSize` to 14, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uibuttongroup` object (e.g., when you issue a delete command or clear the figure containing the `uibuttongroup`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcb0`.

## FontAngle

{normal} | italic | oblique

*Character slant used in the Title.* MATLAB uses this property to select a font from those available on your particular system.

# Uibuttongroup Properties

---

Setting this property to *italic* or *oblique* selects a slanted version of the font, when it is available on your system.

FontName  
string

*Font family used in the Title.* The name of the font in which to display the `Title`. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set `FontName` to the string `FixedWidth`. This string value is case insensitive.

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root `FixedWidthFontName` property, which can be set to the appropriate value for a locale from `startup.m` in the end user's environment. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

FontSize  
integer

*Title font size.* A number specifying the size of the font in which to display the `Title`, in units determined by the `FontUnits` property. The default size is system dependent.

FontUnits  
inches | centimeters | normalized |  
{points} | pixels

*Title font size units.* Normalized units interpret `FontSize` as a fraction of the height of the `uibuttongroup`. When you resize the `uibuttongroup`, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

## FontWeight

light | {normal} | demi | bold

*Weight of characters in the title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to bold causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

ColorSpec

*Color used for title font and 2-D border line.* A three-element RGB vector or one of the MATLAB predefined names, specifying the font or line color. See the `ColorSpec` reference page for more information on specifying color.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

# Uibuttongroup Properties

---

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

---

**Note** Uicontrols of style `radiobutton` and `togglebutton` that are managed by a `uibuttongroup` should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to `off` or `callback` to prevent inadvertent access.

---

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`  
`ColorSpec`

*3-D frame highlight color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`Interruptible`  
`off` | `{on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- ButtonDownFcn
- KeyPressFcn
- KeyReleaseFcn
- WindowButtonDownFcn
- WindowButtonMotionFcn
- WindowButtonUpFcn
- WindowKeyPressFcn
- WindowKeyReleaseFcn
- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

# Uibuttongroup Properties

---

Setting the `Interruptible` property to on (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

Parent  
handle

*Uibuttongroup parent.* The handle of the `uibuttongroup`’s parent figure, `uipanel`, or `uibuttongroup`. You can move a `uibuttongroup` object to another figure, `uipanel`, or `uibuttongroup` by setting this property to the handle of the new parent.

Position  
position rectangle

*Size and location of uibuttongroup relative to parent.* The rectangle defined by this property specifies the size and location of the button group within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the `uibuttongroup` object. `width` and `height` are the dimensions of the `uibuttongroup` rectangle, including the title. All measurements are in units specified by the `Units` property.

## `ResizeFcn`

string or function handle

*Resize callback routine.* MATLAB executes this callback routine whenever a user resizes the `uibuttongroup` and the figure `Resize` property is set to `on`, or in GUIDE, the **Resize behavior** option is set to `Other`. You can query the `uibuttongroup Position` property to determine its new size and position. During execution of the callback routine, the handle to the figure being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

You can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position/Units` paradigm.

For example, consider a GUI layout that maintains an object at a constant height in pixels and attached to the top of the figure, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the `uicontrol` whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the `uicontrol` handle, and the `gcbo` function to retrieve the figure handle. Also note the defensive programming regarding figure `Units`, which the callback requires to be in pixels in order to work

# Uibuttongroup Properties

---

correctly, but which the callback also restores to their previous value afterwards.

```
u = findobj('Tag','StatusBar');
fig = gcb0;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within the `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

Note that the `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## Selected

on | off (read only)

*Is object selected?* This property indicates whether the button group is selected. When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` function to set this property, allowing users to select the object with the mouse.

## SelectedObject

scalar handle

*Currently selected radio button or toggle button uicontrol* in the managed group of components. Use this property to determine the currently selected component or to initialize selection of one of

# Uibuttongroup Properties

the radio buttons or toggle buttons. By default, `SelectedObject` is set to the first `uicontrol` radio button or toggle button that is added. Set it to `[]` if you want no selection. Note that `SelectionChangeFcn` does not execute when this property is set by the user.

`SelectionChangeFcn`  
string or function handle

Callback routine executed when the selected radio button or toggle button changes. If this routine is called as a function handle, `uibuttongroup` passes it two arguments. The first argument, `source`, is the handle of the `uibuttongroup`. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table.

Event Data Structure Field	Description
<code>EventName</code>	'SelectionChanged'
<code>OldValue</code>	Handle of the object selected before this event. <code>[]</code> if none was selected.
<code>NewValue</code>	Handle of the currently selected object.

If you have a button group that contains a set of radio buttons and/or toggle buttons and you want an immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's `SelectionChangeFcn` callback function, not in the individual toggle button `Callback` functions.

If you want another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

# Uibuttongroup Properties

---

---

**Note** For GUIDE GUIs, `hObject` contains the handle of the selected radio button or toggle button. See “Add Code for Components in Callbacks” for more information.

---

`SelectionHighlight`  
{on} | off

*Object highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

`ShadowColor`  
ColorSpec

*3-D frame shadow color.* `ShadowColor` is a three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the `ColorSpec` reference page for more information on specifying color.

`Tag`  
string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

## Title

string

*Title string.* The text displayed in the button group title. You can position the title using the `TitlePosition` property.

If the string value is specified as a cell array of strings or padded string matrix, only the first string in the cell array or padded string matrix is displayed; the rest are ignored. Vertical slash (`'\'`) characters are not interpreted as line breaks and instead show up in the text displayed in the `uibuttongroup` title.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in “Defining Default Values”. To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uibuttongroup(...,'Title','\Default');
```

## TitlePosition

{lefttop} | centertop | righttop |  
leftbottom | centerbottom | rightbottom

*Location of the title.* This property determines the location of the title string, in relation to the `uibuttongroup`.

## Type

string (read-only)

*Object class.* This property identifies the kind of graphics object. For `uibuttongroup` objects, `Type` is always the string `'uipanel'`, because its default properties derive from `uipanel`s.

## UIContextMenu

handle

*Associate a context menu with a uibuttongroup.* Assign this property the handle of a `Uicontextmenu` object. MATLAB displays

# Uibuttongroup Properties

---

the context menu whenever you right-click the `uibuttongroup`. Use the `uicontextmenu` function to create the context menu.

## Units

inches | centimeters | {normalized} |  
points | pixels | characters

*Units of measurement.* MATLAB uses these units to interpret the `Position` property. For the button group itself, units are measured from the lower-left corner of its parent figure window, panel, or button group. For children of the button group, they are measured from the lower-left corner of the button group.

- Normalized units map the lower-left corner of the button group or figure window to (0,0) and the upper-right corner to (1.0,1.0).
- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Any data you want to associate with the `uibuttongroup` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Visible

{on} | off

*Uibuttongroup visibility.* By default, a `uibuttongroup` object is visible. When set to 'off', the `uibuttongroup` is not visible, as are all child objects of the button group. When a button group is hidden in this manner, you can still query and set its properties.

---

**Note** The value of a `uibuttongroup`'s `Visible` property determines whether its child components, such as axes, buttons, `uipanel`s, and other `uibuttongroup`s, are visible. However, changing the `Visible` property of a button group does *not* change the settings of the `Visible` property of its child components even though hiding the button group causes them to be hidden.

---

# uicontextmenu

---

**Purpose** Create context menu

**Syntax** `handle = uicontextmenu('PropertyName',PropertyValue,...)`

**Description** `handle = uicontextmenu('PropertyName',PropertyValue,...)` creates a context menu, which is a menu that appears when the user right-clicks on a graphics object. See [Uicontextmenu Properties](#) for more information.

In its initial state, a context menu has no menu items. You create menu items within the context menu using the `uimenu` function. Menu items appear in the order in which the `uimenu` statements appear. You then associate a context menu with an object by specifying the handle of the context menu as the value for its `UIContextMenu` property.

## Examples

The following statements define a context menu associated with a line on a graph. The menu items enable you to change the line style.

```
% Create axes and save handle
hax = axes;
% Plot three lines
plot(rand(20,3));
% Define a context menu; it is not attached to anything
hcmenu = uicontextmenu;
% Define callbacks for context menu items that change linestyle
hcb1 = ['set(gcf, ''LineStyle'', ''--'')'];
hcb2 = ['set(gcf, ''LineStyle'', '':''')'];
hcb3 = ['set(gcf, ''LineStyle'', ''-'')'];
% Define the context menu items and install their callbacks
item1 = uimenu(hcmenu, 'Label', 'dashed', 'Callback', hcb1);
item2 = uimenu(hcmenu, 'Label', 'dotted', 'Callback', hcb2);
item3 = uimenu(hcmenu, 'Label', 'solid', 'Callback', hcb3);
% Locate line objects
hlines = findall(hax,'Type','line');
% Attach the context menu to each line
for line = 1:length(hlines)
    set(hlines(line),'uicontextmenu',hcmenu)
```

```
end
```

When you right-click on any line (or, on a Macintosh computer with a one-button mouse, press the **Ctrl** key and click), the context menu appears, as shown in the following figure.

To make context menus available immediately, attach them to lines at the time they are plotted. Therefore, when creating a GUI that uses such context menus, place code like the preceding in the callbacks that perform plotting for the GUI.

A best practice is to use function handles for callbacks. Only define callbacks as strings for simple actions. For example, you can add check marks to menu items (using the `Checked` uimenu property) to indicate the current style for each line. To manage the check marks, define the menu item callbacks as function handles. Place the code for the functions in the GUI code file rather than placing callback strings in the figure.

# uicontextmenu

---

Generally, you need to attach context menus to lines at the time they are plotted in order to be sure that the menus are immediately available. Therefore, code such as the above could be placed in or called from the callbacks that perform plotting for the GUI.

## **Tutorials**

See “Context Menus” in the MATLAB Creating Graphical User Interfaces documentation.

## **See Also**

`uibbuttongroup` | `uicontrol` | `uimenu` | `uipanel`

## Purpose

Describe context menu properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uicontextmenu Properties

This section lists all properties useful to `uicontextmenu` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

Property	Purpose
<code>BeingDeleted</code>	This object is being deleted
<code>BusyAction</code>	Callback routine interruption
<code>Callback</code>	Control action
<code>Children</code>	The <code>uimenu</code> s defined for the <code>uicontextmenu</code>
<code>CreateFcn</code>	Callback routine executed during object creation
<code>DeleteFcn</code>	Callback routine executed during object deletion
<code>HandleVisibility</code>	Whether handle is accessible from command line and GUIs
<code>Interruptible</code>	Callback routine interruption mode
<code>Parent</code>	<code>Uicontextmenu</code> object's parent

# Uicontextmenu Properties

---

Property	Purpose
Position	Location of uicontextmenu when Visible is on
Tag	User-specified object identifier
Type	Class of graphics object
UserData	User-specified data
Visible	Uicontextmenu visibility

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## Callback

string

*Control action.* A routine that executes whenever you right-click an object for which a context menu is defined. The routine executes immediately before the context menu is posted. Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

## Children

matrix

The `uimenu` items defined for the `uicontextmenu`.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uicontextmenu` object. MATLAB sets all property values for the `uicontextmenu` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the `uicontextmenu` being created.

Setting this property on an existing `uicontextmenu` object has no effect.

# Uicontextmenu Properties

---

You can define a default `CreateFcn` callback for all new `uicontextmenus`. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontextmenu`. For example, the code

```
set(0,'DefaultUicontextmenuCreateFcn','set(gcbo,...  
    'Visible','on'))
```

creates a default `CreateFcn` callback that runs whenever you create a new context menu. It sets the default `Visible` property of a context menu.

To override this default and create a context menu whose `Visible` property is set to a different value, call `uicontextmenu` with code similar to

```
hpt = uicontextmenu(...,'CreateFcn','set(gcbo,...  
    'Visible','off'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontextmenu` call. In the example above, if instead of redefining the `CreateFcn` property for this `uicontextmenu`, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

string or function handle

*Delete uicontextmenu callback routine.* A callback routine that executes when you delete the uicontextmenu object (for example, when you issue a `delete` command or clear the figure containing the uicontextmenu). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is on.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from

# Uicontextmenu Properties

---

command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`Interruptible`  
`off` | `{on}`

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

# Uicontextmenu Properties

---

For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uicontextmenu’s parent.* The handle of the `uicontextmenu`’s parent object, which must be a figure.

## Position

vector

*Uicontextmenu’s position.* A two-element vector that defines the location of a context menu posted by setting the `Visible` property value to `on`. Specify `Position` as

[x y]

where vector elements represent the horizontal and vertical distances in pixels from the bottom left corner of the figure window.

## Tag

string

*User-specified object label.* The `Tag` property provides a means to identify graphics objects with a user-specified label. This

is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

## Type

string

*Class of graphics object.* For `uicontextmenu` objects, `Type` is always the string `'uicontextmenu'`.

## UserData

matrix

*User-specified data.* Any data you want to associate with the `uicontextmenu` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Visible

on | {off}

*Uicontextmenu visibility.* The `Visible` property can be used in two ways:

- Its value indicates whether the context menu is currently posted. While the context menu is posted, the property value is `on`; when the context menu is not posted, its value is `off`.
- Its value can be set to `on` to force the posting of the context menu. Similarly, setting the value to `off` forces the context menu to be removed. When used in this way, the `Position` property determines the location of the posted context menu.

`uicontextmenu`

# uicontrol

---

**Purpose** Create user interface control object

**Syntax**

```
handle = uicontrol('Name',Value,...)
handle = uicontrol(parent,'Name',Value,...)
handle = uicontrol
uicontrol(uich)
```

**Description** `handle = uicontrol('Name',Value,...)` creates a `uicontrol` and assigns the specified properties and values to it. It assigns the default values to any properties you do not specify. The default `uicontrol` style is `pushbutton`. The default parent is the current figure. See the `Uicontrol Properties` reference page for more information.

`handle = uicontrol(parent,'Name',Value,...)` creates a `uicontrol` in the object specified by the handle, `parent`. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence. `parent` can be the handle of a figure, `uipanel`, or `uibuttongroup`.

`handle = uicontrol` creates a push button in the current figure. The `uicontrol` function assigns all properties their default values.

`uicontrol(uich)` gives focus to the `uicontrol` specified by the handle, `uich`.

`uicontrol` creates a `uicontrol` graphics objects (user interface controls), which you use to implement graphical user interfaces.

## Specifying the Uicontrol Style

When selected, most `uicontrol` objects perform a predefined action. To create a specific type of `uicontrol`, set the `Style` property as one of the strings that follow. You can specify a partial string if it is unique among all the styles. For example, instead of `'radiobutton'`, you can specify `'radio'`.

- `'checkbox'` – A check box generates an action when you select it. Use check boxes to provide a number of independent choices. To activate a check box, click the mouse button on the object. The check box updates its appearance when its state changes.

- 'edit' – Editable text fields enable you to enter or modify text values. Use editable text when you want free text as input. To enable multiple lines of text, set `Max-Min>1`. Multiline edit boxes provide a vertical scroll bar for scrolling. The arrow keys also provide a way to scroll. Obtain the current text by getting the `String` property. The `String` property does not update as you type in an edit box. To execute the callback routine for an edit text control, type in the desired text and then do one of the following:
  - Click another component, the menu bar, or the background of the GUI.
  - For a single line editable text box, press **Enter**.
  - For a multiline editable text box, press **Ctrl+Enter**.
- 'frame'

---

**Note** MathWorks recommends you use `uipanel` or `uibuttongroup` instead of frames.

GUIDE continues to support frames in those GUIs that contain them, but the frame component does not appear in the GUIDE Layout Editor component palette.

---

- 'listbox' – List boxes display a list of items, from which you can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked. The `Min` and `Max` properties control the selection mode:
  - To enable multiple selection of items, set `Max-Min > 1`.
  - To enable selection of only one item at a time, set `Max-Min <= 1`.

The `Value` property stores the row indexes of currently selected list box items, and is a vector value when you select multiple items. After any mouse button up event that changes the `Value` property, MATLAB evaluates the list box's callback routine. To delay action

when multiple items can be selected, you can associate a "Done" push button with the list box. Use the callback for that button to evaluate the list box `Value` property.

List boxes with the `Enable` property set to on differentiate between single and double left clicks. MATLAB sets the figure `SelectionType` property to `normal` or `open` accordingly before evaluating the list box `Callback` property. For enabled list boxes, **Ctrl**-left click and **Shift**-left click also set the figure `SelectionType` property to `normal` or `open`, respectively indicating a single or double click.

- `'popupmenu'` – Pop-up menus (also known as drop-down menus or combo boxes) display a list of choices when you open them with a button-press. When closed, a pop-up menu indicates the current choice. Pop-up menus are useful when you want to provide a number of mutually exclusive choices, but do not want to take up the amount of space that a group of radio buttons requires.
- `'pushbutton'` – Push buttons generate an action when activated. Left-click a push button to activate it. The button appears to depress until you release the mouse button. The callback activates when you release the mouse button while still pointing within the push button.
- `'radiobutton'` – Radio buttons are similar to check boxes, but are intended to be mutually exclusive within a group of related radio buttons. When used this way, you can only select one radio button at any given time). To activate a radio button, click and release the mouse button over it. The easiest way to implement mutually exclusive behavior for a set of radio buttons is to place them within a `uibuttongroup`.
- `'slider'` – Sliders accept numeric input within a specific range when you move the “thumb” button along a bar. The location of the thumb indicates a numeric value, assigned to the `Value` property when you release the mouse button. You can set the minimum, maximum, and current values, and step sizes of a slider.

Move the thumb by doing any one of the following:

- Press the mouse button on the thumb, and drag it along the bar.

- Click in the bar or on arrow buttons located at both ends of the bar.
- Click the keyboard arrow keys when the slider is in focus.
- 'text' – Static text boxes display lines of text. You typically use static text to label other controls, provide information to the user, or indicate values associated with a slider. Users cannot change static text interactively. Static text controls do not activate callback routines when clicked.
- 'togglebutton' – Toggle buttons are similar in appearance to push buttons, but they visually indicate their state, either on (pressed down) or off (up). Clicking a toggle button changes its state, and switches its Value property between Min and Max.

## Tips

- To simulate activation on static text by a mouse click, set the text *object's* Enable property to Inactive, and set its ButtonDownFcn callback to perform an action. For example, the following code displays 'Pressed' in the Command Window when you click on the Click me! text in the running GUI. (Without the set command, it would do nothing.)

```
h = uicontrol('Style','text','String','Click Me!');
set(h,'Enable','Inactive','ButtonDownFcn',...
    'disp(''Text was clicked'')')
```

- Adding a uicontrol to a figure removes the figure toolbar when the figure Toolbar property is 'auto' (which is the default). To prevent this from happening, set the Toolbar property to 'figure'. You can restore the toolbar by selecting **Figure Toolbar** from the **View** menu regardless of this property setting.
- The uicontrol function accepts property name/property value pairs, structures, and cell arrays as input arguments and optionally returns the handle of the created object. You can also use the set and get functions to set and query property values after creating the control.
- A uicontrol object is a child of a figure, uipanel, or uibuttongroup. Therefore, the uicontrol object does not require an axes to exist when placed in a figure window, uipanel, or uibuttongroup.

- When you pause MATLAB and a uicontrol has focus, pressing a keyboard key does not cause MATLAB to resume. Click anywhere outside a uicontrol and then press any key. For more information, see the `pause` function.

## Examples

Create a figure and an axes to contain a 3-D surface plot.

```
figure
hax = axes('Units','pixels');
surf(peaks)
```

Place a uicontrol object to let users change the colormap with a pop-up menu. Supply a function handle as the object's `Callback` property:

```
uicontrol('Style', 'popup',...
         'String', 'jet|hsv|hot|cool|gray',...
         'Position', [20 340 100 50],...
         'Callback', @setmap); % Popup function handle callback
                               % Implemented as a local function
```

Add a different uicontrol. Create a push button that clears the current axes when pressed. Position the button inside the axes at the lower left. All uicontrols have default units of pixels. In this example, the axes has units of pixels, as well.

```
uicontrol('Style', 'pushbutton', 'String', 'Clear',...  
         'Position', [20 20 50 20],...  
         'Callback', 'cla');           % Pushbutton string callback  
                                       % that calls a MATLAB function
```

# uicontrol

Add a slider uicontrol to control the vertical scaling of the surface object. Position it at the bottom right corner of the figure. Then add a text uicontrol as a label for the slider.

```
uicontrol('Style', 'slider',...
         'Min',1,'Max',50,'Value',41,...
         'Position', [400 20 120 20],...
         'Callback', {@surfzlim,hax});
% Uses cell array function handle callback
% Implemented as a local function with an argument
```

```
uicontrol('Style','text',...
         'Position',[400 45 120 20],...
         'String','Vertical Exaggeration')
```

To operate the controls, you need callback functions. The callback for the pop-up menu is a local function called `setmap` that contains the following code.

```
function setmap(hObject,event) %#ok<INUSD>
```

```
    % Called when user activates popup menu
    val = get(hObj, 'Value');
    if val == 1
        colormap(jet)
    elseif val == 2
        colormap(hsv)
    elseif val == 3
        colormap(hot)
    elseif val == 4
        colormap(cool)
    elseif val == 5
        colormap(gray)
    end
end
```

The callback for the slider is also a local function in the same file, and contains the following code.

```
function surfzlim(hObj,event,ax) %#ok<INUSL>
    % Called to set zlim of surface in figure axes
    % when user moves the slider control
    val = 51 - get(hObj, 'Value');
    zlim(ax, [-val val]);
end
```

To use the uicontrols in the example, you need to put all the functions in a MATLAB code file. Copy the following code and paste it into a new file. Save the file as `ex_uicontrol.m` on your search path, and then run it.

```
function ex_uicontrol
    % Example code for uicontrol reference page

    % Create a figure and an axes to contain a 3-D surface plot.
    figure
    hax = axes('Units','pixels');
    surf(peaks)
    % Create a uicontrol object to let users change the colormap
```

```

% with a pop-up menu. Supply a function handle as the object's
% Callback:
uicontrol('Style', 'popup',...
         'String', 'hsv|hot|cool|gray',...
         'Position', [20 340 100 50],...
         'Callback', @setmap);    % Popup function handle callback
                                   % Implemented as a local function

% Add a different uicontrol. Create a push button that clears
% the current axes when pressed. Position the button inside
% the axes at the lower left. All uicontrols have default units
% of pixels. In this example, the axes does as well.
uicontrol('Style', 'pushbutton', 'String', 'Clear',...
         'Position', [20 20 50 20],...
         'Callback', 'cla');      % Pushbutton string callback
                                   % that calls a MATLAB function

% Add a slider uicontrol to control the vertical scaling of the
% surface object. Position it under the Clear button.
uicontrol('Style', 'slider',...
         'Min',1,'Max',50,'Value',41,...
         'Position', [400 20 120 20],...
         'Callback', {@surfzlim,hax});
% Slider function handle callback
% Implemented as a local function

% Add a text uicontrol to label the slider.
uicontrol('Style','text',...
         'Position',[400 45 120 20],...
         'String','Vertical Exaggeration')
end

function setmap(hObj,event) %#ok<INUSD>
% Called when user activates popup menu
val = get(hObj,'Value');
if val ==1

```

# uicontrol

---

```
        colormap(jet)
    elseif val == 2
        colormap(hsv)
    elseif val == 3
        colormap(hot)
    elseif val == 4
        colormap(cool)
    elseif val == 5
        colormap(gray)
    end
end

function surfzlim(hObj,event,ax) %#ok<INUSL>
    % Called to set zlim of surface in figure axes
    % when user moves the slider control
    val = 51 - get(hObj,'Value');
    zlim(ax,[-val val]);
end
```

## How To

- [Examples: Programming GUI Components](#)
- [“A Working GUI with Many Components”](#)

## Purpose

Describe user interface control (`uicontrol`) properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

To change the default value of properties see “Setting Default Property Values”. You can also set default uicontrol properties on the root and figure levels:

```
set(0, 'DefaultUicontrolProperty', PropertyValue...)  
set(gcf, 'DefaultUicontrolProperty', PropertyValue...)
```

where *Property* is the name of the uicontrol property whose default value you want to set and *PropertyValue* is the value you are specifying as the default. Use `set` and `get` to access uicontrol properties.

For information on using these uicontrols within GUIDE, the MATLAB GUI development environment, see Programming GUI Components in the MATLAB Creating GUIs documentation.

## Uicontrol Properties

This section lists all properties useful to `uicontrol` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

Property	Purpose
<code>BackgroundColor</code>	Object background color
<code>BeingDeleted</code>	This object is being deleted
<code>BusyAction</code>	Callback routine interruption
<code>ButtonDownFcn</code>	Button-press callback routine

# Uicontrol Properties

---

<b>Property</b>	<b>Purpose</b>
Callback	Control action
CData	Truecolor image displayed on the control
Children	Uicontrol objects have no children
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
Enable	Enable or disable the uicontrol
Extent	position rectangle (read only)
FontAngle	Character slant
FontName	Font family
FontSize	Font size
FontUnits	Font size units
FontWeight	Weight of text characters
ForegroundColor	Color of text
HandleVisibility	Whether handle is accessible from command line and GUIs
HitTest	Whether selectable by mouse click
HorizontalAlignment	Alignment of label string
Interruptible	Callback routine interruption mode
KeyPressFcn	Key press callback routine
ListboxTop	Index of top-most string displayed in list box
Max	Maximum value (depends on uicontrol object)
Min	Minimum value (depends on uicontrol object)

Property	Purpose
Parent	Uicontrol object's parent
Position	Size and location of uicontrol object
Selected	Whether object is selected
SelectionHighlight	Object highlighted when selected
SliderStep	Slider step size
String	Uicontrol object label, also list box and pop-up menu items
Style	Type of uicontrol object
Tag	User-specified object identifier
TooltipString	Content of object's tooltip
Type	Class of graphics object
UIContextMenu	Uicontextmenu object associated with the uicontrol
Units	Units to interpret position vector
UserData	User-specified data
Value	Current value of uicontrol object
Visible	Uicontrol visibility

BackgroundColor  
ColorSpec

*Object background color.* The color used to fill the uicontrol rectangle. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default color is determined by system settings. See `ColorSpec` for more information on specifying color.

# Uicontrol Properties

---

---

**Note** Platform look and feel for a GUI element can override change requests from MATLAB. It is possible your system will not honor a request to change the background color.

---

**BeingDeleted**  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the **BeingDeleted** property to **on** when the object's delete function callback is called (see the **DeleteFcn** property). It remains set to **on** while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's **BeingDeleted** property before acting.

**BusyAction**  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.

- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string or function handle (GUIDE sets this property)

*Button-press callback routine.* A callback routine that can execute when you press a mouse button while the pointer is on or near a uicontrol. Specifically:

- If the uicontrol's `Enable` property is set to `on`, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the uicontrol or when you click the right mouse button on the control itself.
- If the uicontrol's `Enable` property is set to `inactive` or `off`, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using `selectmoveresize`, for example).

Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the code file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets

# Uicontrol Properties

---

this property to the appropriate string and adds the callback to the code file.

Use the `Callback` property to specify the callback routine that executes when you activate the enabled uicontrol (e.g., click a push button).

## Callback

string or function handle (GUIDE sets this property)

*Control action.* A routine that executes whenever you activate the uicontrol object (e.g., when you click on a push button or move a slider). Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

For examples of `Callback` callbacks for each style of component:

- For GUIDE GUIs, see “Add Code for Components in Callbacks”.
- For programmatically created GUIs, see “Examples: Program GUI Components”.

## CData

matrix

*Truecolor image displayed on control.* A three-dimensional matrix of RGB values that defines a truecolor image displayed on a control, which must be a **push button** or **toggle button**. Each value must be between 0.0 and 1.0. Setting `CData` on a **radio button** or **checkbox** will replace the default `CData` on these controls. The control will continue to work as expected, but its state is not reflected by its appearance when clicked.

For **push buttons** and **toggle buttons**, `CData` overlaps the `String`. In the case of **radio buttons** and **checkboxes**, `CData` takes precedence over `String` and, depending on its size, it can displace the text.

Setting `CData` to `[]` restores the default `CData` for **radio buttons** and **checkboxes**.

**Children**  
matrix

The empty matrix; `uicontrol` objects have no children.

**Clipping**  
{on} | off

This property has no effect on `uicontrol` objects.

**CreateFcn**  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uicontrol` object. MATLAB sets all property values for the `uicontrol` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the `uicontrol` being created.

Setting this property on an existing `uicontrol` object has no effect.

You can define a default `CreateFcn` callback for all new `uicontrols`. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontrol`. For example, the code

```
set(0, 'DefaultUicontrolCreateFcn', 'set(gcbo, ...  
    'BackgroundColor', 'white')')
```

creates a default `CreateFcn` callback that runs whenever you create a new `uicontrol`. It sets the default background color of all new `uicontrols`.

# Uicontrol Properties

---

To override this default and create a uicontrol whose `BackgroundColor` is set to a different value, call `uicontrol` with code similar to

```
hpt = uicontrol(...,'CreateFcn','set(gcbo,...  
'BackgroundColor','blue'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontrol` call. In the example above, if instead of redefining the `CreateFcn` property for this uicontrol, you had explicitly set `BackgroundColor` to `blue`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `white`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Delete uicontrol callback routine.* A callback routine that executes when you delete the uicontrol object (e.g., when you issue a `delete` command or clear the figure containing the uicontrol). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Enable

`{on} | inactive | off`

*Enable or disable the uicontrol.* This property controls how uicontrols respond to mouse button clicks, including which callback routines execute.

- `on` – The uicontrol is operational (the default).
- `inactive` – The uicontrol is not operational, but looks the same as when `Enable` is `on`.
- `off` – The uicontrol is not operational and its image (set by the `Cdata` property) is grayed out.

When you left-click on a uicontrol whose `Enable` property is `on`, MATLAB performs these actions in this order:

- 1** Sets the figure `SelectionType` property.
- 2** Executes the uicontrol `Callback` routine, if any. (Static text components do not use callbacks.)
- 3** Does *not* set the figure `CurrentPoint` property and does *not* execute either the uicontrol `ButtonDownFcn` or the figure `WindowButtonDownFcn` callback.

Single-clicking or double-clicking an enabled uicontrol with the left mouse button sets the figure `SelectionType` property to `normal`, unless the uicontrol `Style` is `listbox`. For list boxes, double-clicking sets the figure `SelectionType` property to `open` on the second of the two clicks, enabling the list box callback to detect a set of multiple choices.

# Uicontrol Properties

---

When you left-click on a uicontrol whose `Enable` property is off or inactive, or when you right-click a uicontrol whose `Enable` property has any value, MATLAB performs these actions in this order:

- 1 Sets the figure `SelectionType` property.
- 2 Sets the figure `CurrentPoint` property.
- 3 Executes the figure `WindowButtonDownFcn` callback, if provided.
- 4 Executes the uicontrol `ButtonDownFcn` callback, if provided.

## Extent

position rectangle (read only)

*Size of uicontrol character string.* A four-element vector that defines the size and position of the character string used to label the uicontrol. It has the form:

`[0,0,width,height]`

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

Since the `Extent` property is defined in the same units as the uicontrol itself, you can use this property to determine proper sizing for the uicontrol with regard to its label. Do this by

- Defining the `String` property and selecting the font using the relevant properties.
- Getting the value of the `Extent` property.
- Defining the `width` and `height` of the `Position` property to be somewhat larger than the `width` and `height` of the `Extent`.

For multiline strings, the `Extent` rectangle encompasses all the lines of text. For single line strings, the `height` element of the `Extent` property returned always indicates the height of a

single line, and its width element always indicates the width of the longest line, even if the string wraps when displayed on the control. Edit boxes are considered multiline if `Max - Min > 1`.

## FontAngle

`{normal} | italic | oblique`

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

## FontName

string

*Font family.* The name of the font in which to display the String. To display and print properly, this must be a font that your system supports. The default font is system dependent.

---

**Note** MATLAB GUIs do not support the Marlett and Symbol font families.

---

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set `FontName` to the string `FixedWidth` (this string value is case sensitive):

```
set(uicontrol_handle, 'FontName', 'FixedWidth')
```

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` and rely on the root `FixedWidthFontName` property to be set correctly in the end user's environment.

# Uicontrol Properties

---

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

---

**Tip** To determine what fonts exist on your system (which can differ from the GUI user's system), use the `uisetfont` GUI to select a font and return its name and other characteristics in a MATLAB structure.

---

**FontSize**  
size in `FontUnits`

*Font size.* A number specifying the size of the font in which to display the String, in units determined by the `FontUnits` property. The default point size is system dependent.

**FontUnits**  
{points} | normalized | inches |  
centimeters | pixels

*Font size units.* This property determines the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the uicontrol. When you resize the uicontrol, MATLAB modifies the screen `FontSize` accordingly. pixels, inches, centimeters, and points are absolute units (1 point =  $\frac{1}{72}$  inch).

**FontWeight**  
light | {normal} | demi | bold

*Weight of text characters.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

ForegroundColor  
ColorSpec

*Color of text.* This property determines the color of the text defined for the `String` property (the uicontrol label). Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See `ColorSpec` for more information on specifying color.

---

**Note** If you change the `ForegroundColor` for a uicontrol `listbox`, MATLAB uses that color for all `listbox` items *except* selected `listbox` items. For selected items MATLAB uses a color that ensures good contrast between the text of selected items and the color that indicates a selection.

---

HandleVisibility  
{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from

# Uicontrol Properties

---

command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

---

**Note** Radio buttons and toggle buttons that are managed by a `uibuttongroup` should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to `off` to prevent inadvertent access.

---

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on uicontrol objects.

`HorizontalAlignment`  
`left | {center} | right`

*Horizontal alignment of label string.* This property determines the justification of the text defined for the `String` property (the uicontrol label):

- `left` — Text is left justified with respect to the uicontrol.
- `center` — Text is centered with respect to the uicontrol.
- `right` — Text is right justified with respect to the uicontrol.

The contents of `edit` and `text` uicontrols are always vertically aligned to the top of the rectangle.

---

**Note** On Microsoft Windows systems, although this property can be specified on all uicontrols, it affects only `edit` and `text` uicontrols.

---

## Interruptible

off | {on}

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

# Uicontrol Properties

---

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## `KeyPressFcn`

string or function handle

*Key press callback function.* A callback routine invoked by a key press when the callback's uicontrol object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX and Microsoft Windows. If no uicontrol has focus, the figure's key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a code file, or any legal MATLAB expression.

If the specified value is the name of a code file, the callback routine can query the figure's `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

# Uicontrol Properties

Event Data Structure Field	Description	Examples:			
		a	=	Shift	Shift/a
Character	Character interpretation of the key that was pressed.	'a'	'='	' '	'A'
Modifier	Current modifier, such as 'control', or an empty cell array if there is no modifier	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	Name of the key that was pressed.	'a'	'equal'	'shift'	'a'

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

**ListboxTop**  
scalar

*Index of top-most string displayed in list box.* This property applies only to the `listbox` style of uicontrol. It specifies which string appears in the top-most position in a list box that is not large enough to display all list entries. `ListboxTop` is an index into the array of strings defined by the `String` property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer.

**Max**  
scalar

*Maximum value.* This property specifies the largest value allowed for the `Value` property. Different styles of uicontrols interpret `Max` differently:

- Check boxes – `Max` is the setting of the `Value` property while the check box is selected.
- Editable text – The `Value` property does not apply. If `Max - Min > 1`, then editable text boxes accept multiline input. If `Max - Min`

$\leq 1$ , then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.

- List boxes – If  $\text{Max} - \text{Min} > 1$ , then list boxes allow multiple item selection. If  $\text{Max} - \text{Min} \leq 1$ , then list boxes do not allow multiple item selection. When they do, `Value` can be a vector of indices.
- Radio buttons – `Max` is the setting of the `Value` property when the radio button is selected.
- Sliders – `Max` is the maximum slider value and must be greater than the `Min` property. The default is 1.
- Toggle buttons – `Max` is the value of the `Value` property when the toggle button is selected. The default is 1.
- Pop-up menus, push buttons, and static text do not use the `Max` property.

`Min`

scalar

*Minimum value.* This property specifies the smallest value allowed for the `Value` property. Different styles of uicontrols interpret `Min` differently:

- Check boxes – `Min` is the setting of the `Value` property while the check box is not selected.
- Editable text – The `Value` property does not apply. If  $\text{Max} - \text{Min} > 1$ , then editable text boxes accept multiline input. If  $\text{Max} - \text{Min} \leq 1$ , then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.
- List boxes – If  $\text{Max} - \text{Min} > 1$ , then list boxes allow multiple item selection. If  $\text{Max} - \text{Min} \leq 1$ , then list boxes allow only single item selection. When they do, `Value` can be a vector of indices.

# Uicontrol Properties

---

- Radio buttons – `Min` is the setting of the `Value` property when the radio button is not selected.
- Sliders – `Min` is the minimum slider value and must be less than `Max`. The default is 0.
- Toggle buttons – `Min` is the value of the `Value` property when the toggle button is not selected. The default is 0.
- Pop-up menus, push buttons, and static text do not use the `Min` property.

Parent  
handle

*Uicontrol parent.* The handle of the uicontrol's parent object. You can move a uicontrol object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

Position  
position rectangle

*Size and location of uicontrol.* The rectangle defined by this property specifies the size and location of the control within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

[left bottom width height]

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the uicontrol object. `width` and `height` are the dimensions of the uicontrol rectangle. All measurements are in units specified by the `Units` property.

On Microsoft Windows systems, the height of pop-up menus is automatically determined by the size of the font. The value you specify for the `height` of the `Position` property has no effect.

The `width` and `height` values determine the orientation of sliders. If `width` is greater than `height`, then the slider is oriented horizontally, If `height` is greater than `width`, then the slider is oriented vertically.

---

**Note** The height of a pop-up menu is determined by the font size. The height you set in the position vector is ignored. The height element of the position vector is not changed.

On Mac platforms, the height of a horizontal slider is constrained. If the height you set in the position vector exceeds this constraint, the displayed height of the slider is the maximum allowed. The height element of the position vector is not changed.

---

## Selected

`on` | `{off}` (read only)

*Is object selected.* When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

`{on}` | `off`

*Object highlight when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

## SliderStep

`[minor_step major_step]`

*Slider step size,* a two-element vector of positive values that indicates the size of the major and minor steps as a percent change in slider value. Both steps should be greater than  $1e-6$ ,

# Uicontrol Properties

---

and `minor_step` should be less than or equal to `major_step`. The slider `Value` changes up or down by `minor_step` when you click the arrow button, and up or down by `major_step` when you click the slider trough, also called the channel.

The actual step size is a function of the specified `SliderStep` and the total slider range (`Max - Min`). The default, `[0.01 0.10]`, provides a 1 percent change for clicks on the arrow button and a 10 percent change for clicks in the trough.

For example, if you create the following slider,

```
uicontrol('Style','slider','Min',1,'Max',7,...  
         'Value',2,'SliderStep',[0.1 0.6])
```

clicking an arrow button moves the thumb indicator toward it by `minor_step*(max-min)`:

```
0.1*(7-1)  
ans =  
    0.6000
```

Clicking the trough moves the thumb indicator toward the mouse pointer by `major_step*(max-min)`:

```
0.6*(7-1)  
ans =  
    3.6000
```

If clicking moves the slider to a value outside the range, the thumb indicator moves only to the `Max` or `Min` value.

As `major_step` increases, the slider thumb indicator grows longer. When `major_step` is 1, the thumb is half as long as the trough. When `major_step` is greater than 1, the thumb continues to grow, slowly approaching the full length of the trough.

See also the `Max`, `Min`, and `Value` properties.

## String

string

*Uicontrol label, list box items, pop-up menu choices.*

**For check boxes, editable text, push buttons, radio buttons, static text, and toggle buttons**, the text displayed on the object. For list boxes and pop-up menus, the set of entries or items displayed in the object.

---

**Note** If you specify a numerical value for `String`, MATLAB converts it to `char` but the result may not be what you expect. If you have numerical data, you should first convert it to a string, e.g., using `num2str`, before assigning it to the `String` property.

---

**For uicontrol objects that display only one line of text** (check box, push button, radio button, toggle button), if the string value is specified as a cell array of strings or padded string matrix, only the first string of a cell array or of a padded string matrix is displayed; the rest are ignored. Vertical slash (`'\'`) characters are not interpreted as line breaks and instead show up in the text displayed in the uicontrol.

**For multiple line editable text or static text controls**, line breaks occur between each row of the string matrix, and each cell of a cell array of strings. Vertical slash (`'\'`) characters and `\n` characters are not interpreted as line breaks, and instead show up in the text displayed in the uicontrol. Text in edit text and static text boxes is always vertically top-aligned. For **editable text**, the `String` property value is set to the string entered by the user when the control loses focus. The `String` property for **static text** can only be set programmatically (or when authoring a GUI in GUIDE).

# Uicontrol Properties

---

To place multiple items on a list box or pop-up menu, you can specify the items in any of the formats shown in the following table.

String Property Format	Example
Cell array of strings	<code>{'one' 'two' 'three'}</code>
Padded string column matrix	<code>['one ' '; 'two ' '; 'three']</code>
String vector using vertical slash ( ) as a line separator	<code>['one two three']</code>

If you specify a component width that is too small to accommodate one or more of the specified strings, MATLAB truncates those strings with an ellipsis. Use the `Value` property to set the index of the initial item selected.

For **check boxes**, **push buttons**, **radio buttons**, **toggle buttons**, and the selected item in **popup menus**, when the specified text is clipped because it is too long for the uicontrol, an ellipsis (...) is appended to the text in the active GUI to indicate that it has been clipped.

For **push buttons** and **toggle buttons**, `CData` overlaps the `String`. In the case of **radio buttons** and **checkboxes**, `CData` takes precedence over `String` and, depending on its size, can displace the text.

---

**Reserved Words** There are three reserved words: `default`, `remove`, `factory` (case sensitive). If you want to use one of these reserved words in the `String` property, you must precede it with a backslash (`'\'`) character. For example,

```
h = uicontrol('Style','edit','String','\default');
```

---

## Style

`{pushbutton} | togglebutton | radiobutton | checkbox | edit | text | slider | frame | listbox | popupmenu`

*Style of uicontrol object to create.* The `Style` property specifies the kind of uicontrol to create. See the `uicontrol` Description section for information on each type.

## Tag

string (GUIDE sets this property)

*User-specified object label.* The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

## TooltipString

string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the uicontrol. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

# Uicontrol Properties

---

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uicontrol('Style','pushbutton');  
s = sprintf('Button tooltip line 1\nButton tooltip line 2');  
set(h,'TooltipString',s)
```

## Type

string (read only)

*Class of graphics object.* For `uicontrol` objects, `Type` is always the string `'uicontrol'`.

## UIContextMenu

handle

*Associate a context menu with uicontrol.* Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the `uicontrol`. Use the `uicontextmenu` function to create the context menu.

## Units

{pixels} | normalized | inches | centimeters | points | characters (GUIDE default: normalized)

*Units of measurement.* MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- Normalized units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).
- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Any data you want to associate with the uicontrol object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Value

scalar or vector

*Current value of uicontrol.* The uicontrol style determines the possible values this property can have:

- Check boxes set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- List boxes set `Value` to a vector of indices corresponding to the selected list entries, where 1 corresponds to the first item in the list.
- Pop-up menus set `Value` to the index of the item selected, where 1 corresponds to the first item in the menu. The Examples section shows how to use the `Value` property to determine which item has been selected.
- Radio buttons set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- Sliders set `Value` to the number indicated by the slider bar.
- Toggle buttons set `Value` to `Max` when they are down (selected) and `Min` when up (not selected).
- Editable text, push buttons, and static text do not set this property.

# Uicontrol Properties

---

Set the `Value` property either interactively with the mouse or through a call to the `set` function. The display reflects changes made to `Value`.

`Visible`

`{on} | off`

*Uicontrol visibility.* By default, all uicontrols are visible. When set to `off`, the uicontrol is not visible, but still exists and you can query and set its properties.

---

**Note** Setting `Visible` to `off` for uicontrols that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

**Purpose**

Open standard dialog box for selecting directory

**Syntax**

```
folder_name = uigetdir
folder_name = uigetdir(start_path)
folder_name = uigetdir(start_path,dialog_title)
```

**Description**

`folder_name = uigetdir` displays a modal dialog box enabling you to navigate the folder hierarchy and select a folder or type the name of a folder. If the folder exists, `uigetdir` returns the selected path when you click **OK**. If you type the name of a folder that does not exist, `uigetdir` returns the name of the current folder. If you click **Cancel**, or close the dialog box, `uigetdir` returns 0. On Microsoft Windows platforms, `uigetdir` opens a dialog box in the base folder (the Windows desktop) with the current folder selected.

`folder_name = uigetdir(start_path)` opens a dialog box with the folder specified by `start_path` selected. If `start_path` is a valid path, the dialog box opens in the specified folder. If `start_path` is an empty string ( ' ') or is not a valid path, the dialog box opens in the current folder.

`folder_name = uigetdir(start_path,dialog_title)` opens a dialog box with the specified title. On Windows and UNIX platforms, the string replaces the default caption inside the dialog box for specifying instructions to the user. The default `dialog_title` is **Select folder to Open**.

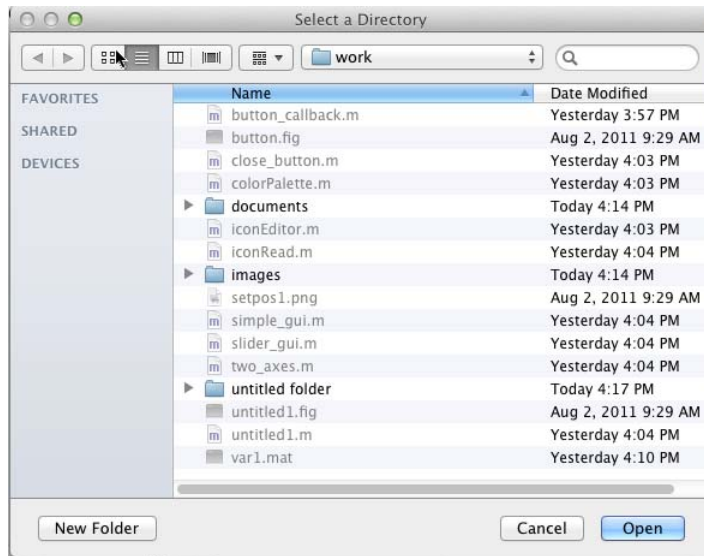

On Windows platforms, you can click the **New Folder** button to add a new folder to the folder hierarchy displayed. You can also drag and drop existing directories into different folders.

On UNIX platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The `dialog_title` string replaces the default title of the dialog box. The dialog box looks similar to the following figure.

On Mac platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The dialog box looks similar to the following figure.

---

**Note** A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in the MATLAB Figure Properties.

---

The `pwd` and `cd` functions return the name of the current folder.

## Examples

The following statement displays directories on the `C:` drive.

```
dname = uigetdir('C:\');
```

A dialog box such as the following displays (on Windows).

If you double-click the Program Files folder, and the MATLAB subfolder, and then click **Select Folder**, `uigetdir` returns `C:\Program Files\MATLABto dname:`

The following statement uses `matlabroot` to display the MATLAB root folder in the dialog box:

```
uigetdir(matlabroot, 'MATLAB Root Directory')
```

Assuming that MATLAB is installed on drive `C:\`, selecting the folder `MATLAB\R2012b\notebook\pc` from the dialog box, returns this string:

```
C:\Program Files\MATLAB\R2012b\notebook\pc
```

## See Also

`uigetfile` | `uiputfile`

**Purpose**

Open standard dialog box for retrieving files

**Syntax**

```
filename = uigetfile
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,
    DialogTitle)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,
    DialogTitle,DefaultName)
[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',
    selectmode)
```

**Description**

`filename = uigetfile` displays a modal dialog box that lists files in the current folder and enables you to select or enter the name of a file. If the file name is valid and the file exists, `uigetfile` returns the file name as a string when you click **Open**. Otherwise `uigetfile` displays an appropriate error message, after which control returns to the dialog box. You can then enter another file name or click **Cancel**. If you click **Cancel** or close the dialog window, `uigetfile` returns 0.

---

**Note** Successful execution of `uigetfile` does not open a file; it only returns the name of an existing file that you identify.

---

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uigetfile` also displays in gray the files that do not match `FilterSpec`. The `uigetfile` function appends 'All Files' to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the \* wildcard.

- If `FilterSpec` is a file name, that file name displays, selected in the **File name** field. The extension of the file is the default filter.
- `FilterSpec` can include a path. That path can contain '.', '..', '\', '/', or '~'. For example, '../\*.\*m' lists all code files in the folder above the current folder.

# uigetfile

---

- If `FilterSpec` is a folder name, `uigetfile` displays the contents of that folder, the **File name** field is empty, and no filter applies. To specify a folder name, make the last character of `FilterSpec` either `'\'` or `'/'`.
- If `FilterSpec` is a cell array of strings, it can include two columns. The first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace standard descriptions in the **Files of type** field. A description cannot be an empty string. The second and third examples illustrate use of a cell array as `FilterSpec`.

If `FilterSpec` is missing or empty, `uigetfile` uses the default list of file types (for example, all MATLAB files).

After you click **Open** and if the file name exists, `uigetfile` returns the name of the file in `FileName` and its path in `PathName`. If you click **Cancel** or close the dialog window, the function sets `FileName` and `PathName` to 0.

`FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click **Cancel** or close the dialog window, the function sets `FilterIndex` to 0.

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec, DialogTitle)` displays a dialog box that has the title `DialogTitle`. To use the default file types and specify a dialog title, enter

```
uigetfile(' ',DialogTitle)
```

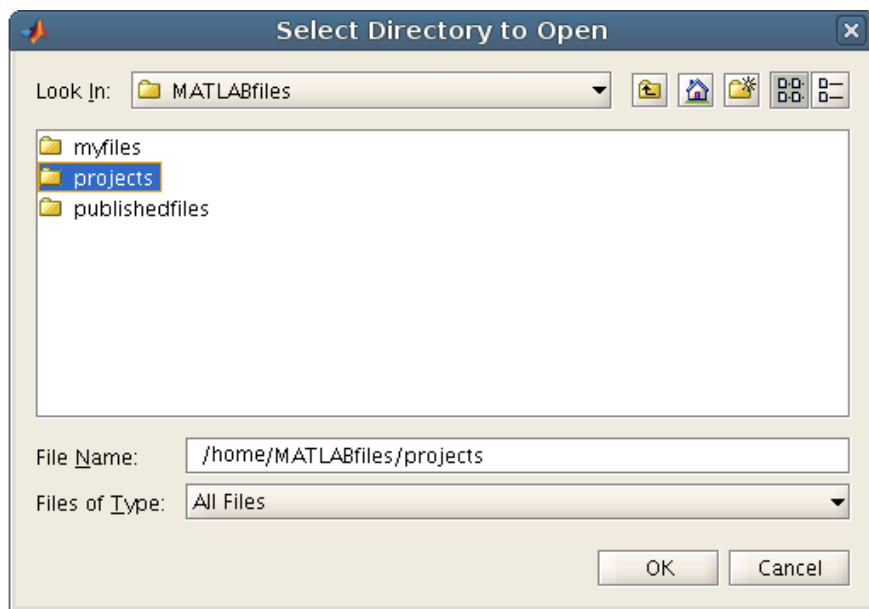

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec, DialogTitle,DefaultName)` displays a dialog box in which the file name specified by `DefaultName` appears in the **File name** field. `DefaultName` can also be a path or a path/filename. In this case, `uigetfile` opens the dialog box in the folder specified by the path. You can use `'.'`, `'..'`, `\`, or `'/'` in the `DefaultName` argument. To specify a folder name, make the last character of `DefaultName` either `'\'` or `'/'`. If the specified path does not exist, `uigetfile` opens the dialog box in the current folder.

[FileName,PathName,FilterIndex] =  
uigetfile(...,'MultiSelect', *selectmode*) opens the dialog box in *multiselect* mode. Valid values for *selectmode* are 'on' and 'off' (the default, which allows single selection only). If 'MultiSelect' is 'on' and you select more than one file in the dialog box, then FileName is a cell array of strings. Each array element contains the name of a selected file. File names in the cell array are sorted in the order your platform uses. If you select multiple files, they must be in the same folder, otherwise MATLAB displays a warning dialog box. Be aware that Microsoft Windows libraries can span multiple folders. PathName is a string identifying the folder containing the files.

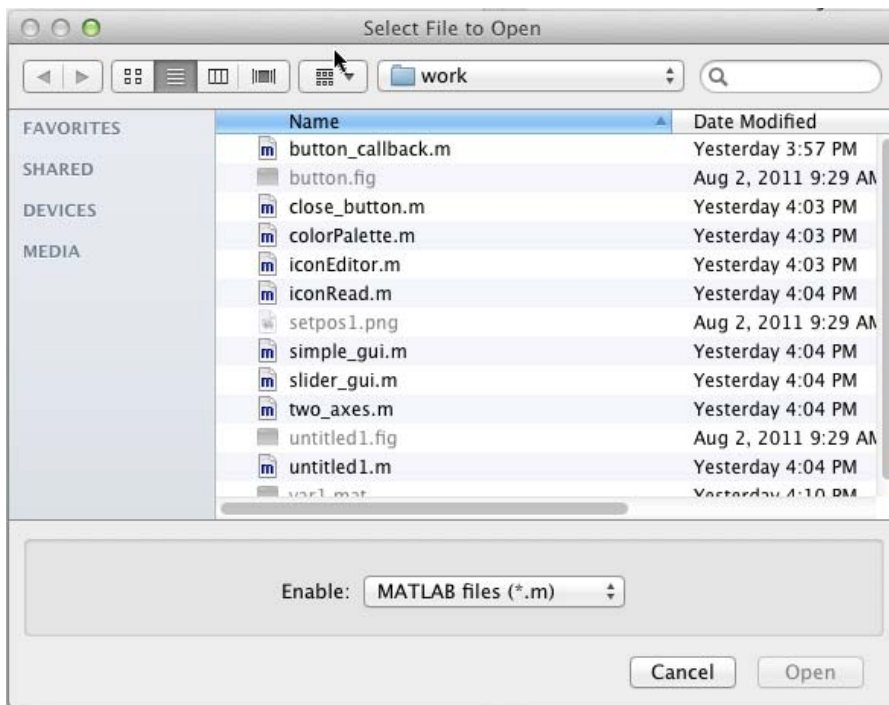

If you include either of the wildcard characters, '\*' or '?', in a file name, uigetfile does not respond to clicking **Open**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

For Windows platforms, the dialog box is the Windows dialog box native to your platform. Depending on your version of Windows, dialogs you see can differ from the figures shown in following examples.

For UNIX platforms, the dialog box is like the one shown in the following figure.

For Mac platforms, the dialog box is like the one shown in the following figure.

**Note** A modal dialog box prevents you from interacting with other windows before responding. To block MATLAB program execution, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in the MATLAB Figure Properties.

## Examples

The following statement displays a dialog box for retrieving a file. The dialog box lists all MATLAB code files within a selected directory. `uigetfile` returns the name and path of the selected file in `FileName` and `PathName`. `uigetfile` appends All Files (\*.\*) to the file types when `FilterSpec` is a string.

```
[FileName,PathName] = uigetfile('*.m','Select the MATLAB code file');
```

# uigetfile

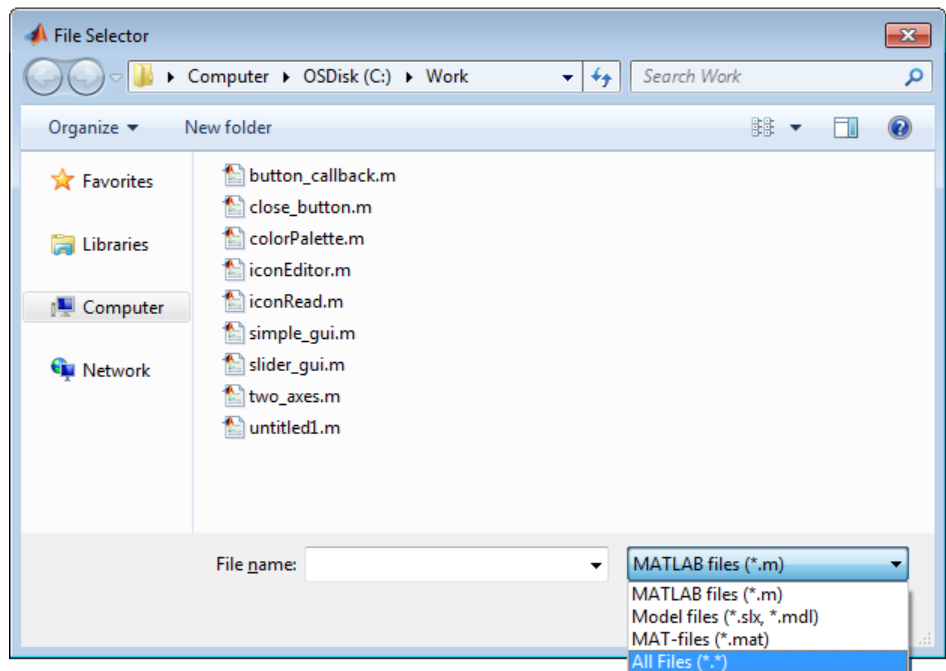

The following figure shows the dialog box with the file type drop-down list open.

To create a list of file types that appears in the file type drop-down list, separate the file extensions with semicolons, as in the following code. `uigetfile` displays a default description for each known file type, such as "Model files" for Simulink `.slx` and `.mdl` files.

```
[filename, pathname] = ...  
    uigetfile({'*.m'; '*.slx'; '*.mat'; '*.*'}, 'File Selector');
```

If you want to create a list of file types and give them descriptions that are different from the defaults, use a cell array, as in the following code. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname] = uigetfile( ...
{'*.m;*.fig;*.mat;*.slx;*.mdl','MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
 '*.m', 'Code files (*.m)'; ...
 '*.fig','Figures (*.fig)'; ...
 '*.mat','MAT-files (*.mat)'; ...
 '*.mdl;*.slx','Models (*.slx, *.mdl)'; ...
 '*.*', 'All Files (*.*)'}, ...
'Pick a file');
```

# uigetfile

The first column of the cell array contains the file extensions, while the second contains your descriptions of the file types. In this example, the first entry of column one contains several extensions, separated by semicolons, which are all associated with the description 'MATLAB Files (\*.m;\*.fig;\*.mat;\*.mdl)'. The code produces the dialog box shown in the following figure.

The following code lets you select a file and then displays a message in the Command Window that summarizes the result.

```
[filename, pathname] = uigetfile('*.*', 'Select a MATLAB code file');  
if isequal(filename,0)  
    disp('User selected Cancel')
```

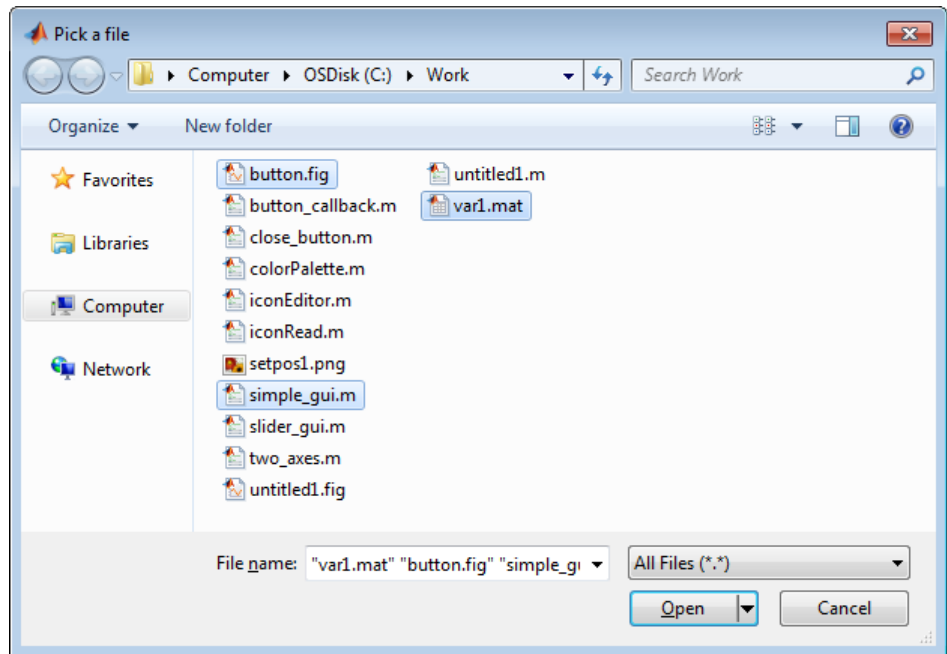

```
else
    disp(['User selected ', fullfile(pathname, filename)])
end
```

---

This code creates a list of file types and gives them descriptions that are different from the defaults. It also enables multiple-file selection. Select multiple files by holding down the **Shift** or **Ctrl** key and clicking on additional file names.

```
[filename, pathname, filterindex] = uigetfile( ...
{ '*.mat', 'MAT-files (*.mat)'; ...
  '*.slx;*.mdl', 'Models (*.slx, *.mdl)'; ...
  *.*', 'All Files (*.*)'}, ...
  'Pick a file', ...
  'MultiSelect', 'on');
```

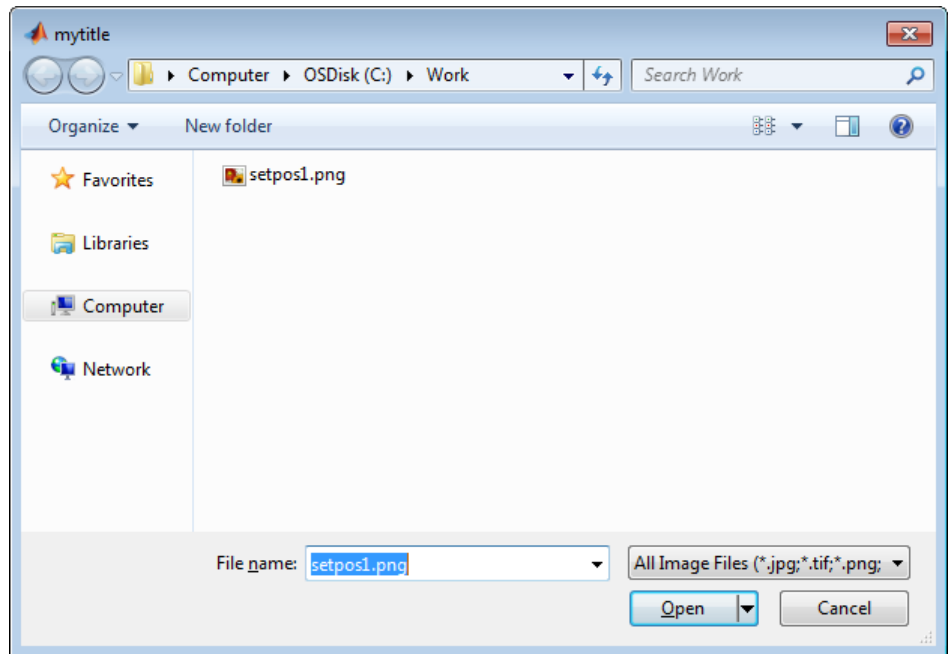

# uigetfile

As mentioned previously, `uigetfile` does not open the file or files you select.

You can use the `DefaultName` argument to specify a start path and a default file name for the dialog box.

```
uigetfile({'*.jpg;*.tif;*.png;*.gif', 'All Image Files';...  
         '*.*', 'All Files' }, 'mytitle', ...  
         'C:\myfiles\my_examples\gbtools\setpos1.png')
```

**Alternatives**

Use the `dir` function to return a filtered or unfiltered list of files in your current folder or a folder you specify. `dir` also can return file attributes.

**See Also**

`uigetdir` | `uiopen` | `uiputfile`

# uigetpref

---

**Purpose** Specify and conditionally open dialog box according to user preference

**Syntax**

```
pref_value = uigetpref(group,pref,title,question,  
    pref_choices)  
[pref_value,dlgshown] = uigetpref(...)  
[...] = uigetpref(... 'Name',value)
```

**Description**

`pref_value = uigetpref(group,pref,title,question, pref_choices)` returns one of the strings in `pref_choices` in either of two ways:

- Displays a multiple-choice dialog box that prompts you to answer a question. The dialog box includes a check box with the label **Do not show this dialog again**.
- Retrieves a previous answer from the preferences data base and returns it without displaying a dialog. No dialog is displayed if you previously selected the check box **Do not show this dialog again**.

`[pref_value,dlgshown] = uigetpref(...)` also returns in `dlgshown` whether or not the dialog displayed.

`[...] = uigetpref(... 'Name',value)` specify optional name-value pairs to control how dialogs display.

**Tips**

- You must supply all input arguments up to and including `pref_choices`.
- `uigetpref` creates specified groups and preferences, if they do not currently exist. To delete a preference group you no longer need, use `rmpref`.
- The string returned in `pref_value` is a preference name (as specified in `pref`), not its button label (as specified in `pref_choices`).
- After you select the check box **Do not show this dialog again** and close the dialog box, the dialog box does not display again for the same preference. To reenable dialogs that are being suppressed by preferences, use the command:

```
uigetpref('clearall')
```

Executing `uigetpref` with this command re-enables *all* preference dialogs you have defined with `uigetpref`, not just the most recent one.

## Input Arguments

### **group**

String specifying the name of the preference group that preference `pref` belongs to. If the group does not already exist, `uigetpref` creates it.

**Default:** None

### **pref**

String specifying the name of the preference that controls whether the dialog displays. If the preference does not already exist, `uigetpref` creates it.

**Default:** None

### **title**

String to display in the dialog box title bar

### **question**

String or cell array of strings specifying a descriptive paragraph for the dialog to display. Use `question` to define what you are asking the user to decide. Clearly state the alternatives and the consequences of choosing among them. The dialog box that `uigetpref` generates inserts line breaks between rows of the string array, between elements of the cell array of strings, and between `'|'` or newline characters within a string vector.

**Default:** None

### **pref\_choices**

String, cell array of strings, or ' | '-separated strings specifying the labels for the dialog box push buttons. The string on the selected push button is returned.

If the internal preference values are different from the strings displayed on the push buttons, provide a 2-by-n cell array of strings. The first row contains the preference strings, and the second row contains the associated push button strings. When `pref_choices` is not a 2-by-n cell array, MATLAB constructs lowercase versions of the button labels and returns them in `pref_value`. If your code tests returned values, make sure it compares them against the appropriate strings.

**Default:** None

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'CheckboxState'**

State of check box when dialog box opens:

- `false` or `0`: Check box is not initially selected.
- `true` or `1`: Check box is initially selected.

**Default:** `0`

### **'CheckboxString'**

String specifying the label for the check box.

**Default:** `'Do not show this dialog again'`

### **'HelpString'**

String specifying the label for **Help** button.

**Default:** No **Help** button displays.

#### **'HelpFcn'**

String or function handle specifying the callback that executes when you click the **Help** button. Also, to have a button to trigger the callback, you must specify the `HelpString` option.

**Default:** `doc('uigetpref')`

#### **'ExtraOptions'**

String or cell array of strings specifying extra buttons. The additional buttons are not mapped to any preference settings. If you click any of these buttons, the dialog closes and `uigetpref` returns the string in value.

**Default:** `{}`

#### **'DefaultButton'**

String specifying the value that `uigetpref` returns if you close the dialog without clicking a button. This string does not have to correspond to any preference or `ExtraOption`.

**Default:** The first button specified in `pref_choices`

## **Output Arguments**

### **pref\_value**

String containing the preference corresponding to the button you press. If you cancel the dialog by clicking its close box, `uigetpref` returns the label of the first button specified in `pref_choices` or the value for `DefaultButton`, if specified. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns the last choice you made (your registered preference) in `pref_value` immediately.

### **dlgshown**

Logical value that specifies the state of the check box when the dialog box closed. The value is 1 if selected, 0 if not selected. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns 0 in `dlgshown` immediately.

## Definitions

### Preferences

Preferences provide the ability to specify how applications behave and how users interact with them. For example, you can set a preference for which products display their documentation in the Help browser, or which messages the Code Analyzer displays. In MathWorks software products, preferences persist across sessions and are stored in a preference data base, the location of which is system-dependent. Use the **Preferences** option on the **File** menu to access all built-in preferences.

`uigetpref` uses the same preference data base as `addpref`, `getpref`, `ispref`, `rmpref`, and `setpref`. However, `uigetpref` registers the preferences it sets as a separate list, so that it and `uisetpref` can manage those preferences.

To modify preferences registered with `uigetpref`, you can use `setpref` and `uisetpref` to explicitly change preference values to 'ask'. If you specify a preference that does not already exist in the preference data base, `uigetpref` creates it.

## Examples

Create a preference dialog for the 'savefigurebeforeclosing' preference in the 'mygraphics' group of preferences.

Call `uigetpref` to display the dialog (or not) from a figure window `CloseRequestFcn` callback. The callback code takes action via a switch statement. The action (to delete or not to delete the figure) depends on whether the answer returned by `uigetpref` was `'always'` or `'never'`:

```
function save_figure_perhaps
% Closes figure conditionally, asking whether to save it first.
% User can suppress the dialog from UIGETPREF permanently by selecting
% "Do not show this dialog again".

fig =(gcf);
[selectedButton dlgshown] = uigetpref(...
    'mygraphics',...           % Group
    'savefigurebeforeclosing',... % Preference
    'Closing Figure',...      % Window title
    {'Do you want to save your figure before closing?'
     ''
     'You can save your figure manually by typing ''hgsave(gcf)'''},...
    {'always','never';'Yes','No'},... % Values and button strings
    'ExtraOptions','Cancel',... % Additional button
    'DefaultButton','Cancel',... % Default choice
    'HelpString','Help',... % String for Help button
    'HelpFcn','doc(''closereq'');'); % Callback for Help button
switch selectedButton
case 'always' % Open a Save dialog (without testing if saved before)
    [fileName,pathName,filterIndex] = uiputfile('fig', ...
        'Save current figure', ...
```

# uigetpref

---

```
                                'untitled.fig');
    if filterIndex == 0          % User cancelled save or named no file
        delete(fig);
    else                        % Use filename returned from UIPUTFILE
        saveas(fig,[pathName fileName])
        delete(fig);
    end
    case 'never'                % Close the figure without saving it
        delete(fig);
    case 'cancel'              % Do not close the figure
        return
    end
end
```

To execute the example, copy it and paste the code into a new program file. Name the file `save_figure_perhaps.m` and place it on your search path. To use the function as a `CloseRequestFcn`, create a figure as follows:

```
figure('CloseRequestFcn','save_figure_perhaps');
```

Clicking the figure close box or selecting **File > Close** displays the dialog box until you select **Do not show this dialog again**.

## Tutorials

- “Preferences”
- “Confirmation Dialogs Preferences”

**Purpose** Import data interactively

**Syntax**

```
uiimport  
uiimport(filename)  
uiimport('-file')  
uiimport('-pastesimal')  
S = uiimport(____)
```

**Description** `uiimport` opens a dialog to interactively load data from a file or the clipboard. MATLAB displays a preview of the data in the file.

`uiimport(filename)` opens the file specified in `filename`.

`uiimport('-file')` presents the file selection dialog first.

`uiimport('-pastesimal')` presents the clipboard contents first.

`S = uiimport(____)` stores the resulting variables as fields in the struct `S`.

# uimenu

---

<b>Purpose</b>	Create menus and menu items on figure windows
<b>Syntax</b>	<pre>handle = uimenu('PropertyName',PropertyValue,...) handle = uimenu(parent,'PropertyName',PropertyValue,...)</pre>
<b>Description</b>	<p><code>handle = uimenu('PropertyName',PropertyValue,...)</code> creates a menu in the current figure's menu bar using the values of the specified properties and assigns the menu handle to <code>handle</code>.</p> <p><code>handle = uimenu(parent,'PropertyName',PropertyValue,...)</code> creates a submenu of a parent menu or a menu item on a context menu specified by <code>parent</code> and assigns the menu handle to <code>handle</code>. If <code>parent</code> refers to a figure instead of another <code>uimenu</code> object or a <code>uicontextmenu</code>, MATLAB software creates a new menu on the referenced figure's menu bar.</p>
<b>Tips</b>	<p>MATLAB adds the new menu to the existing menu bar. If the figure does not have a menu bar, MATLAB creates one. Each menu choice can itself be a menu that displays its items when you select it. <code>uimenu</code> accepts property name/property value pairs as well as structures and cell arrays of properties as input arguments.</p> <p>Use the <code>uimenu Callback</code> property to define the action taken when you activate the created menu item.</p> <p>Uimenu only appear in figures whose <code>Window Style</code> is <code>normal</code>. If a figure containing <code>uimenu</code> children is changed to <code>modal</code>, the <code>uimenu</code> children still exist and are contained in the <code>Children</code> list of the figure, but are not displayed until the <code>WindowStyle</code> is changed to <code>normal</code>.</p> <p>The value of the figure <code>MenuBar</code> property affects the content of the figure menu bar. When <code>MenuBar</code> is <code>figure</code>, a set of built-in menus precedes any user-created <code>uimenu</code>s on the menu bar (MATLAB controls the built-in menus and their handles are not available to the user). When <code>MenuBar</code> is <code>none</code>, <code>uimenu</code>s are the only items on the menu bar (that is, the built-in menus do not appear).</p>

See the Uimenu Properties reference page for more information. You can set and query property values after creating a menu with the `set` and `get` functions.

## Examples

This example creates a menu labeled **Workspace** with menu options for creating a new figure window, saving workspace variables, and exiting MATLAB. In addition, it defines an accelerator key for the Quit option.

```
f = uimenu('Label','Workspace');
    uimenu(f,'Label','New Figure','Callback','figure');
    uimenu(f,'Label','Save','Callback','save');
    uimenu(f,'Label','Quit','Callback','exit',...
        'Separator','on','Accelerator','Q');
```

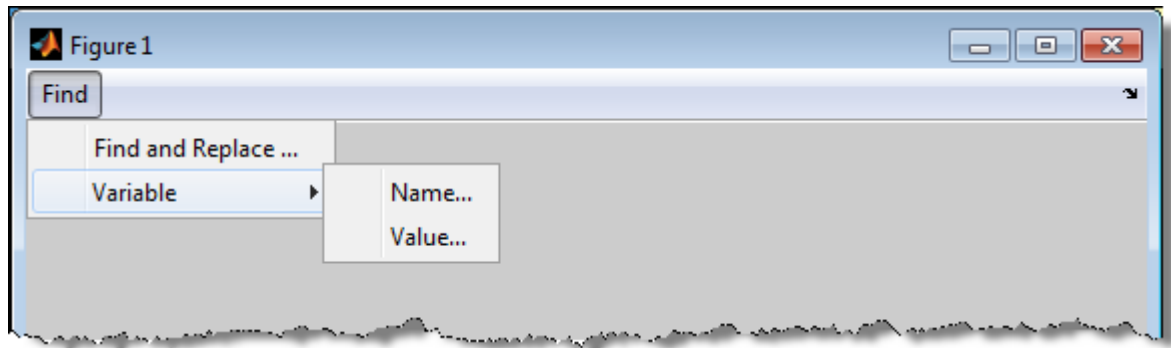

This example creates a new figure with a menu bar that excludes the built-in menus. It creates a **Find** menu with options **Find & Replace**, and **Variable**. For the Variable option, it creates a submenu with options of **Name** and **Value**.

```
f=figure('MenuBar','None');
mh = uimenu(f,'Label','Find');
frh = uimenu(mh,'Label','Find and Replace ...',...
    'Callback','goto');
frh = uimenu(mh,'Label','Variable');
uimenu(frh,'Label','Name...', ...
    'Callback','variable');
```

# uimenu

```
uimenu(frh,'Label','Value...', ...  
      'Callback','value');
```

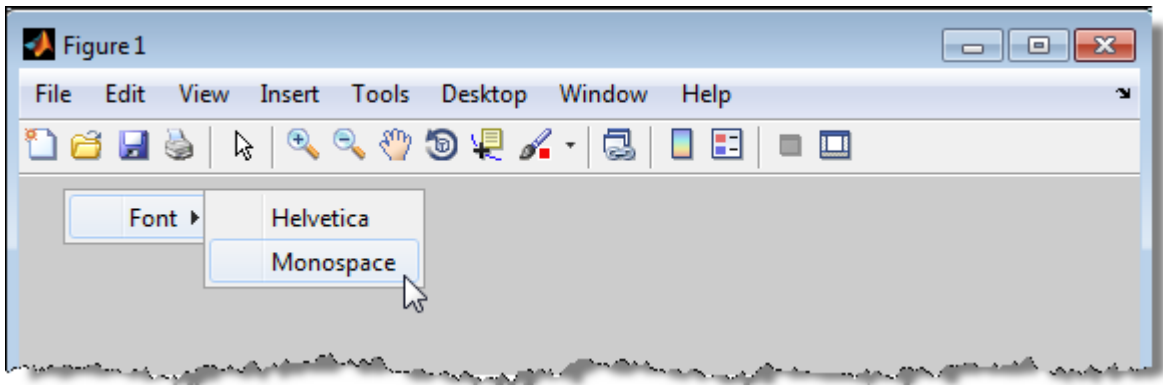

This example creates a context menu, **Font**, on a figure with menu options **Helvetica** and **Monospace**. When you run the code and then right-click anywhere within the figure window, the context menu displays.

```
% Create the UICONTEXTMENU  
cmenu = uicontextmenu;  
  
% Create the parent menu  
fontmenu = uimenu(cmenu, 'label','Font');
```

```
% Create the submenus  
font1 = uimenu(fontmenu, 'label','Helvetica','Callback', 'HelvFont');  
font2 = uimenu(fontmenu, 'label','Monospace','Callback', 'MonoFont');  
set(gcf,'uicontextmenu',cmenu);
```

# Uimenu Properties

---

## Purpose

Describe menu properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

You can set default Uimenu properties on the root, figure and menu levels:

```
set(0, 'DefaultUimenuPropertyName', PropertyValue...)  
set(gcf, 'DefaultUimenuPropertyName', PropertyValue...)  
set(menu_handle, 'DefaultUimenuPropertyName', PropertyValue...)
```

Where *PropertyName* is the name of the Uimenu property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of property see “Setting Default Property Values”

## Uimenu Properties

This section lists all properties useful to `uimenu` objects along with valid values and instructions for their use. Curly braces { } enclose default values.

Property Name	Property Description
Accelerator	Keyboard equivalent
BeingDeleted	This object is being deleted
BusyAction	Callback routine interruption
Callback	Control action
Checked	Menu check indicator
Children	Handles of submenus

Property Name	Property Description
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
Enable	Enable or disable the uimenu
ForegroundColor	Color of text
HandleVisibility	Whether handle is accessible from command line and GUIs
Interruptible	Callback routine interruption mode
Label	Menu label
Parent	Uimenu object's parent
Position	Relative uimenu position
Separator	Separator line mode
Tag	User-specified object identifier
Type	Class of graphics object
UserData	User-specified data
Visible	Uimenu visibility

Accelerator  
character

*Keyboard equivalent.* An alphabetic character specifying the keyboard equivalent for the menu item. This allows users to select a particular menu choice by pressing the specified character in conjunction with another key, instead of selecting the menu item with the mouse. The key sequence is platform specific:

- For Microsoft Windows systems, the sequence is **Ctrl+Accelerator**. Windows reserves these keys for default

# Uimenu Properties

---

menu items: **c**, **v**, and **x**. For more information, see Keyboard shortcuts for Windows on the Microsoft support Web site.

- For Macintosh systems, the sequence is **Cmd**+Accelerator. Apple reserves these keys for default menu items: **a**, **c**, **v**, and **x**. For more information, see Mac OS X keyboard shortcuts on the Apple Computer support Web site.
- For UNIX systems, the sequence is **Ctrl**+Accelerator. These keys are reserved for default menu items: **o**, **p**, **s**, and **w**. Many UNIX applications also use **a**, **c**, **v**, and **x** in the same manner as the other platforms.

Accelerated menu items do not have to be displayed for the accelerator key to work (you can accelerate a submenu). However, some restrictions apply:

- You can define an accelerator only for menu items that do not have children menus.
- Accelerators work only for menu items that directly execute a callback routine.
- The figure must be in focus when entering the accelerator key sequence.

To remove an accelerator, set `Accelerator` to an empty string, ''.

For a cross-platform comparison of accelerators, see the article [Table of Keyboard Shortcuts](#).

**BeingDeleted**  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

`cancel` | `{queue}`

*Callback routine interruption.* If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, the callback associated with the new event uses the value of `BusyAction` to decide whether or not to attempt to interrupt the executing callback.

- If the value is `cancel`, the event is discarded and the second callback does not execute.
- If the value is `queue`, and the `Interruptible` property of the first callback is `on`, the second callback is added to the event queue and executes in its turn after the first callback finishes execution.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. See the `Interruptible` property for information about controlling a callback's interruptibility.

---

## Callback

string or function handle

*Menu action.* A callback routine that executes whenever you activate the menu or its submenu (if one exists). Activation is platform dependent. Typically, it is clicking the menu or, if the menu has one, its submenu. Define this routine as a string that

# Uimenu Properties

---

is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB base workspace.

---

**Caution** Do not use a uimenu callback to dynamically change menu items. Deleting, adding, and replacing menu items in a callback can result in a blank menu on some platforms. You can hide, show, and disable menu items in a callback to achieve the same effect. To fully repopulate menu items, delete and create them outside the callback.

---

Checked

on | {off}

*Menu check indicator.* Setting this property to `on` places a check mark next to the corresponding menu item. Setting it to `off` removes the check mark. You can use this feature to create menus that indicate the state of a particular option. For example, suppose you have a menu item called **Show axes** that toggles the visibility of an axes between visible and invisible each time the user selects the menu item. If you want a check to appear next to the menu item when the axes are visible, add the following code to the callback for the **Show axes** menu item:

```
if strcmp(get(gcbo, 'Checked'), 'on')
    set(gcbo, 'Checked', 'off');
else
    set(gcbo, 'Checked', 'on');
end
```

This changes the value of the `Checked` property of the menu item from `on` to `off` or vice versa each time a user selects the menu item.

Note that there is no formal mechanism for indicating that an unchecked menu item will become checked when selected.

---

**Note** This property is ignored for top level and parent menus.

---

## Children

vector of handles

*Handles of submenus.* A vector containing the handles of all children of the uimenu object. The children objects of uimenu are other uimenu, which function as submenus. You can use this property to reorder the menus.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uimenu object. MATLAB sets all property values for the uimenu before executing the CreateFcn callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uimenu being created.

Setting this property on an existing uimenu object has no effect.

You can define a default CreateFcn callback for all new uimenu. This default applies unless you override it by specifying a different CreateFcn callback when you call `uimenu`. For example, the code

```
set(0, 'DefaultUimenuCreateFcn', 'set(gcbo, ...  
    'Visible', 'on')')
```

creates a default CreateFcn callback that runs whenever you create a new menu. It sets the default `Visible` property of a uimenu object.

To override this default and create a menu whose `Visible` property is set to a different value, call `uimenu` with code similar to

# Uimenu Properties

---

```
hpt = uimenu(..., 'CreateFcn', 'set(gcbo,...  
'Visible','off'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uimenu` call. In the example above, if instead of redefining the `CreateFcn` property for this `uimenu`, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Delete uimenu callback routine.* A callback routine that executes when you delete the `uimenu` object (e.g., when you issue a `delete` command or cause the figure containing the `uimenu` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which is more simply queried using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Enable

{on} | off

*Enable or disable the uimenu.* This property controls whether a menu item can be selected. When not enabled (set to off), the menu Label appears dimmed, indicating the user cannot select it.

## ForegroundColor

ColorSpec X-Windows only

*Color of menu label string.* This property determines color of the text defined for the Label property. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See ColorSpec for more information on specifying color.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes get, findobj, gca, gcf, gco, newplot, cla, clf, and close. Neither is the handle visible in the parent figure's CurrentObject property. Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

- Handles are always visible when HandleVisibility is on.
- Setting HandleVisibility to callback causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

# Uimenu Properties

---

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`Interruptible`  
{on} | off

*Callback routine interruption mode.* If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, that callback attempts to interrupt the first callback. MATLAB processes the callbacks according to these factors:

- The `Interruptible` property of the object whose callback is executing
- Whether the executing callback contains `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statements
- The `BusyAction` property of the object whose callback is waiting to execute

If the `Interruptible` property of the object whose callback is executing is `on` (the default), the callback can be interrupted. Whenever the callback calls one of the `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` functions, the function processes any events in the event queue, including the waiting callback, before performing its defined task.

If the `Interruptible` property of the object whose callback is executing is `off`, the callback cannot be interrupted (except by certain callbacks; see the note below). The `BusyAction` property

of the object whose callback is waiting to execute determines what happens to the callback.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. A figure's `WindowButtonDownFcn` callback routine, or an object's `ButtonDownFcn` or `Callback` routine are processed according to the rules described above.

---

## Label

string

*Menu label.* A string specifying the text label on the menu item. You can specify a mnemonic for the label using the `'&'` character. Except as noted below, the character that follows the `'&'` in the string appears underlined and selects the menu item when you type **Alt+** followed by that character while the menu is visible. The `'&'` character is not displayed. To display the `'&'` character in a label, use two `'&'` characters in the string:

`'O&pen selection'` yields **Open selection**

`'Save && Go'` yields **Save & Go**

`'Save&&Go'` yields **Save & Go**

`'Save& Go'` yields **Save& Go** (the space is not a mnemonic)

# Uimenu Properties

---

---

**Tip** Avoid specifying mnemonics for applications designed to run on Macintosh computers. Accessing menus with mnemonics violates the principles of Apple Human Interface Guidelines. However, you can set the `Accelerator` property to access individual menu items with key sequences on a Mac.

---

Avoid including the reserved words, `default`, `remove`, and `factory`, in menu labels unless you escape them. They are case sensitive. To use one of these words in the `Label` property, escape it by preceding it with a backslash ('\`\`') character. For example:

`'\remove'` yields **remove**

`'\default'` yields **default**

`'\factory'` yields **factory**

## Parent

handle

*Uimenu's parent.* The handle of the uimenu's parent object. The parent of a uimenu object is the figure on whose menu bar it displays, or the uimenu of which it is a submenu. You can move a uimenu object to another figure by setting this property to the handle of the new parent.

## Position

scalar

*Relative menu position.* The value of `Position` indicates placement on the menu bar or within a menu. Top-level menus are placed from left to right on the menu bar according to the value of their `Position` property, with 1 representing the left-most position. The individual items within a given menu are placed from top to bottom according to the value of their `Position` property, with 1 representing the top-most position.

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line above the menu item.

## Tag

string

*User-specified object label.* The Tag property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define Tag as any string.

## Type

string (read only)

*Class of graphics object.* For uimenu objects, Type is always the string 'uimenu'.

## UserData

matrix

*User-specified data.* Any matrix you want to associate with the uimenu object. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Uimenu visibility.* By default, all uimenu are visible. When set to off, the uimenu is not visible, but still exists and you can query and set its properties.

# uint8

---

<b>Purpose</b>	Convert to 8-bit unsigned integer
<b>Syntax</b>	<code>intArray = uint8(array)</code>
<b>Description</b>	<code>intArray = uint8(array)</code> converts the elements of an array into unsigned 8-bit (1-byte) integers of class <code>uint8</code> .
<b>Input Arguments</b>	<b>array</b> Array of any numeric class, such as <code>single</code> or <code>double</code> . If <code>array</code> is already of class <code>uint8</code> , the <code>uint8</code> function has no effect.
<b>Output Arguments</b>	<b>intArray</b> Array of class <code>uint8</code> . Values range from 0 to $2^8 - 1$ . The <code>uint8</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example, <code>uint8(2^8) % 2^8 = 256</code> returns <code>ans =</code> 255
<b>Examples</b>	Convert a double array to <code>uint8</code> : <code>mydata = uint8(magic(10));</code>
<b>Alternatives</b>	When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as <code>zeros</code> , <code>ones</code> or <code>eye</code> ), rather than calling an integer conversion function. For example, <code>I = uint8(zeros(100));</code> % Creates an intermediate array is not as efficient as <code>I = zeros(100, 'uint8');</code> % Preferred

# uint16

---

<b>Purpose</b>	Convert to 16-bit unsigned integer
<b>Syntax</b>	<code>intArray = uint16(array)</code>
<b>Description</b>	<code>intArray = uint16(array)</code> converts the elements of an array into unsigned 16-bit (2-byte) integers of class <code>uint16</code> .
<b>Input Arguments</b>	<b>array</b> Array of any numeric class, such as <code>single</code> or <code>double</code> . If <code>array</code> is already of class <code>uint16</code> , the <code>uint16</code> function has no effect.
<b>Output Arguments</b>	<b>intArray</b> Array of class <code>uint16</code> . Values range from 0 to $2^{16} - 1$ . The <code>uint16</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example, <pre>uint16(2^16) % 2^16 = 65536</pre> returns <pre>ans =     65535</pre>
<b>Examples</b>	Convert a <code>double</code> array to <code>uint16</code> : <pre>mydata = uint16(magic(100));</pre>
<b>Alternatives</b>	When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as <code>zeros</code> , <code>ones</code> or <code>eye</code> ), rather than calling an integer conversion function. For example, <pre>I = uint16(zeros(100)); % Creates an intermediate array</pre> is not as efficient as <pre>I = zeros(100, 'uint16'); % Preferred</pre>

# uint32

---

<b>Purpose</b>	Convert to 32-bit unsigned integer
<b>Syntax</b>	<code>intArray = uint32(array)</code>
<b>Description</b>	<code>intArray = uint32(array)</code> converts the elements of an array into unsigned 32-bit (4-byte) integers of class <code>uint32</code> .
<b>Input Arguments</b>	<b>array</b> Array of any numeric class, such as <code>single</code> or <code>double</code> . If <code>array</code> is already of class <code>uint32</code> , the <code>uint32</code> function has no effect.
<b>Output Arguments</b>	<b>intArray</b> Array of class <code>uint32</code> . Values range from 0 to $2^{32} - 1$ . The <code>uint32</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example, <code>uint32(2^32) % 2^32 = 4294967296</code> returns <code>ans =</code> 4294967295
<b>Examples</b>	Convert a <code>double</code> array to <code>uint32</code> : <code>mydata = uint32(magic(1000));</code>
<b>Alternatives</b>	When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as <code>zeros</code> , <code>ones</code> or <code>eye</code> ), rather than calling an integer conversion function. For example, <code>I = uint32(zeros(100));</code> % Creates an intermediate array is not as efficient as <code>I = zeros(100, 'uint32');</code> % Preferred

- “Arithmetic Operations on Integer Classes”

# uint64

---

**Purpose** Convert to 64-bit unsigned integer

**Syntax** `intArray = uint64(array)`

**Description** `intArray = uint64(array)` converts the elements of an array into unsigned 64-bit (8-byte) integers of class `uint64`.

**Tips** Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, `double` values cannot represent all integers greater than  $2^{53}$  correctly. Before performing arithmetic operations on values larger than  $2^{53}$  in magnitude, convert the values to 64-bit integers. For example,

```
x = uint64(2^53+1);    % Floating-point arithmetic, loses precision
```

is not as accurate as the 64-bit integer arithmetic operation:

```
x = uint64(2^53) + 1; % Preferred
```

**Input Arguments**

**array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint64`, the `uint64` function has no effect.

**Output Arguments**

**intArray**

Array of class `uint64`. Values range from 0 to  $2^{64} - 1$ .

The `uint64` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint64(2^64)    % 2^64 = 18446744073709551616
```

returns

```
ans =  
    18446744073709551615
```

## Examples

Convert a literal value to uint64:

```
x = uint64(9007199254740993);
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint64(zeros(100));    % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint64'); % Preferred
```

## See Also

# uiopen

---

**Purpose** Interactively select file to open and load data

**Syntax**

```
uiopen  
uiopen(type)  
uiopen(filename)  
uiopen(filename, TF)
```

**Description**

uiopen displays the dialog box with the file filter set to all MATLAB files (with file extensions \*.m, \*.mat, \*.fig, \*.mdl, and \*.slx).

uiopen(type) sets the file filter according to the type.

uiopen(filename) displays filename as the default value for **File name** in the dialog box and lists only files having the same extension.

uiopen(filename, TF) directly opens file filename without displaying a dialog box if TF is true, and displays the dialog box if TF is false.

**Tips**

When you select a file and click **open**, uiopen does the following:

- Gets the file using `uigetfile`.
- Opens the file using the `open` command.
  - Files with a file extension of `.m` open in the Editor.
  - Variables stored in files with a file extension of `.mat` appear in the caller's workspace.
  - Files with a file extension of `.fig` open as figure windows.
  - Files with a file extension of `.mdl` or `.slx` open as models in Simulink.
- `uiopen('load')` is the only the form of `uiopen` that you can compile into a standalone application. You can create a file selection dialog box that you can compile using `uigetfile`.
- The `uiopen` dialog box is modal. A modal dialog box prevents you from interacting with other windows until you respond to the modal one.

- uiopen displays the same dialog box that opens when you use the MATLAB desktop toolstrip to open a file. (On the **Home** tab, in the **File** section, click **Open** )

## Input Arguments

### type

String that specifies the kind of file to show in the dialog box (the file filter). Acceptable values for `type` are the following.

Type string	Files Displayed
matlab	All MATLAB files (with file extensions *.m, *.mat, *.fig, *.mdl, and *.slx.)
load	All MAT-files (*.mat)
figure	All figure files (*.fig)
simulink	All Simulink model files (*.mdl and *.slx)
editor	All MATLAB files except for .mat, .fig, and .slx files.

### filename

A string, including the file extension, naming a file to open. The filename can be a wildcard character plus extension. For example, \*.txt displays a list of all files with the file extension .txt.

### TF

A MATLAB expression that evaluates to true or false. If true, filename opens directly, without displaying the dialog.

## Definitions

### Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

## Examples

Filter to display only FIG-files by setting the **Files of type** field to Figures (\*.fig):

```
uiopen('figure')
```

## Alternatives

In MATLAB code or in a command:

- To open a file appropriately based on its file extension, use the `open` function.
- To open a file in the Editor, use the `edit` function.
- To open a MAT-file and load its contents into the workspace, use the `load` function.
- To open a FIG-file, use the `openfig` function.
- To open a file in an application in Microsoft Windows, use the `winopen` function.

**See Also**     `uigetfile` | `uiputfile` | `uisave`

# uipanel

---

## Purpose

Create panel container object

## Syntax

```
h = uipanel('PropertyName1',value1,'PropertyName2',value2,
... )
h = uipanel(parent,'PropertyName1',value1,'PropertyName2',
value2,...)
```

## Description

A `uipanel` groups components. It can contain user interface controls with which the user interacts directly. It can also contain axes, other `uipanel`s, and `uibuttongroups`. It cannot contain ActiveX controls.

`h = uipanel('PropertyName1',value1,'PropertyName2',value2, ...)` creates a `uipanel` container object in a figure, `uipanel`, or `uibuttongroup`. Use the `Parent` property to specify the parent figure, `uipanel`, or `uibuttongroup`. If you do not specify a parent, `uipanel` adds the panel to the current figure. If no figure exists, one is created. See the `Uipanel Properties` reference page for more information.

`h = uipanel(parent,'PropertyName1',value1,'PropertyName2',value2,...)` creates a `uipanel` in the object specified by the handle, `parent`. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence. `parent` must be a figure, `uipanel`, or `uibuttongroup`.

A `uipanel` object can have axes, `uicontrol`, `uipanel`, and `uibuttongroup` objects as children. For the children of a `uipanel`, the `Position` property is interpreted relative to the `uipanel`. If you move the panel, the children automatically move with it and maintain their positions relative to the panel.

After creating a `uipanel` object, you can set and query its property values using `set` and `get`.

## Tips

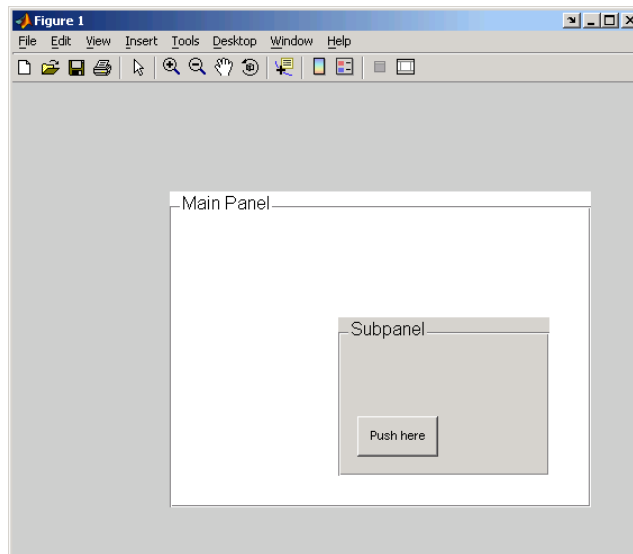

If you set the `Visible` property of a `uipanel` object to `'off'`, any child objects it contains (buttons, button groups, axes, etc.) become invisible along with the panel itself. However, doing this does *not* affect the settings of the `Visible` property of any of its child objects, even though

all of them remain invisible until the uipanel's visibility is set to 'on'. uibuttongroup components also behave in this manner.

## Examples

This example creates a uipanel in a figure, then creates a subpanel in the first panel. Finally, it adds a pushbutton to the subpanel. Both panels use the default Units property value, normalized. Note that default Units for the uicontrol pushbutton is pixels.

```
h = figure;  
hp = uipanel('Title','Main Panel','FontSize',12,...  
            'BackgroundColor','white',...  
            'Position',[.25 .1 .67 .67]);  
hsp = uipanel('Parent',hp,'Title','Subpanel','FontSize',12,...  
             'Position',[.4 .1 .5 .5]);  
hbsp = uicontrol('Parent',hsp,'String','Push here',...  
                'Position',[18 18 72 36]);
```

## See Also

hgtransform | uibuttongroup | uicontrol

# Uipanel Properties

---

## Purpose

Describe panel properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uipanel properties by typing:

```
set(h, 'DefaultUipanelPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uipanel handle. *PropertyName* is the name of the uipanel property and *PropertyValue* is the value you specify as the default for that property.

---

**Note** Default properties you set for uipanel also apply to `uibuttongroups`.

---

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uipanel Properties

This section lists all properties useful to `uipanel` objects along with valid values and a descriptions of their use. Curly braces `{ }` enclose default values.

Property Name	Description
<code>BackgroundColor</code>	Color of the uipanel background
<code>BeingDeleted</code>	This object is being deleted
<code>BorderType</code>	Type of border around the uipanel area.

# Uipanel Properties

<b>Property Name</b>	<b>Description</b>
BorderWidth	Width of the panel border.
BusyAction	Interruption of other callback routines
ButtonDownFcn	Button-press callback routine
Children	All children of the uipanel
Clipping	Clipping of child axes, uipanel, and uibuttongroups to the uipanel. Does not affect child uicontrols.
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
FontAngle	Title font angle
FontName	Title font name
FontSize	Title font size
FontUnits	Title font units
FontWeight	Title font weight
ForegroundColor	Title font color and/or color of 2-D border line
HandleVisibility	Handle accessibility from command line and GUIs
HighlightColor	3-D frame highlight color
HitTest	Selectable by mouse click
Interruptible	Callback routine interruption mode
Parent	Uipanel object's parent
Position	Panel position relative to parent figure or uipanel
ResizeFcn	User-specified resize routine

# Uipanel Properties

Property Name	Description
Selected	Whether object is selected
SelectionHighlight	Object highlighted when selected
ShadowColor	3-D frame shadow color
Tag	User-specified object identifier
Title	Title string
TitlePosition	Location of title string in relation to the panel
Type	Object class
UIContextMenu	Associates uicontextmenu with the uipanel
Units	Units used to interpret the position vector
UserData	User-specified data
Visible	Uipanel visibility.  <hr/> <b>Note</b> Controls the visibility of a uipanel and of its child axes, uibuttongroups, uipanel, and child uicontrols. Setting it does not change their Visible property. <hr/>

BackgroundColor  
ColorSpec

*Color of the uipanel background.* A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the ColorSpec reference page for more information on specifying color.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BorderType

`none` | `{etchedin}` | `etchedout` | `beveledin` | `beveledout`  
| `line`

*Border of the uipanel area.* Used to define the panel area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders.

A line border is 2-D. Use the `HighlightColor` property to specify its color.

## BorderWidth

integer

*Width of the panel border.* The width of the panel borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

## BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

# Uipanel Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string or function handle

*Button-press callback routine.* A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the uipanel. This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using the `selectmoveresize` function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

## `Children`

vector of handles

*Children of the uipanel.* A vector containing the handles of all children of the uipanel. A `uipanel` object's children are axes, uipanels, `uibuttongroups`, and `uicontrols`. You can use this property to reorder the children.

## Clipping

{on} | off

*Clipping mode.* By default, MATLAB clips a uipanel's child axes, uipanel, and uibuttongroups to the uipanel rectangle. If you set `Clipping` to `off`, the axis, uipanel, or uibuttongroup is displayed outside the panel rectangle. This property does not affect child uicontrols which, by default, can display outside the panel rectangle.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uipanel object. MATLAB sets all property values for the uipanel before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the uipanel being created.

Setting this property on an existing uipanel object has no effect.

You can define a default `CreateFcn` callback for all new uipanel. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uipanel`. For example, the code

```
set(0, 'DefaultUipanelCreateFcn', 'set(gcf, ...  
    'FontName', 'arial', 'FontSize', 12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel. It sets the default font name and font size of the uipanel title.

---

**Note** `Uibuttongroup` takes its default property values from `uipanel`. Defining a default property for all uipanel defines the same default property for all `uibuttongroups`.

---

# Uipanel Properties

---

To override this default and create a panel whose `FontName` and `FontSize` properties are set to different values, call `uipanel` with code similar to

```
hpt = uipanel(...,'CreateFcn','set(gcbo,...  
'FontName','times','FontSize',14)')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this `uipanel`, you had explicitly set `FontSize` to 14, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uipanel` object (e.g., when you issue a `delete` command or `clear` the figure containing the `uipanel`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

## FontAngle

{normal} | italic | oblique

*Character slant used in the Title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to *italic* or *oblique* selects a slanted version of the font, when it is available on your system.

## FontName

string

*Font family used in the Title.* The name of the font in which to display the Title. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set `FontName` to the string `FixedWidth` (this string value is case insensitive).

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root `FixedWidthFontName` property which can be set to the appropriate value for a locale from `startup.m` in the end user's environment. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font

## FontSize

integer

*Title font size.* A number specifying the size of the font in which to display the Title, in units determined by the `FontUnits` property. The default size is system dependent.

## FontUnits

inches | centimeters | normalized | {points} | pixels

# Uipanel Properties

---

*Title font size units.* Normalized units interpret `FontSize` as a fraction of the height of the uipanel. When you resize the uipanel, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

## FontWeight

`light` | `{normal}` | `demi` | `bold`

*Weight of characters in the title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

`ColorSpec`

*Color used for title font and 2-D border line.* A three-element RGB vector or one of the MATLAB predefined names, specifying the font or line color. See the `ColorSpec` reference page for more information on specifying color.

## HandleVisibility

`{on}` | `callback` | `off`

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.

- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`  
`ColorSpec`

*3-D frame highlight color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`HitTest`  
{on} | off

*Selectable by mouse click.* `HitTest` determines if the uipanel can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the panel. If `HitTest` is `off`, clicking the panel sets the `CurrentObject` to the closest ancestor of the panel that registers `HitTest`. The uipanel property `HandleVisibility` must be `'on'` for it to become the `CurrentObject`. If the uipanel `HandleVisibility` is `'off'` or `'callback'`, or if the panel and all

# Uipanel Properties

---

its ancestors have `HitTest` set to 'off', the figure `CurrentObject` is the empty matrix.

`Interruptible`  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:

- If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

# Uipanel Properties

---

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uipanel parent.* The handle of the uipanel's parent figure, uipanel, or uibuttongroup. You can move a uipanel object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

## Position

position rectangle

*Size and location of uipanel relative to parent.* The rectangle defined by this property specifies the size and location of the panel within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

[left bottom width height]

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the uipanel object. `width` and `height` are the dimensions of the uipanel rectangle, including the title. All measurements are in units specified by the `Units` property.

## ResizeFcn

function handle or string

*Resize callback routine.* MATLAB executes this callback routine whenever a user manually or programmatically resizes the uipanel, or in GUIDE, the `Resize` behavior option is set to `other`. You can query the uipanel `Position` property to determine its new size and position. During execution of the callback routine, the handle to the uipanel being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

All axes, uipanel, uitable and uicontrol objects that have their `Units` set to `normalized` automatically resize proportionally to the figure. You can define individual resize functions for any such object as needed. For example, you can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position-and-Units` paradigm.

For example, consider a GUI layout that maintains an object attached to the top of the figure at a constant height in pixels, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the uicontrol whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the uicontrol handle, and the `gcbo` function to retrieve the figure handle. The code also does “defensive programming” to save and restores figure `Units`. The callback requires `Units` in pixels in order to work correctly, but takes care not to permanently alter that property.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

# Uipanel Properties

---

You can change the figure `Position` from within a uipanel `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

A figure's uipanel resizes before the figure itself does. Nested uipanel resizes from inner to outer, with child `ResizeFcns` being called before parent `ResizeFcns`.

The `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See `Resize Behavior` for information on creating resize functions using `GUIDE`.

## Selected

on | off (read only)

*Is object selected?* This property indicates whether the panel is selected. When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Object highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

## ShadowColor

ColorSpec

*3-D frame shadow color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the `ColorSpec` reference page for more information on specifying color.

## Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

## Title

string

*Title string.* The text displayed in the panel title. Vertical slash (`'\'`) characters are not interpreted as line breaks and instead show up in the text displayed in the `uipanel` title. You can position the title using the `TitlePosition` property.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in “Defining Default Values”. To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uipanel(...,'Title','\Default');
```

## TitlePosition

{lefttop} | centertop | righttop | leftbottom |  
centerbottom | rightbottom

# Uipanel Properties

---

*Location of the title.* This property determines the location of the title string, in relation to the uipanel.

Type

string (read-only)

*Object class.* This property identifies the kind of graphics object. For uipanel objects, Type is always the string 'uipanel'.

UIContextMenu

handle

*Associate a context menu with a uipanel.* Assign this property the handle of a Uicontextmenu object. MATLAB displays the context menu whenever you right-click the uipanel. Use the uicontextmenu function to create the context menu.

Units

inches | centimeters | {normalized} | points | pixels  
| characters

*Units of measurement.* MATLAB uses these units to interpret the Position property. For the panel itself, units are measured from the lower-left corner of the figure window. For children of the panel, they are measured from the lower-left corner of the panel.

- Normalized units map the lower-left corner of the panel or figure window to (0,0) and the upper-right corner to (1.0,1.0).
- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of Units, it is good practice to return it to its default value after completing your computation so as not

to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Any data you want to associate with the `uipanel` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Visible

{on} | off

*Uipanel visibility.* By default, a `uipanel` object is visible. When set to 'off', the `uipanel` is not visible, as are all child objects of the panel. When a panel is hidden in this manner, you can still query and set its properties.

---

**Note** The value of a `uipanel`'s `Visible` property determines whether its child components, such as axes, buttons, `uibuttongroups`, and other `uipanel`s, are visible. However, changing the `Visible` property of a panel does *not* change the settings of the `Visible` property of its child components even though hiding the panel causes them to be hidden.

---

# uipushtool

---

**Purpose** Create push button on toolbar

**Syntax**

```
hpt = uipushtool
hpt = uipushtool('PropertyName1',value1,'PropertyName2',
    value2,...)
hpt = uipushtool(ht,...)
```

**Description** `hpt = uipushtool` creates a push button on the uitoolbar at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no uitoolbar exists, one is created. The uitoolbar is the parent of the uipushtool. Use the returned handle `hpt` to set properties of the tool. The `ClickedCallback` passes the handle as its first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting `CData` for the tool.

`hpt = uipushtool('PropertyName1',value1,'PropertyName2',value2,...)`, creates a uipushtool and returns a handle to it. `uipushtool` assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the `set` function. You can specify properties as parameter name/value pairs, cell arrays containing parameter names and values, or structures with fields containing parameter names and values as input arguments. For a complete list, see `Uipushtool Properties`. Type `get(hpt)` to see a list of uipushtool object properties and their current values. Type `set(hpt)` to see a list of uipushtool object properties that you can set and their legal property values.

`hpt = uipushtool(ht,...)` creates a button with `ht` as a parent. `ht` must be a uitoolbar handle.

Uipushtools appear in figures whose `Window Style` is 'normal' or 'docked'. Push tools do not appear in figures with 'modal' `WindowStyle`. If you change the `WindowStyle` of a figure containing a uitoolbar and its uipushtool children to 'modal', the uipushtools continue to exist as `Children` of the uitoolbar. However, they do not display until you change the figure `WindowStyle` to 'normal' or 'docked'.

Unlike push buttons, uipushtools have no way to indicate that you have double-clicked them. That is, a double click does not set the figure `SelectionType` property to `'open'`. Double-clicking a uipushtool simply executes its `ClickedCallback` twice in succession. Also, uipushtools cannot have context menus.

## Examples

Create a `uitoolbar` object and places a `uipushtool` object on it. Generate an icon for the tool by reading a GIF file containing a MATLAB icon. Convert the indexed image to a truecolor image before specifying it as `CData`.

```
h = figure('ToolBar','none');
ht = uitoolbar(h);
% Use a MATLAB icon for the tool
[X map] = imread(fullfile(...
    matlabroot,'toolbox','matlab','icons','matlabicon.gif'));
% Convert indexed image and colormap to truecolor
icon = ind2rgb(X,map);
% Create a uipushtool in the toolbar
hpt = uipushtool(ht,'CData',icon,...
    'TooltipString','Toolbar push button',...
    'ClickedCallback',...
    'disp(''Thank you for clicking a uipushtool.'')')
```

**Alternatives**

You can also create toolbars with push tools using GUIDE.

Properties

**Tutorials**

- “GUI with Axes, Menu, and Toolbar”

**How To**

- “Create Toolbars for Programmatic GUIs”

## Purpose

Describe push tool properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uipushtool properties by typing:

```
set(h, 'DefaultUipushtoolPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, a uicontrol handle, or a uipushtool handle. *PropertyName* is the name of the Uipushtool property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see Setting Default Property Values.

## Uipushtool Properties

This section lists all properties useful to uipushtool objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
BeingDeleted	This object is being deleted.
BusyAction	Callback routine interruption.
CData	Truecolor image displayed on the control.
ClickedCallback	Control action.
CreateFcn	Callback routine executed during object creation.
DeleteFcn	Delete uipushtool callback routine.

# Uipushtool Properties

---

Property	Purpose
Enable	Enable or disable the uipushtool.
HandleVisibility	Control access to object's handle.
HitTest	Whether selectable by mouse click
Interruptible	Callback routine interruption mode.
Parent	Handle of uipushtool's parent.
Separator	Separator line mode
Tag	User-specified object label.
TooltipString	Content of object's tooltip.
Type	Object class.
UicontextMenu	Uicontextmenu object associated with the uipushtool
UserData	User specified data.
Visible	Uipushtool visibility.

**BeingDeleted**  
on | {off} (read only)

*This object is being deleted.* The **BeingDeleted** property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the **BeingDeleted** property to on when the object's delete function callback is called (see the **DeleteFcn** property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's **BeingDeleted** property before acting.

**BusyAction**  
cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the **Interruptible** property of the callback controls whether other callbacks can interrupt the *running* callback, see the **Interruptible** property description.

**CData**  
3-dimensional array

*Truecolor image displayed on control.* An  $n$ -by- $m$ -by-3 array of RGB values that defines a truecolor image displayed on either a push button or toggle button. Each value must be between 0.0 and 1.0. If your **CData** array is larger than 16 in the first or second dimension, it may be clipped or cause other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

**ClickedCallback**  
string or function handle

# Uipushtool Properties

---

*Control action.* A routine that executes when the uipushtool's Enable property is set to on, and you press a mouse button while the pointer is on the push tool itself or in a 5-pixel wide border around it.

CreateFcn  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uipushtool object. MATLAB sets all property values for the uipushtool before executing the CreateFcn callback so these values are available to the callback. Within the function, use gcbo to get the handle of the push tool being created.

Setting this property on an existing uipushtool object has no effect.

You can define a default CreateFcn callback for all new uipushtools. This default applies unless you override it by specifying a different CreateFcn callback when you call uipushtool. For example, the code

```
imga(:,:,1) = rand(20);  
imga(:,:,2) = rand(20);  
imga(:,:,3) = rand(20);  
set(0,'DefaultUipushtoolCreateFcn','set(gcbo,''Cdata'',imga)')
```

creates a default CreateFcn callback that runs whenever you create a new push tool. It sets the default image imga on the push tool.

To override this default and create a push tool whose Cdata property is set to a different image, call uipushtool with code similar to

```
a = [.05:.05:0.95];  
imgb(:,:,1) = repmat(a,19,1)';  
imgb(:,:,2) = repmat(a,19,1);
```

```
imgb(:,:,3) = repmat(flipdim(a,2),19,1);  
hpt = uipushtool(...,'CreateFcn','set(gcbo,''CData'',imgb)',...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this push tool, you had explicitly set `CData` to `imgb`, the default `CreateFcn` callback would have set `CData` back to `imga`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uipushtool` object (e.g., when you call the `delete` function or cause the figure containing the `uipushtool` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

# Uipushtool Properties

---

## Enable

{on} | off

*Enable or disable the uipushtool.* This property controls how uipushtools respond to mouse button clicks, including which callback routines execute.

- **on** – The uipushtool is operational (the default).
- **off** – The uipushtool is not operational and its image (set by the `Cdata` property) is grayed out.

When you left-click a uipushtool whose `Enable` property is `on`, MATLAB performs these actions in this order:

- 1** Executes the push tool's `ClickedCallback` routine.
- 2** Does *not* set the figure `CurrentPoint` property and does not execute the figure's `WindowButtonDownFcn` callback.
- 3** Does *not* set the figure `SelectionType` property.

When you left-click a uipushtool whose `Enable` property is `off`, or when you right-click a uipushtool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on uipushtool objects.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`

# Uipushtool Properties

---

- KeyReleaseFcn
- WindowButtonDownFcn
- WindowButtonMotionFcn
- WindowButtonUpFcn
- WindowKeyPressFcn
- WindowKeyReleaseFcn
- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

Parent

handle

*Uipushtool parent.* The handle of the uipushtool’s parent toolbar. You can move a uipushtool object to another toolbar by setting this property to the handle of the new parent.

Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line to the left of the uipushtool.

Tag

string

# Uipushtool Properties

---

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the `Tag` value 'Copy'.

```
h = findobj(uitoolbarhandles, 'Tag', 'Copy')
```

`TooltipString`  
string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the `uipushtool`. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uipushtool;  
s = sprintf('Pushtool tooltip line 1\nPushtool tooltip line 2');  
set(h, 'TooltipString', s)
```

`Type`  
string (read-only)

Object class. This property identifies the kind of graphics object. For `uipushtool` objects, `Type` is always the string 'uipushtool'.

`UIContextMenu`  
handle

*Associate a context menu with uicontrol.* This property has no effect on uipushtool objects.

UserData  
array

*User specified data.* You can specify UserData as any array you want to associate with the uipushtool object. The object does not use this data, but you can access it using the set and get functions.

Visible  
{on} | off

*Uipushtool visibility.* By default, all uipushtools are visible. When set to off, the uipushtool is not visible, but still exists and you can query and set its properties.

# uiputfile

---

**Purpose** Open standard dialog box for saving files

**Syntax**

```
FileName = uiputfile  
[FileName,PathName] = uiputfile  
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)  
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,  
    DialogTitle)  
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,  
    DialogTitle,DefaultName)
```

## Description

---

**Note** Successful execution of `uiputfile` does not create a file; it only returns the name of a new or existing file that you designate.

---

`FileName = uiputfile` displays a modal dialog box for selecting or specifying a file you want to create or save. The dialog box lists the files and folders in the current folder. If the selected or specified file name is valid, `uiputfile` returns it in `FileName`.

`[FileName,PathName] = uiputfile` also returns the path to `FileName` in `PathName`, or if you cancel the dialog, returns 0 for both arguments. If you do not provide any output arguments, the file name alone is returned in `ans`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uiputfile` also displays in gray any files that do not match `FilterSpec`. The `uiputfile` function appends 'All Files' to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the \* and ? wildcard characters. For example, '\*.m' lists all MATLAB program files in a folder.

`FilterSpec` can be a string that contains a file name. `uiputfile` displays the file name selected in the **File name** field and uses the file extension as the default filter. The `FilterSpec` string can include a path, or consist of a path only. To specify a folder only, make the

last character in `DefaultName` `'\'` or `'/'`. A path can contain special path characters, such as `'.'`, `'..'`, `'/'`, `'\'`, or `'~'`. For example, `'../*.m'` lists all program files in the folder above the current folder. If `FilterSpec` is a cell array of strings, the first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace the default descriptions in the **Save as type** pop-up menu. A description cannot be an empty string. See the “Examples” on page 1-6669 for illustration of using cell arrays as `FilterSpec`. If you do not specify `FilterSpec`, `uiputfile` uses the default list of file types (all MATLAB files). `FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click the **Cancel** button, close the dialog window, or if the file does not exist, `uiputfile` returns `FilterIndex` as 0.

```
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,  
DialogTitle) displays a dialog box that has the title DialogTitle.  
To use the default file types and to specify a dialog title, enter  
uiputfile('','DialogTitle')
```

```
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,  
DialogTitle,DefaultName) displays a dialog box in which the file name  
specified by DefaultName appears in the File name field. DefaultName  
can also be a path or a path+filename. To specify a folder only, make  
the last character in DefaultName '\' or '/'. In this case, uiputfile  
opens the dialog box in the folder specified by the path. If you specify a  
path in DefaultName that does not exist, uiputfile opens the dialog  
box in the current folder. You can use '.', '..', '\', '/', or ~ in the  
DefaultName argument.
```

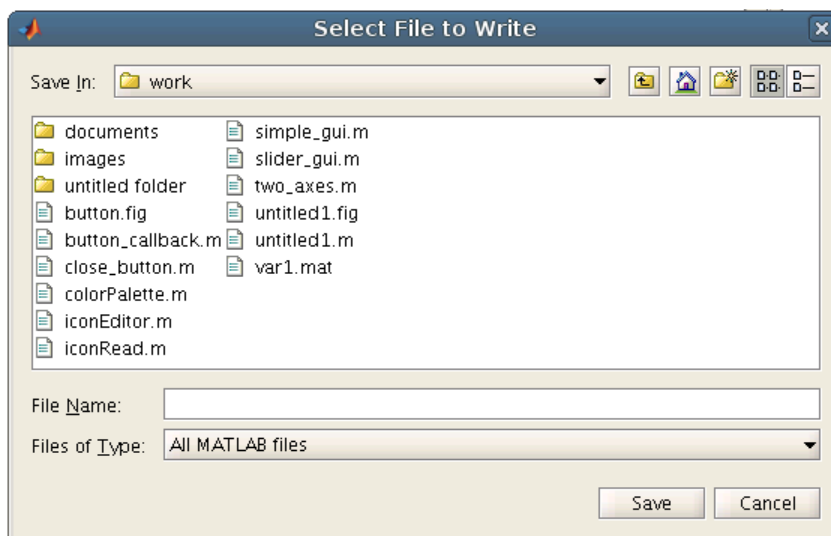

When typing into the dialog box, if you include either of the wildcard characters `'*'` or `'?'` in a file name, `uiputfile` does not respond to clicking **Save**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

If you select or specify an existing file name, a warning dialog box opens stating that the file already exists and asks if you want to replace it.

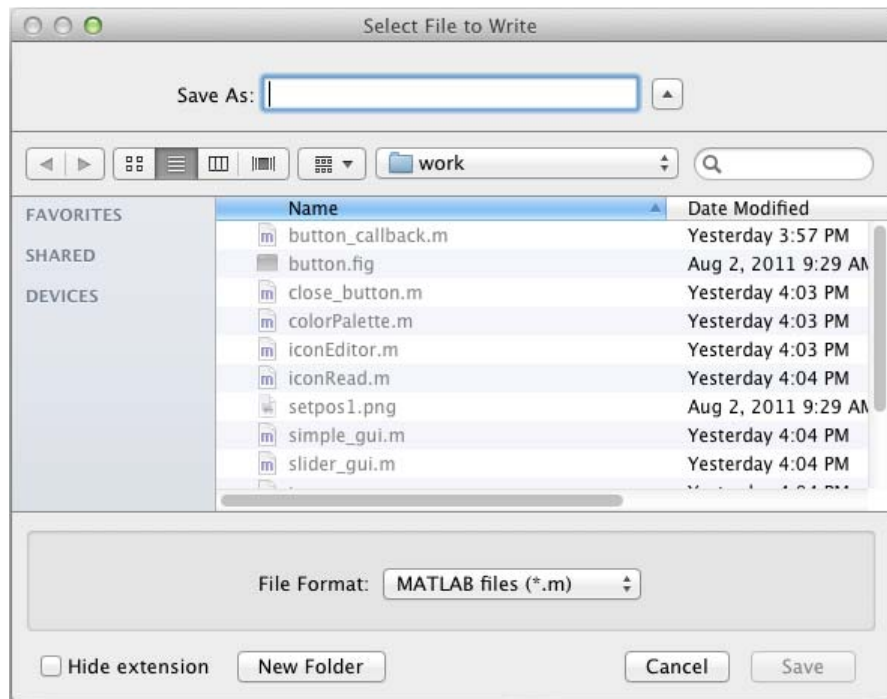

Select **Yes** to replace the existing file or **No** to return to the dialog to select another file name. Selecting **Yes** returns the name of the file. Selecting **No** returns 0.

For Microsoft Windows platforms, the dialog box is the Windows dialog box native to your platform, and thus can differ from what you see in the examples that follow.

For UNIX platforms, the dialog box is like the one shown in the following figure.

For Mac platforms, the dialog box is like the one shown in the following figure.

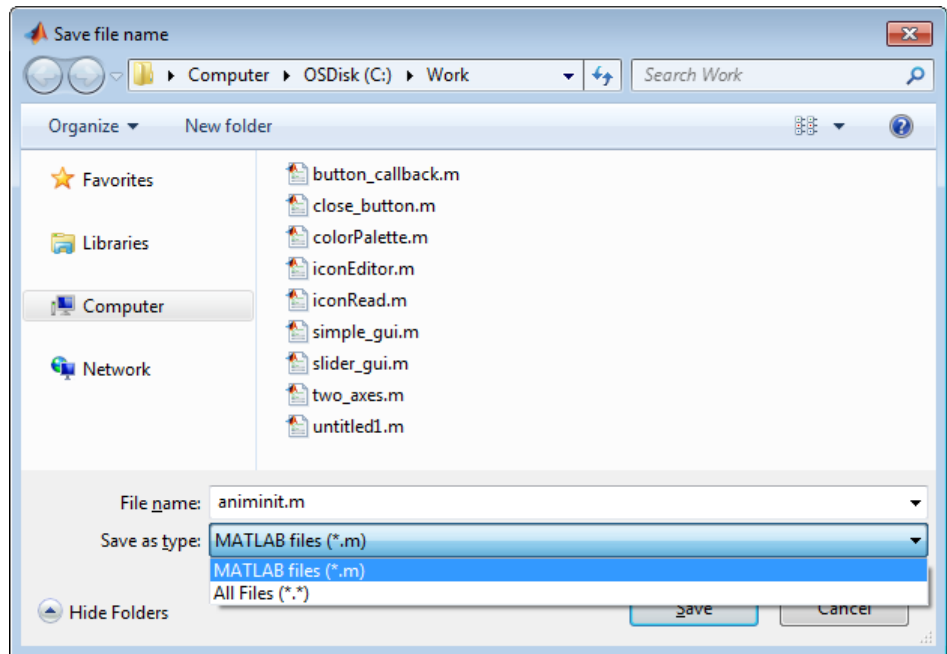

**Note** A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in MATLAB Figure Properties.

## Examples

The following statement displays a dialog box entitled 'Save file name', setting the **File name** field to `animinit.m` and the filter to program files (`*.m`). Because `FilterSpec` is a string, the filter also includes All Files (`*.*`)

```
[file,path] = uiputfile('animinit.m','Save file name');
```

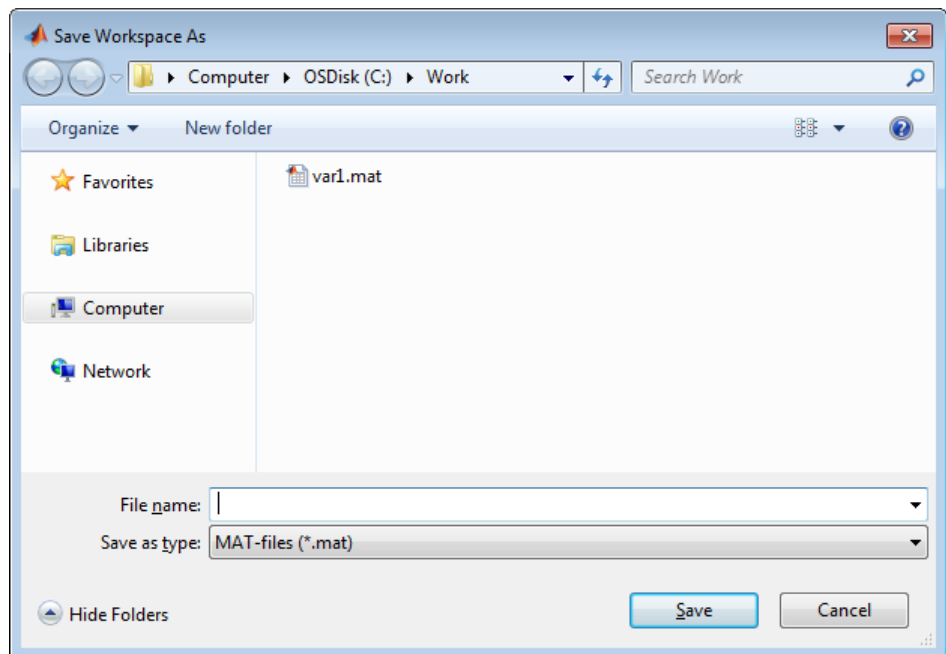

# uiputfile

The following statement displays a dialog box entitled 'Save Workspace As' with the filter set to MAT-files.

```
[file,path] = uiputfile('*.mat','Save Workspace As');
```

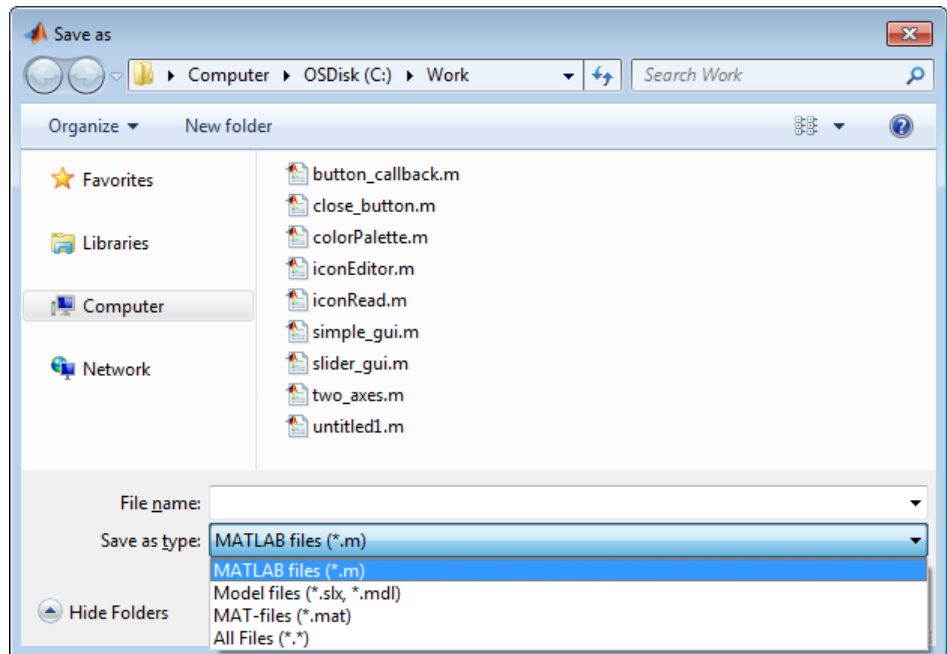

To display several file types in the **Save as type** list box, separate each file extension with a semicolon, as in the following code. `uiputfile` displays a default description for each known file type, such as "Model files" for Simulink `.mdl` and `.slx` files.

```
[filename, pathname] = uiputfile(...  
{ '*.*'; '*.slx'; '*.mat'; '*.*' }, ...  
'Save as');
```

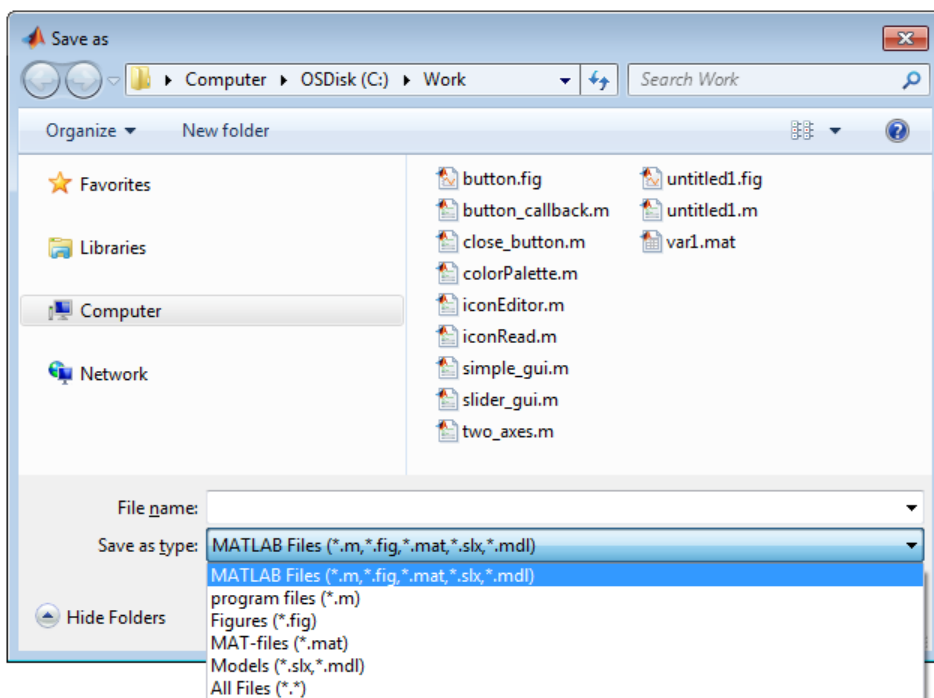

# uiputfile

To create a list of file types and give them descriptions that are different from the defaults, use a cell array. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname, filterindex] = uiputfile( ...  
{ '*.m'; '*.fig'; '*.mat'; '*.slx'; '*.mdl', ...  
'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';  
'*.m', 'program files (*.m)'; ...  
'*.fig', 'Figures (*.fig)'; ...  
'*.mat', 'MAT-files (*.mat)'; ...  
'*.slx;*.mdl', 'Models (*.slx,*.mdl)'; ...  
'*.*', 'All Files (*.*)'}, ...  
'Save as');
```

The first column of the cell array contains the file extensions, while the second contains the descriptions you want to provide for the file types. The first entry of column one contains several extensions separated by semicolons. These file types all associate with the description 'MATLAB Files (\*.m,\*.fig,\*.mat,\*.slx,\*.mdl)'. The code produces the dialog box shown in the following figure.

The following code checks for the existence of the file and displays a message about the result of the file selection operation.

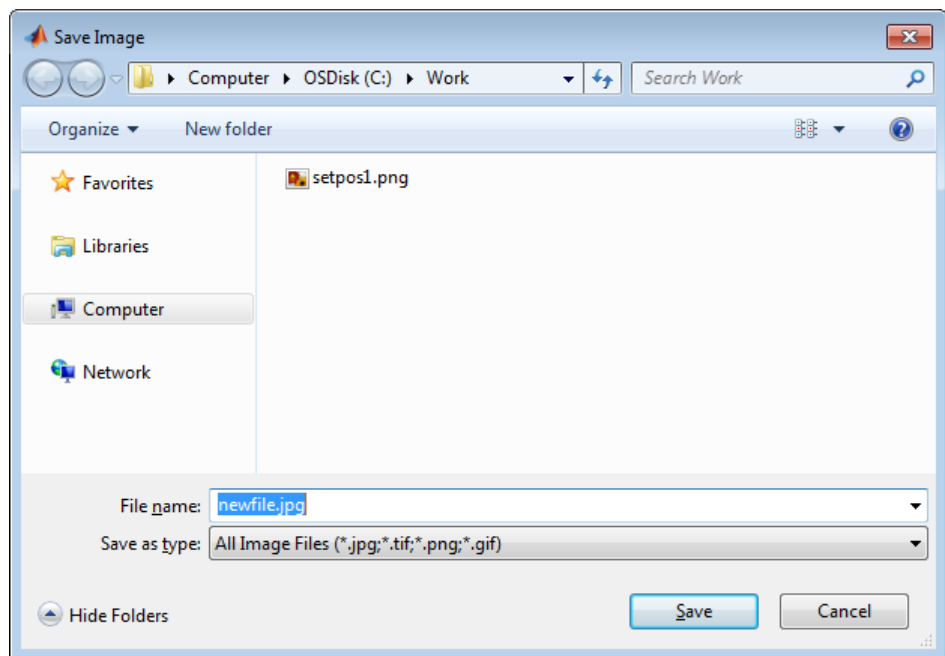

```
[filename, pathname] = uiputfile('*.m','Pick a MATLAB program file');
if isequal(filename,0) || isequal(pathname,0)
    disp('User selected Cancel')
else
```

# uiputfile

```
disp(['User selected ',fullfile(pathname,filename)])  
end
```

Select or enter a file name for saving a figure as an image in one of four formats, described in a cell array.

```
uiputfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...  
          '*.','All Files' },'Save Image',...  
          'C:\Work\newfile.jpg')
```

[save](#) | [uigetdir](#) | [uigetfile](#) | [uisave](#)

<b>Purpose</b>	Resume execution of blocked program
<b>Syntax</b>	<code>uiresume(h)</code>
<b>Description</b>	<code>uiresume(h)</code> resumes the program execution that <code>uiwait</code> suspended.

**Tips**

The `uiwait` and `uiresume` functions block and resume MATLAB program execution. When creating a dialog box, you should have a `uicontrol` component with a callback that calls `uiresume` or a callback that destroys the dialog box. These are the only methods that resume program execution after the `uiwait` function blocks execution.

When used in conjunction with a modal dialog box, `uiresume` can resume the execution of the program that `uiwait` suspended while presenting a dialog box.

**Examples**

This example creates a GUI with a **Continue** push button. The example calls `uiwait` to block MATLAB execution until `uiresume` is called. This happens when the user clicks the **Continue** push button because the push button's `Callback`, which responds to the click, calls `uiresume`.

```
f = figure;  
h = uicontrol('Position',[20 20 200 40],'String','Continue',...  
            'Callback','uiresume(gcf)');  
disp('This will print immediately');  
uiwait(gcf);  
disp('This will print after you click Continue');  
close(f);
```

`gcbf` is the handle of the figure that contains the object whose callback is executing.

“Modal Dialog Box (GUIDE)” is a more complex example for a GUIDE GUI.

**See Also** `dialog` | `figure` | `uicontrol` | `uimenu` | `uiwait` | `waitfor`

# uisave

---

**Purpose** Interactively save workspace variables to MAT-file

**Syntax**

```
uisave
uisave(variables)
uisave(variables,filename)
```

**Description** `uisave`, with no arguments, prompts you for a file name, and then saves all variables from your workspace to that file.

`uisave(variables)` saves one or more workspace variables listed in `variables`.

`uisave(variables,filename)` uses the specified `filename` as the default **File name** in the Save Workspace Variables dialog box, instead of the default `matlab.mat`.

- Tips**
- If you type a name in the **File name** field, such as `my_vars`, and click **Save**, the dialog saves all workspace variables to the file `my_vars.mat`. The default filename is `matlab.mat`.
  - `uisave` calls `uiputfile` to choose a filename.
  - If the filename you specify exists in that folder, `uisave` informs you and gives you a chance to cancel the operation.
  - The `uisave` dialog box is modal.
  - The `uisave` dialog is modal. A modal dialog box prevents you from interacting with other windows until you respond to it.

**Input Arguments**

**variable**  
String containing the name of a variable in the current workspace or cell array of strings when specifying more than one variable.

**Default:** All variables in the current workspace are saved to a MAT-file.

**filename**

String naming a file to appear in the dialog **File name** field when the dialog opens. You can omit a file extension, or specify the file extension as `.mat`.

**Default:** `matlab.mat`

## Definitions

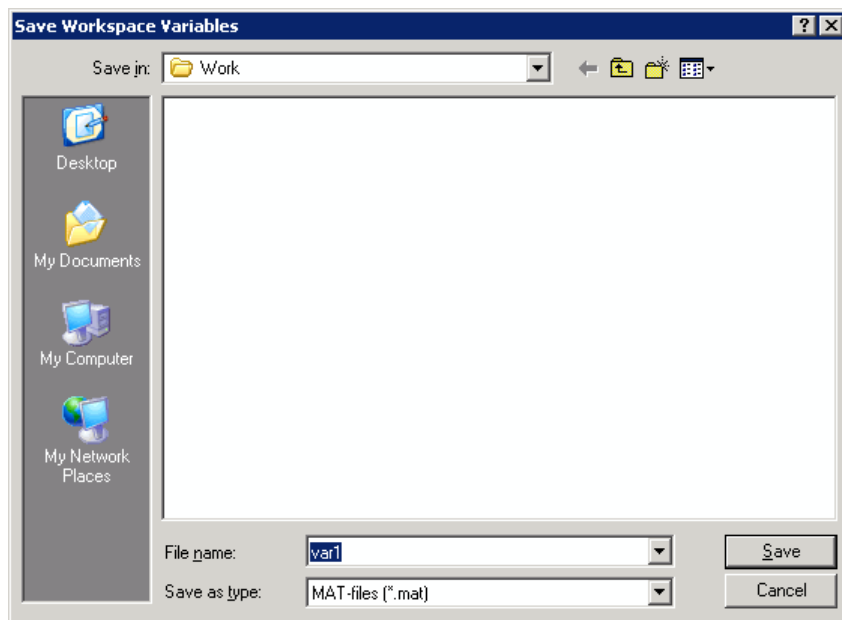

### Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

## Examples

Create workspace variables `h` and `g`, and then display the Save Workspace Variables dialog box in the current folder with the default **File name** set to `var1`.

```
h = 365;  
g = 52;  
uisave({'h', 'g'}, 'var1');
```

Clicking **Save** stores the workspace variables `h` and `g` in the file `var1.mat` in the displayed folder.

## Alternatives

Use any of the following GUI options to save workspace variables:

- Use **File > Save** to save workspace variables.
- Click the Save icon  in the Workspace Browser.
- Select one or more variables in the Workspace Browser, right-click, and choose **Save as** from the context menu.

## See Also

`save` | `uigetfile` | `uiputfile` | `uiopen`

## Tutorials

- “Save, Load, and Delete Workspace Variables”

**Purpose** Open standard dialog box for setting object's ColorSpec

**Syntax**

```
c = uigetcolor  
c = uigetcolor([r g b])  
c = uigetcolor(h)  
c = uigetcolor(...,'dialogTitle')
```

**Description**

`c = uigetcolor` displays a modal color selection dialog appropriate to the platform, and returns the color selected by the user. The dialog box is initialized to white.

`c = uigetcolor([r g b])` displays a dialog box initialized to the specified color, and returns the color selected by the user. `r`, `g`, and `b` must be values between 0 and 1.

`c = uigetcolor(h)` displays a dialog box initialized to the color of the object specified by handle `h`, returns the color selected by the user, and applies it to the object. `h` must be the handle to an object containing a color property.

`c = uigetcolor(...,'dialogTitle')` displays a dialog box with the specified title.

If the user presses **Cancel** from the dialog box, or if any error occurs, the output value is set to the input RGB triple, if provided; otherwise, it is set to 0.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

**See Also** ColorSpec

# uifont

---

**Purpose** Open standard dialog box for setting object's font characteristics

**Syntax**

```
uifont
uifont(h)
uifont(S)
uifont(..., 'DialogTitle')
S = uifont(...)
```

**Description** `uifont` enables you to change font properties (`FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle`) for a `text`, `axes`, or `uicontrol` object. The function returns a structure consisting of font properties and values. You can specify an alternate title for the dialog box.

`uifont` displays a modal dialog box and returns the selected font properties.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`uifont(h)` displays a modal dialog box, initializing the font property values with the values of those properties for the object whose handle is `h`. Selected font property values are applied to the current object. If a second argument is supplied, it specifies a name for the dialog box.

`uifont(S)` displays a modal dialog box, initializing the font property values with the values defined for the specified structure (`S`). `S` must define legal values for one or more of these properties: `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` and the field names must match the property names exactly. If other properties are defined, they are ignored. If a second argument is supplied, it specifies a name for the dialog box.

`uifont(..., 'DialogTitle')` displays a modal dialog box with the title `DialogTitle` and returns the values of the font properties selected in the dialog box.

`S = uifont(...)` returns the properties `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` as fields in a structure. If the user presses **Cancel** from the dialog box or if an error occurs, the output value is set to 0.

## Examples

These statements create a text object, then display a dialog box (labeled Update Font) that enables you to change the font characteristics:

```
h = text(.5,.5,'Figure Annotation');
uifont(h,'Update Font')
```

These statements create two push buttons, then set the font properties of one based on the values set for the other:

```
% Create push button with string ABC
c1 = uicontrol('Style', 'pushbutton', ...
    'Position', [10 10 100 20], 'String', 'ABC');
% Create push button with string XYZ
c2 = uicontrol('Style', 'pushbutton', ...
    'Position', [10 50 100 20], 'String', 'XYZ');
% Display set font dialog box for c1, make selections,
& and save to d
d = uifont(c1);
% Apply those settings to c2
set(c2, d)
```

## See Also

[axes](#) | [text](#) | [uicontrol](#)

# uisetpref

---

**Purpose** Manage preferences used in `uisetpref`

**Syntax** `uisetpref('clearall')`

**Description** `uisetpref('clearall')` resets the value of all preferences registered through `uisetpref` to 'ask'. This causes the dialog box to display when you call `uisetpref`.

---

**Note** Use `setpref` to set the value of a particular preference to 'ask'.

---

**See Also** `setpref` | `uisetpref`

**Purpose** Reorder visual stacking order of objects

**Syntax**

```
uistack(h)
uistack(h,stackopt)
uistack(h,stackopt,step)
```

**Description** `uistack(h)` raises the visual stacking order of the objects specified by the handles in `h` by one level (step of 1). All handles in `h` must have the same parent.

`uistack(h,stackopt)` moves the objects specified by `h` in the stacking order, where `stackopt` is one of the following:

- 'up' – moves `h` up one position in the stacking order
- 'down' – moves `h` down one position in the stacking order
- 'top' – moves `h` to the top of the current stack
- 'bottom' – moves `h` to the bottom of the current stack

`uistack(h,stackopt,step)` moves the objects specified by `h` up or down the number of levels specified by `step`.

---

**Note** In a GUI, axes objects are always at a lower level than `uicontrol` objects. You cannot stack an axes object on top of a `uicontrol` object.

---

See “Set Tab Order in a Programmatic GUI” in the MATLAB documentation for information about changing the tab order.

**Examples** The following code moves the child that is third in the stacking order of the figure handle `hObject` down two positions.

```
v = allchild(hObject)
uistack(v(3), 'down', 2)
```

# uitable

---

**Purpose** Create 2-D graphic table GUI component

**Syntax**

```
uitable
uitable('PropertyName1', value1, 'PropertyName2', value2, ...)
uitable(parent, ...)
handle = uitable(...)
```

**Description** `uitable` creates an empty `uitable` object in the current figure window, using default property values. If no figure exists, a new figure window opens.

`uitable('PropertyName1', value1, 'PropertyName2', value2, ...)` creates a `uitable` object with specified property values. Properties that you do not specify assume the default property values. See the `Uitable Properties` reference page for information about the available properties.

`uitable(parent, ...)` creates a `uitable` object as a child of the specified parent handle `parent`. The parent can be a figure or `uipanel` handle. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence.

`handle = uitable(...)` creates a `uitable` object and returns its handle.

**Tips** After creating a `uitable` object, you can set and query its property values using the `set` and `get` functions.

If the `ColumnEditable` property is `true` for columns you edit, you can change values in a displayed table. By default, this property is `false` for all columns. If a noneditable column contains pop-up choices, only the current choice is visible (and not the pop-up menu control).

If you attempt to create a `uitable` object when running MATLAB on a UNIX<sup>8</sup> system without a Java virtual machine (`matlab -nojvm`) or without a display (`matlab nodisplay`), no table generates and you receive an error.

8. UNIX is a registered trademark of The Open Group in the United States and other countries.

The **CellEditCallback** executes after you edit a value and do any of the following:

- Type **Enter**.
- Click another table cell.
- Click anywhere else within the table.
- Click another control or area within the same figure window.
- Click another window, click again on the GUI containing the table (or use **Alt+Tab** to switch windows), and then perform any of the above four actions.

When the **CellEditCallback** callback executes, **uitable** updates the underlying data matrix (the table **Data** property) to contain the value that the cell now displays.

The **CellSelectionCallback** executes when you select a table cell or remove one from the current selection by **Ctrl**+clicking it. Clicking a cell without pressing any key selects it and deselects all currently selected cells. You can define a range of table cells by **Shift**+clicking an unselected cell after selecting one or more cells. The callback provides event data that identifies the rows and columns of all cells in the current selection.

You cannot select table cells programmatically. Directly clicking cells is the only method of selection.

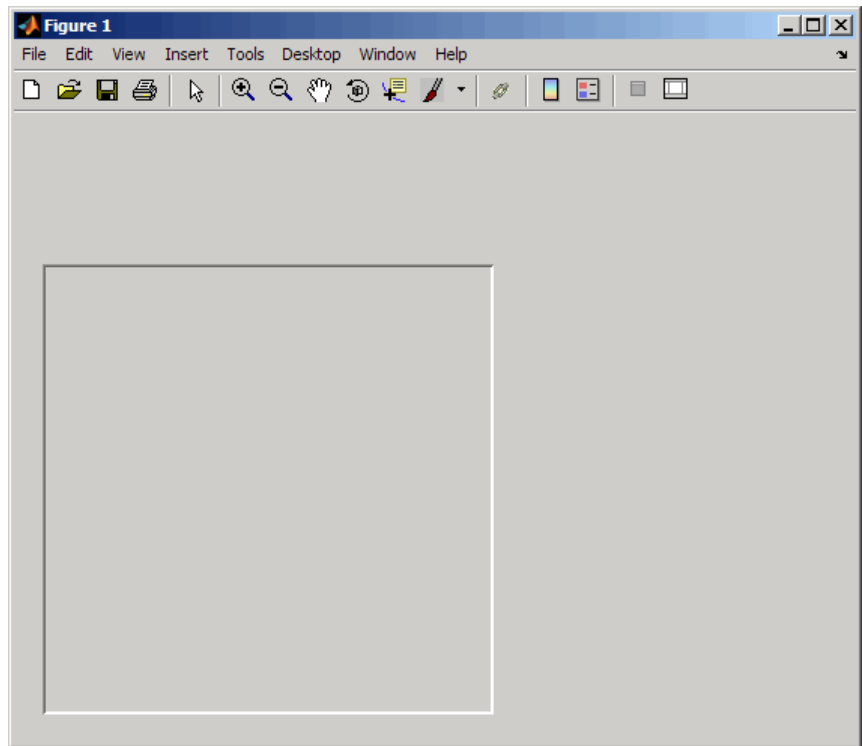

## Examples

Create a table, provide magic-square data, set column widths uniformly, and specify the **uitable** **ColumnWidth** property as a cell array:

- 1 Create a table in the current figure. If no figure exists, one opens:

```
t = uitable;
```

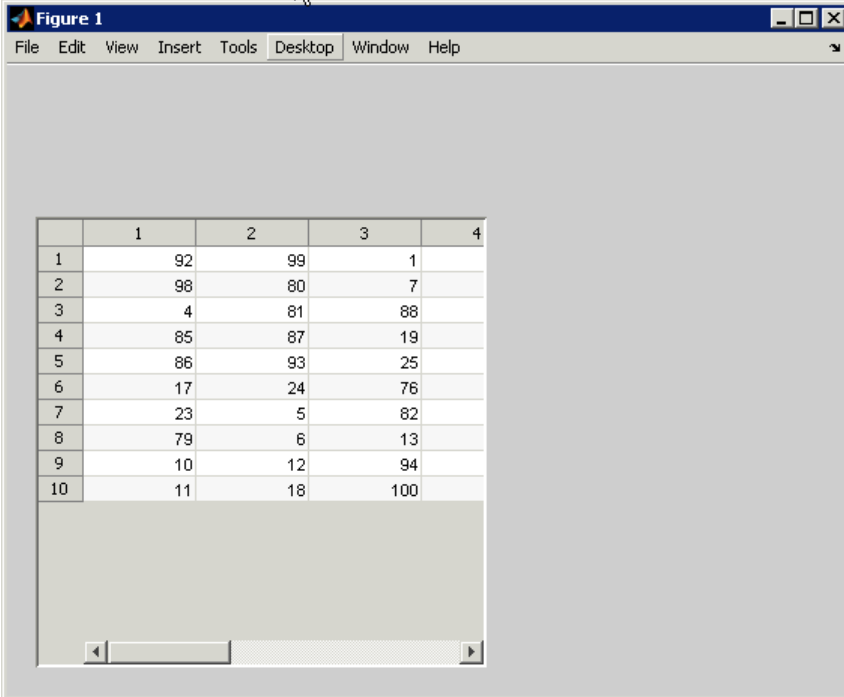

# uitable

- 2** As the table has no content (its Data property is empty), it initially displays no rows or columns. Provide data (a magic square)

```
set(t,'Data',magic(10))
```

	1	2	3	4
1	92	99	1	
2	98	80	7	
3	4	81	88	
4	85	87	19	
5	86	93	25	
6	17	24	76	
7	23	5	82	
8	79	6	13	
9	10	12	94	
10	11	18	100	

- 3** Make the entire table contents visible. Set column widths to 25 pixels uniformly. Specify the `ColumnWidth` property of the table as a cell array.

```
set(t, 'ColumnWidth', {25})
```

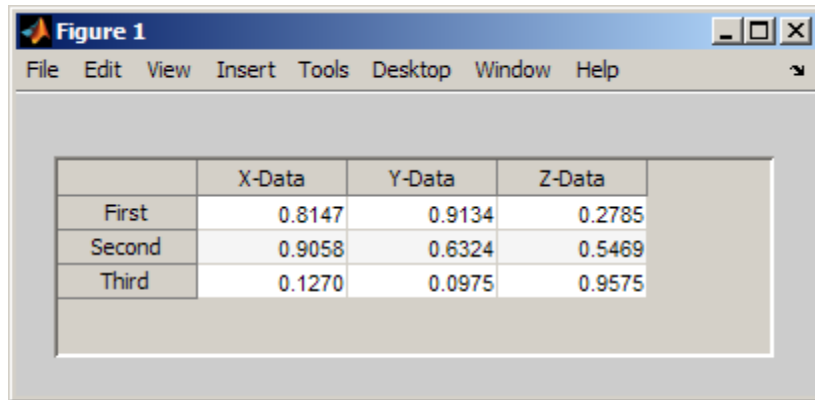

Cell arrays that specify `ColumnWidth` can contain:

- One number (a width measured in pixels, as shown here) or the string 'auto'.
- A cell array containing a list of pixel sizes having up to as many entries as the table has columns .

If a list of column widths has  $n$  entries, where  $n$  is smaller than the number of columns, it sets the first  $n$  column widths only. You can substitute 'auto' for any value in the cell array to have the width of that column calculated automatically.

Create a figure and add a table to contain a 3-by-3 data matrix. The code specifies the column names, row names, parent, and position of the table:

```
f = figure('Position',[200 200 400 150]);
dat = rand(3);
cnames = {'X-Data','Y-Data','Z-Data'};
rnames = {'First','Second','Third'};
t = uitable('Parent',f,'Data',dat,'ColumnName',cnames,...
           'RowName',rnames,'Position',[20 20 360 100]);
```

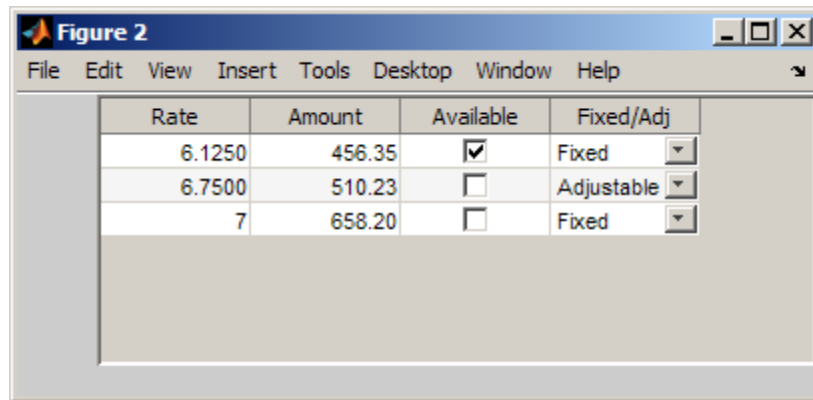

Create a table to contain a 3-by-4 array that contains numeric, logical, and string data, as follows:

- First column (**Rate**): Numeric, with three decimals (not editable)
- Second column (**Amount**): Currency (not editable)
- Third column (**Available**): Check box (editable)
- Fourth column (**Fixed/Adj**): Pop-up menu with two choices: Fixed and Adjustable (editable)
- Specify the RowName property as empty to remove row names from the table.

```
f = figure('Position',[100 100 400 150]);
```

# uitable

```
dat = {6.125, 456.3457, true, 'Fixed';...
       6.75, 510.2342, false, 'Adjustable';...
       7, 658.2, false, 'Fixed'}};
columnname = {'Rate', 'Amount', 'Available', 'Fixed/Adj'};
columnformat = {'numeric', 'bank', 'logical', {'Fixed' 'Adjustable'}};
columneditable = [false false true true];
t = uitable('Units','normalized','Position',...
           [0.1 0.1 0.9 0.9], 'Data', dat,...
           'ColumnName', columnname,...
           'ColumnFormat', columnformat,...
           'ColumnEditable', columneditable,...
           'RowName', []);
```

Rate	Amount	Available	Fixed/Adj
6.1250	456.35	<input checked="" type="checkbox"/>	Fixed
6.7500	510.23	<input type="checkbox"/>	Adjustable
7	658.20	<input type="checkbox"/>	Fixed

## Alternatives

You can add tables to GUIs you create with “Table”.

**How To**

- “Table”

# Uitable Properties

---

## Purpose

Describe table properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uitable properties by typing:

```
set(h, 'DefaultUitablePropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uitable handle. *PropertyName* is the name of the uitable property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uitable Properties

This section lists all properties useful to uitable objects along with valid values and descriptions of their use. In the property descriptions, curly braces { } enclose default values.

Property Name	Description
BackgroundColor	Background color of cells.
BeingDeleted	This object is being deleted.
BusyAction	Callback routine interruption
ButtonDownFcn	Button-press callback routine
CellEditCallback	Callback when data in a cell is changed.

# Uitable Properties

Property Name	Description
CellSelectionCallback	Callback when cell is selected
Children	uitable objects have no children
Clipping	Does not apply to uitable objects
ColumnEditable	Determines data in a column as editable
ColumnFormat	Determines display and editability of columns
ColumnName	Column header label
ColumnWidth	Width of each column in pixels
CreateFcn	Callback routine during object creation
Data	Table data
DeleteFcn	Callback routine during object deletion
Enable	Enable or disable the uitable
Extent	Size of uitable rectangle
FontAngle	Character slant of cell content
FontName	Font family for cell content
FontSize	Font size of cell content
FontUnits	Font size units for cell content
FontWeight	Weight of cell text characters
ForegroundColor	Color of text in cells
HandleVisibility	Control access to object's handle
HitTest	Selectable by mouse click
Interruptible	Callback routine interruption mode
KeyPressFcn	Key press callback function
Parent	uitable parent

# Uitable Properties

---

Property Name	Description
Position	Size and location of uitable
RearrangeableColumns	Location of the column
RowName	Row header label names
RowStriping	Color striping of label rows
Selected	Is object selected?
SelectionHighlight	Object highlight when selected
Tag	Use-specified object label
TooltipString	Content of tooltip for object
Type	Class of graphics object
UIContextMenu	Associate context menu with uitable
Units	Units of measurement
UserData	User-specified data
Visible	uitable visibility

## BackgroundColor

1-by-3 or 2-by-3 matrix of RGB triples

*Cell background color.* Color used to fill the uitable cells. Specify as an 1-by-3 or 2-by-3 matrix of RGB triples, such as [.8 .9 .8] or [1 1 .9; .9 1 1]. Each row is an RGB triplet of real numbers between 0.0 and 1.0 that defines one color. (Color names are not allowed.) The default is a 1-by-3 matrix of platform-dependent colors. See ColorSpec for information about RGB colors.

Row 2 of the matrix is used only if the `RowStriping` property is on. The table background is not striped unless both `RowStriping` is on and the `BackgroundColor` color matrix has two rows.

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to on when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

# Uitable Properties

---

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string or function handle (GUIDE sets this property)

*Button-press callback routine.* A callback routine that can execute when you press a mouse button while the pointer is on or near a `uitable`. Specifically:

- If the `uitable Enable` property is set to `on`, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the `uitable` or when you click the right mouse button on the control itself.
- If the `uitable Enable` property is set to `inactive` or `off`, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on.

Define this routine as a string that is a valid MATLAB expression or the name of a MATLAB function file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the program file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets this property to the appropriate string and adds the callback to the program file.

## CellEditCallback

function handle, cell array containing function handle and additional arguments, or string (not recommended)

*Callback to edit user-entered data*

Callback function executed when the user modifies a table cell. It can perform evaluations, validations, or other customizations. If this function is called as a function handle, `uitable` passes it two arguments. The first argument, `source`, is the handle of the `uitable`. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table. All fields in the event data structure are read only.

Event Data Structure Field	Type	Description
Indices	1-by-2 matrix	Row index and column index of the cell the user edited.
PreviousData	1-by-1 matrix or cell array	Previous data for the changed cell. The default is an empty matrix, [ ].
EditData	String	User-entered string.

# Uitable Properties

---

<b>Event Data Structure Field</b>	<b>Type</b>	<b>Description</b>
NewData	1-by-1 matrix or cell array	<p>Value that <code>uitable</code> wrote to <code>Data</code>. It is either the same as <code>EditData</code> or a converted value, for example, 2 where <code>EditData</code> is '2' and the cell is numeric.</p> <p>Empty if <code>uitable</code> detected an error in the user-entered data and did not write it to <code>Data</code>.</p>
Error	String	<p>Error that occurred when <code>uitable</code> tried to convert the <code>EditData</code> string into a value appropriate for <code>Data</code>. For example, <code>uitable</code> could not convert the <code>EditData</code> string consistent with the <code>Column Format</code> property, if any, or the data type for the changed cell.</p> <p>Empty if <code>uitable</code> wrote the value to <code>Data</code>.</p> <p>If <code>Error</code> is not empty, the <code>CellEditCallback</code> can pass the error string to the user or can attempt to manipulate the data. For example, the string 'pi' would raise an error in a numeric cell but the <code>CellEditCallback</code> could convert it to its numerical equivalent and store it in <code>Data</code> without passing the error to the user.</p>

When a user edits a cell, `uitable` first attempts to store the user-entered value in `Data`, converting the value if necessary. It then calls the `CellEditCallback` and passes it the event data structure. If there is no `CellEditCallback` and the user-entered data results in an error, the contents of the cell reverts to its previous value and no error is displayed. The `CellEditCallback`

is issued when the user has modified a table cell and presses **Enter** or clicks anywhere outside the cell.

## CellSelectionCallback

function handle, cell array containing function handle and additional arguments, or string (not recommended)

*Callback that executes when cell is selected.* Callback function that executes when the user highlights a cell by navigating to it or clicking it. For multiple selection, this callback executes when new cells are added to the selection. The callback includes event data, a structure with one member

Event Data Structure Field	Type	Description
Indices	n-by-2 matrix	Row index and column index of the cells the user currently has selected

Once a cell selection has been made, cells within it can be removed one at a time by **Ctrl**-clicking them.

## Children

matrix

The empty matrix; `uitable` objects have no children.

## Clipping

{on} | off

This property has no effect on `uitable` objects.

## ColumnEditable

logical 1-by-n matrix | scalar logical value | {} empty matrix ([ ])

*Determines if column is user-editable.*

# Editable Properties

---

Determines if the data can be edited by the end user. Each value in the cell array corresponds to a column. `false` is default because the developer needs to have control over changes users potentially might make to data.

Specify elements of a logical matrix as `true` if the data in a column is editable by the user or `false` if it is not. An empty matrix indicates that no columns are editable.

Columns that contain check boxes or pop-up menus must be editable for the user to manipulate these controls. If a column that contains pop-up menus is not editable, the currently selected choice appears without displaying the pop-up control. The Elements of the `ColumnEditable` matrix must be in the same order as columns in the `Data` property. If you do not specify `ColumnEditable`, the default is an empty matrix (`[]`).

`ColumnFormat`  
cell array of strings

*Cell display formatting.* Determines how the data in each column displays and is edited. Elements of the cell array must be in the same order as table columns in the `Data` property. If you do not want to specify a display format for a particular column, enter `[]` as a placeholder. If no format is specified for a column, the default display is determined by the data type of the data in the cell. Default `ColumnFormat` is an empty cell array (`{}`). In most cases, the default is similar to the command window.

Elements of the cell array must be one of the strings described in the following table.

Cell Format	Description
'char'	<p>Displays a left-aligned string.</p> <p>To edit, the user types a string that replaces the existing string.</p>
'logical'	<p>Displays a check box.</p> <p>To edit, the user checks or unchecks the check box. <code>uitable</code> sets the corresponding <code>Data</code> value to <code>true</code> or <code>false</code> accordingly.</p> <p>Initially, the check box is checked if the corresponding <code>Data</code> value would produce</p>
'numeric'	<p>Displays a right-aligned string equivalent to the command window, for numeric data. If the cell <code>Data</code> value is boolean, then 1 or 0 is displayed. If the cell <code>Data</code> value is not numeric and not boolean, then NaN is displayed.</p> <p>To edit, the user can enter any string. This enables a user to enter a value such as 'pi' that can be converted to its numeric equivalent by a <code>CellEditCallback</code>. The <code>uitable</code> function first attempts to convert the user-entered string to a numeric value and store it in <code>Data</code>. It then calls the <code>CellEditCallback</code>. See <code>CellEditCallback</code> for more information.</p>

# Uitable Properties

---

Cell Format	Description
1-by-n cell array of strings that define a pop-up menu, e.g., {'one' 'two' 'three'}	<p>Displays a pop-up menu.</p> <p>To edit, the user makes a selection from the pop-up menu. <code>uitable</code> sets the corresponding Data value to the selected menu item.</p> <p>The initial values for the pop-up menus in the column are the corresponding strings in Data. These initial values do not have to be items in the pop-up menu. See Example 3 on the <code>uitable</code> reference page.</p>
Valid string accepted by the format function, e.g., 'short' or 'bank'	<p>Displays the Data value using the specified format. For example, for a two-column table, <code>set(htable, 'ColumnFormat', {'short', 'bank'})</code>.</p>

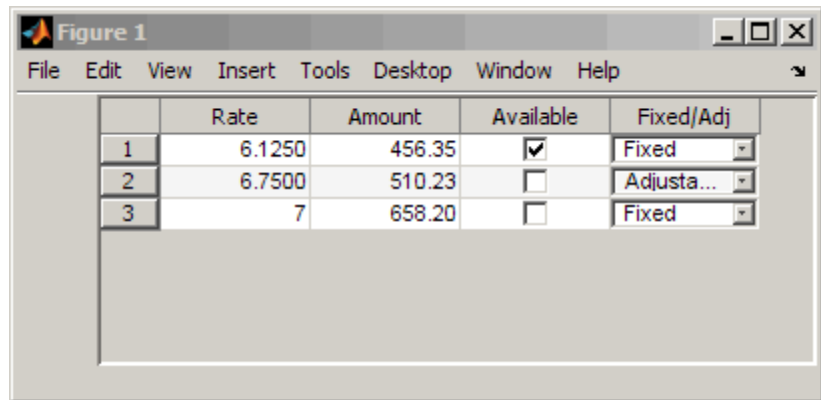

In some cases, you may need to insert an appropriate column in Data. If Data is a numerical or logical matrix, you must first convert it to a cell array using the `mat2cell` function.

## Data and ColumnFormat

When you create a table, you must specify value of Data. The Data property dictates what type of data can exist in any given cell. By default, the value of the Data also dictates the display of the cell to the end user, unless you specify a different format using the `ColumnFormat` property.

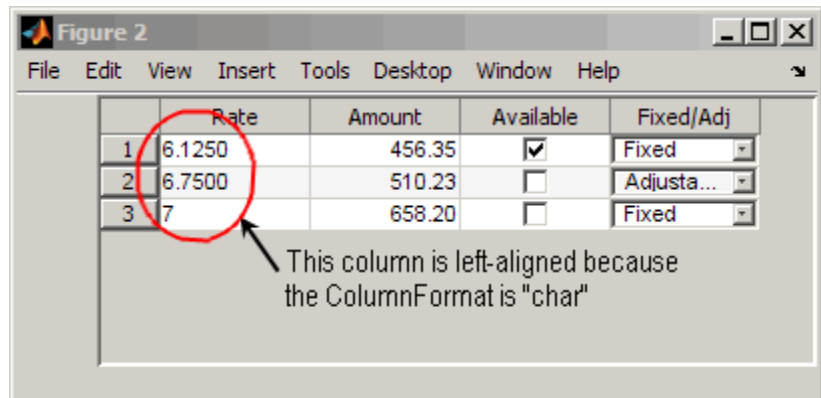

# Uitable Properties

	Rate	Amount	Available	Fixed/Adj
1	6.1250	456.35	<input checked="" type="checkbox"/>	Fixed
2	6.7500	510.23	<input type="checkbox"/>	Adjusta...
3	7	658.20	<input type="checkbox"/>	Fixed

ColumnFormat controls the presentation of the Data to the end user. Therefore, if you specify a ColumnFormat of char (or pick **Text** from the Table Property Editor), you are asking the table to display the Data associated with that column as a string. For example, if the Data for a particular column is numeric, and you specify the ColumnFormat as char, then the display of the numeric data will be left-aligned

	Rate	Amount	Available	Fixed/Adj
1	6.1250	456.35	<input checked="" type="checkbox"/>	Fixed
2	6.7500	510.23	<input type="checkbox"/>	Adjusta...
3	7	658.20	<input type="checkbox"/>	Fixed

This column is left-aligned because the ColumnFormat is "char"

# Editable Properties

If your column is editable and the user enters a number, the number will be left-aligned. However, if the user enters a text string, the table displays a **NaN**.

	Rate	Amount	Available	Fixed/Adj
1	6.1250	456.35	<input checked="" type="checkbox"/>	Fixed
2	6.7500	510.23	<input type="checkbox"/>	Adjusta...
3	NaN	658.20	<input type="checkbox"/>	Fixed

Another possible scenario is that the value Data is char and you set the ColumnFormat to be a pop-up menu. Here, if the value of the Data in the cell matches one of the pop-up menu choices you define in ColumnFormat, then the Data is shown in the cell. If it does not match, then the cell defaults to display the first option from the choices you specify in ColumnFormat. Similarly, if Data is numeric or logical with the ColumnFormat as pop-up menu, if the Data value in the cell does not match any of the choices you specify in ColumnFormat, the cell defaults to display the first option in the pop-menu choice.

This table describes how Data values correspond with your ColumnFormat when the columns are editable.

ColumnFormat Selections		
numeric	char	logical

# Uitable Properties

<b>Data Type</b>	numeric	Values match. MATLAB displays numbers as is.	MATLAB converts the text string entered to a double. See <code>str2double</code> for more information. If string cannot be converted, <b>NaN</b> is displayed.	Does not work: warning is thrown. <hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown <hr/>
	char	MATLAB converts the entered number to a text string.	Values match. MATLAB displays the string as is.	Does not work: warning is thrown. <hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown <hr/>
	logical	Does not work: warning is thrown. <hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown <hr/>	If text string entered is <code>true</code> or <code>false</code> , MATLAB converts string to the corresponding logical value and displays it. For all others, it Does not work: warning is thrown.	Values match. MATLAB displays logical value as a check box as is.

# Uitable Properties

---

			<b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown	
--	--	--	-------------------------------------------------------------------------------------------------	--

If you get a mismatch error, you have the following options:

- Change the `ColumnFormat` or value of `Data` to match.
- Implement the `CellEditCallback` to handle custom data conversion.

## `ColumnName`

1-by-*n* cell array of strings | {'numbered'} | empty matrix ([])

*Column heading names.* Each element of the cell array is the name of a column. Multiline column names can be expressed as a string vector separated by vertical slash (|) characters, e.g., 'Standard|Deviation'

For sequentially numbered column headings starting with 1, specify `ColumnName` as 'numbered'. This is the default.

To remove the column headings, specify `ColumnName` as the empty matrix ([]).

The number of columns in the table is the larger of `ColumnName` and the number of columns in the `Data` property matrix or cell array.

## `ColumnWidth`

1-by-*n* cell array or 'auto'

*Column widths.* The width of each column in units of pixels. Column widths are always specified in pixels; they do not obey the `Units` property. Each column in the cell array corresponds to a column in the uitable. By default, the width of the column name, as specified in `ColumnName`, along with some other factors, is used to determine the width of a column. If `ColumnWidth` is a cell array and the width of a column is set to 'auto' or if **auto** is selected for that column in the Property Inspector GUI for columns, the column width defaults to a size determined by the table. The table decides the default size using a number of factors, including the `ColumnName` and the minimum column size.

To default all column widths in an existing table, use

```
set(uitable_handle, 'ColumnWidth', 'auto')
```

To default some column widths but not others, use a cell array containing a mixture of pixel values and 'auto'. For example,

```
set(uitable_handle, 'ColumnWidth', {64 'auto' 40 40 'auto' 72})
```

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uitable object. MATLAB sets all property values for the uitable before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the uitable being created.

Setting this property on an existing uitable object has no effect.

You can define a default `CreateFcn` callback for all new uitables. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitable`. For example, the code

```
set(0, 'DefaultUitableCreateFcn', 'set(gcb0, ...
```

# Uitable Properties

---

```
'BackgroundColor','blue')')
```

creates a default `CreateFcn` callback that runs whenever you create a new uitable. It sets the default background color of all new uitables.

To override this default and create a uitable whose `BackgroundColor` is set to a different value, call `uitable` with code similar to

```
hpt = uitable(...,'CreateFcn','set(gcbo,...  
'BackgroundColor','white')')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitable` call. In the example above, if instead of redefining the `CreateFcn` property for this uitable, you had explicitly set `BackgroundColor` to `white`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `blue`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Data

matrix or cell array of numeric, logical, or character data

*Data content of uitable.* The matrix or cell array must be 2–dimensional. A cell array can mix data types.

Use `get` and `set` to modify `Data`. For example,

```
data = get(tablehandle, 'Data')
data(event.indices(1), event.indices(2)) = pi();
set(tablehandle, 'Data', data);
```

See `CellEditCallback` for information about the event data structure. See `ColumnFormat` for information about specifying the data display format.

The number of rows in the table is the larger of `RowName` and the number of rows in `Data`. The number of columns in the table is the larger of `ColumnName` and the number of columns in `Data`.

## DeleteFcn

string or function handle

*Delete uitable callback routine.* A callback routine that executes when you delete the `uitable` object (e.g., when you issue a `delete` command or `clear` the figure containing the `uitable`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Enable

{on} | inactive | off

*Enable or disable the uitable.* This property determines how `uitables` respond to mouse button clicks, including which callback routines execute.

- `on` – The `uitable` is operational (the default).

# Uitable Properties

---

- `inactive` – The uitable is not operational, but looks the same as when `Enable` is on.
- `off` – The uitable is not operational and its image is grayed out.

When you left-click on a uitable whose `Enable` property is on, MATLAB performs these actions in this order:

- 1** Sets the figure's `SelectionType` property.
- 2** Executes the uitable's `CellSelectionCallback` routine (but only for table cells, not header cells). Row and column indices of the cells the user selects continuously update the `Indices` field in the `eventdata` passed to the callback.
- 3** Does not set the figure's `CurrentPoint` property and does not execute either the table's `ButtonDownFcn` or the figure's `WindowButtonDownFcn` callback.

When you left-click on a uitable whose `Enable` property is `off`, or when you right-click a uitable whose `Enable` property has any value, MATLAB performs these actions in this order:

- 1** Sets the figure's `SelectionType` property.
- 2** Sets the figure's `CurrentPoint` property.
- 3** Executes the figure's `WindowButtonDownFcn` callback.

## Extent

position rectangle (read only)

*Size of uitable rectangle.* A four-element vector of the form `[0,0,width,height]` that contains the calculated values of the largest extent of the table based on the current `Data`, `RowName` and `ColumnName` property values. Calculation depends on column and row widths, when they are available. The calculated extent can be larger than the figure.

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

When the uitable's `Units` property is set to `'Normalized'`, its `Extent` is measured relative to the figure, regardless of whether the table is contained in (parented to) a `uipanel` or not.

You can use this property to determine proper sizing for the uitable with respect to its content. Do this by setting the `width` and `height` of the uitable `Position` property to the width and height of the `Extent` property. However, doing this can cause the table to extend beyond the right or top edge of the figure and/or its `uipanel` parent, if any, for tables with large extents.

## FontAngle

`{normal} | italic | oblique`

*Character slant of cell content.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

## FontName

string

*Font family for cell content.* The name of the font in which to display cell content. To display and print properly, this must be a font that your system supports. The default font is system dependent.

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set `FontName` to the string `FixedWidth` (this string value is case sensitive):

```
set(uitable_handle, 'FontName', 'FixedWidth')
```

# Uitable Properties

---

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` and rely on the root `FixedWidthFontName` property to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

**FontSize**  
size in `FontUnits`

*Font size for cell contents.* A number specifying the size of the font in which to display cell contents, in units determined by the `FontUnits` property. The default point size is system dependent. If `FontUnits` is set to `normalized`, `FontSize` is a number between 0 and 1.

**FontUnits**  
{points} | normalized | inches |  
centimeters | pixels

*Font size units for cell contents.* This property determines the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the uitable. When you resize the uitable, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point =  $\frac{1}{72}$  inch).

**FontWeight**  
light | {normal} | demi | bold

*Weight of cell text characters.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to **bold** causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

1-by-3 matrix of RGB triples or a color name

*Color of text in cells.* Determines the color of the text defined for cell contents. Text in all cells share the current color. Specify as a 1-by-3 matrix of RGB triples, such as [0 0 .8] or as a color name. The default is a 1-by-3 matrix of platform-dependent colors. See `ColorSpec` for information about specifying RGB colors.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine

# Uitable Properties

---

invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* When `HitTest` is `off`, the `ButtonDownFcn` callback does not execute.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`

- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

# Uitable Properties

---

For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## `KeyPressFcn`

string or function handle

*Key press callback function.* A callback routine invoked by a key press when the callback’s uitable object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX and Microsoft Windows. If no uitable has focus, the figure’s key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a MATLAB function file, or any legal MATLAB expression.

If the specified value is the name of a function code file, the callback routine can query the figure’s `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

Event Data Structure Field	Description	Examples:			
		a	=	Shift	Shift/a
Character	Character interpretation of the key that was pressed.	'a'	'='	' '	'A'
Modifier	Current modifier, such as 'control', or an empty cell array if there is no modifier	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	Name of the key that was pressed.	'a'	'equal'	'shift'	'a'

The uitable `KeyPressFcn` callback executes for all keystrokes, including arrow keys or when a user edits cell content.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

**Parent**  
handle

*Uitable parent.* The handle of the uitable’s parent object. You can move a uitable object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

**Position**  
position rectangle

*Size and location of uitable.* The rectangle defined by this property specifies the size and location of the table within the parent figure window, ui, or uibuttongroup. Specify `Position` as a 4–element vector:

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the uitable object.

# Uitable Properties

---

width and height are the dimensions of the uitable rectangle. All measurements are in units specified by the Units property.

---

**Note** If you are specifying both Units and Position in the same call to uitable, specify Units first if you want Position to be interpreted using those units.

---

RearrangeableColumns  
on | {off}

*This object can be rearranged.* The RearrangeableColumns property provides a mechanism that you can use to reorder the columns in the table. All columns are rearrangeable when this property is turned on. MATLAB software sets the RearrangeableColumns property to off by default.

When this property is on, the user of a table can move any column of data (but not the row labels) at a time left or right to reorder it by clicking and dragging its header. Rearranging columns does not affect the ordering of columns in the table's Data, only the user's view of it.

RowName  
1-by-n cell array of strings | {'numbered'} | empty matrix ([])

*Row heading names.* Each element of the cell array is the name of a row. Row names are restricted to one line of text.

For sequentially numbered row headings starting with 1, specify RowName as 'numbered'. This is the default.

To remove the row headings, specify RowName as the empty matrix ( []).

The number of rows in the table is the larger of RowName and the number of rows in the Data property matrix or cell array.

## RowStripping

{on} | off

*Color striping of table rows.* When RowStripping is on, the background of consecutive rows of the table display in the pair of colors that the BackgroundColor color matrix specifies. The first color matrix row applies to odd-numbered rows, and the second to even-numbered rows. If the BackgroundColor matrix has only one row, it is applied to all rows (that is, no striping occurs).

When RowStripping is off, the first color specified for BackgroundColor is applied to all rows.

## Selected

on | {off}

*Is object selected.* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Object highlight when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string (GUIDE sets this property)

*User-specified object label.* The Tag property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as

# Uitable Properties

---

global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

**TooltipString**  
string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the uitable. When the user moves the mouse pointer over the table and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitable;  
s = sprintf('UITable tooltip line 1\nUITable tooltip line 2');  
set(h,'TooltipString',s)
```

**Type**  
string (read only)

*Class of graphics object.* For uitable objects, `Type` is always the string `'uitable'`.

**UIContextMenu**  
handle

*Associate a context menu with uitable.* Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the uitable. Use the `uicontextmenu` function to create the context menu.

**Units**  
{pixels} | normalized | inches | centimeters | points | characters (GUIDE default: normalized)

*Units of measurement.* MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- Normalized units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter `x`, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

## `UserData`

matrix

*User-specified data.* Any data you want to associate with the uitable object. MATLAB does not use this data, but you can access it using `set` and `get`.

## `Visible`

{on} | off

*Uitable visibility.* By default, all uitables are visible. When set to `off`, the uitable is not visible, but still exists and you can query and set its properties.

---

**Note** Setting `Visible` to `off` for uitables that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

# uitoggletool

---

**Purpose** Create toggle button on toolbar

**Syntax**

```
htt = uitoggletool
htt = uitoggletool('PropertyName1',value1,'PropertyName2',
    value2,...)
htt = uitoggletool(ht,...)
```

**Description** `htt = uitoggletool` creates a toggle button on the `uitoolbar` at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no `uitoolbar` exists, one is created. The `uitoolbar` is the parent of the `uitoggletool`. Use the returned handle `htt` to set properties of the `uitoggletool`. The `OnCallback`, `OffCallback` and `ClickedCallback` use the handle as their first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting `CData` for the tool. Type `get(htt)` to see a list of `uitoggletool` object properties and their current values. Type `set(htt)` to see a list of `uitoggletool` object properties you can set and legal property values.

`htt = uitoggletool('PropertyName1',value1,'PropertyName2',value2,...)` assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the `set` function. You can specify properties as parameter name/value pairs, cell arrays containing parameter names and values, or structures with fields containing parameter names and values as input arguments. For a complete list, see `Uitoggletool Properties`. Type `get(htt)` to see a list of `uipushtool` object properties and their current values. Type `set(htt)` to see a list of `uipushtool` object properties that you can set and their legal property values.

`htt = uitoggletool(ht,...)` creates a button with `ht` as a parent. `ht` must be a `uitoolbar` handle.

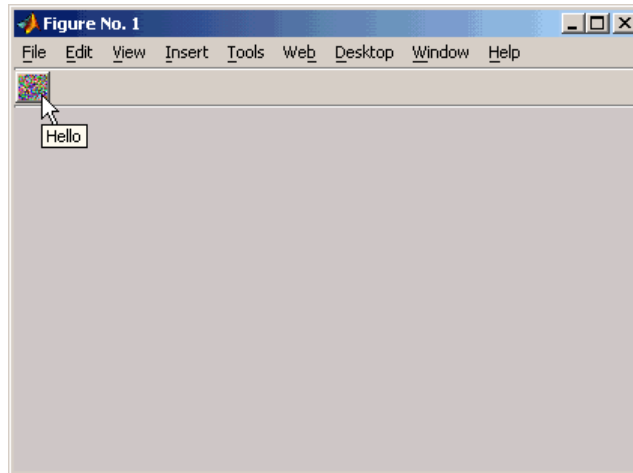

Toggle tools appear in figures whose `Window Style` is `normal` or `docked`. They do not appear in figures with a `'modal'` `WindowStyle`. If the `WindowStyle` property of a figure containing a tool bar and its toggle tool children changes to `modal`, the toggle tools continue to exist

as Children of the tool bar. The toggle tools do not display until you change the `WindowState` to normal or docked.

## Examples

Create a `uitoolbar` object and places a `uitoggletool` object on it by specifying the toolbar handle as the toggle tool parent. Generate a random set of colors for the tool icon and specify a tool tip.

```
h = figure('ToolBar','none');
ht = uitoolbar(h);
a = rand(16,16,3);
htt = uitoggletool(ht,'CData',a,'TooltipString','Hello');
```

## Alternatives

You can create toolbars with toggle tools using GUIDE.

# Uitoggletool Properties property

---

## Purpose

Describe toggle tool properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoggletool properties by typing:

```
set(h, 'DefaultUitoggletoolPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, a uitoolbar handle, or a uitoggletool handle. *PropertyName* is the name of the Uitoggletool property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see “Setting Default Property Values”.

## Properties

This section lists all properties useful to uitoggletool objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
BeingDeleted	This object is being deleted.
BusyAction	Callback routine interruption.
CData	Truecolor image displayed on the toggle tool.
ClickedCallback	Control action independent of the toggle tool position.

# Uitoggletool Properties property

Property	Purpose
CreateFcn	Callback routine executed during object creation.
DeleteFcn	Callback routine executed during object deletion.
Enable	Enable or disable the uitoggletool.
HandleVisibility	Control access to object's handle.
HitTest	Whether selectable by mouse click
Interruptible	Callback routine interruption mode.
OffCallback	Control action when toggle tool is set to the off position.
OnCallback	Control action when toggle tool is set to the on position.
Parent	Handle of uitoggletool's parent toolbar.
Separator	Separator line mode.
State	Uitoggletool state.
Tag	User-specified object label.
TooltipString	Content of object's tooltip.
Type	Object class.
UicontextMenu	Uicontextmenu object associated with the uitoggletool
UserData	User specified data.
Visible	Uitoggletool visibility.

**BeingDeleted**  
on | {off} (read only)

*This object is being deleted.* The **BeingDeleted** property provides a mechanism that you can use to determine if objects are

# Uitoggletool Properties property

---

in the process of being deleted. MATLAB software sets the `BeingDeleted` property to on when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## CData

3-dimensional array

*Truecolor image displayed on control as its icon.* An  $n$ -by- $m$ -by-3 array of RGB values that defines a truecolor image displayed

# Uitoggletool Properties property

---

on either a push button or toggle button. Each value must be between 0.0 and 1.0. If your CData array is larger than 16 in the first or second dimension, it can be clipped or result in other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

## ClickedCallback

string or function handle

*Control action independent of the toggle tool position.* A routine that executes after either the OnCallback routine or OffCallback routine runs to completion. The uitoggletool Enable property must be set to on.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uitoggletool object. MATLAB sets all property values for the uitoggletool before executing the CreateFcn callback so these values are available to the callback. Within the function, use gcbo to get the handle of the toggle tool being created.

Setting this property on an existing uitoggletool object has no effect.

You can define a default CreateFcn callback for all new uitoggletools. This default applies unless you override it by specifying a different CreateFcn callback when you call uitoggletool. For example, the statement,

```
set(0, 'DefaultUitoggletoolCreateFcn', ...  
    'set(gcbo, 'Enable', 'off')')
```

creates a default CreateFcn callback that runs whenever you create a new toggle tool. It sets the toggle tool Enable property to off.

# Uitoggletool Properties property

---

To override this default and create a toggle tool whose `Enable` property is set to `on`, you could call `uitoggletool` with code similar to

```
htt = uitoggletool(...,'CreateFcn',...  
                        'set(gcbo,'Enable','on')',...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitoggletool` call. In the example above, if instead of redefining the `CreateFcn` property for this toggle tool, you had explicitly set `Enable` to `on`, the default `CreateFcn` callback would have set `CData` back to `off`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

`DeleteFcn`  
string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uitoggletool` object (e.g., when you call the `delete` function or cause the figure containing the `uitoggletool` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

# Uitoggletool Properties property

---

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

## Enable

{on} | off

*Enable or disable the uitoggletool.* This property controls how uitoggletools respond to mouse button clicks, including which callback routines execute.

- **on** – The uitoggletool is operational (the default).
- **off** – The uitoggletool is not operational and its icon (set by the `Cdata` property) is grayed out.

When you left-click on a uitoggletool whose `Enable` property is `on`, MATLAB performs these actions in this order:

- 1** Executes the toggle tool `OnCallback` or `OffCallback` routine, depending on its current state, and its `ClickedCallback` routine.
- 2** Does *not* set the figure `CurrentPoint` property and does *not* execute the figure's `WindowButtonDownFcn` callback.
- 3** Does *not* set the figure `SelectionType` property.

When you left-click a uitoggletool whose `Enable` property is `off`, or when you right-click a uitoggletool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

## HandleVisibility

{on} | callback | off

# Uitoggletool Properties property

---

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is on.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on `uitoggletool` objects.

`Interruptible`  
`off | {on}`

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Uitoggletool Properties property

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to on (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

`OffCallback`  
string or function handle

# Uitoggletool Properties property

---

*Control action.* A routine that executes if the uitoggletool's Enable property is set to on, and either

- The toggle tool State is set to off.
- The toggle tool is set to the off position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

The ClickedCallback routine, if there is one, runs after the OffCallback routine runs to completion.

## OnCallback

string or function handle

*Control action.* A routine that executes if the uitoggletool's Enable property is set to on, and either

- The toggle tool State is set to on.
- The toggle tool is set to the on position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

The ClickedCallback routine, if there is one, runs after the OffCallback routine runs to completion.

## Parent

handle

*Uitoggletool parent.* The handle of the uitoggletool's parent toolbar. You can move a uitoggletool object to another toolbar by setting this property to the handle of the new parent.

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line to left of the uitoggletool.

# Uitoggletool Properties property

---

## State

on | {off}

*Uitoggletool state.* When the state is on, the toggle tool appears in the down, or pressed, position. When the state is off, it appears in the up position. Changing the state causes the appropriate `OnCallback` or `OffCallback` routine to run.

## Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the `Tag` value 'Bold'.

```
h = findobj(uitoolbarhandles, 'Tag', 'Bold')
```

## TooltipString

string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the `uitoggletool`. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitoggletool;  
s = sprintf('Toggletool tooltip line 1\nToggletool tooltip line 2');  
set(h, 'TooltipString', s)
```

# Uitoggletool Properties property

---

## Type

string (read-only)

Object class. This property identifies the kind of graphics object. For uitoggletool objects, Type is always the string 'uitoggletool'.

## UIContextMenu

handle

*Associate a context menu with uicontrol.* This property has no effect on uitoggletool objects.

## UserData

array

*User specified data.* You can specify UserData as any array you want to associate with the uitoggletool object. The object does not use this data, but you can access it using the set and get functions.

## Visible

{on} | off

*Uitoggletool visibility.* By default, all uitoggletools are visible. When set to off, the uitoggletool is not visible, but still exists and you can query and set its properties.

# uitoolbar

---

**Purpose** Create toolbar on figure

**Syntax**

```
ht =  
uitoolbar('PropertyName1',value1,'PropertyName2',value2,  
    ...)  
ht = uitoolbar(h,...)
```

**Description**

ht = uitoolbar('PropertyName1',value1,'PropertyName2',value2, ...) creates an empty toolbar at the top of the current figure window, and returns a handle to it. uitoolbar assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the set function.

Type get(ht) to see a list of uitoolbar object properties and their current values. Type set(ht) to see a list of uitoolbar object properties that you can set and legal property values. See the Uitoolbar Properties reference page for more information.

ht = uitoolbar(h,...) creates a toolbar with h as a parent. h must be a figure handle.

**Tips** uitoolbar accepts property name/property value pairs, as well as structures and cell arrays of properties as input arguments.

Uitoolbars appear in figures whose Window Style is normal or docked. They do not appear in figures whose WindowStyle is modal. If the WindowStyle property of a figure containing a uitoolbar is changed to modal, the uitoolbar still exists and is contained in the Children list of the figure, but is not displayed until the WindowStyle is changed to normal or docked.

**Examples** This example creates a figure with no toolbar, then adds a toolbar to it.

```
h = figure('ToolBar','none')  
ht = uitoolbar(h)
```

# Uitoolbar Properties

---

## Purpose

Describe toolbar properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoolbar properties by typing:

```
set(h, 'DefaultUitoolbarPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uitoolbar handle. *PropertyName* is the name of the Uitoolbar property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see Setting Default Property Values.

## Uitoolbar Properties

This section lists all properties useful to uitoolbar objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
BeingDeleted	This object is being deleted.
BusyAction	Callback routine interruption.
Children	Handles of uitoolbar's children.
CreateFcn	Callback routine executed during object creation.
DeleteFcn	Callback routine executed during object deletion.
HandleVisibility	Control access to object's handle.

Property	Purpose
HitTest	Whether selectable by mouse click
Interruptible	Callback routine interruption mode.
Parent	Handle of uitoolbar's parent.
Tag	User-specified object identifier.
Type	Object class.
UicontextMenu	Uicontextmenu object associated with the uitoolbar
UserData	User specified data.
Visible	Uitoolbar visibility.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to on when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

# Uitoolbar Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## Children

vector of handles

*Handles of tools on the toolbar.* A vector containing the handles of all children of the `uitoolbar` object, in the order in which they appear on the toolbar. The children objects of `uitoolbars` are `uipushtools` and `uitoggletools`. You can use this property to reorder the children.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uitoolbar` object. MATLAB sets all property values for the `uitoolbar` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the toolbar being created.

Setting this property on an existing `uitoolbar` object has no effect.

You can define a default `CreateFcn` callback for all new uitoolbars. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitoolbar`. For example, the statement,

```
set(0, 'DefaultUitoolbarCreateFcn', ...  
    'set(gcbo, 'Visibility', 'off')')
```

creates a default `CreateFcn` callback that runs whenever you create a new toolbar. It sets the toolbar visibility to `off`.

To override this default and create a toolbar whose `Visibility` property is set to `on`, you could call `uitoolbar` with a call similar to

```
ht = uitoolbar(..., 'CreateFcn', ...  
    'set(gcbo, 'Visibility', 'on')', ...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitoolbar` call. In the example above, if instead of redefining the `CreateFcn` property for this toolbar, you had explicitly set `Visibility` to `on`, the default `CreateFcn` callback would have set `Visibility` back to `off`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

# Uitoolbar Properties

---

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback function that executes when the uitoolbar object is deleted (e.g., when you call the `delete` function or cause the figure containing the uitoolbar to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

Within the function, use `gcbo` to get the handle of the toolbar being deleted.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI

(such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on uitoolbar objects.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

# Uitoolbar Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

Parent

handle

*Uitoolbar parent.* The handle of the uitoolbar’s parent figure. You can move a uitoolbar object to another figure by setting this property to the handle of the new parent.

Tag

string

*User-specified object identifier.* The Tag property provides a means to identify graphics objects with a user-specified label. You can define Tag as any string.

With the `findobj` function, you can locate an object with a given Tag property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the Tag value 'FormatTb'.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

Type

string (read-only)

# Uitoolbar Properties

---

Object class. This property identifies the kind of graphics object. For uitoolbar objects, Type is always the string 'uitoolbar'.

UIContextMenu  
handle

*Associate a context menu with uicontrol.* This property has no effect on uitoolbar objects.

UserData  
array

*User specified data.* You can specify UserData as any array you want to associate with the uitoolbar object. The object does not use this data, but you can access it using the `set` and `get` functions.

Visible  
{on} | off

*Uitoolbar visibility.* By default, all uitoolbars are visible. When set to `off`, the uitoolbar is not visible, but still exists and you can query and set its properties.

---

<b>Purpose</b>	Block program execution and wait to resume
<b>Syntax</b>	<pre>uiwait uiwait(h) uiwait(h,timeout)</pre>
<b>Description</b>	<p><code>uiwait</code> blocks execution until <code>uiresume</code> is called or the current figure is deleted. This syntax is the same as <code>uiwait(gcf)</code>.</p> <p><code>uiwait(h)</code> blocks execution until <code>uiresume</code> is called or the figure <code>h</code> is deleted.</p> <p><code>uiwait(h,timeout)</code> blocks execution until <code>uiresume</code> is called, the figure <code>h</code> is deleted, or <code>timeout</code> seconds elapse. The minimum value of <code>timeout</code> is 1. If <code>uiwait</code> receives a smaller value, it issues a warning and uses a 1 second <code>timeout</code>.</p>
<b>Tips</b>	<p>The <code>uiwait</code> and <code>uiresume</code> functions block and resume MATLAB and Simulink program execution. <code>uiwait</code> also blocks the execution of Simulink models. The functions <code>pause</code> (with no argument) and <code>waitfor</code> also block execution in this manner. <code>uiwait</code> is a convenient way to use the <code>waitfor</code> command. You typically use it in conjunction with a dialog box. It provides a way to block the execution of the MATLAB program that created the dialog, until the user responds to the dialog box. When used in conjunction with a modal dialog, <code>uiwait</code> can block the execution of the program file <i>and</i> restrict user interaction to the dialog only.</p>
<b>Examples</b>	<p>This example creates a GUI with a <b>Continue</b> push button. The example calls <code>uiwait</code> to block MATLAB execution until <code>uiresume</code> is called. This happens when the user clicks the <b>Continue</b> push button because the push button's <code>Callback</code>, which responds to the click, calls <code>uiresume</code>.</p> <pre>f = figure; h = uicontrol('Position',[20 20 200 40],'String','Continue',...              'Callback','uiresume(gcf)'); disp('This will print immediately'); uiwait(gcf);</pre>

# uiwait

---

```
disp('This will print after you click Continue');  
close(f);
```

gcbf is the handle of the figure that contains the object whose callback is executing.

**Purpose**           Unary minus

**Syntax**            C = -A  
C = uminus(A)

**Description**      C = -A negates the elements of A and stores the result in C.

C = uminus(A) is an alternative way to execute -A, but is rarely used. It enables operator overloading for classes.

**Input Arguments**   **A - Input array**  
scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**  
single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char  
**Complex Number Support:** Yes

**Examples**           **Negate Elements of Matrix**

Create a 2-by-2 matrix, A.

```
A = [1 -3; -2 4]
```

```
A =
```

```
     1     -3
    -2     4
```

Negate the elements of A.

```
C = -A
```

```
C =
```

# uminus, -

---

```
-1  3
 2 -4
```

<b>Purpose</b>	Undo previous checkout from source control system (UNIX platforms)
<b>Syntax</b>	<pre>undocheckout('filename') undocheckout({'filename1','filename2', ..., 'filenamen'})</pre>
<b>Description</b>	<p><code>undocheckout('filename')</code> makes the file <code>filename</code> available for checkout, where <code>filename</code> does not reflect any of the changes you made after you last checked it out. Use the full path for <code>filename</code> and include the file extension.</p> <p><code>undocheckout({'filename1','filename2', ..., 'filenamen'})</code> makes <code>filename1</code> through <code>filenamen</code> available for checkout, where the files do not reflect any of the changes you made after you last checked them out. Use the full paths for the file names and include the file extensions.</p>
<b>Examples</b>	<p>Undo the checkouts of <code>/myserver/myfiles/clock.m</code> and <code>/myserver/myfiles/calendar.m</code> from the source control system:</p> <pre>undocheckout({'/myserver/myfiles/clock.m', ... '/myserver/myfiles/calendar.m'})</pre>
<b>See Also</b>	<code>checkin</code>   <code>checkout</code>   <code>verctrl</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Undo the Checkout (UNIX Platforms)”</li></ul>

# unicode2native

---

**Purpose** Convert Unicode character representation to numeric bytes

**Syntax**  
`bytes = unicode2native(unicodestr)`  
`bytes = unicode2native(unicodestr,encoding)`

**Description** `bytes = unicode2native(unicodestr)` converts a char vector of Unicode character representations, `unicodestr`, to the user default encoding, and returns the bytes as a `uint8` vector, `bytes`. Output vector `bytes` has the same general array shape as the `unicodestr` input. You can save the output of `unicode2native` to a file using the `fwrite` function.

`bytes = unicode2native(unicodestr,encoding)` converts `unicodestr` to the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string ('') or a name or alias for an encoding scheme. Some examples are 'UTF-8', 'latin1', 'US-ASCII', and 'Shift\_JIS'. If `encoding` is unspecified or is the empty string (''), the default encoding scheme is used.

**Examples** This example begins with two strings containing Unicode character representations. It assumes that string `str1` contains text in a Western European language and string `str2` contains Japanese text. The example writes both strings into the same file, using the ISO-8859-1 character encoding scheme for the first string and the Shift-JIS encoding scheme for the second string. The example uses `unicode2native` to convert the two strings to the appropriate encoding schemes.

```
fid = fopen('mixed.txt', 'w');
bytes1 = unicode2native(str1, 'ISO-8859-1');
fwrite(fid, bytes1, 'uint8');
bytes2 = unicode2native(str2, 'Shift_JIS');
fwrite(fid, bytes2, 'uint8');
fclose(fid);
```

**See Also** `native2unicode`

**Purpose**

Set union of two arrays

**Syntax**

```
C = union(A,B)
C = union(A,B, 'rows')
[C,ia,ib] = union(A,B)
[C,ia,ib] = union(A,B, 'rows')

[C,ia,ib] = union( __ ,setOrder)

[C,ia,ib] = union(A,B, 'legacy')

[C,ia,ib] = union(A,B, 'rows', 'legacy')
```

**Description**

`C = union(A,B)` returns the combined data from A and B with no repetitions.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `union` returns the combined values from A and B. The values of C are in sorted order.
- If A and B are tables, then `union` returns the combined set of rows from both tables. The rows of table C are in sorted order.

`C = union(A,B, 'rows')` treats each row of A and each row of B as single entities and returns the combined rows from A and B with no repetitions. The rows of C are in sorted order.

The 'rows' option does not support cell arrays.

`[C,ia,ib] = union(A,B)` also returns index vectors `ia` and `ib`.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then the values in C are a sorted combination of the values of A(`ia`) and B(`ib`).
- If A and B are tables, then C is a sorted combination of the rows of A(`ia,:`) and B(`ib,:`).

# union

---

`[C,ia,ib] = union(A,B,'rows')` also returns index vectors `ia` and `ib`, such that the rows of `C` are a sorted combination of the rows of `A(ia,:)` and `B(ib,:)`.

`[C,ia,ib] = union(___,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`, and then `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = union(A,B,'legacy')` and `[C,ia,ib] = union(A,B,'rows','legacy')` preserve the behavior of the `union` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

## Input Arguments

### A,B - Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays  
| cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, cell arrays of strings, or tables.

`A` and `B` must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of `C` are the sorted union of the categories from `A` and `B`.

If you specify the 'rows' option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, A and B can be objects with the following class methods:

- sort (or sortrows for the 'rows' option)
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### setOrder - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: C = union([5 5 3],[1 2],'sorted') returns C = [1 2 3 5].
'stable'	The values (or rows) in C return in the same order as they appear in A and B. For example: C = union([5 5 3],[1 2],'stable') returns C = [5 3 1 2].

## Output Arguments

### C - Combined data of A and B

vector | matrix | table

Combined data of A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of **C** when the inputs are vector or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then **C** is a column vector unless both **A** and **B** are row vectors.
- If the 'rows' flag is not specified and both **A** and **B** are row vectors, then **C** is a row vector.
- If the 'rows' flag is specified, then **C** is a matrix containing the combined rows of **A** and **B**.

The class of the inputs **A** and **B** determines the class of **C**:

- If the class of **A** and **B** are the same, then **C** is the same class.
- If you combine a `char` or `nondouble` numeric class with `double`, then **C** is the same class as the `nondouble` input.
- If you combine a `logical` class with `double`, then **C** is `double`.
- If you combine a cell array of strings with `char`, then **C** is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then **C** is a categorical array.

## **ia - Index to A**

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** indicates the values (or rows) in **A** that contribute to the union. If a value (or row) appears multiple times in **A**, then **ia** contains the index to the first occurrence of the value (or row). If a value appears in both **A** and **B**, then **ia** contains the index to the first occurrence in **A**.

## **ib - Index to B**

column vector

Index to **B**, returned as a column vector when the 'legacy' flag is not specified. **ib** indicates the values (or rows) in **B** that contribute to the union. If there is a repeated value (or row) appearing exclusively in **B**,

then `ib` contains the index to the first occurrence of the value. If a value (or row) appears in both A and B, then `ib` does not contain an index to the value (or row).

## Examples

### Union of Two Vectors

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors A and B.

```
C = union(A,B)
```

```
C =
```

```
     1     3     5     7
```

### Union of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false
4	D	true
5	E	false

```
B =
```

Var1	Var2	Var3
------	------	------

# union

---

```
-----  
1      A      false  
3      C      false  
5      E      false  
7      G      false  
9      I      false
```

Find the union of tables A and B.

```
C = union(A,B)
```

```
C =
```

```
Var1    Var2    Var3  
-----  
1      A      false  
2      B      true  
3      C      false  
4      D      true  
5      E      false  
7      G      false  
9      I      false
```

## Union of Two Vectors and Their Indices

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors A and B, as well as the index vectors, ia and ib.

```
[C,ia,ib] = union(A,B)
```

```
C =
```

```
1      3      5      7
```

```
ia =
```

```
  3
  1
  2
```

```
ib =
```

```
  1
```

The values in C are the combined values of A(ia) and B(ib).

### Union of Two Tables and Their Indices

Define a table, A, of gender, age, and height for three people.

```
A = table(['M';'M';'F'],[27;52;31],[74;68;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty'})
```

```
A =
```

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Fred	M	52	68
Betty	F	31	64

Define a table, B with the same variables as A.

```
B = table(['F';'M'],[64;68],[31;47],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe'})
```

```
B =
```

	Gender	Height	Age
--	--------	--------	-----

# union

---

Meg	F	64	31
Joe	M	68	47

Find the union of tables A and B, as well as the index vectors, `ia` and `ib`.

```
[C,ia,ib] = union(A,B)
```

C =

	Gender	Age	Height
Betty	F	31	64
Ted	M	27	74
Joe	M	47	68
Fred	M	52	68

ia =

```
3  
1  
2
```

ib =

```
2
```

The data for `Meg` and `Betty` are the same. `union` only returns the index from A, which corresponds to `Betty`.

## Union of Rows in Two Matrices

Define two matrices with a row in common.

```
A = [2 2 2; 0 0 1];  
B = [1 2 3; 2 2 2; 2 2 2];
```

Find the combined rows of A and B, with no repetition, as well as the index vectors ia and ib.

```
[C,ia,ib] = union(A,B,'rows')
```

```
C =
```

```
     0     0     1
     1     2     3
     2     2     2
```

```
ia =
```

```
     2
     1
```

```
ib =
```

```
     1
```

The rows of C are the combined rows of A(ia,:) and B(ib,).

### **Union of Two Vectors with Specified Output Order**

Use the setOrder argument to specify the ordering of the values in C.

Specify 'stable' if you want the values in C to have the same order as in A and B.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'stable')
```

```
C =
```

```
     5     7     1     3
```

# union

---

```
ia =
```

```
1  
2  
3
```

```
ib =
```

```
1
```

Alternatively, you can specify 'sorted' order.

```
A = [5 7 1]; B = [3 1 1];  
[C,ia,ib] = union(A,B,'sorted')
```

```
C =
```

```
1 3 5 7
```

```
ia =
```

```
3  
1  
2
```

```
ib =
```

```
1
```

## Union of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN 1]; B = [4 NaN NaN];
```

Find the union of vectors A and B.

```
C = union(A,B)
```

```
C =
```

```
     1     4     5  NaN  NaN  NaN
```

union treats NaN values as distinct.

### Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Combine the elements of A and B.

```
[C,ia,ib] = union(A,B)
```

```
C =
```

```
     'cat'     'dog'     'dog '     'fish'     'fish '     'horse'
```

```
ia =
```

```
     2
     1
     3
     4
```

```
ib =
```

```
     1
```

3

union treats trailing white space in cell arrays of strings as distinct characters.

## **Union of Vectors of Different Classes and Shapes**

Create a column vector character array.

```
A = ['A'; 'B'; 'C'], class(A)
```

```
A =
```

```
A
```

```
B
```

```
C
```

```
ans =
```

```
char
```

Create a row vector containing elements of numeric type double.

```
B = [68 69 70], class(B)
```

```
B =
```

```
68    69    70
```

```
ans =
```

```
double
```

The union of A and B returns a column vector character array.

```
C = union(A,B), class(C)
```

```
C =
```

```
A
```

```
B
```

```
C
```

```
D
```

```
E
```

```
F
```

```
ans =
```

```
char
```

### **Union of Char and Cell Array of Strings**

Create a character array containing the letters a , b, and c.

```
A = ['a'; 'b'; 'c'];  
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings containing the letters c, d, and e.

```
B = {'c', 'd', 'e'};  
class(B)
```

```
ans =
```

```
cell
```

# union

---

Combine the elements of A and B.

```
C = union(A,B)
```

```
C =
```

```
    'a'  
    'b'  
    'c'  
    'd'  
    'e'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

## Preserve Legacy Behavior of union

Use the 'legacy' flag to preserve the behavior of union from R2012b and prior releases in your code.

Find the union of A and B with the current behavior.

```
A = [5 7 1]; B = [3 1 1];  
[C1,ia1,ib1] = union(A,B)
```

```
C1 =
```

```
    1    3    5    7
```

```
ia1 =
```

```
    3
```

```

    1
    2

```

```

ib1 =
    1

```

Find the union of A and B, and preserve the legacy behavior.

```

A = [5 7 1]; B = [3 1 1];
[C2,ia2,ib2] = union(A,B,'legacy')

```

```

C2 =
    1     3     5     7

```

```

ia2 =
    1     2

```

```

ib2 =
    3     1

```

## Tips

- To find the union with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `union(A(:,vars),B(:,vars))`, where `vars` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

## See Also

`unique` | `intersect` | `ismember` | `issorted` | `setdiff` | `setxor` | `sort`

## Concepts

- “Combine Categorical Arrays”

# unique

---

**Purpose** Unique values in array

**Syntax**

```
C = unique(A)
C = unique(A,'rows')
[C,ia,ic] = unique(A)
[C,ia,ic] = unique(A,'rows')

[C,ia,ic] = unique(A,setOrder)

[C,ia,ic] = unique(A,'rows',setOrder)

[C,ia,ic] = unique(A,'legacy')

[C,ia,ic] = unique(A,'rows','legacy')

[C,ia,ic] = unique(A,occurrence,'legacy')

[C,ia,ic] = unique(A,'rows',occurrence,'legacy')
```

**Description**

`C = unique(A)` returns the same data as in `A`, but with no repetitions.

- If `A` is a numeric array, logical array, character array, categorical array, or a cell array of strings, then `unique` returns the unique values in `A`. The values of `C` are in sorted order.
- If `A` is a table, then `unique` returns the unique rows in `A`. The rows of table `C` are in sorted order.

`C = unique(A,'rows')` treats each row of `A` as a single entity and returns the unique rows of `A`. The rows of the array `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic`.

- If `A` is a numeric array, logical array, character array, categorical array, or a cell array of strings, then `C = A(ia)` and `A = C(ic)`.

- If  $A$  is a table, then  $C = A(ia,:)$  and  $A = C(ic,:)$ .

`[C,ia,ic] = unique(A,'rows')` also returns index vectors `ia` and `ic`, such that  $C = A(ia,:)$  and  $A = C(ic,:)$ .

`[C,ia,ic] = unique(A,setOrder)` and `[C,ia,ic] = unique(A,'rows',setOrder)` return  $C$  in a specific order. `setOrder='sorted'` returns the values (or rows) of  $C$  in sorted order. `setOrder='stable'` returns the values (or rows) of  $C$  in the same order as  $A$ . If no value is specified, the default is 'sorted'.

`[C,ia,ic] = unique(A,'legacy')`, `[C,ia,ic] = unique(A,'rows','legacy')`, `[C,ia,ic] = unique(A,occurrence,'legacy')`, and `[C,ia,ic] = unique(A,'rows',occurrence,'legacy')` preserve the behavior of the `unique` function from R2012b and prior releases.

The 'legacy' option does not support categorical arrays or tables.

## Input Arguments

### A - Input array

numeric array | logical array | character array | categorical array | cell array of strings | table

Input array, specified as a numeric array, logical array, character array, categorical array, cell array of strings, or table.

If  $A$  is a table, `unique` does not take row names into account. Two rows that have the same values, but different names, are considered equal.

Furthermore,  $A$  can be an object with the following class methods:

- `sort` (or `sortrows` for the 'rows' option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### setOrder - Order flag

# unique

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: C = unique([5 5 3 4], 'sorted') returns C = [3 4 5].
'stable'	The values (or rows) in C return in the same order as in A. For example: C = unique([5 5 3 4], 'stable') returns C = [5 3 4].

## occurrence - Occurrence flag for legacy behavior

'last' (default) | 'first'

Occurrence flag for legacy behavior, specified as 'first' or 'last', indicates whether ia should contain the first or last indices to repeated values found in A.

Occurrence Flag	Meaning
'last'	If there are repeated values (or rows) in A, then ia contains the index to the last occurrence of the repeated value. For example: [C,ia,ic] = unique([9 9 9], 'last', 'legacy') returns ia = 3.
'first'	If there are repeated values (or rows) in A, then ia contains the index to the first occurrence of the repeated value. For example: [C,ia,ic] = unique([9 9 9], 'first', 'legacy') returns ia = 1.

## Output Arguments

### **C** - Unique data of A

vector | matrix | table

Unique data of A, returned as a vector, matrix, or table. The following describes the shape of C when the input, A, is a vector or a matrix:

- If the 'rows' flag is not specified and A is a row vector, then C is a row vector.
- If the 'rows' flag is not specified and A is not a row vector, then C is a column vector.
- If the 'rows' flag is specified, then C is a matrix containing the unique rows of A.

The class of C is the same as the class of the input A.

### **ia** - Index to A

column vector

Index to A, returned as a column vector of indices to the first occurrence of repeated elements. When the 'legacy' flag is specified, ia is a row vector that contains indices to the last occurrence of repeated elements.

The indices satisfy  $C = A(ia)$  (or  $C = A(ia, :)$  for the 'rows' option).

### **ic** - Index to C

column vector

Index to C, returned as a column vector when the 'legacy' flag is not specified. ic contains indices, such that  $A = C(ic)$  (or  $A = C(ic, :)$  for the 'rows' option).

## Examples

### Unique Values in Vector

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of A.

# unique

---

```
C = unique(A)
```

```
C =
```

```
     2     5     9
```

## Unique Rows in Table

Define a table with repeated data.

```
Name = {'Fred'; 'Betty'; 'Bob'; 'George'; 'Jane'};
```

```
Age = [38; 43; 38; 40; 38];
```

```
Height = [71; 69; 64; 67; 64];
```

```
Weight = [176; 163; 131; 185; 131];
```

```
A = table(Age, Height, Weight, 'RowNames', Name)
```

```
A =
```

	Age	Height	Weight
	---	-----	-----
Fred	38	71	176
Betty	43	69	163
Bob	38	64	131
George	40	67	185
Jane	38	64	131

Find the unique rows of A.

```
C = unique(A)
```

```
C =
```

	Age	Height	Weight
	---	-----	-----
Bob	38	64	131
Fred	38	71	176
George	40	67	185
Betty	43	69	163

`unique` returns the rows of `A` in sorted order by the first variable, `Age` and then by the second variable, `Height`.

### Unique Values and Their Indices

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of `A` and the index vectors `ia` and `ic`, such that `C = A(ia)` and `A = C(ic)`.

```
[C, ia, ic] = unique(A)
```

```
C =
```

```
     2     5     9
```

```
ia =
```

```
     2
     4
     1
```

```
ic =
```

```
     3
     1
     3
     2
```

### Unique Rows in Matrix

Define a matrix with a repeated row.

```
A = [9 2 9 5; 9 2 9 0; 9 2 9 5];
```

# unique

---

Find the unique rows of A and the index vectors `ia` and `ic`, such that `C = A(ia,:)` and `A = C(ic,:)`.

```
[C, ia, ic] = unique(A, 'rows')
```

```
C =
```

```
     9     2     9     0
     9     2     9     5
```

```
ia =
```

```
     2
     1
```

```
ic =
```

```
     2
     1
     2
```

Notice that the second row in A is identified as unique even though the elements 9, 2, and 9 are repeated in the other rows.

## Unique Values in Vector with Specified Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as in A.

```
A = [9 2 9 5];
[C, ia, ic] = unique(A, 'stable')
```

```
C =
```

```
     9     2     5
```

```
ia =
```

```
1  
2  
4
```

```
ic =
```

```
1  
2  
1  
3
```

Alternatively, you can specify 'sorted' order.

```
[C, ia, ic] = unique(A, 'sorted')
```

```
C =
```

```
2    5    9
```

```
ia =
```

```
2  
4  
1
```

```
ic =
```

```
3  
1  
3
```

2

## Unique Values in Array Containing NaNs

Define a vector containing NaN.

```
A = [5 5 NaN NaN];
```

Find the unique values of A.

```
C = unique(A)
```

```
C =
```

```
5 NaN NaN
```

unique treats NaN values as distinct.

## Unique Entries in Cell Array of Strings

Define a cell array of strings.

```
A = {'one', 'two', 'twenty-two', 'One', 'two'};
```

Find the unique strings contained in A.

```
C = unique(A)
```

```
C =
```

```
'One' 'one' 'twenty-two' 'two'
```

## Cell Array of Strings with Trailing White Space

Define a cell array of strings, A, where some of the strings have trailing white space.

```
A = {'dog', 'cat', 'fish', 'horse', 'dog ', 'fish '};
```

Find the unique strings contained in A.

```
C = unique(A)
```

```
C =
```

```
    'cat'    'dog'    'dog '    'fish'    'fish '    'horse'
```

unique treats trailing white space in cell arrays of strings as distinct characters.

### Preserve Legacy Behavior of unique

Use the 'legacy' flag to preserve the behavior of unique from R2012b and prior releases in your code.

Find the unique elements of A with the current behavior.

```
A = [9 2 9 5];
```

```
[C1, ia1, ic1] = unique(A)
```

```
C1 =
```

```
    2    5    9
```

```
ia1 =
```

```
    2
    4
    1
```

```
ic1 =
```

```
    3
    1
    3
    2
```

Find the unique elements of A, and preserve the legacy behavior.

# unique

---

```
[C2, ia2, ic2] = unique(A, 'legacy')
```

```
C2 =
```

```
     2     5     9
```

```
ia2 =
```

```
     2     4     3
```

```
ic2 =
```

```
     3     1     3     2
```

## Tips

- To find unique rows in table A with respect to a subset of variables, you can use column subscripting. For example, you can use `unique(A(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

## Purpose

Summary of packages and classes in MATLAB Unit Test Framework

## Description

The `matlab.unittest` package consists of the following classes and packages:

<code>matlab.unittest.constraints</code>	Summary of classes in MATLAB Constraints Interface
<code>matlab.unittest.diagnostics</code>	Summary of classes in MATLAB Diagnostics Interface
<code>matlab.unittest.fixtures</code>	Summary of classes in MATLAB Fixtures Interface
<code>matlab.unittest.plugins</code>	Summary of classes in MATLAB Plugins Interface
<code>matlab.unittest.qualifications</code>	Summary of classes in MATLAB Qualifications Interface
<code>matlab.unittest.Test</code>	Specification of a single test method
<code>matlab.unittest.TestCase</code>	Superclass of all <code>matlab.unittest</code> test classes
<code>matlab.unittest.TestResult</code>	Result of running test suite
<code>matlab.unittest.TestRunner</code>	Class for running tests in <code>matlab.unittest</code> framework
<code>matlab.unittest.TestSuite</code>	Class for grouping tests to run

## Purpose

Execute UNIX command and return output

## Syntax

```
status = unix(command)
[status,cmdout] = unix(command)
[status,cmdout] = unix(command,'-echo')
```

## Description

`status = unix(command)` calls the UNIX operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = unix(command)` additionally returns the standard output of the command to `cmdout`. This syntax is most useful for commands that do not require user input.

`[status,cmdout] = unix(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

## Input Arguments

### **command - UNIX command**

string

UNIX command, specified as a string. The command executes in a UNIX shell, which might not be the shell from which you launched MATLAB.

**Example:** 'ls'

## Output Arguments

### **status - Command exit status**

0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, `status` is 0. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (&), then `status` is the exit status upon command launch.

- If `command` does not include the ampersand character (&), then `status` is the exit status upon command completion.

### **cmdout - Output of operating system command**

string

Output of the operating system command, returned as a string.

## **Examples**

### **Save UNIX Command Exit Status and Output**

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = unix(command);
status
```

```
status =
```

```
0
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

## **Tips**

- To execute the operating system command in the background, include the trailing character, &, in the `command` argument (for example, 'emacs &'). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note** If `command` includes the trailing & character, `cmdout` is empty.

---

- The `unix` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while

the `unix` function executes. This can lead to corrupted output when `unix` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

## Algorithms

MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

## Concepts

- “Running External Commands, Scripts, and Programs”

<b>Purpose</b>	Unload shared library from memory
<b>Syntax</b>	<code>unloadlibrary libname</code>
<b>Description</b>	<code>unloadlibrary libname</code> unloads library <code>libname</code> from memory.
<b>Limitations</b>	<ul style="list-style-type: none"><li>• Use with libraries that are loaded using the <code>loadlibrary</code> function.</li></ul>
<b>Input Arguments</b>	<p><b>libname - Name of shared library</b> <i>string</i></p> <p>Name of shared library, specified as a string. If you call <code>loadlibrary</code> using the <code>alias</code> option, then you must use the alias name for the <code>libname</code> argument.</p> <p><b>Data Types</b> <i>char</i></p>
<b>Examples</b>	<p><b>Unload Library</b></p> <p>Add path to examples folder.</p> <pre>addpath(fullfile(matlabroot,'extern','examples','shrlib'))</pre> <p>Load the library, if it is not already loaded.</p> <pre>if ~libisloaded('shrlibsample')     loadlibrary('shrlibsample') end</pre> <p>Clean up.</p> <pre>unloadlibrary shrlibsample</pre>
<b>Tips</b>	<ul style="list-style-type: none"><li>• To unload a MEX-file, use the <code>clear</code> function.</li></ul>
<b>See Also</b>	<code>loadlibrary</code>   <code>libisloaded</code>   <code>clear</code>

# unmesh

---

<b>Purpose</b>	Convert edge matrix to coordinate and Laplacian matrices	
<b>Syntax</b>	$[L,XY] = \text{unmesh}(E)$	
<b>Description</b>	$[L,XY] = \text{unmesh}(E)$ returns the Laplacian matrix $L$ and mesh vertex coordinate matrix $XY$ for the $M$ -by-4 edge matrix $E$ . Each row of the edge matrix must contain the coordinates $[x1\ y1\ x2\ y2]$ of the edge endpoints.	
<b>Input Arguments</b>	$E$	$M$ -by-4 edge matrix $E$ .
<b>Output Arguments</b>	$L$	Laplacian matrix representation of the graph.
	$XY$	Mesh vertex coordinate matrix.
<b>Examples</b>	Take a simple example of a square with vertices at $(1,1)$ , $(1,-1)$ , $(-1,-1)$ , and $(-1,1)$ , where the connections between vertices are the four perpendicular edges of the square plus one diagonal connection between $(-1, -1)$ and $(1,1)$ .	

The edge matrix E for this graph is:

```
E=[1 1 1 -1; % edge from 1 to 2
1 -1 -1 -1; % edge from 2 to 3
-1 -1 -1 1; % edge from 3 to 4
-1 -1 1 1; % edge from 4 to 1
-1 1 1 1] % edge from 3 to 1
```

Use unmesh to create the output matrices,

```
[A,XY]=unmesh(E);
4 vertices:
4/4
```

The Laplacian matrix is defined as

# unmesh

---

$$L_{ij} = \begin{cases} \deg(v_i) & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and } v_i \text{ is adjacent to } v_j \\ 0 & \text{otherwise} \end{cases}$$

unmesh returns the Laplacian matrix L in sparse notation.

L

L =

(1,1)	3
(2,1)	-1
(3,1)	-1
(4,1)	-1
(1,2)	-1
(2,2)	2
(4,2)	-1
(1,3)	-1
(3,3)	2
(4,3)	-1
(1,4)	-1
(2,4)	-1
(3,4)	-1

To see L in regular matrix notation, use the full command.

full(L)

ans =

3	-1	-1	-1
-1	2	0	-1
-1	0	2	-1
-1	-1	-1	3

The mesh coordinate matrix XY returns the coordinates of the corners of the square.

XY

XY =

-1	-1
-1	1
1	-1
1	1

**See Also**

[gplot](#) | [treepplot](#)

# unmkpp

---

**Purpose** Piecewise polynomial details

**Syntax** `[breaks,coefs,l,k,d] = unmkpp(pp)`

**Description** `[breaks,coefs,l,k,d] = unmkpp(pp)` extracts, from the piecewise polynomial `pp`, its breaks `breaks`, coefficients `coefs`, number of pieces `l`, order `k`, and dimension `d` of its target. Create `pp` using `spline` or the spline utility `mkpp`.

**Examples** This example creates a description of the quadratic polynomial

$$\frac{-x^2}{4} + x$$

as a piecewise polynomial `pp`, then extracts the details of that description.

```
pp = mkpp([-8 -4],[-1/4 1 0]);  
[breaks,coefs,l,k,d] = unmkpp(pp)
```

```
breaks =  
    -8    -4
```

```
coefs =  
   -0.2500    1.0000         0
```

```
l =  
    1
```

```
k =  
    3
```

```
d =  
    1
```

**See Also** `mkpp` | `ppval` | `spline`

**Purpose** Unregister all event handlers associated with COM object events at run time

**Syntax** `h.unregisterallevents`  
`unregisterallevents(h)`

**Description** `h.unregisterallevents` unregisters all events previously registered with COM object `h`. After calling `unregisterallevents`, the object no longer responds to any events until you register them again using the `registerevent` function.

`unregisterallevents(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Register and unregister events for an instance of the `mwsamp` control, using the `eventlisteners` function to see the event handler associated with each event:

- 1 Register three events and their respective handler routines.

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', ...
    [0 0 200 200], f, ...
    {'Click' 'myclick'; 'Db1Click' 'my2click'; ...
    'MouseDown' 'mymoused'});
h.eventlisteners
```

MATLAB displays:

```
ans =
    'click'          'myclick'
    'dblclick'      'my2click'
    'mousedown'     'mymoused'
```

- 2 Unregister all events simultaneously with `unregisterallevents`. `eventlisteners` returns an empty cell array, indicating that there are no longer any events registered with the control:

# unregisterallevents

---

```
h.unregisterallevents;  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    {}
```

## See Also

[events \(COM\)](#) | [eventlisteners](#) | [registerevent](#) | [unregisterevent](#)  
| [isevent](#)

**Purpose** Unregister event handler associated with COM object event at run time

**Syntax** `h.unregisterevent(eventhandler)`  
`unregisterevent(h, eventhandler)`

**Description** `h.unregisterevent(eventhandler)` unregisters specific event handler routines from their corresponding events. Once you unregister an event, the object no longer responds to the event.

`unregisterevent(h, eventhandler)` is an alternate syntax.

You can unregister events at any time after creating a control. The `eventhandler` argument, which is a cell array, specifies both events and event handlers.

```
h.unregisterevent({'event_name',@event_handler});
```

Specify events in the `eventhandler` argument using the names of the events. Strings used in the `eventhandler` argument are not case sensitive. `unregisterevent` does not accept numeric event identifiers.

COM functions are available on Microsoft Windows systems only.

**Examples** Unregister events for a control:

- 1 Create an `mwsamp` control and register all events with the same handler routine, `sampev`. Use `eventlisteners` to see the event handler used by each event. In this case, each event, when fired, calls `sampev.m`:

```
f = figure ('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2', ...  
    [0 0 200 200], f, ...  
    'sampev');  
h.eventlisteners
```

MATLAB displays:

# unregisterevent

---

```
ans =  
    'Click'          'sampev'  
    'DbClick'       'sampev'  
    'MouseDown'     'sampev'  
    'Event_Args'    'sampev'
```

- 2** Unregister just the `dblclick` event. Now, when you list the registered events using `eventlisteners`, `dblclick` is no longer registered and the control does not respond when you double-click the mouse over it:

```
h.unregisterevent({'dblclick' 'sampev'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'Click'          'sampev'  
    'MouseDown'     'sampev'  
    'Event_Args'    'sampev'
```

- 3** Now, register the `click` and `dblclick` events with a different event handler for `myclick` and `my2click`, respectively:

```
h.unregisterallevents;  
h.registerevent({'click' 'myclick'; ...  
    'dblclick' 'my2click'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'click'          'myclick'  
    'dblclick'       'my2click'
```

- 4** Unregister these same events by specifying event names and their handler routines in a cell array. `eventlisteners` now returns an

empty cell array, meaning that no events are registered for the `mwsamp` control:

```
h.unregisterevent({'click' 'myclick'; ...  
    'dblclick' 'my2click'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    {}
```

---

Unregister Microsoft Excel workbook events:

- 1 Create a Workbook object and register two events with the event handler routines, `EvtActivateHndlr` and `EvtDeactivateHndlr`:

```
myApp = actxserver('Excel.Application');  
wbs = myApp.Workbooks;  
wb = wbs.Add;wb.registerevent({'Activate' 'EvtActivateHndlr'; ...  
    'Deactivate' 'EvtDeactivateHndlr'})  
wb.eventlisteners
```

MATLAB shows the events with the corresponding event handlers.

```
ans =  
    'Activate'      'EvtActivateHndlr'  
    'Deactivate'   'EvtDeactivateHndlr'
```

- 2 Next, unregister the `Deactivate` event handler:

```
wb.unregisterevent({'Deactivate' 'EvtDeactivateHndlr'})  
wb.eventlisteners
```

MATLAB shows the remaining registered event (`Activate`) with its corresponding event handler.

# unregisterevent

---

```
ans =  
    'Activate'      'EvtActivateHndlr'
```

## How To

- “Writing Event Handlers”

**Purpose**

Unstack data from single variable into multiple variables

**Syntax**

```
W = unstack(T,vars,ivar)
W = unstack(T,vars,ivar,Name,Value)
[W,it] = stack( ___ )
```

**Description**

`W = unstack(T,vars,ivar)` converts the tall table, `T`, to an equivalent table, `W`, that is in wide format. `unstack` unstacks a single variable in `T`, specified by `vars`, into multiple variables in `W`. In general, `W` contains more variables, but fewer rows, than `T`.

An indicator variable in `T`, specified by `ivar`, determines which variable in `W` contains each value in `var` after it is unstacked. `unstack` treats the remaining variables in `T` as grouping variables. Each unique combination of values in the grouping variables identifies a group of rows in `T` that will be unstacked into a single row of `W`.

`W = unstack(T,vars,ivar,Name,Value)` converts the table `T` to wide format with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify how `unstack` converts variables from `T` to variables in `W`.

`[W,it] = stack( ___ )` also returns an index vector, `it`, indicating the correspondence between rows in `W` and rows in `T`. You can use any of the previous input arguments.

**Input Arguments****T - Tall table**

table

Tall table, specified as a table. `T` must contain data variables to unstack, `vars`, and an indicator variable, `ivars`. The remaining variables in `T` are either grouping variables or constant variables.

**vars - Variables in T to unstack**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in  $T$  to unstack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

### **ivar - Indicator variable in $T$**

positive integer | variable name

Indicator variable in  $T$ , specified as a positive integer or a variable name. The variable specified by `ivar` indicates which variable in  $W$  each value in `var` is unstacked into.

`ivar` can be a numeric vector, logical vector, character array, cell array of strings, or categorical vector.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'AggregationFunction', @mean` applies the aggregation function `@mean` to the values in `vars`.

### **'GroupingVariables' - Grouping variables in $T$ that define groups of rows**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Grouping variables in  $T$  that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. Each group of rows in  $T$  becomes one row in  $W$ .

The default is all the variables in  $T$  not listed in `vars` or `ivar`.

**'ConstantVariables' - Variables constant within a group**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables constant within a group, specified as the comma-separated pair consisting of 'ConstantVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. The default is no variables.

The values for these variables in W are taken from the first row in each group in T.

**'NewDataVariableNames' - Names for new data variables in W**

cell array of strings

Names for new data variables in W, specified as the comma-separated pair consisting of 'NewDataVariableNames' and a cell array of strings. The default is strings based on the values of the grouping variable specified in `ivar`.

**'AggregationFunction' - Aggregation function from values in vars to single value**

function handle

Aggregation function from values in `vars` to single value, specified as the comma-separated pair consisting of 'AggregationFunction' and a function handle. `unstack` applies this function to rows from the same group that have the same value in `ivar`. The function must aggregate the data values into a single value.

For a numeric data variable, the default is `@sum`. For nonnumeric variables, there is no default function, and you must specify the 'AggregationFunction' name-value pair argument if multiple rows in the same group have the same value in `ivar`.

## Output Arguments

### W - Wide table

table

Wide table, returned as a table. W contains the unstacked data variables, the grouping variables, and the first value of each group from any constant variables.

The order of the data in W is based on the order of the unique values in the grouping variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

### it - Index to T

column vector

Index to T, returned as a column vector. For each row in W, the index vector, it, identifies the index of the first value in the corresponding group of rows in T.

## Examples

### Separate One Variable into Three Variables

Create a table indicating the amount of snowfall in various towns for various storms.

```
Storm = [3;3;1;3;1;1;4;2;4;2;4;2];  
Town = {'T1';'T3';'T1';'T2';'T2';'T3';...  
        'T2';'T1';'T3';'T3';'T1';'T2'};  
Snowfall = [0;3;5;5;9;10;12;13;15;16;17;21];
```

```
T = table(Storm,Town,Snowfall)
```

```
T =
```

Storm	Town	Snowfall
3	'T1'	0

3	'T3'	3
1	'T1'	5
3	'T2'	5
1	'T2'	9
1	'T3'	10
4	'T2'	12
2	'T1'	13
4	'T3'	15
2	'T3'	16
4	'T1'	17
2	'T2'	21

T contains three snowfall entries for each storm, one for each town.

Separate the variable `Snowfall` into three variables, one for each town specified in the variable, `Town`.

```
W = unstack(T, 'Snowfall', 'Town')
```

W =

Storm	T1	T2	T3
3	0	5	3
1	5	9	10
4	17	12	15
2	13	21	16

Each row in `W` contains data from rows in `T` that have the same value in the grouping variable, `Storm`. The order of the unique values in `Storm` determines the order of the data in `W`.

### Apply Aggregation Function to Each Group

Unstack data and apply an aggregation function to multiple rows in the same group that have the same values in the indicator variable.

Create a table containing data on the price of two stocks over 2 days.

# unstack

---

```
Date = [repmat({'4/12/2008'},6,1);...
        repmat({'4/13/2008'},5,1)];
Stock = {'Stock1','Stock2','Stock1','Stock2';...
        'Stock2','Stock2','Stock1','Stock2';...
        'Stock2','Stock1','Stock2'};
Price = [60.35;27.68;64.19;25.47;28.11;27.98;...
        63.85;27.55;26.43;65.73;25.94];
```

```
T = table(Date,Stock,Price)
```

```
T =
```

Date	Stock	Price
'4/12/2008'	'Stock1'	60.35
'4/12/2008'	'Stock2'	27.68
'4/12/2008'	'Stock1'	64.19
'4/12/2008'	'Stock2'	25.47
'4/12/2008'	'Stock2'	28.11
'4/12/2008'	'Stock2'	27.98
'4/13/2008'	'Stock1'	63.85
'4/13/2008'	'Stock2'	27.55
'4/13/2008'	'Stock2'	26.43
'4/13/2008'	'Stock1'	65.73
'4/13/2008'	'Stock2'	25.94

T contains two prices for STOCK1 during the first day and four prices for STOCK2 during the first day.

Create a table containing separate variables for each stock and one row for each day. Use Date as the grouping variable and apply the aggregation function, @mean, to the numeric values from the variable, Price, for each group.

```
[W,it] = unstack(T,'Price','Stock',...
                'AggregationFunction',@mean)
```

W =

Date	Stock1	Stock2
'4/12/2008'	62.27	27.31
'4/13/2008'	64.79	26.64

it =

1  
7

W contains the average price for each stock grouped by date.

it identifies the index of the first value for each group of rows in T. The first value for the group '4/13/2008' is in the seventh row of T.

## Tips

- You can specify more than one data variable in T, and each variable becomes a set of unstacked data variables in W. Use a vector of positive integers, a cell array containing multiple variable names, or a logical vector to specify vars. The one indicator variable, specified by the input argument, ivar, applies to all data variables specified by vars.

## Definitions

### Grouping Variables

Grouping variables are utility variables used to group, or categorize, data. Grouping variables are useful for summarizing or visualizing data by group. You can define groups in your table by specifying one or more grouping variables.

A grouping variable can be any of the following:

- Categorical vector
- Cell array of strings
- Character array

# unstack

---

- Numeric vector, typically containing positive integers
- Logical vector

Rows that have the same grouping variable value belong to the same group. If you use multiple grouping variables, rows that have the same combination of grouping variable values belong to the same group.

`stack` | `join`

**Purpose** Extract contents of tar file

**Syntax**

```
untar(tarfilename)
untar(tarfilename,outputdir)
untar(url, ___)
filenames = untar( ___ )
```

**Description** `untar(tarfilename)` extracts the archived contents of `tarfilename` into the current directory and sets the files' attributes. It overwrites any existing files with the same names as those in the archive if the existing files' attributes and ownerships permit it. For example, if you rerun `untar` on the same `tarfilename`, MATLAB software does not overwrite files with a read-only attribute; instead, `untar` displays a warning for such files. On Microsoft Windows platforms, the hidden, system, and archive attributes are not set.

`tarfilename` is a string specifying the name of the tar file. `tarfilename` is gunzipped to a temporary directory and deleted if its extension ends in `.tgz` or `.gz`. If an extension is omitted, `untar` searches for `tarfilename` appended with `.tgz`, `.tar.gz`, or `.tar`. `tarfilename` can include the directory name; otherwise, the file must be in the current directory or in a directory on the MATLAB path.

`untar(tarfilename,outputdir)` uncompresses the archive `tarfilename` into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`untar(url, ___)` extracts the tar archive from an Internet URL. The URL must include the protocol type (for example, `'http://'` or `'ftp://'`). MATLAB downloads the URL to a temporary directory, and then deletes it.

`filenames = untar( ___)` extracts the tar archive and returns the names of the extracted files in the string cell array `filenames`. If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

## Examples

### Using tar and untar to Copy Files

Copy all .m files in the current directory to the directory backup.

```
tar('myfiles.tar.gz','*.m');  
untar('myfiles','backup');
```

### Using untar with URL

Run untar to list Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory ncm.

```
url = 'http://www.mathworks.com/moler/ncm.tar.gz';  
ncmFiles = untar(url,'ncm')
```

## See Also

gzip | gunzip | tar | unzip | zip

**Purpose** Correct phase angles to produce smoother phase plots

**Syntax**

```
Q = unwrap(P)
Q = unwrap(P,tol)
Q = unwrap(P,[],dim)
Q = unwrap(P,tol,dim)
```

**Description** `Q = unwrap(P)` corrects the radian phase angles in a vector `P` by adding multiples of  $\pm 2\pi$  when absolute jumps between consecutive elements of `P` are greater than or equal to the default jump tolerance of  $\pi$  radians. If `P` is a matrix, `unwrap` operates columnwise. If `P` is a multidimensional array, `unwrap` operates on the first nonsingleton dimension.

`Q = unwrap(P,tol)` uses a jump tolerance `tol` instead of the default value,  $\pi$ .

`Q = unwrap(P,[],dim)` unwraps along `dim` using the default tolerance.

`Q = unwrap(P,tol,dim)` uses a jump tolerance of `tol`.

---

**Note** A jump tolerance less than  $\pi$  has the same effect as a tolerance of  $\pi$ . For a tolerance less than  $\pi$ , if a jump is greater than the tolerance but less than  $\pi$ , adding  $\pm 2\pi$  would result in a jump larger than the existing one, so `unwrap` chooses the current point. If you want to eliminate jumps that are less than  $\pi$ , try using a finer grid in the domain.

---

## Examples

### Example 1

The following phase data comes from the frequency response of a third-order transfer function. The phase curve jumps 3.5873 radians between `w = 3.0` and `w = 3.5`, from -1.8621 to 1.7252.

```
w = [0:.2:3,3.5:1:10];
p = [    0
     -1.5728
     -1.5747
     -1.5772
```

# unwrap

---

```
-1.5790  
-1.5816  
-1.5852  
-1.5877  
-1.5922  
-1.5976  
-1.6044  
-1.6129  
-1.6269  
-1.6512  
-1.6998  
-1.8621  
1.7252  
1.6124  
1.5930  
1.5916  
1.5708  
1.5708  
1.5708 ];  
semilogx(w,p,'b*-' ), hold
```

Using `unwrap` to correct the phase angle, the resulting jump is 2.6959, which is less than the default jump tolerance  $\pi$ . This figure plots the new curve over the original curve.

```
semilogx(w,unwrap(p),'r*-')
```

# unwrap

## Example 2

Array P features smoothly increasing phase angles except for discontinuities at elements (3,1) and (1,2).

```
P = [ 0 7.0686 1.5708 2.3562
      0.1963 0.9817 1.7671 2.5525
      6.6759 1.1781 1.9635 2.7489
      0.5890 1.3744 2.1598 2.9452 ]
```

The function  $Q = \text{unwrap}(P)$  eliminates these discontinuities.

```
Q =
      0 7.0686 1.5708 2.3562
      0.1963 7.2649 1.7671 2.5525
      0.3927 7.4613 1.9635 2.7489
      0.5890 7.6576 2.1598 2.9452
```

**See Also**

abs | angle

# unzip

---

**Purpose** Extract contents of zip file

**Syntax**

```
unzip(zipfilename)
unzip(zipfilename,outputdir)
filenames = unzip(zipfilename,outputdir)
```

**Description** `unzip(zipfilename)` extracts the archived contents of `zipfilename` into the current folder, preserving the files' attributes and timestamps. The `unzip` function can extract files from your local system or files from an Internet URL.

`unzip(zipfilename,outputdir)` extracts the contents of `zipfilename` into the folder `outputdir`.

`filenames = unzip(zipfilename,outputdir)` returns the names of the extracted files in the string cell array `filenames`. Specifying `outputdir` is optional.

- Tips**
- `unzip` does not support password-protected or encrypted zip archives.
  - If any files in the target folder have the same name as files in the zip file, and you have write permission to the files, `unzip` overwrites the existing files with the archived versions. If you do not have write permission, `unzip` issues a warning.
  - Extract files that contain non-7-bit ASCII characters on a machine that has the appropriate language/encoding settings.

**Input Arguments**

**zipfilename**

String that specifies the name of the zip file.

If `zipfilename` does not include the full path, `unzip` searches for the file in the current folder and along the MATLAB path. If you do not specify the file extension, `unzip` appends `.zip`.

If you are downloading a URL, `zipfilename` must include the protocol type (for example, `http://`). The `unzip` function downloads the URL to the temporary folder on your system, and deletes the URL on cleanup.

**outputdir**

String that specifies the target folder for the extracted files.

**Default:** current folder ('.')

**Output Arguments****entrynames**

Cell array of strings that contain the paths of the extracted files.

If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

**Examples**

Copy the example MAT-files to the folder archive:

```
% Zip the example MAT-files to examples.zip
zip('examples.zip','*.mat',...
    fullfile(matlabroot,'toolbox','matlab','demos'))
```

```
% Unzip examples.zip to the folder 'archive'
unzip('examples','archive')
```

---

Download Cleve Moler's "Numerical Computing with MATLAB" examples to the output folder ncm:

```
url = 'http://www.mathworks.com/moler/ncm.zip';
ncmFiles = unzip(url,'ncm')
```

**Alternatives**

To extract files from a zip file using the Current Folder browser, select the zip file, right-click to open the context menu, and then select **Extract**.

`fileattrib` | `gzip` | `gunzip` | `tar` | `untar` | `zip`

# uplus, +

---

**Purpose** Unary plus

**Syntax**  
C = +A  
C = uplus(A)

**Description** C = +A returns array A and stores it in C.

C = uplus(A) is an alternate way to execute +A, but is rarely used. It enables operator overloading for classes.

**Input Arguments** **A - Input array**  
scalar | vector | matrix | multidimensional array  
Input array, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**  
single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char  
**Complex Number Support:** Yes

**Examples** **Unary Plus of Matrix**

Create a 2-by-2 matrix, A.

```
A = [1 -3; -2 4]
```

```
A =
```

```
     1     -3  
    -2     4
```

Use unary plus on A.

```
C = +A
```

```
C =
```

1 -3  
-2 4

C and A are the same.

**See Also**

uminus | plus

# upper

---

**Purpose** Convert string to uppercase

**Syntax** `t = upper('str')`  
`B = upper(A)`

**Description** `t = upper('str')` converts any lowercase characters in the string `str` to the corresponding uppercase characters and leaves all other characters unchanged.

`B = upper(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `upper` to each string within `A`.

**Examples** `upper('attention!')` is ATTENTION!.

**Tips** Character sets supported:

- PC: Windows Latin-1
- Other: ISO Latin-1 (ISO 8859-1)

**See Also** `lower`

**Purpose** Download URL content to MATLAB string

**Syntax**

```
str = urlread(URL)
str = urlread(URL,Name,Value)
[str,status] = urlread( ___ )
```

**Description** `str = urlread(URL)` downloads the HTML Web content from the specified URL into the string `str`. `urlread` does not retrieve hyperlink targets and images.

`str = urlread(URL,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[str,status] = urlread( ___ )` suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0

## Input Arguments

### URL - Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

**Example:** `'http://www.mathworks.com/matlabcentral'`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

### 'Get' - Data to send to the Web form using the GET method

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of 'get' and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Get' includes the data in the URL, separated by ? and & characters.

**Example:** 'Get', {'term', 'urlread'}

## **'Post' - Data to send to the Web form using the POST method**

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of 'post' and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Post' submits the data as part of the request headers, not explicitly in the URL.

## **'Charset' - Character encoding**

string

Character encoding, specified as the comma-separated pair consisting of 'Charset' and a string. If you do not specify Charset, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, Charset defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

**Example:** 'Charset', 'ISO-8859-1'

## **'Timeout' - Timeout duration**

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of 'Timeout' and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

**Example:** 'Timeout',10

**'UserAgent' - Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

**Example:** 'UserAgent', 'MATLAB R2012b'

**'Authentication' - HTTP authentication mechanism**

'Basic'

HTTP authentication mechanism, specified as the comma-separated pair consisting of 'Authentication' and a string. Currently, only the value 'Basic' is supported. 'Authentication', 'Basic' specifies basic authentication.

If you include the Authentication argument, you must also include the Username and Password arguments.

**'Username' - User identifier**

string

User identifier, specified as the comma-separated pair consisting of 'Username' and a string. If you include the Username argument, you must also include the Password and Authentication arguments.

**Example:** 'Username', 'myName'

**'Password' - User authentication password**

string

User authentication password, specified as the comma-separated pair consisting of 'Password' and a string. If you include the Password argument, you must also include the Username and Authentication arguments.

**Example:** 'Password', 'myPassword123'

# urlread

---

## Output Arguments

### **str** - Contents of the file at the specified URL

string

Contents of the file at the specified URL, returned as a string. For example, if the URL corresponds to an HTML page, `str` contains the text and markup in the HTML file. If the URL corresponds to a binary file, `str` is not readable.

### **status** - Download status

1 | 0

Download status, returned as either 1 or 0. When the download is successful, `status` is 1. Otherwise, `status` is 0.

## Examples

### **Download Web Content by Specifying Complete URL**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...  
          '?term=urlread'];  
str = urlread(fullURL);
```

`urlread` reads from the specified URL and downloads the HTML content to the string `str`.

### **Download Web Content Related to a Term**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';  
str = urlread(URL, 'Get', {'term', 'urlread'});
```

`urlread` reads from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlread` and downloads the HTML content to the string `str`.

### Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...  
          '?term=urlread'];  
str = urlread(fullURL,'Timeout',5);
```

### Tips

- `urlread` saves Web content to a string. To save content to a file, use `urlwrite`.
- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

### See Also

`urlwriteftp` | `webmget` |

### Concepts

- “Specify Proxy Server Settings for Connecting to the Internet”

# urlwrite

---

**Purpose** Download URL content and save to file

**Syntax** `urlwrite(URL,filename)`  
`urlwrite(URL,filename,Name,Value)`  
  
`[filestr,status] = urlwrite( __ )`

**Description** `urlwrite(URL,filename)` reads Web content at the specified URL and saves it to the file specified by `filename`.

`urlwrite(URL,filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[filestr,status] = urlwrite( __ )` stores the file path in variable `filestr`, and suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0.

## Input Arguments

### **URL - Content location**

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

**Example:** `'http://www.mathworks.com/matlabcentral'`

### **filename - Name of file to store Web content**

string

Name of the file to store the Web content, specified as a string. If you do not specify the path for `filename`, `urlwrite` saves the file in the current folder.

**Example:** `'myfile.html'`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

## **'Get' - Data to send to the Web form using the GET method**

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

**Example:** `'Get',{'term','urlread'}`

## **'Post' - Data to send to the Web form using the POST method**

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

## **'Charset' - Character encoding**

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the

file. If the character encoding cannot be determined, Charset defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

**Example:** 'Charset', 'ISO-8859-1'

## **'Timeout' - Timeout duration**

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of 'Timeout' and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

**Example:** 'Timeout', 10

## **'UserAgent' - Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

**Example:** 'UserAgent', 'MATLAB R2012b'

## **'Authentication' - HTTP authentication mechanism**

'Basic'

HTTP authentication mechanism, specified as the comma-separated pair consisting of 'Authentication' and a string. Currently, only the value 'Basic' is supported. 'Authentication', 'Basic' specifies basic authentication.

If you include the Authentication argument, you must also include the Username and Password arguments.

## **'Username' - User identifier**

string

User identifier, specified as the comma-separated pair consisting of 'Username' and a string. If you include the Username argument, you must also include the Password and Authentication arguments.

**Example:** 'Username', 'myName'

### **'Password' - User authentication password**

string

User authentication password, specified as the comma-separated pair consisting of 'Password' and a string. If you include the Password argument, you must also include the Username and Authentication arguments.

**Example:** 'Password', 'myPassword123'

## **Output Arguments**

### **filestr - Path of the file**

string

Path of the file specified by filename, returned as a string.

### **status - Download status**

1 | 0

Download status, returned as either 1 or 0. When the download is successful, status is 1. Otherwise, status is 0.

## **Examples**

### **Download Web Content by Specifying Complete URL**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to urlwrite. Save the results to samples.html in the current directory.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
           '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename);
```

View the file.

```
web(filename)
```

## Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current directory.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';  
filename = 'samples.html';  
urlwrite(URL,filename,'get',{'term','urlwrite'});
```

`urlwrite` downloads the HTML content from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlwrite` and writes it to `samples.html`.

## Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...  
          '?term=urlwrite'];  
filename = 'samples.html';  
urlwrite(fullURL,filename,'Timeout',5);
```

### Tips

- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

`urlreadmget` | `webftp` |

### Concepts

- “Specify Proxy Server Settings for Connecting to the Internet”

<b>Purpose</b>	Determine if Java feature is available								
<b>Syntax</b>	<code>tf = usejava(feature)</code>								
<b>Description</b>	<code>tf = usejava(feature)</code> returns logical 1 (true) if the specified feature is supported. Otherwise, it returns logical 0 (false). Use for error handling if Java feature is unavailable.								
<b>Input Arguments</b>	<p><b>feature - Java feature</b> 'awt'   'desktop'   'jvm'   'swing'</p> <p>Java feature, specified as one of these values:</p> <table><tr><td>'awt'</td><td>Java GUI components in the Abstract Window Toolkit (AWT) components are available.</td></tr><tr><td>'desktop'</td><td>MATLAB interactive desktop is running.</td></tr><tr><td>'jvm'</td><td>Java Virtual Machine software (JVM) is running.</td></tr><tr><td>'swing'</td><td>Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.</td></tr></table>	'awt'	Java GUI components in the Abstract Window Toolkit (AWT) components are available.	'desktop'	MATLAB interactive desktop is running.	'jvm'	Java Virtual Machine software (JVM) is running.	'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.
'awt'	Java GUI components in the Abstract Window Toolkit (AWT) components are available.								
'desktop'	MATLAB interactive desktop is running.								
'jvm'	Java Virtual Machine software (JVM) is running.								
'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.								
<b>Examples</b>	<p><b>Display Error Message</b></p> <p>Use the following code snippet to test that the AWT GUI components are available before attempting to display a Java Frame.</p> <pre>if usejava('awt')     myFrame = java.awt.Frame; else     disp('Unable to open a Java Frame'); end</pre>								

If the AWT is not available on your system, MATLAB displays the message.

## Call error Function

Use the following code snippet to terminate a script if MATLAB does not have access to JVM software.

The variable, `filename`, is a function that contains Java code.

```
if ~usejava('jvm')
    error([filename ' requires Java to run.']);
end
```

## See Also

## Concepts

- “Bringing Java Classes into MATLAB Workspace”

**Purpose** View or change user portion of search path

**Syntax** `userpath`

```
userpath(newpath)
userpath('reset')
userpath('clear')
```

**Description** `userpath` returns a string specifying the first folder on the search path. MATLAB adds the *userpath* to the search path upon startup.

`userpath(newpath)` sets the primary *userpath* folder to `newpath`. The `newpath` folder appears at the top of the search path immediately and at startup in future sessions. MATLAB removes the folder previously specified by *userpath* from the search path.

`userpath('reset')` sets the primary *userpath* folder to the default for that platform, creating the Documents/MATLAB (or My Documents/MATLAB) folder, if it does not exist. MATLAB immediately adds the default folder to the top of the search path, and also adds it to the search path at startup in future sessions. On Linux, the MATLAB directory is not created if the Documents directory does not exist.

`userpath('clear')` clears the value for the primary *userpath* immediately, and for future MATLAB sessions. MATLAB removes the folder previously specified by *userpath* from the search path.

## Input Arguments

### **newpath - New userpath value**

string

New userpath value, specified as a string. `newpath` must be an absolute path.

**Example:** `'C:\myFolder'`

## Examples

### View userpath Folder

This example assumes *userpath* is set to the default value on the Windows XP platform, My Documents\MATLAB. Start MATLAB and display the current folder:

```
pwd
```

```
H:\My Documents\MATLAB
```

In this example, H is the drive at which My Documents is located.

Confirm that the current folder is the *userpath*.

```
userpath
```

```
H:\My Documents\MATLAB;
```

Display the search path.

```
path
```

```
MATLABPATH
```

```
H:\My Documents\MATLAB  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

MATLAB returns the search path. The *userpath* portion is at the top.

### Set New Value for userpath

Assume *userpath* is set to the default value on the Windows XP platform, My Documents\MATLAB. Change the value from the default for *userpath* to C:\Research\_Project.

```
newpath = 'C:\Research_Project';  
userpath(newpath)
```

View the effect of the change on the search path.

```
path
```

```
MATLABPATH
```

```
C:\Research_Project  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

MATLAB displays the search path, with the new value for *userpath* portion at the top. Note that MATLAB automatically removed the previous value of *userpath*, H:\My Documents\MATLAB, from the search path when you assigned a new value to *userpath*.

### **Clear the Value for userpath**

Assume *userpath* is set to the default value and you do not want any folders to be added to the search path upon startup. Confirm the default is currently set.

```
userpath
```

```
H:\My Documents\MATLAB;
```

Verify that the *userpath* folder is at the top of the search path.

```
path
```

```
MATLABPATH
```

```
H:\My Documents\MATLAB  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

Clear the value.

```
userpath('clear')
```

# userpath

---

Verify the result.

```
userpath
```

```
ans =  
    ''
```

Confirm the *userpath* folder was removed from the search path.

```
path
```

```
MATLABPATH
```

```
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

---

**Note** By default, the startup folder is the *userpath* folder when you start MATLAB by double-clicking the shortcut on Windows platforms, or by double-clicking the application on Macintosh platforms. If you clear the value for *userpath*, the startup folder will not necessarily be on the search path. Removing the *userpath* folder from the search path *and* saving the changes to the path has the same effect.

---

## Tips

- On Macintosh and UNIX platforms, you can automatically add subfolders to the top of the search path upon startup by specifying the path for the subfolders via the MATLABPATH environment variable.

## Concepts

- “What Is the MATLAB Search Path?”
- “MATLAB Startup Folder”

## Purpose

Check validity of array

## Syntax

```
validateattributes(A,classes,attributes)
validateattributes(A,classes,attributes,argIndex)
validateattributes(A,classes,attributes,funcName)
validateattributes(A,classes,attributes,funcName,varName)
validateattributes(A,classes,attributes,funcName,varName,
    argIndex)
```

## Description

`validateattributes(A,classes,attributes)` validates that array `A` belongs to at least one of the specified classes (or its subclass) and has all of the specified attributes. If `A` does not meet the criteria, MATLAB throws an error and displays a formatted error message. Otherwise, `validateattributes` completes without displaying any output.

`validateattributes(A,classes,attributes,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validateattributes(A,classes,attributes,funcName)` includes the specified function name in generated error identifiers.

`validateattributes(A,classes,attributes,funcName,varName)` includes the specified variable name in generated error messages.

`validateattributes(A,classes,attributes,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

## Input Arguments

### A - Input

any type of array

Input, specified as any type of array.

# validateattributes

---

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char | struct | cell  
| function\_handle

**Complex Number Support:** Yes

## classes - Valid data types

cell array of strings

Valid data types, specified as a cell array of strings. Each string can be the name of any built-in or custom class, including:

'single'	Single-precision number
'double'	Double-precision number
'int8'	Signed 8-bit integer
'int16'	Signed 16-bit integer
'int32'	Signed 32-bit integer
'int64'	Signed 64-bit integer
'uint8'	Unsigned 8-bit integer
'uint16'	Unsigned 16-bit integer
'uint32'	Unsigned 32-bit integer
'uint64'	Unsigned 64-bit integer
'logical'	Logical true or false
'char'	Character or string
'struct'	Structure array
'cell'	Cell array
'function_handle'	function handle

'numeric'	Any data type for which the <code>isa(A, 'numeric')</code> function returns true, including <code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code> , <code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code> , <code>single</code> , or <code>double</code>
'<class_name>'	Any other class name

## Data Types

`cell`

### attributes - Valid attributes

`cell` array of strings

Valid attributes, specified as a cell array of strings.

Some attributes also require numeric values, such as attributes that specify the size or number of elements of `A`. For these attributes, the numeric value or vector must immediately follow the attribute name string in the cell array.

Attributes that describe the size and shape of array `A`:

'2d'	Two-dimensional array, including scalars, vectors, matrices, and empty arrays
'3d'	Array with three or fewer dimensions
'column'	Column vector, N-by-1
'row'	Row vector, 1-by-N
'scalar'	Scalar value, 1-by-1
'vector'	Row or column vector, or a scalar value
'size', [d1,...,dN]	Array with dimensions d1-by-...-by-dN. To skip checking a particular dimension, specify NaN for that dimension, such as [3,4,NaN,2].
'numel', N	Array with N elements
'ncols', N	Array with N columns

# validateattributes

---

'nrows', N	Array with N rows
'ndims', N	N-dimensional array
'square'	Square matrix; in other words, a two-dimensional array with equal number of rows and columns
'diag'	Diagonal matrix
'nonempty'	No dimensions that equal zero
'nonsparse'	Array that is not sparse

Attributes that specify valid ranges for values in A:

'>', N	All values greater than N
'>=', N	All values greater than or equal to N
'<', N	All values less than N
'<=', N	All values less than or equal to N

Attributes that check types of values in a numeric or logical array, A:

'binary'	Array of ones and zeros
'even'	Array of even integers (includes zero)
'odd'	Array of odd integers
'integer'	Array of integer values
'real'	Array of real values
'finite'	Array of finite values
'nonnan'	No NaN (Not a Number) elements
'nonnegative'	No elements less than zero
'nonzero'	No elements equal to zero

'positive'	No elements less than or equal to zero
'decreasing'	Each element of a column is less than the previous element and no element is NaN
'increasing'	Each element of a column is greater than the previous element and no element is NaN
'nondecreasing'	Each element of a column is greater than or equal to the previous element and no element is NaN
'nonincreasing'	Each element of a column is less than or equal to the previous element and no element is NaN

## Data Types

cell

### **funcName - Name of function whose input you are validating**

string

Name of function whose input you are validating, specified as a string. If you specify an empty string, '', the validateattribute function ignores the funcName input.

## Data Types

char

### **varName - Name of input variable**

string

Name of input variable, specified as a string. If you specify an empty string, '', the validateattribute function ignores the varName input.

## Data Types

char

### **argIndex - Position of input argument**

positive integer

Position of input argument, specified as a positive integer.

# validateattributes

---

## Data Types

double

## Examples

### Validate the Size of an Array

```
classes = {'numeric'};
attributes = {'size',[4,6,2]};
```

```
A = rand(3,5,2);
validateattributes(A,classes,attributes)
```

Expected input to be of size 4x6x2 when it is actually size 3x5x2.

Because A did not match the specified attributes, MATLAB throws an error message.

### Validate Array Monotonicity

Determine if an array is increasing or nondecreasing.

```
A = [1 5 8 2;
     9 6 9 4]
validateattributes(A, {'double'},{'nondecreasing'})
validateattributes(A, {'double'},{'increasing'})
```

A =

```
     1     5     8     2
     9     6     9     4
```

Since A is both increasing and nondecreasing, `validateattributes` does not throw an error for either attribute check.

Setting `A(2,3)` equal to `A(1,3)` results in a column that is no longer strictly increasing, so `validateattributes` throws an error.

```
A(2,3) = 8
validateattributes(A, {'double'},{'increasing'})
```

A =

```
    1    5    8    2
    9    6    8    4
```

Expected input to be increasing valued.

However, the columns remain nondecreasing since each column element is equal to or greater than the next. The following code does not throw an error.

```
validateattributes(A, {'double'}, {'nondecreasing'})
```

## Check the Attributes of a Complex Number

Assuming that `a` is to be the second input argument to a function, check that it is nonnegative.

```
a = complex(1,1);
validateattributes(a, {'numeric'}, {'nonnegative'}, 2);
```

Expected input number 2 to be nonnegative.

Because complex numbers lack a well-defined ordering in the complex plane, `validateattributes` does not recognize them as positive or negative.

## Ensure Array Values Are Within a Specified Range

Check that the values in an array are 8-bit integers between 0 and 10.

Assume that this code occurs in a function called `Rankings`.

```
classes = {'uint8', 'int8'};
attributes = {'>', 0, '<', 10};
funcName = 'Rankings';
A = int8(magic(4));
```

```
validateattributes(A, classes, attributes, funcName)
```

# validateattributes

---

```
Error using Rankings
Expected input to be an array with all of the values < 10.
```

## Validate Function Input Parameters Using inputParser

Create a custom function that checks input parameters with `inputParser`, and use `validateattributes` as the validating function for the `addRequired` and `addOptional` methods.

Define the function.

```
function a = findArea(shape,dim1,varargin)
    p = inputParser;
    charchk = {'char'};
    numchk = {'numeric'};
    nempty = {'nonempty'};

    addRequired(p,'shape',@(x)validateattributes(x,charchk,nempty));
    addRequired(p,'dim1',@(x)validateattributes(x,numchk,nempty));
    addOptional(p,'dim2',1,@(x)validateattributes(x,numchk,nempty));
    parse(p,shape,dim1,varargin{:});

    switch shape
        case 'circle'
            a = pi * dim1.^2;
        case 'rectangle'
            a = dim1 .* p.Results.dim2;
    end
end
```

Call the function with a nonnumeric third input.

```
myarea = findArea('rectangle',3,'x')
```

```
Error using findArea (line 10)
Argument 'dim2' failed validation with error:
Expected input to be one of these types:
```

```
double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64
```

Instead its type was char.

## Validate Arguments of a Function

Check the inputs of a function and include information about the input name and position in generated error.

Define the function.

```
function v = findVolume(shape,ht,wd,ln)
    validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
    validateattributes(ht,{'numeric'},{'nonempty'},mfilename,'Height',2)
    validateattributes(wd,{'numeric'},{'nonempty'},mfilename,'Width',3)
    validateattributes(ln,{'numeric'},{'nonempty'},mfilename,'Length',4)
```

Call the function without the shape input string.

```
vol = findVolume(10,7,4)
```

```
Error using findVolume
Expected input number 1, Shape, to be one of these types:
```

```
char
```

Instead its type was double.

```
Error in findVolume (line 2)
validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
```

The function name becomes part of the error identifier.

```
MException.last.identifier
```

```
ans =
```

```
MATLAB:findVolume:invalidType
```

## See Also

[validatestring](#) | [is\\*](#) | [isa](#) | [isnumericinputParser](#) |

# validatestring

---

**Purpose** Check validity of text string

**Syntax**

```
validStr = validatestring(str,validStrings)
validStr = validatestring(str,validStrings,argIndex)
validStr = validatestring(str,validStrings,funcName)
validStr =
validatestring(str,validStrings,funcName,varName)
validStr =
validatestring(str,validStrings,funcName,varName,
    argIndex)
```

**Description** `validStr = validatestring(str,validStrings)` checks the validity of text string `str`. If `str` is an unambiguous, case-insensitive match to a string in cell array `validStrings`, the `validatestring` function returns the matching string in `validStr`. Otherwise, MATLAB throws an error and issues a formatted error message.

`validStr = validatestring(str,validStrings,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validStr = validatestring(str,validStrings,funcName)` includes the specified function name in generated error identifiers.

`validStr = validatestring(str,validStrings,funcName,varName)` includes the specified variable name in generated error messages.

`validStr = validatestring(str,validStrings,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

**Input Arguments**

**str**  
String to validate, of type `char`.

**validStrings**

Cell array of allowed strings.

## **funcName**

String that specifies the name of the function whose input you are validating. If you specify an empty string, '', the validatestring function ignores the funcname input.

## **varName**

String that specifies the name of the input variable. If you specify an empty string, '', the validatestring function ignores the varName input.

## **argIndex**

Positive integer that specifies the position of the input argument.

## **Output Arguments**

## **validStr**

String that contains the element of validStrings that is an unambiguous, case-insensitive match to str.

<b>Example – Match 'ball' with . . .</b>	<b>Return Value</b>	<b>Type of Match</b>
ball, barn, bell	ball	Exact match
balloon, barn	balloon	Partial match (leading characters)
ballo, balloo, balloon	ballo (shortest match)	Multiple partial matches where each string is a subset of another
balloon, ballet	Error	Multiple partial matches to unique strings
barn, bell	Error	No match

# validatestring

---

## Examples

Check whether a string is in a set of valid values.

```
str = 'won';
validStrings = {'wind', 'wonder', 'when'};

validStr = validatestring(str, validStrings)
```

Because `str` is a partial match to a unique string, this code returns

```
validStr =
    wonder
```

However, if `str` is a partial match to multiple strings, and the strings are not subsets of each other, `validatestring` throws an error and displays a formatted message.

```
str = 'won';
validStrings = {'wonder', 'wondrous', 'wonderful'};

validStr = validatestring(str, validStrings)
```

The error message is

Expected argument to match one of these strings:

```
wonder, wondrous, wonderful
```

The input, 'won', matched more than one valid string.

---

Check inputs to a custom function, and include information about the input name and position in generated errors.

```
function a = findArea(shape, ht, wd, units)
    a = 0;
    expectedShapes = {'square', 'rectangle', 'triangle'};
    expectedUnits = {'cm', 'm', 'in', 'ft', 'yds'};
```

```
shapeName = validatestring(shape,expectedShapes,mfilename,'Shape',4)
unitAbbrev = validatestring(units,expectedUnits,mfilename,'Units',4)
```

When you call the function with valid input strings,

```
myarea = findArea('rect',10,3,'cm')
```

the function stores the inputs in local variables `shapeName` and `unitAbbrev`:

```
shapeName =
    rectangle
```

```
unitAbbrev =
    cm
```

However, if the inputs are not valid, such as

```
myarea = findArea('circle',10,3,'cm')
```

MATLAB displays

```
Error using findArea
Expected argument 1, Shape, to match one of these strings:
```

```
    square, rectangle, triangle
```

The input, 'circle', did not match any of the valid strings.

The function name is part of the error identifier, so

```
MException.last.identifier
```

returns

```
MATLAB:findArea:unrecognizedStringChoice
```

## See Also

[validateattributes](#) | [is\\*](#) | [isa](#) | [inputParser](#)

# containers.Map.values

---

**Purpose** Identify values in containers.Map object

**Syntax**  
`valueSet = values(mapObj)`  
`valueSet = values(mapObj, keySet)`

**Description**  
`valueSet = values(mapObj)` returns all of the values in `mapObj`.  
`valueSet = values(mapObj, keySet)` returns values that correspond to the specified keys.

**Input Arguments**  
**mapObj**  
Object of class `containers.Map`.

**keySet**  
Cell array that specifies keys in `mapObj`.

**Output Arguments**  
**valueSet**  
Cell array containing values from `mapObj`. If you specify `keySet`, the `valueSet` array has the same size and dimensions as `keySet`.

## Examples **Get All Values in a Map**

Create a map, and view all values in the map:

```
myKeys = {'a', 'b', 'c'};  
myValues = [1, 2, 3];  
mapObj = containers.Map(myKeys, myValues);
```

```
valueSet = values(mapObj)
```

This code returns 1-by-3 cell array `valueSet`:

```
valueSet =  
    [1]    [2]    [3]
```

## Get Selected Values in a Map

View the values corresponding to keys a and c in `mapObj`, created in the previous example:

```
keySet = {'a', 'c'};
valueSet = values(mapObj, keySet)
```

This code returns 1-by-2 cell array `valueSet`:

```
valueSet =
    [1]    [3]
```

## See Also

[containers.Map](#) | [keys](#) | [isKey](#)

# vander

---

**Purpose** Vandermonde matrix

**Syntax** `A = vander(v)`

**Description** `A = vander(v)` returns the Vandermonde matrix whose columns are powers of the vector `v`, that is,  $A(i, j) = v(i)^{(n-j)}$ , where  $n = \text{length}(v)$ .

**Examples** `vander(1:.5:3)`

`ans =`

```
    1.0000    1.0000    1.0000    1.0000    1.0000
    5.0625    3.3750    2.2500    1.5000    1.0000
   16.0000    8.0000    4.0000    2.0000    1.0000
   39.0625   15.6250    6.2500    2.5000    1.0000
   81.0000   27.0000    9.0000    3.0000    1.0000
```

**See Also** `gallery`

**Purpose**

Variance

**Syntax**

```
V = var(X)
V = var(X,1)
V = var(X,w)
V = var(X,w,dim)
```

**Description**

`V = var(X)` returns the variance of `X` for vectors. For matrices, `var(X)` is a row vector containing the variance of each column of `X`. For `N`-dimensional arrays, `var` operates along the first nonsingleton dimension of `X`. The result `V` is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples.

`var` normalizes `V` by  $N - 1$  if  $N > 1$ , where  $N$  is the sample size. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples. For  $N = 1$ , `V` is normalized by 1.

`V = var(X,1)` normalizes by  $N$  and produces the second moment of the sample about its mean. `var(X,0)` is equivalent to `var(X)`.

`V = var(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `var` operates, and its elements must be nonnegative. If `X(i)` is assumed to have variance proportional to  $1/w(i)$ , then  $V * \text{mean}(w)/w(i)$  is an estimate of the variance of `X(i)`. In other words,  $V * \text{mean}(w)$  is an estimate of variance for an observation given weight 1.

`V = var(X,w,dim)` takes the variance along the dimension `dim` of `X`. Pass in 0 for `w` to use the default normalization by  $N - 1$ , or 1 to use  $N$ .

The variance is the square of the standard deviation (STD).

**Examples**

Create a matrix and find the variance along the dimensions.

```
X = [4 -2 1; 9 5 7]
var(X,0,1)
ans =
```

## var

---

```
12.5000  24.5000  18.0000
```

```
var(X,0,2)
```

```
ans =
```

```
9
```

```
4
```

### See Also

[corrcoef](#) | [cov](#) | [mean](#) | [median](#) | [std](#)

**Purpose** Variable-length input argument list

**Syntax** varargin

**Description** varargin is an input variable in a function definition statement that allows the function to accept any number of input arguments. Specify varargin using lowercase characters, and include it as the last input argument after any explicitly declared inputs. When the function executes, varargin is a 1-by- $N$  cell array, where  $N$  is the number of inputs that the function receives after the explicitly declared inputs.

### **Examples** **Variable Number of Function Inputs**

Define a function in a file named `varlist.m` that accepts a variable number of inputs and displays the values of each input.

```
function varlist(varargin)
    fprintf('Number of arguments: %d\n',nargin);
    celldisp(varargin)
```

Call `varlist` with several inputs.

```
varlist(ones(3),'some text',pi)
```

```
Number of arguments: 3
```

```
varargin{1} =
     1     1     1
     1     1     1
     1     1     1
```

```
varargin{2} =
some text
```

```
varargin{3} =
3.1416
```

# varargin

---

## varargin and Declared Inputs

Define a function in a file named `varlist2.m` that expects inputs `X` and `Y`, and accepts a variable number of additional inputs.

```
function varlist2(X,Y,varargin)
    fprintf('Total number of inputs = %d\n',nargin);

    nVarargs = length(varargin);
    fprintf('Inputs in varargin(%d):\n',nVarargs)
    for k = 1:nVarargs
        fprintf('    %d\n', varargin{k})
    end
```

Call `varlist2` with more than two inputs.

```
varlist2(10,20,30,40,50)
```

```
Total number of inputs = 5
Inputs in varargin(3):
    30
    40
    50
```

- “Support Variable Number of Inputs”

## Concepts

- “Argument Checking in Nested Functions”

**Purpose** Variable-length output argument list

**Syntax** varargout

**Description** varargout is an output variable in a function definition statement that allows the function to return any number of output arguments. Specify varargout using lowercase characters, and include it as the last output argument after any explicitly declared outputs. When the function executes, varargout is a 1-by- $N$  cell array, where  $N$  is the number of outputs requested after the explicitly declared outputs.

## Examples **Variable Number of Function Outputs**

Define a function in a file named `sizeout.m` that returns an output size vector `s` and a variable number of additional scalar values.

```
function [s,varargout] = sizeout(x)
nout = max(nargout,1) - 1;
s = size(x);
for k=1:nout
    varargout{k} = s(k);
end
```

Output `s` contains the dimensions of the input array `x`. Additional outputs correspond to the individual dimensions within `s`.

Call `sizeout` on a three-dimensional array and request three outputs.

```
[s,rows,cols] = sizeout(rand(4,5,2))
```

```
s =
    4     5     2
```

```
rows =
    4
```

```
cols =
    5
```

# varargout

---

## **See Also**

`varargin` | `nargout` | `nargin` | `nargoutchk` | `narginchk` | `inputname`

**Purpose**

Apply function to table variables

**Syntax**

```
B = varfun(func,A)
B = varfun(func,A,Name,Value)
```

**Description**

`B = varfun(func,A)` applies the function `func` separately to each variable of the table `A` and returns the results in the table `B`.

The function `func` must take one input argument and return arrays with the same number of rows each time it is called. The *i*th variable in the output table, `B{: , i}`, is equal to `func(A{: , i})`.

`B = varfun(func,A,Name,Value)` applies the function `func` separately to each variable of the table `A` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables to pass to the function.

**Input Arguments****func - Function**

function handle

Function, specified as a function handle. You can define the function in a file or as an anonymous function. If `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

Use the `'OutputFormat','cell'` name-value pair argument, if the function `func` take one input argument and returns arrays with a different numbers of rows each time it is called. Otherwise, `func` must return arrays with the same number of rows.

**Example:** `func = @(x) x.^2;` computes the square of each element of an input.

**A - Input table**

table

Input table, specified as a table.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'InputVariables',2` uses only the second variable in `A` as an input to `func`.

## **'InputVariables' - Variables of A to pass to func**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `varfun` only passes the variables in `A` where the specified function returns 1 (`true`).

## **'GroupingVariables' - One or more variables in A that define groups of rows**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in `A` that have the same grouping variable values belong to the same group. `varfun` applies `func` to each group of rows within each of the variables of `A`, rather than to each entire variable.

The output, B, has one row for each group when you specify 'OutputFormat', 'uniform' or 'OutputFormat', 'cell'. When you specify 'OutputFormat', 'table', the sizes of the outputs from func determine how many rows of B correspond to each group. When multiple rows of B correspond to a group, varfun appends a unique identifier to the row names.

### 'OutputFormat' - Format of B

'table' (default) | 'uniform' | 'cell'

Format of B, specified as the comma-separated pair consisting of 'OutputFormat' and either the string 'uniform', 'table', or 'cell'.

'table' varfun returns a table with one variable for each variable in A (or each variable specified with 'InputVariables'). For grouped computation, B, also contains the grouping variables.

'table' allows you to use a function that returns values of different sizes or data types for the different variables in A. However, for ungrouped computation, func must return arrays with the same number of rows each time it is called. For grouped computation, func must return values with the same number of rows each time it is called for a given group.

This is the default output format.

'uniform' varfun concatenates the values into a vector. func must return a scalar with the same data type each time it is called.

'cell' varfun returns B as a cell array. 'cell' allows you to use a function that returns values of different sizes or data types.

### 'ErrorHandler' - Function to call if func fails

function handle

# varfun

---

Function to call if `func` fails, specified as the comma-separated pair consisting of 'ErrorHandler' and a function handle. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Index of the variable for which the error occurred.
<code>name</code>	Name of the variable for which the error occurred.

- The set of input arguments to function `func` at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
warning(S.identifier, S.message);
A = NaN; B = NaN;
```

## Output Arguments

### **B** - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Apply Element-wise Function

Define and apply an element-wise function to the variables of a table to square all the elements.

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =
```

Var1	Var2
0.71	0.23
-2.05	0.12
-0.35	-0.18
-0.82	0.23
1.57	0.41

Define the anonymous function to find the square of an input.

```
func = @(x) x.^2;
```

Apply the function to all the variables of table A.

```
B = varfun(func,A)
```

```
B =
```

Fun_Var1	Fun_Var2
0.5041	0.0529
4.2025	0.0144
0.1225	0.0324
0.6724	0.0529
2.4649	0.1681

The variables of B have names based on the function and the variable names from A.

### **Apply Function that Returns Scalar From Vector**

Compute the mean of each variable in a 5-by-2 table.

# varfun

---

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

A =

Var1	Var2
0.71	0.23
-2.05	0.12
-0.35	-0.18
-0.82	0.23
1.57	0.41

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

func uses an existing MATLAB function to define the operation.

Apply the function to all the variables of table A.

```
B = varfun(func,A)
```

B =

mean_Var1	mean_Var2
-0.188	0.162

B is a table containing the average value from each variable.

To return a numeric vector instead of a table, you can use `B = varfun(func,A,'OutputFormat','uniform')`.

## Apply Function to Groups Within Variables

Compute the group-wise means of variables in a table, A, and return them as rows in a table, B.

Create a table where one variable defines groups.

```
A = table({'test2';'test1';'test2';'test3';'test1'},...
         [0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

A =

Var1	Var2	Var3
'test2'	0.71	0.23
'test1'	-2.05	0.12
'test2'	-0.35	-0.18
'test3'	-0.82	0.23
'test1'	1.57	0.41

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

func uses an existing MATLAB function to define the operation.

Apply the function to each group of data defined by Var1.

```
B = varfun(func,A,'GroupingVariables','Var1')
```

B =

	Var1	GroupCount	mean_Var2	mean_Var3
test1	'test1'	2	-0.24	0.265
test2	'test2'	2	0.18	0.025
test3	'test3'	1	-0.82	0.23

B contains row names based on the grouping variables and a variable called GroupCount to indicate the number of entries from table A in that group.

# varfun

---

## Concepts

- “Anonymous Functions”

**Purpose** Vectorize expression

**Syntax** `vectorize(s)`  
`vectorize(f)`

**Description** `vectorize(s)` where `s` is a string expression, inserts a `.` before any `^`, `*` or `/` in `s`. The result is a character string.

---

**Note** `vectorize` will not accept inline function objects (`f`) in a future release.

---

`vectorize(f)` where `f` is an inline function object, vectorizes the formula for `f`. The result is the vectorized version of the function.

**See Also** `inline` | `cd` | `dbtype` | `delete` | `dir` | `path` | `what` | `who`

# ver

---

**Purpose** Version information for MathWorks products

**Syntax**

```
ver
ver product

product_info = ver(product)
```

**Description** ver displays:

- A header containing the current MATLAB product family version number, license number, operating system, and version of Java software for the MATLAB product.
- The version numbers for MATLAB and all other installed MathWorks products.

ver product displays, in addition to the header information:

- The current version number for product, where product is the name of the folder that contains the Contents.m file for the product you are inquiring about.

product\_info = ver(product) returns product information to the structure array, product\_info.

## Input Arguments

### product - product-specific information

string

The product or toolbox for which you want to view version information, specified as a string.

To determine the string to use, run the following code, substituting the name of a product function for *toolbxfcn*:

```
n = 'toolbxfcn';
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

## Output Arguments

### **product\_info - product name, version, release, and date**

structure array

Product name, version, release, and date, returned as a structure array with these fields: Name, Version, Release, and Date. If a license is a trial version, the value in the Version field is preceded by the letter T

## Examples

### **Version for All Installed Products**

Display version information for all installed products. The output shown here is representative. Your results may differ.

```
ver
```

```
-----
MATLAB Version: 8.2.0.29 (R2013b)
MATLAB License Number: 234567
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot (T
-----
```

```
MATLAB                               Version 8.2
Simulink                             Version 8.2
Control System Toolbox               Version 9.6
```

### **Version for a Particular Product**

Display version information for MATLAB and the Control System Toolbox product. The output shown here is representative. Your results may differ.

1. Determine the product name for Control System Toolbox by setting `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss';
pat = '(?<=^[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

```
ans=
control
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
ver control
```

```
-----  
MATLAB Version: 8.2.0.29 (R2013b)  
MATLAB License Number: 234567  
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service Pa  
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM)  
-----  
Control System Toolbox Version 9.6
```

### **Structure Containing Version for the MATLAB family of products**

Create a structure containing version information, and then display the structure values. The output shown here is representative. Your results may differ.

```
v = ver;  
for k = 1:length(v)  
    fprintf('%s\n', v(k).Name);  
    fprintf('  Version: %s\n', v(k).Version);  
end
```

```
MATLAB  
  Version: 8.2
```

```
MATLAB Builder JA  
  Version: 2.3
```

```
MATLAB Builder NE  
  Version: 4.2
```

```
MATLAB Compiler  
  Version: 5.0
```

```
My Custom Toolbox
```

Version: 1.0

## Structure Containing Version for a Particular Product

Create a structure containing version information for just the Symbolic Math Toolbox™ product. The output shown here is representative. Your results may differ.

1. Determine the product name for Symbolic Math Toolbox by setting `n` to the name of a function unique to Symbolic Math Toolbox, such as `sym`:

```
n = 'sym';  
pat = '(?<=^[\\/]toolbox[\\/])(^[\\/]+';  
regexp(which(n), pat, 'match', 'once')
```

```
ans =
```

```
symbolic
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
v = ver('symbolic')
```

```
v =
```

```
    Name: 'Symbolic Math Toolbox'  
    Version: '5.11'  
    Release: '(R2013b)'  
    Date: '19-May-2013'
```

## Concepts

- “Information About your Installation”
- “Create Help Summary Files (Contents.m)”

# verctrl

---

**Purpose** Source control actions (Windows platforms)

**Syntax**

```
verctrl('action',{filename1,'filename2',...},0)
result=verctrl('action',{filename1,'filename2',...},0)
verctrl('action','filename',0)
result=verctrl('isdiff','filename',0)
list = verctrl('all_systems')
```

**Description** verctrl('action',{filename1,'filename2',...},0) performs the source control operation specified by 'action' for a single file or multiple files. Enter one file as a string; specify multiple files using a cell array of strings. Use the full paths for each file name and include the extensions. Specify 0 as the last argument. Complete the resulting dialog box to execute the operation. Available values for 'action' are as follows:

<b>action Argument</b>	<b>Purpose</b>
'add'	Adds files to the source control system. Files can be open in the Editor or closed when added.
'checkin'	Checks files into the source control system, storing the changes and creating a new version.
'checkout'	Retrieves files for editing.
'get'	Retrieves files for viewing and compiling, but not editing. When you open the files, they are labeled as read-only.
'history'	Displays the history of files.
'remove'	Removes files from the source control system. It does not delete the files from disk, but only from the source control system.

<b>action Argument</b>	<b>Purpose</b>
'runsccl'	Starts the source control system. The file name can be an empty string.
'uncheckout'	Cancels a previous checkout operation and restores the contents of the selected files to the precheckout version. All changes made to the files since the checkout are lost.

`result=verctrl('action',{'filename1','filename2',...},0)` performs the source control operation specified by *action* on a single file or multiple files. The action can be any one of: 'add', 'checkin', 'checkout', 'get', 'history', or 'undocheckout'. `result` is a logical 1 (true) when you complete the operation by clicking **OK** in the resulting dialog box, and is a logical 0 (false) when you abort the operation by clicking **Cancel** in the resulting dialog box.

`verctrl('action','filename',0)` performs the source control operation specified by *action* for a single file. Use the absolute path for *filename*. Specify 0 as the last argument. Complete any resulting dialog boxes to execute the operation. Available values for *action* are as follows:

<b>action Argument</b>	<b>Purpose</b>
'showdiff'	Displays the differences between a file and the latest checked in version of the file in the source control system.
'properties'	Displays the properties of a file.

`result=verctrl('isdiff','filename',0)` compares `filename` with the latest checked in version of the file in the source control system. `result` is a logical 1 (true) when the files are different, and is a logical 0

(false) when the files are identical. Use the full path for 'filename'. Specify 0 as the last argument.

`list = verctrl('all_systems')` displays in the Command Window a list of all source control systems installed on your computer.

## Examples

### Check In a File

Check in D:\file1.ext to the source control system:

```
result = verctrl('checkin','D:\file1.ext', 0)
```

This opens the Check in file(s) dialog box. Click **OK** to complete the check in. MATLAB displays

```
result = 1
```

indicating the checkin was successful.

### Add Files to the Source Control System

Add D:\file1.ext and D:\file2.ext to the source control system.

```
verctrl('add',{'D:\file1.ext','D:\file2.ext'}, 0)
```

This opens the Add to source control dialog box. Click **OK** to complete the operation.

### Display the Properties of a File

Display the properties of D:\file1.ext.

```
verctrl('properties','D:\file1.ext', 0)
```

This opens the source control properties dialog box for your source control system. The function is complete when you close the properties dialog box.

### Show Differences for a File

To show the differences between the version of file1.ext that you just edited and saved, with the last version in source control, run

```
verctrl('showdiff','D:\file1.ext',0)
```

MATLAB displays differences dialog boxes and results specific to your source control system. After checking in the file, if you run this statement again, MATLAB displays

```
??? The file is identical to latest version under source control.
```

### List All Installed Source Control Systems

To view all of the source control systems installed on your computer, type

```
list = verctrl ('all_systems')
```

MATLAB displays all the source control systems currently installed on your computer. For example:

```
list =  
'Microsoft Visual SourceSafe'  
'ComponentSoftware RCS'
```

### See Also

### How To

- “Source Control Interface on Microsoft Windows”

# verLessThan

---

**Purpose** Compare toolbox version to specified version string

**Syntax** `verLessThan(toolbox, version)`

**Description** `verLessThan(toolbox, version)` returns logical 1 (true) if the version of the toolbox specified by the string `toolbox` is older than the version specified by the string `version`, and logical 0 (false) otherwise. Use this function when you want to write code that can run across multiple versions of the MATLAB software, when there are differences in the behavior of the code in the different versions.

The `toolbox` argument is a string enclosed within single quotation marks that contains the name of a MATLAB toolbox folder. The `version` argument is a string enclosed within single quotation marks that contains the version to compare against. This argument must be in the form `major[.minor[.revision]]`, such as 7, 7.1, or 7.0.1. If `toolbox` does not exist, MATLAB generates an error.

To specify `toolbox`, find the folder that holds the `Contents.m` file for the toolbox and use that folder name. To see a list of all toolbox folder names, enter the following statement in the MATLAB Command Window:

```
dir([matlabroot '/toolbox'])
```

## Examples

These examples illustrate usage of the `verLessThan` function.

### Example 1 – Checking For the Minimum Required Version

```
if verLessThan('simulink', '4.0')
    error('Simulink 4.0 or higher is required.');
```

```
end
```

### Example 2 – Choosing Which Code to Run

```
if verLessThan('matlab', '7.0.1')
% -- Put code to run under MATLAB 7.0.0 and earlier here --
else
% -- Put code to run under MATLAB 7.0.1 and later here --
```

```
end
```

### Example 3 – Looking Up the Folder Name

Find the name of the Data Acquisition Toolbox folder:

```
dir([matlabroot '/toolbox/d*'])
```

```
    daq      database    des      distcomp  dotnetbuilder  
dastudio  datafeed    dials    dml       dspblks
```

Use the toolbox folder name, daq, to compare the Data Acquisition Toolbox software version that MATLAB is currently running against version number 3:

```
verLessThan('daq', '3')  
ans =  
    1
```

# version

---

**Purpose** Version number for MATLAB and libraries

**Syntax**

```
version
version -date
version -description
version -release
version -java
v = version('-versionOption')
[v d] = version
```

**Description**

`version` returns in `ans` the version and release number for the MATLAB software currently running.

`version -date` returns in `ans` the release date for the MATLAB software.

`version -description` returns in `ans` a description of the version. Usually, the description is for special versions, such as beta versions.

`version -release` returns in `ans` the release number for the MATLAB software currently running.

`version -java` returns in `ans` the version of the Sun Microsystems™ JVM software that MATLAB is using.

`v = version('-versionOption')`, where *versionOption* is one of the above option strings, is an alternate form of the syntax.

`[v d] = version` returns the version and release number in string `v` and the release date in string `d`. No input arguments are allowed in this syntax.

**Examples**      **Display MATLAB Version**

```
version

ans =

8.2.0.29 (R2013b)
```

## Display MATLAB Release

Display the release, prefaced by a descriptor.

```
['Release R' version('-release')]
```

```
ans =
```

```
Release R2013b
```

## Get Release Version and Date as Separate Strings

```
[v d] = version
```

```
v =
```

```
8.2.0.29 (R2013b)
```

```
d =
```

```
May 19, 2013
```

## Display Java Version

```
version -java
```

```
ans =
```

```
Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Ser
```

## How To

- “Check for Software Updates”

# vertcat

---

**Purpose** Concatenate arrays vertically

**Syntax** `C = vertcat(A1,...,AN)`

**Description** `C = vertcat(A1,...,AN)` vertically concatenates arrays `A1,...,AN`. All arrays in the argument list must have the same number of columns.

- If the inputs are multidimensional arrays, `vertcat` concatenates N-dimensional arrays along the first dimension. The remaining dimensions must match.
- If the inputs are tables, `vertcat` concatenates by matching variable names. Variable names for all tables must be identical, except for order. Row names, when present, must be unique across tables.

`vertcat` fills in default row names when some of the inputs have names and some do not. `vertcat` assigns values for each table property (except for `RowNames`) using the first nonempty value for the corresponding property in the tables `A1,...,AN`.

`vertcat` also concatenates character strings. Each string being concatenated must have the same number of characters.

MATLAB calls `C = vertcat(A1, A2, ...)` for the syntax `C = [A1; A2; ...]` when any of the inputs are an object.

**Tips** You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”.

**Examples** **Vertically Concatenate Two Matrices**

Create a 5-by-3 matrix, `A`.

```
A = magic(5);  
A(:, 4:5) = []
```

```
A =
```

```
    17    24     1  
    23     5     7  
     4     6    13  
    10    12    19  
    11    18    25
```

Create a 3-by-3 matrix, B.

```
B = magic(3)*100
```

```
B =
```

```
    800    100    600  
    300    500    700  
    400    900    200
```

Vertically concatenate A and B.

```
C = vertcat(A,B)
```

```
C =
```

```
    17    24     1  
    23     5     7  
     4     6    13  
    10    12    19  
    11    18    25  
    800    100    600  
    300    500    700  
    400    900    200
```

### Vertically Concatenate Two Tables

Create a table, A, with three rows and five variables.

# vertcat

```
A = table([5;6;5],[ 'M'; 'M'; 'M'],[45;41;40],[45;32;34],{'NY'; 'CA'; 'MA'},...
    'VariableNames',{'Age' 'Gender' 'Height' 'Weight' 'Birthplace'},...
    'RowNames',{'Thomas' 'Gordon' 'Percy'})
```

A =

	Age	Gender	Height	Weight	Birthplace
Thomas	5	M	45	45	'NY'
Gordon	6	M	41	32	'CA'
Percy	5	M	40	34	'MA'

Create a table, B, with the same variables as A except for order.

```
B = table(['F'; 'M'; 'F'],[6;6;5],{'AZ'; 'NH'; 'CO'},[31;42;33],[39;43;40],...
    'VariableNames',{'Gender' 'Age' 'Birthplace' 'Weight' 'Height'})
```

B =

	Gender	Age	Birthplace	Weight	Height
F		6	'AZ'	31	39
M		6	'NH'	42	43
F		5	'CO'	33	40

Vertically concatenate tables A and B.

```
C = vertcat(A,B)
```

C =

	Age	Gender	Height	Weight	Birthplace
Thomas	5	M	45	45	'NY'
Gordon	6	M	41	32	'CA'
Percy	5	M	40	34	'MA'
Row4	6	F	39	31	'AZ'
Row5	6	M	43	42	'NH'

```
Row6      5      F      40      33      'CO'
```

The variables of **C** are in the same order as the variables of **A** and default row names are used for the rows from **B**.

**See Also**

`horzcat` | `cat`

**How To**

- “Redefining Concatenation for Your Class”

# vertcat (tscollection)

---

**Purpose** Vertical concatenation for tscollection objects

**Syntax** `tsc = vertcat(tsc1,tsc2,...)`

**Description** `tsc = vertcat(tsc1,tsc2,...)` performs  
`tsc = [tsc1;tsc2;...]`

This operation appends tscollection objects. The time vectors must not overlap. The last time in tsc1 must be earlier than the first time in tsc2. All tscollection objects to be concatenated must have the same timeseries members.

**See Also** `horzcat (tscollection) | tscollection`

**Purpose** (Will be removed) Return simplices attached to specified vertices

---

**Note** `vertexAttachments(TriRep)` will be removed in a future release. Use `vertexAttachments(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `SI = vertexAttachments(TR, VI)`

**Description** `SI = vertexAttachments(TR, VI)` returns the vertex-to-simplex information for the specified vertices `VI`. For 2-D triangulations in MATLAB, the triangles `SI` are arranged in counter-clockwise order around the attached vertex `VI`.

**Input Arguments**

<code>TR</code>	Triangulation representation
<code>VI</code>	<code>VI</code> is a column vector of indices into the array of points representing the vertex coordinates, <code>TR.X</code> . The simplices associated with vertex <code>i</code> are the <code>i</code> 'th entry in the cell array. If <code>VI</code> is not specified the vertex-simplex information for the entire triangulation is returned.

**Output Arguments**

<code>SI</code>	Cell array of indices of the simplices attached to a vertex. A cell array is used to store the information because the number of simplices associated with each vertex can vary. The simplices associated with vertex <code>i</code> are in the <code>i</code> 'th entry in the cell array <code>SI</code> .
-----------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Definitions** A simplex is a triangle/tetrahedron or higher dimensional equivalent.

# TriRep.vertexAttachments

---

## Examples

### Example 1

Load a 2-D triangulation and use TriRep to compute the vertex-to-triangle relations.

```
load trimesh2d
trep = TriRep(tri, x, y);
```

Find the indices of the tetrahedra attached to the first vertex:

```
Tv = vertexAttachments(trep, 1)
Tv{:}
```

### Example 2

Perform a direct query of a 2-D triangulation created using DelaunayTri.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
```

Find the triangles attached to vertex 5:

```
t = vertexAttachments(dt,5);
```

Plot the triangulation:

```
triplot(dt);
hold on;
```

Plot the triangles attached to vertex 5 (in red):

```
triplot(dt(t{:},:),x,y,'Color','r');
hold off;
```

**See Also** [delaunayTriangulation](#) | [triangulation](#)

# VideoReader

---

**Purpose** Read video files

**Description** Use the `VideoReader` function with the `read` method to read video data from a file into the MATLAB workspace.

The file formats that `VideoReader` supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	AVI (.avi), Motion JPEG 2000 (.mj2)
All Windows	MPEG-1 (.mpg), Windows Media Video (.wmv, .asf, .asx), and any format supported by Microsoft DirectShow®.
Windows 7	MPEG-4, including H.264 encoded video (.mp4, .m4v), Apple QuickTime Movie (.mov), and any format supported by Microsoft Media Foundation.
Macintosh	MPEG-1 (.mpg), MPEG-4, including H.264 encoded video (.mp4, .m4v), Apple QuickTime Movie (.mov), and any format supported by QuickTime as listed on <a href="http://support.apple.com/kb/HT3775">http://support.apple.com/kb/HT3775</a> .
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on <a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> , including Ogg Theora (.ogg).

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

**Construction** `obj = VideoReader(filename)` constructs `obj` to read video data from the file named `filename`. If it cannot construct the object for any reason, `VideoReader` generates an error.

`obj = VideoReader(filename,Name,Value)` constructs the object with additional options specified by one or more `Name,Value` pair

arguments. Name is 'Tag' or 'UserData' and Value is the corresponding value. You can specify two name and value pair arguments in any order as Name1,Value1,Name2,Value2.

## Input Arguments

### filename

String in single quotation marks that specifies the video file to read. The VideoReader constructor searches for the file on the MATLAB path.

### Name-Value Pair Arguments

Optional comma-separated pairs of Name,Value arguments, where Name is 'Tag' or 'UserData' and Value is the corresponding value. You can specify two name and value pair arguments in any order as Name1,Value1,Name2,Value2.

### Tag

String that identifies the object.

**Default:** ''

### UserData

Generic field for data of any class that you want to add to the object.

**Default:** []

## Properties

All properties are read-only except Tag and UserData.

### BitsPerPixel

Bits per pixel of the video data.

### Duration

# VideoReader

---

Total length of the file in seconds.

## **FrameRate**

Frame rate of the video in frames per second.

## **Height**

Height of the video frame in pixels.

## **Name**

Name of the file associated with the object.

## **NumberOfFrames**

Total number of frames in the video stream.

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `VideoReader` cannot determine the number of frames until you read the last frame. When you construct the object, `VideoReader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = VideoReader('varFrameRateFile.wmv');  
lastFrame = read(vidObj, inf);  
numFrames = vidObj.NumberOfFrames;
```

For more information, see “Read Variable Frame Rate Video” in the MATLAB Data Import and Export documentation..

## **Path**

String containing the full path to the file associated with the reader.

## **Tag**

String that identifies the object.

**Default:** ''

## Type

Class name of the object: 'VideoReader'.

## UserData

Generic field for data of any class that you want to add to the object.

**Default:** []

## VideoFormat

String indicating the MATLAB representation of the video format.

Video Format	Value of VideoFormat
AVI or MPEG-4 files with RGB24 video	'RGB24'
AVI files with indexed video	'Indexed'
AVI files with grayscale video	'Grayscale'

For Motion JPEG 2000 files, VideoFormat is one of the following.

Format of Image Data	Value of VideoFormat
Single-band uint8	'Mono8'
Single-band int8	'Mono8 Signed'
Single-band uint16	'Mono16'
Single-band int16	'Mono16 Signed'
Three-banded uint8	'RGB24'
Three-banded int8	'RGB24 Signed'
Three-banded uint16	'RGB48'
Three-banded int16	'RGB48 Signed'

## Width

# VideoReader

---

Width of the video frame in pixels.

## Methods

<code>get</code>	Query property values for video reader object
<code>getFileFormats</code>	File formats that <code>VideoReader</code> supports
<code>read</code>	Read video frame data from file
<code>set</code>	Set property values for video reader object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Construct a `VideoReader` object for the example movie file `xylophone.mp4` and view its properties:

```
xyloObj = VideoReader('xylophone.mp4','Tag','My reader object');  
get(xyloObj)
```

---

Read and play back the movie file `xylophone.mp4`:

```
xyloObj = VideoReader('xylophone.mp4');  
  
nFrames = xyloObj.NumberOfFrames;  
vidHeight = xyloObj.Height;  
vidWidth = xyloObj.Width;  
  
% Preallocate movie structure.  
mov(1:nFrames) = ...  
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...  
          'colormap', []);  
  
% Read one frame at a time.
```

```
for k = 1 : nFrames
    mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])

% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

## See Also

## How To

- “Read Video Files”

# VideoWriter

---

**Purpose** Write video files

**Description** Use the `VideoWriter` object with the `open`, `writeVideo`, and `close` methods to create video files from figures, still images, or MATLAB movies. `VideoWriter` can create uncompressed AVI and Motion JPEG 2000 compressed AVI files on all platforms, and MPEG-4 files on Windows 7 and Mac OS X 10.7 and higher. `VideoWriter` supports files larger than 2 GB, which is the limit for `avifile`.

To set video properties, `VideoWriter` includes predefined *profiles* such as 'Uncompressed AVI' or 'MPEG-4'.

**Construction** `writerObj = VideoWriter(filename)` constructs a `VideoWriter` object to write video data to an AVI file with Motion JPEG compression.

`writerObj = VideoWriter(filename,profile)` applies a set of properties tailored to a specific file format (such as 'MPEG-4' or 'Uncompressed AVI') to a `VideoWriter` object.

## Input Arguments

### **filename**

String enclosed in single quotation marks that specifies the name of the file to create.

`VideoWriter` supports these file extensions:

<code>.avi</code>	AVI file
<code>.mj2</code>	Motion JPEG 2000 file
<code>.mp4</code> or <code>.m4v</code>	MPEG-4 file (systems with Windows 7 or Mac OS X 10.7 and later)

If you do not specify a valid file extension, `VideoWriter` appends the extension `.avi`, `.mj2` or `.mp4`, depending on the `profile`. If you do not specify a value for `profile`, then `VideoWriter` creates a Motion JPEG compressed AVI file with the extension `.avi`.

## profile

String enclosed in single quotation marks that describes the type of file to create. Specifying a profile sets default values for video properties such as `VideoCompressionMethod`. Possible values:

'Archival'	Motion JPEG 2000 file with lossless compression
'Motion JPEG AVI'	Compressed AVI file using Motion JPEG codec
'Motion JPEG 2000'	Compressed Motion JPEG 2000 file
'MPEG-4'	Compressed MPEG-4 file with H.264 encoding (systems with Windows 7 or Mac OS X 10.7 and later)
'Uncompressed AVI'	Uncompressed AVI file with RGB24 video
'Indexed AVI'	Uncompressed AVI file with indexed video
'Grayscale AVI'	Uncompressed AVI file with grayscale video

**Default:** 'Motion JPEG AVI'

## Properties

### ColorChannels

Number of color channels in each output video frame. (Read-only)

AVI and MPEG-4 files with RGB24 data have three color channels. Indexed and Grayscale AVI files have one color channel. The number of channels for Motion JPEG 2000 files depends on the input data to the `writeVideo` method: one for monochrome image data, three for color data.

### Colormap

P-by-3 numeric matrix that contains color information about the video file. The colormap can have a maximum of 256 entries of type `uint8` or `double`. The entries of the colormap must be integers. Each row of `Colormap` specifies the red, green, and blue components of a single color. The colormap can be set explicitly before the call to `open`, or using the `colormap` field of a movie frame structure at the time of writing the first frame.

Only applies to objects associated with Indexed AVI files.

After you call `open`, you cannot change the `Colormap` value.

**Default:** none

## **CompressionRatio**

Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. The data is compressed as much as possible, up to the specified target.

Only available for objects associated with Motion JPEG 2000 files. After you call `open`, you cannot change the `CompressionRatio` value. If you previously set `LosslessCompression` to `true`, setting `CompressionRatio` generates an error.

**Default:** 10

## **Duration**

Scalar value specifying the duration of the file in seconds.  
(Read-only)

## **FileFormat**

String specifying the type of file to write: `'avi'`, `'mp4'`, or `'mj2'`.  
(Read-only)

## **Filename**

String specifying the name of the file. (Read-only)

## **FrameCount**

Number of frames written to the video file. (Read-only)

## **FrameRate**

Rate of playback for the video in frames per second. After you call `open`, you cannot change the `FrameRate` value.

**Default:** 30

## **Height**

Height of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame height for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a row of black pixels at the bottom.

## **LosslessCompression**

Boolean value (logical `true` or `false`) only available for objects associated with Motion JPEG 2000 files. If `true`:

- The `writeVideo` method uses reversible mode so that the decompressed data is identical to the input data.
- `VideoWriter` ignores any specified value for `CompressionRatio`.

After you call `open`, you cannot change the `LosslessCompression` value.

**Default:** `false` for the 'Motion JPEG 2000' profile, `true` for the 'Archival' profile

## **MJ2BitDepth**

# VideoWriter

---

Number of least significant bits in the input image data, from 1 to 16.

Only available for objects associated with Motion JPEG 2000 files. If you do not specify a value before calling the `open` method, `VideoWriter` sets the bit depth based on the input data type. For example, if the input data to `writeVideo` is an array of `uint8` or `int8` values, `MJ2BitDepth` is 8.

## **Path**

String specifying the fully qualified path. (Read-only)

## **Quality**

Integer from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.

Only available for objects associated with the MPEG-4 or Motion JPEG AVI profile. After you call `open`, you cannot change the `Quality` value.

**Default:** 75

## **VideoBitsPerPixel**

Number of bits per pixel in each output video frame. (Read-only)

AVI and MPEG-4 files have 24 bits per pixel (8 bits for each of three color bands).

For Motion JPEG 2000 files, the number of bits per pixel depends on the value of `MJ2BitDepth` and the number of bands of image data. For example, if the input data to `writeVideo` is a three-dimensional array of `uint16` or `int16` values, the default value of `MJ2BitDepth` is 16, and `VideoBitsPerPixel` is 48 (three times the bit depth).

## **VideoCompressionMethod**

String indicating the type of video compression: 'None', 'H.264', 'Motion JPEG', or 'Motion JPEG 2000'. (Read-only)

## VideoFormat

String indicating the MATLAB representation of the video format. (Read-only)

Video Format	Value of VideoFormat
AVI or MPEG-4 files with RGB24 video	'RGB24'
AVI files with indexed video	'Indexed'
AVI files with grayscale video	'Grayscale'

For Motion JPEG 2000 files, VideoFormat depends on the value of MJ2BitDepth and the format of the input image data to the writeVideo method. For example, if you do not specify the MJ2BitDepth property, VideoWriter sets the format as shown in this table.

Format of Image Data	Value of VideoFormat
Single-band uint8	'Mono8'
Single-band int8	'Mono8 Signed'
Single-band uint16	'Mono16'
Single-band int16	'Mono16 Signed'
Three-banded uint8	'RGB24'
Three-banded int8	'RGB24 Signed'
Three-banded uint16	'RGB48'
Three-banded int16	'RGB48 Signed'

## Width

# VideoWriter

---

Width of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame width for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a column of black pixels along the right side.

## Methods

<code>close</code>	Close file after writing video data
<code>getProfiles</code>	List profiles and file formats supported by <code>VideoWriter</code>
<code>open</code>	Open file for writing video data
<code>writeVideo</code>	Write video data to file

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### View and Set Object Properties

Construct a `VideoWriter` object and view its properties.

```
writerObj = VideoWriter('newfile.avi')
```

Set the frame rate to 60 frames per second, using the `FrameRate` property.

```
writerObj.FrameRate = 60;
```

### AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
```

```
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);  
axis tight  
set(gca, 'nextplot', 'replacechildren');  
set(gcf, 'Renderer', 'zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20  
    surf(sin(2*pi*k/20)*Z,Z)  
    frame = getframe;  
    writeVideo(writerObj, frame);  
end  
  
close(writerObj);
```

## See Also

[VideoReader](#) | [mmfileinfo](#)

# view

---

**Purpose** Viewpoint specification

**Syntax**

```
view(az,e1)
view([az,e1])
view([x,y,z])
view(2)
view(3)
view(ax,...)
[az,e1] = view
```

**Description** The position of the viewer (the viewpoint) determines the orientation of the axes. You specify the viewpoint in terms of azimuth and elevation, or by a point in three-dimensional space.

`view(az,e1)` and `view([az,e1])` set the viewing angle for a three-dimensional plot. The azimuth, `az`, is the horizontal rotation about the  $z$ -axis as measured in degrees from the negative  $y$ -axis. Positive values indicate counterclockwise rotation of the viewpoint. `e1` is the vertical elevation of the viewpoint in degrees. Positive values of elevation correspond to moving above the object; negative values correspond to moving below the object.

`view([x,y,z])` sets the view direction to the Cartesian coordinates  $x$ ,  $y$ , and  $z$ . The magnitude of  $(x,y,z)$  is ignored.

`view(2)` sets the default two-dimensional view, `az = 0`, `e1 = 90`.

`view(3)` sets the default three-dimensional view, `az = 37.5`, `e1 = 30`.

`view(ax,...)` uses axes `ax` instead of the current axes.

`[az,e1] = view` returns the current azimuth and elevation.

**Tips** Azimuth is a polar angle in the  $x$ - $y$  plane, with positive angles indicating counterclockwise rotation of the viewpoint. Elevation is the angle above (positive angle) or below (negative angle) the  $x$ - $y$  plane.

This diagram illustrates the coordinate system. The arrows indicate positive directions.

## Examples

View the object from directly overhead.

```
az = 0;  
el = 90;  
view(az, el);
```

Set the view along the  $y$ -axis, with the  $x$ -axis extending horizontally and the  $z$ -axis extending vertically in the figure.

```
view([0 0]);
```

Rotate the view about the  $z$ -axis by  $180^\circ$ .

```
az = 180;  
el = 90;  
view(az, el);
```

# view

---

## See Also

[hgtransform](#) | [rotate3d](#) | [CameraPosition](#) | [CameraTarget](#) | [CameraViewAngle](#) | [Projection](#)

## How To

- “View Overview”
-

**Purpose** View transformation matrices

**Syntax**

```
viewmtx
T = viewmtx(az,e1)
T = viewmtx(az,e1,phi)
T = viewmtx(az,e1,phi,xc)
```

**Description** viewmtx computes a 4-by-4 orthographic or perspective transformation matrix that projects four-dimensional homogeneous vectors onto a two-dimensional view surface (e.g., your computer screen).

`T = viewmtx(az,e1)` returns an *orthographic* transformation matrix corresponding to azimuth `az` and elevation `e1`. `az` is the azimuth (i.e., horizontal rotation) of the viewpoint in degrees. `e1` is the elevation of the viewpoint in degrees. This returns the same matrix as the commands

```
view(az,e1)
T = view
```

but does not change the current view.

`T = viewmtx(az,e1,phi)` returns a *perspective* transformation matrix. `phi` is the perspective viewing angle in degrees. `phi` is the subtended view angle of the normalized plot cube (in degrees) and controls the amount of perspective distortion.

Phi	Description
0 degrees	Orthographic projection
10 degrees	Similar to telephoto lens
25 degrees	Similar to normal lens
60 degrees	Similar to wide-angle lens

`T = viewmtx(az,e1,phi,xc)` returns the perspective transformation matrix using `xc` as the target point within the normalized plot cube (i.e., the camera is looking at the point `xc`). `xc` is the target point that is the

center of the view. You specify the point as a three-element vector,  $x_c = [x_c, y_c, z_c]$ , in the interval  $[0,1]$ . The default value is  $x_c = [0,0,0]$ .

A four-dimensional homogenous vector is formed by appending a 1 to the corresponding three-dimensional vector. For example,  $[x, y, z, 1]$  is the four-dimensional vector corresponding to the three-dimensional point  $[x, y, z]$ .

## Examples

Determine the projected two-dimensional vector corresponding to the three-dimensional point  $(0.5, 0.0, -3.0)$  using the default view direction. Note that the point is a column vector.

```
A = viewmtx(-37.5,30);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)
x2d =
    0.3967
   -2.4459
```

These vectors trace the edges of a unit cube:

```
x = [0 1 1 0 0 0 1 1 0 0 1 1 1 1 0 0];
y = [0 0 1 1 0 0 0 1 1 0 0 0 1 1 1 1];
z = [0 0 0 0 0 1 1 1 1 1 1 0 0 1 1 0];
```

Transform the points in these vectors to the screen, then plot the object.

```
A = viewmtx(-37.5,30);
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:);
y2(:) = x2d(2,:);
figure
plot(x2,y2)
```

Use a perspective transformation with a 25 degree viewing angle:

```
A = viewmtx(-37.5,30,25);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)/x2d(4) % Normalize
x2d =
    0.1777
   -1.8858
```

Transform the cube vectors to the screen and plot the object:

```
figure
A = viewmtx(-37.5,30,25);
```

```
[m,n] = size(x);  
x4d = [x(:),y(:),z(:),ones(m*n,1)]';  
x2d = A*x4d;  
x2 = zeros(m,n); y2 = zeros(m,n);  
x2(:) = x2d(1,:)./x2d(4,:);  
y2(:) = x2d(2,:)./x2d(4,:);  
plot(x2,y2)
```

## Tutorials

- “Defining Scenes with Cameras”

**Purpose** Compare two text files, MAT-Files, binary files, Zip files, or folders

**Syntax**

```
visdiff('fname1', 'fname2')  
visdiff('filename1', 'filename2', 'type')
```

**Description** `visdiff('fname1', 'fname2')` opens the Comparison Tool and presents the differences between the two files or folders. Either ensure that the two files or folders appear on the MATLAB path, or provide the full path for each file or folder. You can compare files or any combination of folders, zip files, or Simulink manifests.

If you have Simulink Report Generator™ software, you can select a pair of Simulink models to compare XML text files generated from them.

`visdiff('filename1', 'filename2', 'type')` opens the Comparison Tool and presents the differences between the two files using the specified comparison type. *type* can be 'text' or 'binary'. If you do not specify *type*, `visdiff` creates the default comparison type for your selected files. The *type* option does not apply when comparing folders.

If there are multiple comparison types available for your selections (e.g., text, binary, file list, or XML comparison), you can create a new comparison and choose a different comparison type.

**1** In the Comparison Tool, click the New comparison button.

The dialog box Select Files or Folders for Comparison opens and shows your previous comparison selections in the drop-down lists.

**2** Change the comparison type and click **Compare**.

## Examples

### Specifying Files or Folders to Compare

The `visdiff` function accepts fully qualified file names, relative file names, or names of files on the MATLAB path.

If the files you want to compare appear on the MATLAB path or in the current folder, you can specify the file names without the full path, for example:

```
visdiff('lengthofline.m', 'lengthofline2.m')
```

or

```
visdiff('lengthofline', 'lengthofline2')
```

If the files you want to compare are not on the path, either specify the full path to each file, or add the folders to the path.

For example, to specify the fully qualified file names to compare two example files:

```
visdiff(fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'gatlin.mat'), ...  
fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'gatlin2.mat'))
```

Specify the full path to files as follows:

```
visdiff('C:\Work\comp\lengthofline.m', 'C:\Work\comp\lengthofline2.m')
```

You can specify paths to files relative to the current folder. For the preceding example, if the current folder is `Work`, then the relative paths are:

```
visdiff('comp\lengthofline.m', 'comp\lengthofline2.m')
```

### Compare Two Text Files

To view a comparison of the two example files, `lengthofline.m` and `lengthofline2.m`:

```
visdiff(fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', ...  
'examples', 'lengthofline.m'), fullfile(matlabroot, 'help', ...
```

```
'techdoc','matlab_env','examples','lengthofline2.m'))
```

For information about using the report features, see “Comparing Text Files”.

---

**Note** If the text files you compare are XML files, you see different results if you have MATLAB Report Generator installed. For details, see “Comparing Files and Folders”.

---

### Compare Two MAT-Files

To compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...  
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

For information about the report features, see “Comparing MAT-Files”.

### Compare Two Binary Files

The following example code adds a folder containing two MEX-files to the MATLAB path, and then compares the files:

```
addpath([matlabroot '\extern\examples\shrlib'])  
visdiff('shrlibsample.mexw32', 'yprime.mexw32')
```

The Comparison Tool opens and indicates that the files are different, but does not provide details about the differences.

For more information on binary comparisons, see “Comparing Binary Files”.

### Compare Two Folders or Zip Files

You can perform file list comparisons for any combinations of folders and zip files. To view an example folder comparison and instructions for using the report features, see “Comparing Folders and Zip Files”.

## Compare Files and Specify Type

To compare two example text files and specify comparison type as binary:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...  
'examples','lengthofline.m'), fullfile(matlabroot,'help',...  
'techdoc','matlab_env','examples','lengthofline2.m'), 'binary')
```

If you do not specify type, `visdiff` creates the default comparison type for your selected files, in this case, text comparison. By changing to the binary comparison type you could examine differences such as end-of-line characters.

Similarly, when you compare XML files without specifying type, you get a hierarchical XML comparison report. If instead you want a text or binary comparison, you can specify "text" or "binary" comparison types to see more details. When you compare zip files, the default comparison type is a file list comparison, and you might want to specify a binary comparison instead.

## Alternatives

As an alternative to the `visdiff` function, compare files and folders using any of these GUI methods:

- From the Current Folder browser:
  - Select a file or folder. Right-click the file or folder, and select **Compare Against**.
  - For two files or subfolders in the same folder, select the files or folders. Then, right-click, and select **Compare Selected Files/Folders**.
- From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare** and then select the files or folders to compare.
- If you have a file open in the Editor, on the **Editor** tab, in the **File** section, click **Compare**. Alternatively, under **Compare**, you can choose a file to compare against, or compare with the autosave

version or the version on disk. See “Comparing Files with Autosave Version or Version on Disk”.

**How To**

- “Comparing Files and Folders”

# volumebounds

---

**Purpose** Coordinate and color limits for volume data

**Syntax**

```
lims = volumebounds(X,Y,Z,V)
lims = volumebounds(X,Y,Z,U,V,W)
lims = volumebounds(V), lims = volumebounds(U,V,W)
```

**Description** `lims = volumebounds(X,Y,Z,V)` returns the x, y, z, and color limits of the current axes for scalar data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax cmin cmax]
```

You can pass this vector to the `axis` command.

`lims = volumebounds(X,Y,Z,U,V,W)` returns the x, y, and z limits of the current axes for vector data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax]
```

`lims = volumebounds(V)`, `lims = volumebounds(U,V,W)` assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(V)`.

**Examples** This example uses `volumebounds` to set the axis and color limits for an isosurface generated by the `flow` function.

```
[x y z v] = flow;
p = patch(isosurface(x,y,z,v,-3));
isonormals(x,y,z,v,p)
daspect([1 1 1])
isocolors(x,y,z,flipdim(v,2),p)
shading interp
axis(volumebounds(x,y,z,v))
view(3)
camlight
lighting phong
```

**See Also** [isosurface](#) | [streamslice](#)

# voronoi

---

**Purpose** Voronoi diagram

---

**Note** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `voronoi`.

---

**Syntax**

```
voronoi(x,y)
voronoi(x,y,TRI)
voronoi(dt)
voronoi(AX,...)
voronoi(...,'LineStyle')
h = voronoi(...)
[vx,vy] = voronoi(...)
```

**Description**

`voronoi(x,y)` plots the bounded cells of the Voronoi diagram for the points `x,y`. Lines-to-infinity are approximated with an arbitrarily distant endpoint.

`voronoi(x,y,TRI)` uses the triangulation `TRI` instead of computing internally.

`voronoi(dt)` uses the Delaunay triangulation `dt` instead of computing it.

`voronoi(AX,...)` plots into `AX` instead of `gca`.

`voronoi(...,'LineStyle')` plots the diagram with color and line style specified.

`h = voronoi(...)` returns, in `h`, handles to the line objects created.

`[vx,vy] = voronoi(...)` returns the finite vertices of the Voronoi edges in `vx` and `vy`.

---

**Note** For the topology of the Voronoi diagram, i.e., the vertices for each Voronoi cell, use `voronoin`.

```
[v,c] = voronoin([x(:) y(:)])
```

---

## Definitions

Consider a set of coplanar points  $P$ . For each point  $P_x$  in the set  $P$ , you can draw a boundary enclosing all the intermediate points lying closer to  $P_x$  than to other points in the set  $P$ . Such a boundary is called a *Voronoi polygon*, and the set of all Voronoi polygons for a given point set is called a *Voronoi diagram*.

## Visualization

Use one of these methods to plot a Voronoi diagram:

- If you provide no output argument, `voronoi` plots the diagram.
- To gain more control over color, line style, and other figure properties, use the syntax `[vx,vy] = voronoi(...)`. This syntax returns the vertices of the finite Voronoi edges, which you can then plot with the `plot` function.
- To fill the cells with color, use `voronoin` with `n = 2` to get the indices of each cell, and then use `patch` and other plot functions to generate the figure. Note that `patch` does not fill unbounded cells with color.

## Examples

### Example 1

This code uses the `voronoi` function to plot the Voronoi diagram for 10 randomly generated points.

```
x = gallery('uniformdata',[1 10],0);  
y = gallery('uniformdata',[1 10],1);  
voronoi(x,y)
```

# voronoi

---

## Example 2

This code uses the vertices of the finite Voronoi edges to plot the Voronoi diagram for the same 10 points.

```
x = gallery('uniformdata',[1 10],0);  
y = gallery('uniformdata',[1 10],1);  
[vx, vy] = voronoi(x,y);  
plot(x,y,'r+',vx,vy,'b-'); axis equal
```

Note that you can add this code to get the figure shown in Example 1.

```
xlim([min(x) max(x)])
ylim([min(y) max(y)])
```

### Example 3

This code uses `voronoin` and `patch` to fill the bounded cells of the same Voronoi diagram with color.

```
x = gallery('uniformdata',[10 2],5);
[v,c]=voronoin(x);
for i = 1:length(c)
if all(c{i}~=1) % If at least one of the indices is 1,
                % then it is an open region and we can't
                % patch that.
patch(v(c{i},1),v(c{i},2),i); % use color i.
end
```

# voronoi

---

end

| [voronoin](#)

**Purpose** (Will be removed) Voronoi diagram

---

**Note** `voronoiDiagram(DelaunayTri)` will be removed in a future release. Use `voronoiDiagram(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

**Syntax** `[V, R] = voronoiDiagram(DT)`

**Description** `[V, R] = voronoiDiagram(DT)` returns the vertices `V` and regions `R` of the Voronoi diagram of the points `DT.X`. The region `R{i}` is a cell array of indices into `V` that represents the Voronoi vertices bounding the region. The Voronoi region associated with the `i`'th point, `DT.X(i)` is `R{i}`. For 2-D, vertices in `R{i}` are listed in adjacent order, i.e. connecting them will generate a closed polygon (Voronoi diagram). For 3-D the vertices in `R{i}` are listed in ascending order.

The Voronoi regions associated with points that lie on the convex hull of `DT.X` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

**Input Arguments**

<code>DT</code>	Delaunay triangulation.
-----------------	-------------------------

# DelaunayTri.voronoiDiagram

---

## Output Arguments

V	numv-by-ndim matrix representing the coordinates of the Voronoi vertices, where numv is the number of vertices and ndim is the dimension of the space where the points reside.
R	Vector cell array of length(DR.X), representing the Voronoi cell associated with each point.

## Definitions

The *Voronoi diagram* of a discrete set of points  $X$  decomposes the space around each point  $X(i)$  into a region of influence  $R\{i\}$ . Locations within the region are closer to point  $i$  than any other point. The region of influence is called the Voronoi region. The collection of all the Voronoi regions is the Voronoi diagram.

The *convex hull* of a set of points  $X$  is the smallest convex polygon (or polyhedron in higher dimensions) containing all of the points of  $X$ .

## Examples

Compute the Voronoi Diagram of a set of points:

```
X = [ 0.5    0
      0     0.5
      -0.5  -0.5
      -0.2  -0.1
      -0.1   0.1
       0.1  -0.1
       0.1   0.1 ]
dt = DelaunayTri(X)
[V,R] = voronoiDiagram(dt)
```

## See Also

[voronoi](#) | [voronoin](#) | [triangulation](#) | [delaunayTriangulation](#)

**Purpose**

N-D Voronoi diagram

**Syntax**

[V,C] = voronoin(X)  
 [V,C] = voronoin(X,options)

**Description**

[V,C] = voronoin(X) returns Voronoi vertices V and the Voronoi cells C of the Voronoi diagram of X. V is a numv-by-n array of the numv Voronoi vertices in n-dimensional space, each row corresponds to a Voronoi vertex. C is a vector cell array where each element contains the indices into V of the vertices of the corresponding Voronoi cell. X is an m-by-n array, representing m n-dimensional points, where n > 1 and m >= n+1.

The first row of V is a point at infinity. If any index in a cell of the cell array is 1, then the corresponding Voronoi cell contains the first point in V, a point at infinity. This means the Voronoi cell is unbounded.

voronoin uses Qhull.

[V,C] = voronoin(X,options) specifies a cell array of strings options to be used in Qhull. The default options are

- {'Qbb'} for 2- and 3-dimensional input
- {'Qbb','Qx'} for 4 and higher-dimensional input

If options is [], the default options are used. If code is {''}, no options are used, not even the default. For more information on Qhull and its options, see <http://www.qhull.org>.

**Visualization**

You can plot individual bounded cells of an n-dimensional Voronoi diagram. To do this, use convhulln to compute the vertices of the facets that make up the Voronoi cell. Then use patch and other plot functions to generate the figure.

**Examples**

**Example 1**

Let

```
x = [ 0.5    0
      0      0.5
```

# voronoin

---

```
-0.5  -0.5
-0.2  -0.1
-0.1   0.1
 0.1  -0.1
 0.1   0.1 ]
```

then

```
[V,C] = voronoin(x)
```

V =

```
      Inf      Inf
 0.3833  0.3833
 0.7000 -1.6500
 0.2875  0.0000
-0.0000  0.2875
-0.0000 -0.0000
-0.0500 -0.5250
-0.0500 -0.0500
-1.7500  0.7500
-1.4500  0.6500
```

C =

```
[1x4 double]
[1x5 double]
[1x4 double]
[1x4 double]
[1x4 double]
[1x5 double]
[1x4 double]
```

Use a for loop to see the contents of the cell array C.

```
for i=1:length(C), disp(C{i}), end
```

```
 4   2   1   3
10   5   2   1   9
 9   1   3   7
```

```

10   8   7   9
10   5   6   8
 8   6   4   3   7
 6   4   2   5

```

In particular, the fifth Voronoi cell consists of 4 points:  $V(10, :)$ ,  $V(5, :)$ ,  $V(6, :)$ ,  $V(8, :)$ .

### Example 2

The following example illustrates the options input to `voronoin`. The commands

```

X = [-1 -1; 1 -1; 1 1; -1 1];
[V,C] = voronoin(X)

```

return an error message.

```

? qhull input error: can not scale last coordinate. Input is
cocircular
  or cospherical. Use option 'Qz' to add a point at infinity.

```

The error message indicates that you should add the option 'Qz'. The following command passes the option 'Qz', along with the default 'Qbb', to `voronoin`.

```

[V,C] = voronoin(X,{'Qbb','Qz'})
V =

```

```

  Inf   Inf
   0     0

```

C =

```

[1x2 double]
[1x2 double]
[1x2 double]
[1x2 double]

```

# voronoin

---

## Algorithms

voronoin is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>.

**Purpose**

Open or update wait bar dialog box

**Syntax**

```
h = waitbar(x,'message')
waitbar(x,'message','CreateCancelBtn','button_callback')
waitbar(x,'message',property_name,property_value,...)
waitbar(x)
waitbar(x,h)
waitbar(x,h,'updated message')
```

**Description**

A wait bar is a figure that displays what percentage of a calculation is complete as the calculation proceeds by progressively filling a bar with red from left to right.

`h = waitbar(x,'message')` displays a wait bar of fractional length `x`. The wait bar figure displays until the code that controls it closes it or the user clicks its Close Window button. Its (figure) handle is returned in `h`. The argument `x` must be between 0 and 1.

---

**Note** Wait bars are not modal figures (their `WindowStyle` is `'normal'`). They often appear to be modal because the computational loops within which they are called prevent interaction with the Command Window until they terminate. For more information, see `WindowStyle` in the MATLAB Figure Properties documentation.

---

`waitbar(x,'message','CreateCancelBtn','button_callback')` specifying `CreateCancelBtn` adds a **Cancel** button to the figure that executes the MATLAB commands specified in `button_callback` when the user clicks the **Cancel** button or the **Close Figure** button. `waitbar` sets both the **Cancel** button callback and the figure `CloseRequestFcn` to the string specified in `button_callback`.

`waitbar(x,'message',property_name,property_value,...)` optional arguments `property_name` and `property_value` enable you to set figure properties for the waitbar.

`waitbar(x)` subsequent calls to `waitbar(x)` extend the length of the bar to the new position `x`. Successive values of `x` normally increase. If they decrease, the wait bar runs in reverse.

`waitbar(x,h)` extends the length of the bar in the wait bar `h` to the new position `x`.

`waitbar(x,h,'updated message')` updates the message text in the waitbar figure, in addition to setting the fractional length to `x`.

## Examples

### Example 1 – Basic Wait Bar

Typically, you call `waitbar` repeatedly inside a `for` loop that performs a lengthy computation. For example:

```
h = waitbar(0,'Please wait...');
steps = 1000;
for step = 1:steps
    % computations take place here
    waitbar(step / steps)
end
close(h)
```

### Example 2 – Wait Bar with Dynamic Text and Cancel Button

Adding a **Cancel** button allows user to abort the computation. Clicking it sets a logical flag in the figure's application data (`appdata`). The function tests for that value within the main loop and exits the loop as soon as the flag has been set. The example iteratively approximates the value of  $\pi$ . At each step, the current value is encoded as a string and displayed in the wait bar's message field. When the function finishes,

it destroys the wait bar and returns the current estimate of  $\pi$  and the number of steps it ran.

Copy the following function to a code file and save it as `approxpi.m`. Execute it as follows, allowing it to run for 10,000 iterations.

```
[estimated_pi steps] = approxpi(10000)
```

You can click **Cancel** or close the window to abort the computation and return the current estimate of  $\pi$ .

```
function [valueofpi step] = approxpi(steps)
% Converge on pi in steps iterations, displaying waitbar.
% User can click Cancel or close button to exit the loop.
% Ten thousand steps yields error of about 0.001 percent.

h = waitbar(0,'1','Name','Approximating pi...',...
           'CreateCancelBtn',...
           'setappdata(gcf,'canceling',1)');
setappdata(h,'canceling',0)
% Approximate as  $\pi^2/8 = 1 + 1/9 + 1/25 + 1/49 + \dots$ 
pisqover8 = 1;
denom = 3;
valueofpi = sqrt(8 * pisqover8);
for step = 1:steps
    % Check for Cancel button press
    if getappdata(h,'canceling')
        break
    end
    % Report current estimate in the waitbar's message field
    waitbar(step/steps,h,sprintf('%12.9f',valueofpi))
    % Update the estimate
    pisqover8 = pisqover8 + 1 / (denom * denom);
    denom = denom + 2;
    valueofpi = sqrt(8 * pisqover8);
end
delete(h)      % DELETE the waitbar; don't try to CLOSE it.
```

# waitbar

---

The function sets the figure Name property to describe what is being computed. In the for loop, calling waitbar sets the fractional progress indicator and displays intermediate results. the code `waitbar(i/steps,h,sprintf('%12.9f',valueofpi))` sets the wait bar's message variable to a string representation of the current estimate of  $\pi$ . Naturally, the extra computation involved makes iterations last longer than they need to, but such feedback can be helpful to users.

---

**Note** You should call `delete` to remove a wait bar when you give it a `CloseRequestFcn`, as in the preceding code; calling `close` does not close it, and makes its `Cancel` and `Close Window` buttons unresponsive. This happens because the figure's `CloseRequestFcn` recursively calls itself. In such a situation you must forcibly remove the wait bar, for example like this:

```
set(0,'ShowHiddenHandles','on')
delete(get(0,'Children'))
```

However, as issuing these commands will delete all open figures—not just the wait bar—it is best never to use `close` in a `CloseRequestFcn` to close a window.

---

`close` | `delete` | `dialog` | `msgbox` | `getappdata` | `setappdata`

**Purpose**

Block execution and wait for event or condition

**Syntax**

```
waitfor(h)
waitfor(h, 'PropertyName')
waitfor(h, 'PropertyName', PropertyValue)
```

**Description**

`waitfor(h)` blocks the caller from executing statements until the graphics object identified by handle `h` closes (is deleted). `h` must be scalar. When object `h` no longer exists, `waitfor` returns, enabling execution to resume. If the object does not exist, `waitfor` returns immediately without processing any events.

`waitfor(h, 'PropertyName')` blocks the caller from executing until the value of `'PropertyName'` (any property of the graphics object `h`) changes or `h` closes (is deleted). If `'PropertyName'` is not a valid property for the object, `waitfor` returns immediately without processing any events.

`waitfor(h, 'PropertyName', PropertyValue)` blocks the caller from executing until the value of `'PropertyName'` for the graphics object `h` changes to the specific value `PropertyValue` or `h` closes (is deleted). If the value of `'PropertyName'` is already `PropertyValue`, `waitfor` returns immediately without processing any events.

**Definitions**

- `waitfor` blocks execution so that command-line expressions and subsequent statements in the blocked file do not execute until a specified condition occurs.
- While `waitfor` prevents its caller from continuing, callbacks that respond to various events (for example, pressing a mouse button) can still run, unaffected by `waitfor`.
- `waitfor` also blocks Simulink models from executing, but callbacks do still execute.
- `waitfor` can block nested function calls. For example, a callback invoked while `waitfor` is active can invoke `waitfor`.
- If you type **Ctrl+C** in the Command Window while `waitfor` is blocking execution, the executing program terminates. To avoid

terminating, the program can call `waitfor` within a `try/catch` block that handles the exception that typing **Ctrl+C** generates. To learn more, see the third following example.

## Examples

Create a plot and pause execution of the rest of the statements until you close the figure window:

```
f = warndlg('This is a warning.', 'A Warning Dialog');
disp('This prints immediately');
drawnow      % Necessary to print the message
waitfor(f);
disp('This prints after you close the warning dialog');
```

---

Suspend execution until name of figure changes:

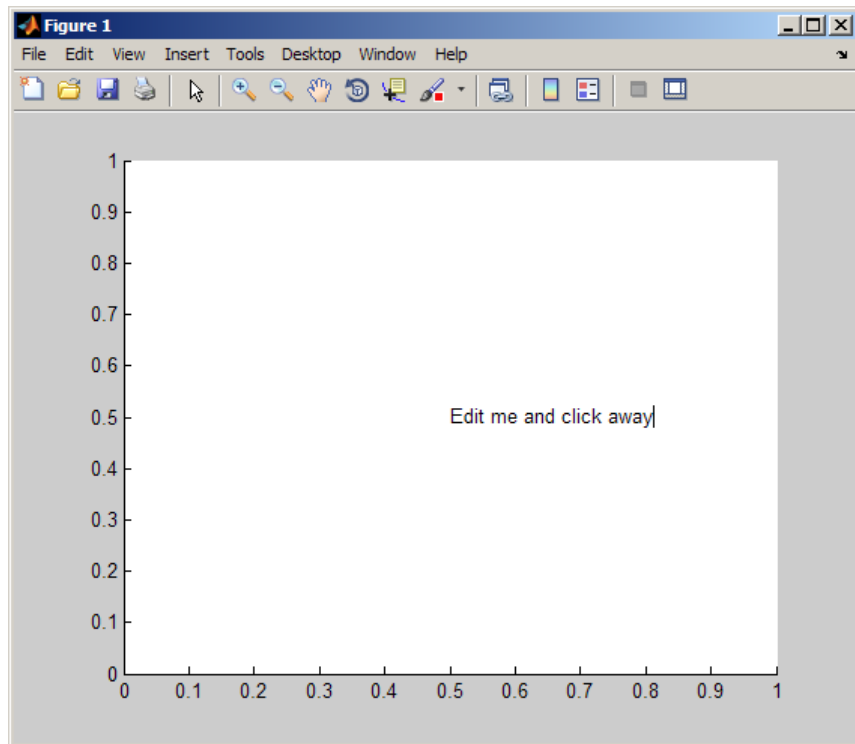

```
f = figure('Name', datestr(now));
h = uicontrol('String', 'Change Name', 'Position', [20 20 100 30], ...
'Callback', 'set(gcf, 'Name', datestr(now))');
disp('This prints immediately');
drawnow      % Necessary to print the message
waitfor(f, 'Name');
disp('This prints after button click that changes the figure''s name');
```

---

Display text object and wait for user to edit it:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH, 'Editing', 'on', 'BackgroundColor', [1 1 1]);
disp('This prints immediately. ');
drawnow
waitfor(textH, 'Editing', 'off');
set(textH, 'BackgroundColor', [1 1 0]);
disp('This prints after text editing is complete.');
```

If you close the figure while `waitfor` is executing, an error occurs because the code attempts to access handles of objects that no longer exist. You can handle the error by enclosing code starting with the call to `waitfor` in a `try/catch` block, as follows:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately.');
```

`drawnow`

```
% Use try/catch block to handle errors, such as deleting figure
try
    waitfor(textH,'Editing','off');
    set(textH,'BackgroundColor',[1 1 0]);
```

# waitfor

---

```
        disp('This prints after text editing is complete.');
```

```
catch ME
```

```
    disp('This prints if figure is deleted:')
```

```
    disp(ME.message)
```

```
    % You can place other code to respond to the error here
```

```
end
```

The ME variable is a MATLAB Exception object that you can use to determine the type of error that occurred. For more information, see “Respond to an Exception”.

## How To

- “Control Callback Execution and Interruption”

<b>Purpose</b>	Wait for key press or mouse-button click
<b>Syntax</b>	<code>k = waitforbuttonpress</code>
<b>Description</b>	<p><code>k = waitforbuttonpress</code> blocks the caller's execution stream until the function detects that the user has clicked a mouse button or pressed a key while the figure window is active. The function returns</p> <ul style="list-style-type: none"><li>• 0 if it detects a mouse button click</li><li>• 1 if it detects a key press</li></ul> <p>If a <code>WindowButtonDownFcn</code> is defined for the figure, its callback is executed before <code>waitforbuttonpress</code> returns a value.</p> <p>Only keys that generate characters cause the function to return. Pressing any of the following keys by itself does nothing: <b>Ctrl</b>, <b>Shift</b>, <b>Alt</b>, <b>Caps_lock</b>, <b>Num_lock</b>, <b>Scroll_lock</b>.</p> <p>Additional information about the event that causes execution to resume is available through the figure <code>CurrentCharacter</code>, <code>SelectionType</code>, and <code>CurrentPoint</code> properties.</p> <p>You can interrupt <code>waitforbuttonpress</code> by typing <b>Ctrl+C</b>, but an error results unless the function is called from within a <code>try/catch</code> block. You also receive an error from <code>waitforbuttonpress</code> if you close the figure by clicking the <b>X</b> close box unless you call <code>waitforbuttonpress</code> within a <code>try/catch</code> block.</p>

**Examples** These statements display text in the Command Window when the user either clicks a mouse button or types a key in the figure window:

```
w = waitforbuttonpress;
if w == 0
    disp('Button click')
else
    disp('Key press')
end
```

# waitforbuttonpress

---

## See Also

`dragrect` | `ginput` | `rbbox` | `waitfor`

**Purpose**

Open warning dialog box

**Syntax**

```
h = warndlg
h = warndlg(warningstring)
h = warndlg(warningstring,dlgname)
h = warndlg(warningstring,dlgname,createmode)
```

**Description**

`h = warndlg` displays a dialog box named Warning Dialog containing the string `This is the default warning string`. The `warndlg` function returns the handle of the dialog box in `h`. The warning dialog box disappears after the user clicks **OK**.

`h = warndlg(warningstring)` displays a dialog box with the title Warning Dialog containing the string specified by `warningstring`. The `warningstring` argument can be any valid string format – cell arrays are preferred.

To use multiple lines in your warning, define `warningstring` using either of the following:

- `sprintf` with newline characters separating the lines

```
warndlg(sprintf('Message line 1 \n Message line 2'))
```

- Cell arrays of strings

```
warndlg({'Message line 1';'Message line 2'})
```

`h = warndlg(warningstring,dlgname)` displays a dialog box with title `dlgname`.

`h = warndlg(warningstring,dlgname,createmode)` specifies whether the warning dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `warningstring` and `dlgname`. The `createmode` argument can be a string or a structure.

If `createmode` is a string, it must be one of the values shown in the following table.

createmode Value	Description
modal	Replaces the warning dialog box having the specified Title, that was last created or clicked on, with a modal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
non-modal (default)	Creates a new nonmodal warning dialog box with the specified parameters. Existing warning dialog boxes with the same title are not deleted.
replace	Replaces the warning dialog box having the specified Title, that was last created or clicked on, with a nonmodal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

If you open a dialog with `errorDlg`, `msgbox`, or `warndlg` using 'CreateMode', 'modal' and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see `WindowState` in the Figure Properties.

---

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings `'tex'` or `'none'`. The default value for `Interpreter` is `'none'`.

## Examples

The statement

```
warndlg('Pressing OK will clear memory','!! Warning !!')
```

displays this dialog box:

## See Also

# warning

---

**Purpose** Warning message

**Syntax**

```
warning('message')
warning('message', a1, a2,...)
warning('message_id', 'message')
warning('message_id', 'message', a1, a2, ..., an)
s = warning(state, 'message_id')
s = warning(state, mode)
```

**Description**

`warning('message')` displays descriptive text message and sets the warning state that `lastwarn` returns. If `message` is an empty string (`' '`), `warning` resets the warning state but does not display any text.

`warning('message', a1, a2,...)` displays a message string that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `message` is converted to one of the values `a1, a2, ...` in the argument list.

---

**Note** MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. See Example 3 below.

---

`warning('message_id', 'message')` attaches a unique identifier, or `message_id`, to the warning message. The identifier enables you to single out certain warnings during the execution of your program, controlling what happens when the warnings are encountered.

`warning('message_id', 'message', a1, a2, ..., an)` includes formatting conversion characters in `message`, and the character translations in arguments `a1, a2, ..., an`.

`s = warning(state, 'message_id')` is a warning control statement that enables you to indicate how you want MATLAB to act on certain warnings. The `state` argument can be `'on'`, `'off'`, or `'query'`. The `message_id` argument can be a message identifier string, `'all'`, or `'last'`.

Output `s` is a structure array that indicates the previous state of the selected warnings. The structure has the fields `identifier` and `state`.

`s = warning(state, mode)` is a warning control statement that enables you to display a stack trace or display more information with each warning. The `state` argument can be `'on'`, `'off'`, or `'query'`. The `mode` argument can be `'backtrace'` or `'verbose'`.

## Examples

### Example 1

Generate a warning that displays a simple string:

```
if ~ischar(p1)
    warning('Input must be a string')
end
```

### Example 2

Generate a warning string that is defined at run-time. The first argument defines a message identifier for this warning:

```
warning('MATLAB:paramAmbiguous', ...
        'Ambiguous parameter name, "%s".', param)
```

### Example 3

MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. In the single argument case shown below, `\n` is taken to mean `backslash-n`. It is not converted to a newline character:

```
warning('In this case, the newline \n is not converted.')
Warning: In this case, the newline \n is not converted.
```

But, when more than one argument is specified, MATLAB does convert special characters. This is true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
warning('WarnTests:convertTest', ...
        'In this case, the newline \n is converted.')
Warning: In this case, the newline
```

# warning

---

is converted.

## Example 4

Turn on one particular warning, saving the previous state of this one warning in `s`. Remember that this nonquery syntax performs an implicit query prior to setting the new state:

```
s = warning('on', 'Control:parameterNotSymmetric');
```

After doing some work that includes making changes to the state of some warnings, restore the original state of all warnings:

```
warning(s)
```

**Purpose** Waterfall plot

**Syntax**

```
waterfall(Z)
waterfall(X,Y,Z)
waterfall(...,C)
waterfall(axes_handles,...)
h = waterfall(...)
```

**Description** The `waterfall` function draws a mesh similar to the `meshz` function, but it does not generate lines from the columns of the matrices. This produces a “waterfall” effect.

`waterfall(Z)` creates a waterfall plot using  $x = 1:\text{size}(Z,2)$  and  $y = 1:\text{size}(Z,1)$ .  $Z$  determines the color, so color is proportional to surface height.

`waterfall(X,Y,Z)` creates a waterfall plot using the values specified in  $X$ ,  $Y$ , and  $Z$ .  $Z$  also determines the color, so color is proportional to the surface height. If  $X$  and  $Y$  are vectors,  $X$  corresponds to the columns of  $Z$ , and  $Y$  corresponds to the rows, where  $\text{length}(x) = n$ ,  $\text{length}(y) = m$ , and  $[m,n] = \text{size}(Z)$ .  $X$  and  $Y$  are vectors or matrices that define the  $x$ - and  $y$ -coordinates of the plot.  $Z$  is a matrix that defines the  $z$ -coordinates of the plot (i.e., height above a plane). If  $C$  is omitted, color is proportional to  $Z$ .

`waterfall(...,C)` uses scaled color values to obtain colors from the current colormap. Color scaling is determined by the range of  $C$ , which must be the same size as  $Z$ . MATLAB performs a linear transformation on  $C$  to obtain colors from the current colormap.

`waterfall(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = waterfall(...)` returns the handle of the `patch` graphics object used to draw the plot.

# waterfall

---

## Tips

For column-oriented data analysis, use `waterfall(Z')` or `waterfall(X',Y',Z')`.

## Examples

Produce a waterfall plot of the peaks function.

```
figure  
[X,Y,Z] = peaks(30);  
waterfall(X,Y,Z)
```

## Algorithms

The range of X, Y, and Z, or the current setting of the axes `Xlim`, `Ylim`, and `Zlim` properties, determines the range of the axes (also set by `axis`). The range of C, or the current setting of the axes `CLim` property, determines the color scaling (also set by `caxis`).

The `CData` property for the patch graphics objects specifies the color at every point along the edge of the patch, which determines the color of the lines.

The `waterfall` plot looks like a mesh surface; however, it is a patch graphics object. To create a surface plot similar to `waterfall`, use the `meshz` function and set the `MeshStyle` property of the surface to `'Row'`. For a discussion of parametric surfaces and related color properties, see `surf`.

# wavinfo

---

**Purpose** Information about WAVE (.wav) sound file

---

**Note** `wavinfo` will be removed in a future release. Use `audioinfo` instead.

---

**Syntax** `[m d] = wavinfo(filename)`

**Description** `[m d] = wavinfo(filename)` returns information about the contents of the WAVE sound file specified by the string *filename*. Enclose the *filename* input in single quotes.

*m* is the string 'Sound (WAV) file', if *filename* is a WAVE file. Otherwise, it contains an empty string ('').

*d* is a string that reports the number of samples in the file and the number of channels of audio data. If *filename* is not a WAVE file, it contains the string 'Not a WAVE file'.

**See Also** `audioplayer` | `audiorecorder` | `audioread` | `audiowrite`

**Purpose** Play recorded sound on PC-based audio output device

---

**Note** wavplay will be removed in a future release. Use audioplayer instead.

---

**Syntax**

```
wavplay(y,Fs)
wavplay(y,Fs,mode)
```

**Description** wavplay(y,Fs) plays the audio signal stored in the vector y on a PC-based audio output device. Fs is the integer sample rate in Hz (samples per second). The default value for Fs is 11025 Hz. wavplay supports only 1- or 2-channel (mono or stereo) audio signals. To play in stereo, y must be a two-column matrix.

wavplay(y,Fs,mode) specifies how wavplay interacts with the command line. The string mode is one of the following:

- 'sync' (default): You do not have access to the command line until the sound has finished playing (a blocking device call).
- 'async': You have immediate access to the command line as soon as the sound begins to play on the audio output device (a nonblocking device call). If you call wavplay again in async mode while the audio is playing, wavplay blocks access to the command line until the original playback completes.

The audio signal y can be one of four data types. The number of bits used to quantize and play back each sample depends on the data type.

#### Data Types for wavplay

Data Type	Quantization
Double-precision (default value)	16 bits/sample
Single-precision	16 bits/sample

## Data Types for wavplay (Continued)

Data Type	Quantization
16-bit signed integer	16 bits/sample
8-bit unsigned integer	8 bits/sample

### Tips

The `wavplay` function is for use only with 32-bit Microsoft Windows operating systems. To play audio data on other platforms, use `audioplayer`.

### Examples

The MAT-files `gong.mat` and `chirp.mat` both contain an audio signal `y` and a sampling frequency `Fs`. Load and play the `gong` and the `chirp` audio signals. Change the names of these signals in between load commands and play them sequentially using the `'sync'` option for `wavplay`.

```
load chirp;
y1 = y; Fs1 = Fs;
load gong;
wavplay(y1,Fs1,'sync') % The chirp signal finishes before the
wavplay(y,Fs)          % gong signal begins playing.
```

### See Also

`audioplayer` | `audioinfo` | `audioread` | `audiowrite`

**Purpose** Read WAVE (.wav) sound file

---

**Note** wavread will be removed in a future release. Use audioread instead.

---

**Syntax**

```
y = wavread(filename)
[y, Fs] = wavread(filename)
[y, Fs, nbits] = wavread(filename)
[y, Fs, nbits, opts] = wavread(filename)
[ ___ ] = wavread(filename, N)
[ ___ ] = wavread(filename, [N1 N2])
[ ___ ] = wavread( ___, fmt)
siz = wavread(filename, 'size')
```

**Description** `y = wavread(filename)` loads a WAVE file specified by the string `filename`, returning the sampled data in `y`. If `filename` does not include an extension, `wavread` appends `.wav`.

`[y, Fs] = wavread(filename)` returns the sample rate (`Fs`) in Hertz used to encode the data in the file.

`[y, Fs, nbits] = wavread(filename)` returns the number of bits per sample (`nbits`).

`[y, Fs, nbits, opts] = wavread(filename)` returns a structure `opts` of additional information contained in the WAV file. The content of this structure differs from file to file. Typical structure fields include `opts.fmt` (audio format information) and `opts.info` (text that describes the title, author, etc.).

`[ ___ ] = wavread(filename, N)` returns only the first `N` samples from each channel in the file.

`[ ___ ] = wavread(filename, [N1 N2])` returns only samples `N1` through `N2` from each channel in the file.

[ \_\_\_ ] = wavread( \_\_\_, *fmt*) specifies the data format of *y* used to represent samples read from the file. *fmt* can be either of the following values, or a partial match (case-insensitive):

- 'double'      Double-precision normalized samples (default).
- 'native'      Samples in the native data type found in the file.

*siz* = wavread(*filename*, 'size') returns the size of the audio data contained in *filename* instead of the actual audio data, returning the vector *siz* = [*samples channels*].

## Output Scaling

The range of values in *y* depends on the data format *fmt* specified. Some examples of output scaling based on typical bit-widths found in a WAV file are given below for both 'double' and 'native' formats.

## Native Formats

Number of Bits	MATLAB Data Type	Data Range
8	uint8 (unsigned integer)	$0 \leq y \leq 255$
16	int16 (signed integer)	$-32768 \leq y \leq +32767$
24	int32 (signed integer)	$-2^{23} \leq y \leq 2^{23}-1$
32	single (floating point)	$-1.0 \leq y < +1.0$

**Double Formats**

Number of Bits	MATLAB Data Type	Data Range
N<32	double	-1.0 ≤ y < +1.0
N=32	double	-1.0 ≤ y ≤ +1.0 Note: Values in y might exceed -1.0 or +1.0 for the case of N=32 bit data samples stored in the WAV file.

wavread supports multi-channel data, with up to 32 bits per sample.

wavread supports Pulse-code Modulation (PCM) data format only.

**Examples**

Create a WAV file from the example file handel.mat, and read portions of the file back into MATLAB.

```
% Create WAV file in current folder.
load handel.mat

hfile = 'handel.wav';
wavwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits, readinfo] = wavread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = wavread(hfile, nsamples);
```

# wavread

---

```
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = wavread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = wavread(hfile, [startpos endpos]);
sound(y3, Fs);
```

## See Also

```
mmfileinfo | audioinfo | audiowrite | audioread | audioplayer
| audiorecorder | sound
```

**Purpose** Record sound using PC-based audio input device

---

**Note** wavrecord will be removed in a future release. Use audiorecorder instead.

---

**Syntax**

```
y = wavrecord(n,Fs)
y = wavrecord( __ ,ch)
y = wavrecord( __ , 'dtype')
```

**Description** `y = wavrecord(n,Fs)` records `n` samples of an audio signal, sampled at a rate of `Fs` Hz (samples per second). The default value for `Fs` is 11025 Hz.

`y = wavrecord( __ ,ch)` uses `ch` number of input channels from the audio device. `ch` can be either 1 or 2, for mono or stereo, respectively. The default value for `ch` is 1.

`y = wavrecord( __ , 'dtype')` uses the data type specified by the string `'dtype'` to record the sound. The following table lists the string values for `'dtype'` along with the corresponding bits per sample and acceptable data range for `y`.

<b>dtype</b>	<b>Bits/sample</b>	<b>y Data Range</b>
'double'	16	$-1.0 \leq y < +1.0$
'single'	16	$-1.0 \leq y < +1.0$
'int16'	16	$-32768 \leq y \leq +32767$
'uint8'	8	$0 \leq y \leq 255$

**Tips** Standard sampling rates for PC-based audio hardware are 8000, 11025, 22050, and 44100 samples per second. Stereo signals are returned as two-column matrices. The first column of a stereo audio matrix corresponds to the left input channel, while the second column corresponds to the right input channel.

# wavrecord

---

The `wavrecord` function is for use only with 32-bit Microsoft Windows operating systems. To record audio data from audio input devices on other platforms, use `audiorecorder`.

## Examples

Record 5 seconds of 16-bit audio sampled at 11025 Hz. Play back the recorded sound using `wavplay`. Speak into your audio device (or produce your audio signal) while the `wavrecord` command runs.

```
Fs = 11025;  
y = wavrecord(5*Fs,Fs,'int16');  
wavplay(y,Fs);
```

## See Also

`audiorecorder` | `audioinfo` | `audioread` | `audiowrite`

**Purpose** Write WAVE (.wav) sound file

---

**Note** wavwrite will be removed in a future release. Use audiowrite instead.

---

**Syntax**

```
wavwrite(y, filename)
wavwrite(y, Fs, filename)
wavwrite(y, Fs, N, filename)
```

**Description** wavwrite(y, filename) writes the data stored in the variable *y* to a WAVE file called *filename*. The *filename* input is a string enclosed in single quotes. The data has a sample rate of 8000 Hz and is assumed to be 16-bit. Each column of the data represents a separate channel. Therefore, stereo data should be specified as a matrix with two columns.

wavwrite(y, Fs, filename) writes the data stored in the variable *y* to a WAVE file called *filename*. The data has a sample rate of *Fs* Hz and is assumed to be 16-bit.

wavwrite(y, Fs, N, filename) writes the data stored in the variable *y* to a WAVE file called *filename*. The data has a sample rate of *Fs* Hz and is *N*-bit, where *N* is 8, 16, 24, or 32.

### Input Data Ranges

The range of values in *y* depends on the number of bits specified by *N* and the data type of *y*. The following tables list the valid input ranges based on the value of *N* and the data type of *y*.

If *y* contains integer data:

N Bits	y Data Type	y Data Range	Output Format
8	uint8	$0 \leq y \leq 255$	uint8
16	int16	$-32768 \leq y \leq +32767$	int16
24	int32	$-2^{23} \leq y \leq 2^{23} - 1$	int32

If  $y$  contains floating-point data:

<b>N Bits</b>	<b><math>y</math> Data Type</b>	<b><math>y</math> Data Range</b>	<b>Output Format</b>
8	single or double	$-1.0 \leq y < +1.0$	uint8
16	single or double	$-1.0 \leq y < +1.0$	int16
24	single or double	$-1.0 \leq y < +1.0$	int32
32	single or double	$-1.0 \leq y \leq +1.0$	single

For floating point data where  $N < 32$ , amplitude values are clipped to the range  $-1.0 \leq y < +1.0$ .

---

**Note** 8-, 16-, and 24-bit files are type 1 integer pulse code modulation (PCM). 32-bit files are written as type 3 normalized floating point.

---

## See Also

| `audiorecorder` | `sound`

**Purpose**

Open Web page or file in browser

**Syntax**

```
web
web(url)
web(url,opt)
web(url,opt1,...,optN)

stat = web( ___ )
[stat,h] = web( ___ )
[stat,h,url] = web( ___ )
```

**Description**

`web` opens an empty MATLAB Web browser.

`web(url)` opens the page specified by `url` in the MATLAB Web browser. If multiple browsers are open, the page displays in the one that was most recently used.

`web(url,opt)` opens the page using the specified browser option, such as `'-new'` to create a new browser instance or `'-browser'` to use the system browser.

`web(url,opt1,...,optN)` opens the page using one or more browser options.

`stat = web( ___ )` returns the status of the operation: 0 if successful, 1 or 2 if unsuccessful. You can include any of the input arguments in previous syntaxes.

`[stat,h] = web( ___ )` returns a handle to a MATLAB Web browser that allows you to close it using the command `close(h)`. If you do not specify any inputs to the `web` function, such as `[stat,h] = web`, then the handle corresponds to the most recently used MATLAB Web browser.

[stat,h,url] = web( \_\_\_ ) returns the URL of the current page in the MATLAB Web browser.

## Input Arguments

### url - Web page address or file location

string

Web page address or file location, specified as a string. File locations can include an absolute or relative path.

If url corresponds to a file in the installed product documentation, then the page displays in the MATLAB Help browser instead of the Web browser.

**Example:** 'http:\\www.mathworks.com'

**Example:** 'myfolder/myfile.html'

### opt - Browser option

'-browser' | '-new' | '-noaddressbox' | '-notoolbar'

Browser option, specified as one of the following strings. Options can appear in any order.

- '-browser' Opens the page in a system browser window instead of the MATLAB Web browser. On Microsoft Windows and Apple Macintosh platforms, the operating system determines the system Web browser. On other systems, the default is the Mozilla® Firefox® browser, but you can change the default using MATLAB Web preferences.
- '-new' Opens the page in a new MATLAB Web browser window. Does not apply to the system browser.

- '-noaddressbox' Opens the page in a browser that does not display the address box. Only applies to new instances of the MATLAB Web browser.
- '-notoolbar' Opens the page in a browser that does not display a toolbar or address box. Only applies to new instances of the MATLAB Web browser.

**Example:** '-new', '-noaddressbox'

## Output Arguments

### **stat - Browser status**

0 | 1 | 2

Browser status, returned as an integer with one of these values:

- 0 Found and launched system browser.
- 1 Could not find system browser.
- 2 Found, but could not launch system browser.

### **h - Handle to most recent MATLAB Web browser**

scalar

Handle to the most recent MATLAB Web browser, returned as a scalar instance of the associated Java class.

If you do not request the handle when you open the page, be aware that this handle might not correspond to your most recent use of the `web` function. Other MATLAB functionality also uses the `web` function, such as links to external sites from the Help browser.

### **url - Current page address**

string

Current page address in the most recent MATLAB Web browser, returned as a string.

## Examples

### Web Page in MATLAB Web Browser

Open the MathWorks Web site home page.

```
url = 'http://www.mathworks.com';  
web(url)
```

Open the page in a new instance of the browser that does not include a toolbar.

```
web(url, '-new', '-notoolbar')
```

### File in MATLAB Web Browser

View an HTML file that resides on your system.

Create an HTML file by publishing an example program file. Copy the program file to the current folder so that the code can run during the publishing process.

```
program = fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', 'examples', 'f  
copyfile(program);  
htmlFile = publish('fourier_demo2.m');
```

View a file by specifying the file name.

```
web(htmlFile)
```

Alternatively, you can use the `file:///` URL scheme, as long as you include the full path. The `publish` function returns the path in the `htmlFile` output.

```
url = ['file:///', htmlFile];  
web(url)
```

### Web Page in System Browser

Open the MathWorks Web site home page in the system browser.

```
url = 'http://www.mathworks.com';  
web(url, '-browser')
```

## Email from System Browser

Send email from your system browser's default mail application using the `mailto:` URL scheme.

To run this example, replace the value for `email` with a valid email address.

```
email = 'myaddress@provider.ext';  
url = ['mailto:',email];  
web(url)
```

## Handle to MATLAB Web Browser

Open the MathWorks Web site home page, and then close the browser using its handle.

```
url = 'http://www.mathworks.com';  
[stat,h] = web(url);
```

Close the browser window.

```
close(h)
```

## Text Displayed in MATLAB Web Browser

View formatted text using the `text://` URL scheme.

```
web('text://<html><h1>Hello World</h1></html>')
```

## Tips

- If you plan to deploy an application that calls the `web` function using the MATLAB Compiler product, then use the `'-browser'` option.
- If you are displaying Japanese streaming text in the MATLAB Web browser, specify a header that includes the `charset` attribute. For example:

```
web(['text://<html><head><meta http-equiv="content-type" ' ' ...  
' content="text/html; charset=utf-8"></head><body>TEXT</body></html> ' ])
```

## **See Also**

`urlread` | `urlwrite`

## **Concepts**

- “Web Browsers and MATLAB”
- “Specify Proxy Server Settings for Connecting to the Internet”
- “Specify the System Browser for UNIX Platforms”

## Purpose

Day of week

## Syntax

```
DayNumber = weekday(D)
[DayNumber,DayName] = weekday(D)
[DayNumber,DayName] = weekday(D,DayForm)
[DayNumber,DayName] = weekday(D,language)
[DayNumber,DayName] = weekday(D,DayForm,language)
```

## Description

`DayNumber = weekday(D)` returns a number representing the day of the week for each element in `D`.

`[DayNumber,DayName] = weekday(D)` additionally returns abbreviated English names for the day of the week, in `DayName`.

`[DayNumber,DayName] = weekday(D,DayForm)` returns the name for the day of the week in the format specified by `DayForm`, in US English.

`[DayNumber,DayName] = weekday(D,language)` returns the abbreviated name for the day of the week in the language of the locale specified in `language`.

`[DayNumber,DayName] = weekday(D,DayForm,language)` returns the name for the day of the week in the specified format and in the language of the specified locale. You can specify `DayForm` and `language` in either order.

## Input Arguments

### **D - Serial date numbers or date strings**

vector | matrix | string | cell array of strings | character array

Serial date numbers or date strings. Date numbers can be specified as a vector or matrix. Date strings can be specified as a single string, a cell array of strings, or a character array. If `D` is a cell array of strings, it must be 1-by-`n` or `n`-by-1.

# weekday

---

If D is a single date string, a cell array of date strings, or a character array of date strings, the date strings can be in one of the following formats.

Date String Format	Example
dd-mmm-yyyy	01-Mar-2000
mm/dd/yyyy	03/01/2000
yyyy-mm-dd	2000-03-01

For date strings in other formats, first convert them to serial date numbers using the `datenum` function, before passing them to `weekday`.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | cell

## DayForm - Format of output day names

'short' (default) | 'long'

Format of the output day names, specified as one of the following strings.

DayForm	Format of DayName Names	Example
'short'	Abbreviated name	Mon
'long'	Full name	Monday

## language - Output language of day names

'en\_US' (default) | 'local'

Output language of day names in `DayName`, specified as one of the following strings.

language	Description
'en_US'	US English
'local'	Language of the current locale

## Output Arguments

### DayNumber - Value representing day of week

array of integers in the range [1,7]

Value representing the day of the week, returned as an array of integers in the range [1,7], where 1 represents Sunday, and 7 represents Saturday.

- If input D is a numeric array, then the size of DayNumber is equivalent to the size of D.
- If input D is a cell array of strings, then DayNumber is an m-by-1 vector, where m is equivalent to the length of D.

### DayName - Name of day of week

character array

Name of the day of the week, returned as a character array. The content of DayName depends on DayForm.

- If DayForm is 'short', then DayName contains an abbreviated name (for example, Tues).
- If DayForm is 'long', then DayName contains the full name of the weekday (for example, Tuesday).

DayName is m-by-n, where m is the number of serial date numbers or date strings in D.

## Examples

### Return Day of Week of a Date String

Determine the day of the week of December 21, 2012.

```
D = '21-Dec-2012';
[DayNumber,DayName] = weekday(D)
```

# weekday

---

```
DayNumber =
```

```
    6
```

```
DayName =
```

```
Fri
```

December 21, 2012 falls on a Friday.

## **Return Full Day Names of Multiple Date Numbers**

Return the full name of the day of the week for a vector of serial date numbers.

```
D = [734999;735015];  
DayForm = 'long';  
[DayNumber,DayName] = weekday(D,DayForm)
```

```
DayNumber =
```

```
    5
```

```
    7
```

```
DayName =
```

```
Thursday
```

```
Saturday
```

## **Return Full Day Names in Local Language**

Return day names in U.S. English using the language input argument.

```
D = 728647;  
DayForm = 'long';  
language = 'en_US';
```

```
[DayNumber, DayName] = weekday(D, DayForm, language)
```

```
DayNumber =
```

```
2
```

```
DayName =
```

```
Monday
```

In U.S. English, the name of the day of the week is Monday.

Return day names in the language of the current locale.

```
language = 'local';
```

```
[DayNumber, DayName] = weekday(D, DayForm, language)
```

```
DayNumber =
```

```
2
```

```
DayName =
```

```
Lundi
```

In a French locale, the name of the day of the week is Lundi.

## **Return Day of Week of a Date String in Custom Format**

Determine the day of the week for a date specified in the format `mmm.dd.yyyy`. Call `datenum` inside of `weekday` to specify the format of the input date string.

```
[DayNumber, DayName] = weekday(datenum('Dec.21.2012', 'mmm.dd.yyyy'))
```

```
DayNumber =
```

# weekday

---

6

DayName =

Fri

## **See Also**

[datenum](#) | [datevec](#) | [eomday](#)

**Purpose** List MATLAB files in folder

**Syntax**

```

what
what folderName
what className
what packageName
s = what(' folderName ')

```

**Description**

what lists the path for the current folder, and lists all files and folders relevant to MATLAB found in the current folder. Files listed are M, MAT, MEX, MDL, SLX, and P-files. Folders listed are all class and package folders.

what *folderName* lists path, file, and folder information for *folderName*.

what *className* lists path, file, and folder information for method folder @*className*. For example, what cfit lists the MATLAB files and folders in toolbox/curvefit/curvefit/@cfit.

what *packageName* lists path, file, and folder information for package folder +*packageName*. For example, what commsrc lists the MATLAB files and folders in toolbox/comm/comm/+commsrc.

s = what(' *folderName* ') returns the results in a structure array with the fields shown in the following table.

Field	Description
path	Path to folder
m	Cell array of MATLAB program file names
mat	Cell array of MAT-file names
mex	Cell array of MEX-file names
mdl	Cell array of MDL-file names
slx	Cell array of SLX-file names
p	Cell array of P-file names

# what

Field	Description
classes	Cell array of class folders
packages	Cell array of package folders

## Examples

List the MATLAB files and folders in C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012b:

```
what audiovideo
```

```
MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo
```

```
FileFormatInfo
```

```
Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo
```

```
internal writer
```

```
MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo
```

```
Contents          auinfo          mmcompinfo      wavplay
audiodevinfo      auread          mmfileinfo      wavread
audioinfo         auwrite         movie2avi       wavrecord
audioplayerreg    avgate          mu2lin          wavwrite
audioread         avifinfo        prefspanel
audiorecorderreg aviinfo         sound
audiouniquename  aviread         soundsc
audiowrite        lin2mu          wavfinfo
```

```
MAT-files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo
```

```
chirp             handel          splat
gong              laughter        train
```

Classes in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

```
VideoReader    audioplayer    avifile
VideoWriter    audiorecorder  mmreader
```

Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

```
audiovideo
```

---

Obtain a structure array containing the file and folder names in `toolbox/matlab/codetools` that are relevant to MATLAB, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012a:

```
s = what('codetools')
```

```
s =
```

```
    path: 'C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\codetools'
         m: {77x1 cell}
         mat: {0x1 cell}
         mex: {0x1 cell}
         mdl: {0x1 cell}
         slx: {0x1 cell}
         p: {0x1 cell}
    classes: {2x1 cell}
    packages: {3x1 cell}
```

---

Find the supporting files for one of the packages in the Communications System Toolbox product:

```
p1 = what('comm');
p1.packages
ans =
```

# what

---

```
'gpu'  
'internal'  
  
ans =  
  
    'internal'.  
.  
.  
p2 = what('commsrc');  
p2.m  
ans =  
    'abstractJitter.m'  
    'abstractPulse.m'  
    'combinedjitter.m'  
    'diracjitter.m'  
    'periodicjitter.m'  
    'randomjitter.m'
```

**Alternatives** Use the Current Folder browser to view the list of files in a folder.

**See Also** [dir](#) | [exist](#) | [lookfor](#) | [ls](#) | [which](#) | [who](#)

**How To**

- “Working with Files and Folders”

**Purpose** Release Notes

---

**Note** whatsnew will be removed in a future release.

---

**Syntax** whatsnew

**Description** whatsnew displays the MATLAB Release Notes in the Help browser, presenting information about new features, problems from previous releases that have been fixed in the current release, and compatibility issues.

**See Also** help | version

# which

---

**Purpose** Locate functions and files

**Syntax**

```
which item
which fun1 in fun2

which ___ -all

str = which(item)
str = which(fun1,'in',fun2)

str = which(___, '-all')
```

**Description** `which item` displays the full path for `item`.

- If `item` is a MATLAB function in an M or P file, or a Simulink model in an SLX or MDL file, then `which` displays the full path for the corresponding file. `item` must be on the MATLAB path.
- If `item` is a method in a loaded Java class, then `which` displays the package, class, and method name for that method.
- If `item` is a workspace variable, then `which` displays a message identifying `item` as a variable.
- If `item` is a file name including the extension, and it is in the current working folder or on the MATLAB path. then `which` displays the full path of `item`.

If `item` is an overloaded function or method, then `which item` returns only the path of the first function or method found.

`which fun1 in fun2` displays the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`which ___ -all` displays the paths to all items on the MATLAB path with the requested name. Such items include methods of instantiated

classes. You can use `-all` with the input arguments of any of the previous syntaxes.

`str = which(item)` returns the full path for `item` in the string, `str`.

`str = which(fun1, 'in', fun2)` returns the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`str = which(___, '-all')` returns the results of `which` in the string or cell array of strings, `str`. You can use this syntax with any of the input arguments in the previous syntax group.

## Input Arguments

### **item - Function or file to locate**

*string*

Function or file to locate, specified as a string. When using the function form of `which`, enclose all input strings in single quotes. `item` can be in one of the following forms.

Form of the <code>item</code> Input	Path to Display
<i>fun</i>	Display full path for <code>fun</code> , which can be a MATLAB function, Simulink model,
<i>classname/method</i>	Display full path for the file that defines a method in a MATLAB class. For
<i>private/fun</i>	Limit the search to private functions named <code>fun</code> . For example, <code>which private/orthog</code> or <code>which('private/orthog')</code> displays the path for <code>orthog.m</code> in the <code>/private</code> subfolder of the parent folder.

anywhere else.

# which

Form of the item Input	Path to Display
<code>classname/private/function</code>	Limit the search to private methods defined by the MATLAB class, <code>classname</code> .
<code>fun(a1,...,an)</code>	Display the path to the implementation of function <code>fun</code> which would be invoked if called with the input arguments <code>a1,...,an</code> . Use this syntax to query overloaded functions. See the Example, “Locate Function Invoked with Given Input Arguments” on page 1-6972.

## fun1 - Function to locate

string

Function to locate, specified as a string. `fun1` can be the name of a function, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see “Locate Function Invoked with Given Input Arguments” on page 1-6972.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

## fun2 - Calling file

string

Calling file, specified as a string. `fun2` can be the name of a file, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see “Locate Function Invoked with Given Input Arguments” on page 1-6972.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

## Output Arguments

### str - Function or file location

string | cell array of strings

Function or file location, returned as a string, or returned as a cell array of strings if you use `'-all'`.

- If `item` is a workspace variable, then `str` is the string 'variable'.
- If `str` is a cell array of strings, then each row of `str` identifies a function, and the functions are in order of precedence.

## Examples

### Locate MATLAB Function

Locate the `pinv` function.

```
which pinv
```

```
matlabroot\toolbox\matlab\matfun\pinv.m
```

`pinv` is in the `matfun` folder of MATLAB.

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('pinv');
```

### Locate Method in a Loaded Java Class

Create an instance of the Java class. This loads the class into MATLAB.

```
myDate = java.util.Date;
```

Locate the `setMonth` method.

```
which setMonth
```

```
setMonth is a Java method % java.util.Date method
```

### Locate Function in a MATLAB Class

Find the `fopen` function used on MATLAB `serial` class objects.

```
which serial/fopen
```

# which

---

```
matlabroot\toolbox\matlab\iofun\@serial\fopen.m
% serial method
```

MATLAB displays the path for `fopen.m` in the class folder, `@serial`.

## Locate Private Function

Find the `orthog` function in a private folder.

```
which private/orthog
```

```
matlabroot\toolbox\matlab\elmat\private\orthog.m
% Private to elmat
```

MATLAB displays the path for `orthog.m` in the `/private` subfolder of `toolbox/matlab/elmat`.

## Determine if Local Function is Called

Determine which `parseargs` function is called by `area.m`.

```
which parseargs in area
```

```
matlabroot\toolbox\matlab\specgraph\area.m (parseargs)
% Subfunction of area
```

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('parseargs','in','area');
```

## Locate Function Invoked with Given Input Arguments

Suppose you have a `matlab.io.MatFile` object that corresponds to the example MAT-file `'topography.mat'`:

```
matObj = matfile('topography.mat');
```

Display the path of the implementation of `who` that is invoked when called with the input argument (`matObj`).

```
which who(matObj)
```

```
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
% matlab.io.MatFile method
```

Store the result to a string.

```
str = which('who(matObj)')
```

```
str =
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
```

If you do not specify the input argument (`matObj`), then `which` returns only the path of the first function or method found.

```
which who
```

```
built-in (matlabroot\toolbox\matlab\general\who)
```

## Locate All Items with Given Name

Display the paths to all items on the MATLAB path with the name `fopen`.

```
which fopen -all
```

```
built-in (matlabroot\toolbox\matlab\iofun\fopen)
matlabroot\toolbox\matlab\iofun\@serial\fopen.m % serial me
matlabroot\toolbox\shared\instrument\@icinterface\fopen.m % icinterfa
matlabroot\toolbox\instrument\instrument\@i2c\fopen.m
% i2c method
```

## Return Path Names as Strings

Return the results of `which` in the string `str`.

You must use the function form of `which`, enclosing all arguments in parentheses and single quotes.

```
str = which('private/stradd', '-all');
whos str
```

# which

---

Name	Size	Bytes	Class	Attributes
str	2x1	650	cell	

## Tips

- For more information about how MATLAB uses scope and precedence when calling a function, see “Function Precedence Order”.

## Limitations

- When the class is not loaded, `which` only finds methods if they are defined in separate files in an `@-folder` and are not in any packages.

## See Also

`dir` | `doc` | `exist` | `lookfor` | `mfilename` | `path` | `type` |  
`what` | `who` | `fileparts`

**Purpose** Repeatedly execute statements while condition is true

**Syntax**

```
while expression
    statements
end
```

**Description** `while expression, statements, end` repeatedly executes one or more MATLAB program *statements* in a loop as long as an expression remains true.

An evaluated expression is true when the result is nonempty and contains all nonzero elements (logical or real numeric). Otherwise, the expression is false.

Expressions can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

---

**Note** Within the condition *expression* of an `if` or `while` statement, logical operators `&` and `|` behave as short-circuit operators. This behavior is the same as `&&` and `||`, respectively. Since `&&` and `||` consistently short-circuit in `if` and `while` condition expressions and statements, it is good practice to use `&&` and `||` instead of `&` and `|` within *expression*.

---

## Tips

- If you inadvertently create an infinite loop (that is, a loop that never ends on its own), stop execution of the loop by pressing **Ctrl+C**.
- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- You can nest any number of `while` statements. Each `while` statement requires an end keyword.

# while

---

## Examples

Find the first integer  $n$  for which `factorial(n)` is a 100-digit number.

```
n = 1;
nFactorial = 1;
while nFactorial < 1e100
    n = n + 1;
    nFactorial = nFactorial * n;
end
```

---

Count the number of lines of code in the file `magic.m`, skipping all blank lines and comments.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) || strncmp(line,'% ',1) || ~ischar(line)
        continue
    end
    count = count + 1;
end
fprintf('%d lines\n',count);
fclose(fid);
```

---

Find the root of the polynomial  $x^3 - 2x - 5$  using interval bisection.

```
a = 0; fa = -Inf;
b = 3; fb = Inf;
while b-a > eps*b
    x = (a+b)/2;
    fx = x^3-2*x-5;
    if fx == 0
        break
    elseif sign(fx) == sign(fa)
        a = x; fa = fx;
```

```
        else
            b = x; fb = fx;
        end
    end
end
disp(x)
```

---

Take advantage of short-circuiting to avoid error or warning messages.

```
x = 42;
while exist('myfunction.m') && (myfunction(x) >= pi)
    disp('Condition is true')
    break
end
```

# whitebg

---

**Purpose** Change axes background color

**Syntax**

```
whitebg  
whitebg(fig)  
whitebg(ColorSpec)  
whitebg(fig, ColorSpec)  
whitebg(fig, ColorSpec)  
whitebg(fig)
```

**Description** `whitebg` complements the colors in the current figure.

`whitebg(fig)` complements colors in all figures specified in the vector `fig`.

`whitebg(ColorSpec)` and `whitebg(fig, ColorSpec)` change the color of the axes, which are children of the figure, to the color specified by `ColorSpec`. Without a figure specification, `whitebg` or `whitebg(ColorSpec)` affects the current figure and the root's default properties so subsequent plots and new figures use the new colors.

`whitebg(fig, ColorSpec)` sets the default axes background color of the figures in the vector `fig` to the color specified by `ColorSpec`. Other axes properties and the figure background color can change as well so that graphs maintain adequate contrast. `ColorSpec` can be a 1-by-3 RGB color or a color string such as 'white' or 'w'.

`whitebg(fig)` complements the colors of the objects in the specified figures. This syntax is typically used to toggle between black and white axes background colors, and is where `whitebg` gets its name. Include the root window handle (0) in `fig` to affect the default properties for new windows or for `clf reset`.

**Tips** `whitebg` works best in cases where all the axes in the figure have the same background color.

`whitebg` changes the colors of the figure's children, with the exception of shaded surfaces. This ensures that all objects are visible against the new background color. `whitebg` sets the default properties on the root such that all subsequent figures use the new background color.

## Examples

Set the background color to blue-gray.

```
whitebg([0 .5 .6])
```

Set the background color to blue.

```
whitebg('blue')
```

## See Also

[ColorSpec](#) | [colordef](#)

# who

---

**Purpose** List variables in workspace

**Syntax**

```
who
who(variables)
who(location)
who(variables,location)
c = who(variables,location)
```

**Description**

`who` lists in alphabetical order all variables in the currently active workspace.

`who(variables)` lists only the specified variables.

`who(location)` lists variables in the specified location: 'global' for the global workspace, or '-file' for a MAT-file. For MAT-files, you must also include the file name as an input.

`who(variables,location)` lists the specified variables in the specified location. The `location` input can appear before or after `variables`.

`c = who(variables,location)` stores the names of the variables in cell array `c`. Specifying `variables` and `location` is optional.

**Tips**

- The `who` function displays the variable list unless you specify an output argument.
- When used within a nested function, the `who` function lists the variables in the workspaces of that function and all functions containing that function, grouped by workspace. This applies whether you call `who` from your function code or from the MATLAB debugger.

**Input Arguments**

**variables**

Strings that specify the variables to list. Use one of these forms:

<code>var1, var2, ...</code>	List the specified variables. Use the '*' wildcard to match patterns. For example, <code>who('A*')</code> lists all variables that start with A.
<code>'-regex', expressions</code>	List variables whose names match the specified regular expressions.

**Default:** '\*' (all variables)

### location

String that indicates whether to list variables from the global workspace or from a file:

<code>'global'</code>	Global workspace.
<code>'-file', filename</code>	MAT-file. The <i>filename</i> input can include the full, relative, or partial path.

**Default:** '' (current workspace)

## Output Arguments

**c**  
Cell array of strings that correspond to each variable name.

## Examples

Display information about variables in the current workspace whose names start with the letter a:

```
who a*
```

---

Show variables stored in MAT-file `durer.mat`:

```
who -file durer
```

This code returns:

Your variables are:

```
X          caption  map
```

---

Store the variable names from `durer.mat` in cell array `durerInfo`:

```
durerInfo = who('-file', 'durer');
```

Display the contents of cell array `durerInfo`:

```
for k=1:length(durerInfo)
    disp(durerInfo{k})
end
```

This code returns:

```
X
  caption
  map
```

---

Suppose that a file `mydata.mat` contains variables with names that start with `java` and end with `Array`. Display information about those variables:

```
whos -file mydata -regexp \<java.*Array\>
```

---

Call `who` within a nested function (`get_date`):

```
function who_demo
date_time = datestr(now);

[str pos] = textscan(date_time, '%s%s%s', ...
                    1, 'delimiter', '- :');
```

```
get_date(str);

function get_date(d)
    day = d{1};
    mon = d{2};
    year = d{3};
    who
end

end
```

When you run `who_demo`, the `who` function displays the variables by function workspace (although the name of the function does not appear in the output):

Your variables are:

```
d          mon          ans          pos
day        year        date_time  str
```

## Alternatives

To view the variables in the workspace, use the Workspace browser. To view the contents of MAT-files, use the Details Panel of the Current Folder Browser.

# matlab.io.MatFile.who

---

<b>Purpose</b>	Names of variables in MAT-file				
<b>Syntax</b>	<pre>varlist = who(matObj) varlist = who(matObj,variables)</pre>				
<b>Description</b>	<p><code>varlist = who(matObj)</code> lists alphabetically all variables in the MAT-file associated with <code>matObj</code>. Optionally, returns the list in cell array <code>varlist</code>.</p> <p><code>varlist = who(matObj,variables)</code> lists the specified variables.</p>				
<b>Input Arguments</b>	<p><b>matObj</b> Object created by the <code>matfile</code> function.</p> <p><b>variables</b> Names of variables in the MAT-file corresponding to <code>matObj</code>. Use one of these forms:</p> <table><tr><td><code>var1,...,varN</code></td><td>Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>who(matobj,'A*')</code>.</td></tr><tr><td><code>'-regexp',expressions</code></td><td>Regular expression strings that describe variable names.</td></tr></table>	<code>var1,...,varN</code>	Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>who(matobj,'A*')</code> .	<code>'-regexp',expressions</code>	Regular expression strings that describe variable names.
<code>var1,...,varN</code>	Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>who(matobj,'A*')</code> .				
<code>'-regexp',expressions</code>	Regular expression strings that describe variable names.				
<b>Output Arguments</b>	<p><b>varlist</b> Cell array of strings that correspond to each variable name.</p>				
<b>Examples</b>	<p>Display a list of variables in the example file <code>topography.mat</code>:</p> <pre>matObj = matfile('topography.mat'); who(matObj)</pre> <p>This code returns:</p>				

Your variables are:

topo            topolegend   topomap1    topomap2

## **See Also**

matfile | whos

# whos

---

**Purpose** List variables in workspace, with sizes and types

**Syntax** `whos`  
`whos(variables)`  
`whos(location)`  
`whos(variables,location)`

`S = whos( __ )`

**Description** `whos` displays in alphabetical order all variables in the currently active workspace, with information about their sizes and types.

`whos(variables)` displays only the specified variables.

`whos(location)` displays variables in the specified location.

`whos(variables,location)` displays the specified variables in the specified location. The `location` and `variables` inputs can appear in either order.

`S = whos( __ )` stores information about the variables in structure array, `S`, using no input arguments, or any of the input arguments from the previous syntaxes.

**Input Arguments**

**variables - Variables to display**

strings

Variables to display, specified as one or more strings in one of the following forms.

Form of Variables Input	Variable Names
<code>var1 ... varN</code>	List the named variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>whos('A*')</code> lists all variables in the workspace that start with A.
<code>'-regex',expr1 ... exprN</code>	List only the variables that match the regular expressions, specified as strings. For example, <code>whos('-regex','^Mon','^Tues')</code> lists only the variables in the workspace that begin with Mon or Tues.

### location - Location of variables

`'global' | 'file',filename`

Location of variables, specified as one of the following strings.

Value of location	Location of Variables
<code>'global'</code>	Global workspace.
<code>'-file',filename</code>	MAT-file. The <i>filename</i> input can include the full, relative, or partial path. For example, <code>whos('file','myFile.mat')</code> lists all variables in the MAT-file named <code>myFile.mat</code> .  <code>whos('-file',filename)</code> does not return the sizes of any MATLAB objects in file <i>filename</i> .

# whos

---

## Output Arguments

### S - Information about variables

nested structure array

Information about variables, returned as a nested structure array that contains a scalar struct for each variable. Each scalar struct contains these fields.

Field	Description
name	Name of the variable.
size	Dimensions of the variable array.
bytes	Number of bytes allocated for the variable array.
class	Class of the variable. If the variable has no value, class is '(unassigned)'.
global	True if the variable is global; otherwise, false.
sparse	True if the variable is sparse; otherwise, false.
complex	True if the variable is complex; otherwise, false.
nesting	Structure with these fields: <ul style="list-style-type: none"><li>function — Name of the nested or outer function that defines the variable.</li><li>level — Nesting level of that function.</li></ul>
persistent	True if the variable is persistent; otherwise, false.

## Examples

### Display Information About Workspace Variables

Display information about variables in the current workspace whose names start with the letter a.

```
whos('a*')
```

### Display Variables Stored in a MAT-File

Display all variables stored in the MAT-file, `durer.mat`.

```
whos('-file','durer.mat')
```

Name	Size	Bytes	Class	Attributes
X	648x509	2638656	double	
caption	2x28	112	char	
map	128x3	3072	double	

Show only variables in the MAT-file with names that end with ion.

```
whos('-file','durer.mat','-regexp','ion$')
```

Name	Size	Bytes	Class	Attributes
caption	2x28	112	char	

### Store Variable Information in a Structure Array

Store information about the variables in `durer.mat` in structure array `S`.

```
S = whos('-file','durer.mat');
```

Display the contents of `S`.

```
for k = 1:length(S)
    disp([' ' S(k).name ...
         ' ' mat2str(S(k).size) ...
         ' ' S(k).class]);
end
```

```
X [648 509] double
caption [2 28] char
map [128 3] double
```

### Create Function to Display Variable Attribute Information

In the Editor, create a function that creates variables with various persistent, global, sparse, and complex attributes, and then displays information about them.

# whos

---

```
function show_attributes
persistent p;
global g;
p = 1;
g = 2;
s = sparse(eye(5));
c = [4+5i 9-3i 7+6i];
whos
```

When you call the function, `show_attributes` displays the attributes.

```
show_attributes
```

Name	Size	Bytes	Class	Attributes
c	1x3	48	double	complex
g	1x1	8	double	global
p	1x1	8	double	persistent
s	5x5	128	double	sparse

## Call whos Within a Nested or Anonymous Function

Create a function, `whos_demo`, that contains a nested function, `get_date`. Call `whos` within the nested function.

```
function whos_demo
date_time = datestr(now);

C = strsplit(date_time,{'-', ''});
get_date(C);

    function get_date(d)
        day = d{1};
        mon = d{2};
        year = d{3};
        whos
    end
```

```
end
```

When you run the `whos_demo` function, `whos` displays the variables of the nested `get_date` function, and all functions that contain it, grouped by function workspace. This applies whether you call `whos` from your function code or from the MATLAB debugger.

```
whos_demo
```

Name	Size	Bytes	Class	Attributes
---- get_date -----				
d	1x3	372	cell	
day	1x2	4	char	
mon	1x3	6	char	
year	1x13	26	char	
---- whos_demo -----				
C	1x3	372	cell	
ans	0x0	0	(unassigned)	
date_time	1x20	40	char	

When called within an anonymous function, variables in the anonymous function also display in a group, titled with the function's signature

## Tips

- You also can view the contents of MAT-files using the Details Panel of the Current Folder browser.

## Algorithms

`whos` returns the number of bytes each variable occupies in the workspace, not in a MAT-file. Version 7 MAT-files and later are compressed, so the number of bytes in the file is typically fewer than the number of bytes required in the workspace.

## Concepts

- “What Is the MATLAB Workspace?”

# matlab.io.MatFile.whos

---

<b>Purpose</b>	Names, sizes, and types of variables in MAT-file				
<b>Syntax</b>	<code>details = whos(matObj)</code> <code>details = whos(matObj,variables)</code>				
<b>Description</b>	<code>details = whos(matObj)</code> returns information about all variables in the MAT-file associated with <code>matObj</code> . <code>details = whos(matObj,variables)</code> returns information about the specified variables.				
<b>Input Arguments</b>	<b>matObj</b> Object created by the <code>matfile</code> function. <b>variables</b> Names of variables in the MAT-file corresponding to <code>matObj</code> . Use one of these forms:  <code>var1,...,varN</code> Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>whos(matobj,'A*')</code> .  <code>'-regexp',expressions</code> Regular expression strings that describe variable names.				
<b>Output Arguments</b>	<b>details</b> Structure array with these fields (identical to the structure returned by the <code>whos</code> function):  <table><tr><td><code>name</code></td><td>Variable name</td></tr><tr><td><code>size</code></td><td>Dimensions of the variable</td></tr></table>	<code>name</code>	Variable name	<code>size</code>	Dimensions of the variable
<code>name</code>	Variable name				
<code>size</code>	Dimensions of the variable				

<code>bytes</code>	Number of bytes allocated for the array when you load the entire variable
<code>class</code>	Class (data type) of the variable
<code>global</code>	Whether the variable is global (true or false)
<code>sparse</code>	Whether the variable is sparse
<code>complex</code>	Whether the variable is complex
<code>nesting</code>	Structure with these fields: <ul style="list-style-type: none"><li><code>function</code> — Name of the nested or outer function that defines the variable</li><li><code>level</code> — Nesting level</li></ul>
<code>persistent</code>	Whether the variable is persistent

## Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');  
whos(matObj)
```

This code returns:

Name	Size	Bytes	Class	Attributes
<code>topo</code>	180x360	518400	double	
<code>topolegend</code>	1x3	24	double	
<code>topomap1</code>	64x3	1536	double	
<code>topomap2</code>	128x3	3072	double	

---

Without loading any data, find the size and number of dimensions of the variable `topo` in `topography.mat`:

```
matObj = matfile('topography.mat');  
info = whos(matObj, 'topo');
```

# matlab.io.MatFile.whos

---

```
sizeX = info.size  
nDimsX = length(sizeX)
```

This code returns:

```
sizeX =  
    180    360
```

```
nDimsX =  
        2
```

## See Also

[matfile](#) | [size](#)

**Purpose** Number of table variables

**Syntax** `W = width(T)`

**Description** `W = width(T)` returns the number of variables in table `T`.  
`width(T)` is equivalent to `size(T,2)`.

**Input Arguments** **T - Input table**  
 table

Input table, specified as a table.

Variables in a table can have multiple columns, but `width(T)` only counts the number of variables.

**Examples** **Number of Variables in Table**

Create a table, `T`.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

`T =`

	Age	Height	Weight	BloodPressure	
	—	—	—	—	
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

# width

---

Find the number of variables in table T.

```
W = width(T)
```

```
W =
```

```
4
```

T contains 4 variables; `width` does not count the row names.

The variable `BloodPressure` counts as one variable even though it contains two columns.

## See Also

```
height | size | numel
```

**Purpose** Wilkinson's eigenvalue test matrix

**Syntax** `W = wilkinson(n)`

**Description** `W = wilkinson(n)` returns one of J. H. Wilkinson's eigenvalue test matrices. It is a symmetric, tridiagonal matrix with pairs of nearly, but not exactly, equal eigenvalues.

**Examples** `wilkinson(7)`

```
ans =
```

```
 3   1   0   0   0   0   0
 1   2   1   0   0   0   0
 0   1   1   1   0   0   0
 0   0   1   0   1   0   0
 0   0   0   1   1   1   0
 0   0   0   0   1   2   1
 0   0   0   0   0   1   3
```

The most frequently used case is `wilkinson(21)`. Its two largest eigenvalues are both about 10.746; they agree to 14, but not to 15, decimal places.

# winopen

---

**Purpose** Open file in appropriate application (Windows)

**Syntax** `winopen(fileName)`

**Description** `winopen(fileName)` opens `fileName` in the associated Microsoft Windows application. The application is associated with the extension in `fileName` in the Windows operating system. `filename` is a string enclosed in single quotes. `winopen` uses a Windows shell command, and performs the same action as double-clicking the file in the Windows Explorer program. That is, `winopen` calls the application associated the file extension to open the file. Use an absolute or relative path for `fileName`.

**Examples** Open the file `thesis.doc`, located in the current folder, in the Microsoft Word program:

```
winopen('thesis.doc')
```

---

Open `myresults.html` in the system Web browser:

```
winopen('D:/myfiles/myresults.html')
```

---

On Microsoft Windows platforms, open the current folder in the Windows Explorer tool:

```
winopen(cd)
```

---

To open a file on the MATLAB path, use `winopen` with `which`. For example, to open the `meshgrid` function in the Editor, use:

```
winopen(which('meshgrid'))
```

**See Also** `dos` | `open` | `web`

**How To**

- “Opening and Running Files”

# winqueryreg

---

**Purpose** Item from Windows registry

**Syntax**

```
valnames = winqueryreg('name', 'rootkey', 'subkey')  
value = winqueryreg('rootkey', 'subkey', 'valname')  
value = winqueryreg('rootkey', 'subkey')
```

**Description** `valnames = winqueryreg('name', 'rootkey', 'subkey')` returns all value names in `rootkey\subkey` of Microsoft Windows operating system registry to a cell array of strings. The first argument is the literal quoted string, 'name'.

`value = winqueryreg('rootkey', 'subkey', 'valname')` returns the value for value name `valname` in `rootkey\subkey`.

If the value retrieved from the registry is a string, `winqueryreg` returns a string. If the value is a 32-bit integer, `winqueryreg` returns the value as an integer of the MATLAB software type `int32`.

`value = winqueryreg('rootkey', 'subkey')` returns a value in `rootkey\subkey` that has no value name property.

---

**Note** The literal **name** argument and the `rootkey` argument are case-sensitive. The `subkey` and `valname` arguments are not.

---

**Tips** This function works only for the following registry value types:

- strings (`REG_SZ`)
- expanded strings (`REG_EXPAND_SZ`)
- 32-bit integer (`REG_DWORD`)

**Examples** **Example 1**

Get the value of `CLSID` for the MATLAB sample Microsoft COM control `mwsampctrl.2`:

```
winqueryreg 'HKEY_CLASSES_ROOT' 'mwsamp.mwsampctrl.2\clsid'
```

```
ans =  
    {5771A80A-2294-4CAC-A75B-157DCDDD3653}
```

## Example 2

Get a list in variable `mousechar` for registry subkey `Mouse`, which is under subkey `Control Panel`, which is under root key `HKEY_CURRENT_USER`.

```
mousechar = winqueryreg('name', 'HKEY_CURRENT_USER', ...  
    'control panel\mouse');
```

For each name in the `mousechar` list, get its value from the registry and then display the name and its value:

```
for k=1:length(mousechar)  
    setting = winqueryreg('HKEY_CURRENT_USER', ...  
        'control panel\mouse', mousechar{k});  
    str = sprintf('%s = %s', mousechar{k}, num2str(setting));  
    disp(str)  
end
```

```
ActiveWindowTracking = 0  
DoubleClickHeight = 4  
DoubleClickSpeed = 830  
DoubleClickWidth = 4  
MouseSpeed = 1  
MouseThreshold1 = 6  
MouseThreshold2 = 10  
SnapToDefaultButton = 0  
SwapMouseButtons = 0
```

# wk1info

---

**Purpose** Determine whether file contains 1-2-3 WK1 worksheet

---

**Note** `wk1info` has been removed.

---

**Syntax** `[extens, typ] = wk1info(filename)`

**Description** `[extens, typ] = wk1info(filename)` returns the string 'WK1' in `extens`, and '1-2-3 Spreadsheet' in `typ` if the file `filename` contains a readable worksheet. The `filename` input is a string enclosed in single quotes.

**Examples** This example returns information on spreadsheet file `matA.wk1`:

```
[extens, typ] = wk1info('matA.wk1')
```

```
extens =  
    WK1  
typ =  
    123 Spreadsheet
```

**See Also** `xlsread` | `xlswrite` | `dlmread` | `dlmwrite`

## Purpose

Read Lotus 1-2-3 WK1 spreadsheet file into matrix

---

**Note** wk1read has been removed.

---

## Syntax

```
M = wk1read(filename)
M = wk1read(filename,r,c)
M = wk1read(filename,r,c,range)
```

## Description

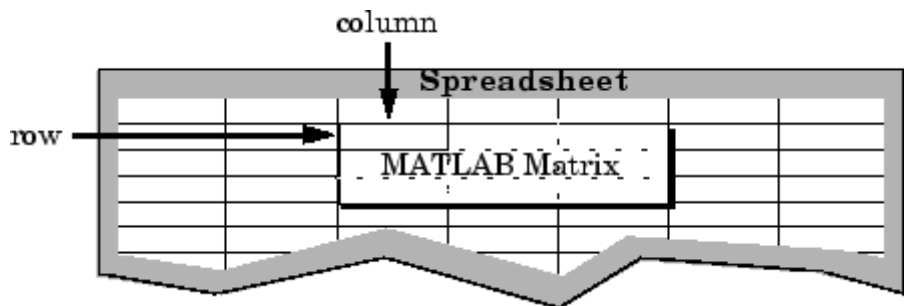

`M = wk1read(filename)` reads a Lotus1-2-3 WK1 spreadsheet file into the matrix `M`. The `filename` input is a string enclosed in single quotes.

`M = wk1read(filename,r,c)` starts reading at the row-column cell offset specified by `(r,c)`. `r` and `c` are zero based so that `r=0, c=0` specifies the first value in the file.

`M = wk1read(filename,r,c,range)` reads the range of values specified by the parameter `range`, where `range` can be

- A four-element vector specifying the cell range in the format

```
[upper_left_row upper_left_col lower_right_row lower_right_col]
```

- A cell range specified as a string, for example, 'A1...C5'
- A named range specified as a string, for example, 'Sales'

## Examples

Create a 8-by-8 matrix A and export it to Lotus spreadsheet matA.wk1:

```
A = [1:8; 11:18; 21:28; 31:38; 41:48; 51:58; 61:68; 71:78]
```

```
A =
```

1	2	3	4	5	6	7	8
11	12	13	14	15	16	17	18
21	22	23	24	25	26	27	28
31	32	33	34	35	36	37	38
41	42	43	44	45	46	47	48
51	52	53	54	55	56	57	58
61	62	63	64	65	66	67	68
71	72	73	74	75	76	77	78

```
wk1write('matA.wk1', A);
```

To read in a limited block of the spreadsheet data, specify the upper left row and column of the block using zero-based indexing:

```
M = wk1read('matA.wk1', 3, 2)
```

```
M =
```

33	34	35	36	37	38
43	44	45	46	47	48
53	54	55	56	57	58
63	64	65	66	67	68
73	74	75	76	77	78

To select a more restricted block of data, you can specify both the upper left and lower right corners of the block you want imported. Read in a range of values from row 4, column 3 (defining the upper left corner) to row 6, column 6 (defining the lower right corner). Note that, unlike the second and third arguments, the range argument [4 3 6 6] is one-based:

```
M = wk1read('matA.wk1', 3, 2, [4 3 6 6])
```

```
M =
```

33	34	35	36
43	44	45	46
53	54	55	56

**See Also**

xlsread

# wk1write

## Purpose

Write matrix to Lotus 1-2-3 WK1 spreadsheet file

---

**Note** wk1write has been removed.

---

## Syntax

```
wk1write(filename,M)
wk1write(filename,M,r,c)
```

## Description

wk1write(filename,M) writes the matrix M into a Lotus1-2-3 WK1 spreadsheet file named filename. The filename input is a string enclosed in single quotes.

wk1write(filename,M,r,c) writes the matrix starting at the spreadsheet location (r,c). r and c are zero based so that r=0, c=0 specifies the first cell in the spreadsheet.

## Examples

Write a 4-by-5 matrix A to spreadsheet file matA.wk1. Place the matrix with its upper left corner at row 2, column 3 using zero-based indexing:

```
A = [1:5; 11:15; 21:25; 31:35]
```

```
A =
```

1	2	3	4	5
11	12	13	14	15
21	22	23	24	25
31	32	33	34	35

```
wk1write('matA.wk1', A, 2, 3)
```

```
M = wk1read('matA.wk1')
```

```
M =
```

```
    0    0    0    0    0    0    0    0
    0    0    0    0    0    0    0    0
    0    0    0    1    2    3    4    5
    0    0    0   11   12   13   14   15
    0    0    0   21   22   23   24   25
    0    0    0   31   32   33   34   35
```

## See Also

# workspace

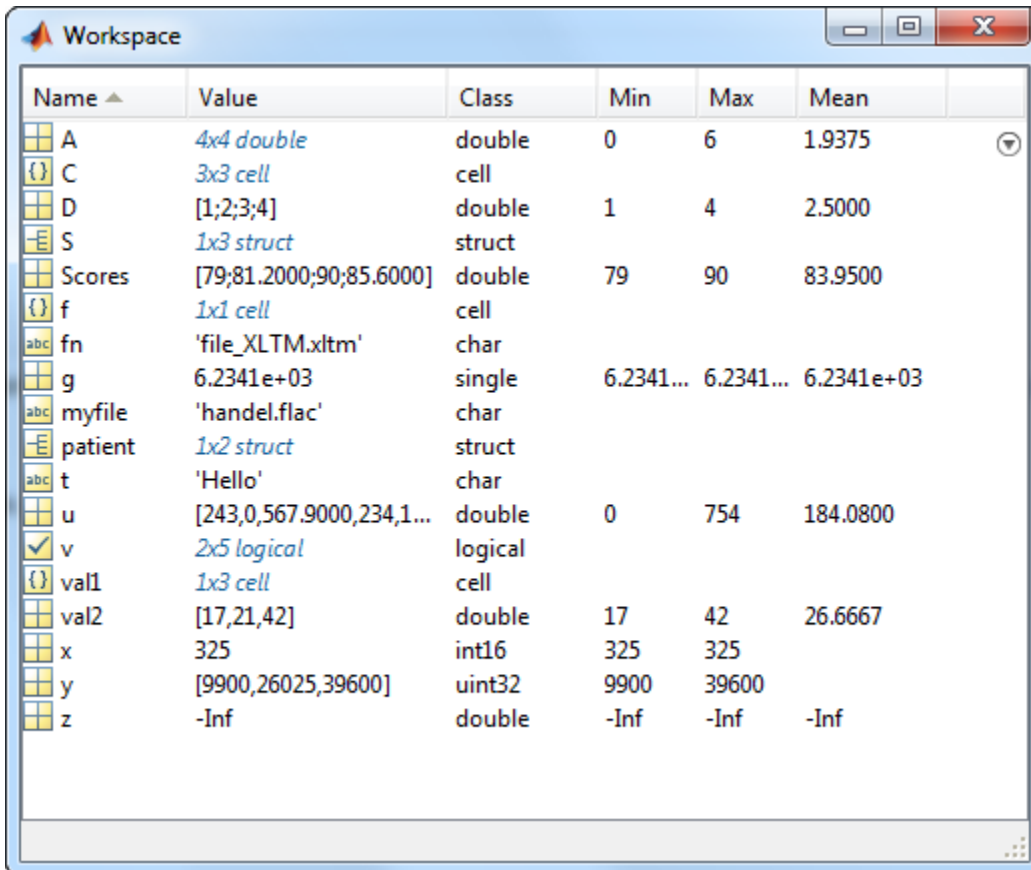

---

**Purpose** Open Workspace browser to manage workspace

**Syntax** workspace

**Description** workspace displays the Workspace browser, a graphical user interface that allows you to view and manage the contents of the workspace in MATLAB. It provides a graphical representation of the whos display, and allows you to perform the equivalent of the clear, load, open, and save functions.

The Workspace browser also displays and automatically updates statistical calculations for each variable, which you can choose to show or hide.

Name ▲	Value	Class	Min	Max	Mean	
A	4x4 double	double	0	6	1.9375	
C	3x3 cell	cell				
D	[1;2;3;4]	double	1	4	2.5000	
S	1x3 struct	struct				
Scores	[79;81.2000;90;85.6000]	double	79	90	83.9500	
f	1x1 cell	cell				
fn	'file_XLTM.xltn'	char				
g	6.2341e+03	single	6.2341...	6.2341...	6.2341e+03	
myfile	'handel.flac'	char				
patient	1x2 struct	struct				
t	'Hello'	char				
u	[243,0,567.9000,234,1...	double	0	754	184.0800	
v	2x5 logical	logical				
val1	1x3 cell	cell				
val2	[17,21,42]	double	17	42	26.6667	
x	325	int16	325	325		
y	[9900,26025,39600]	uint32	9900	39600		
z	-Inf	double	-Inf	-Inf	-Inf	

You can edit a value directly in the Workspace browser for small numeric and character arrays. To see and edit a graphical representation of larger variables and for other classes, double-click the variable in the Workspace browser. The variable displays in the Variables editor, where you can view the full contents and make changes.

**See Also** [openvar](#) | [who](#)

**How To** [• “What Is the MATLAB Workspace?”](#)

# writetable

---

**Purpose** Write table to file

**Syntax**  
`writetable(T)`  
`writetable(T,filename)`  
`writetable( __ ,Name,Value)`

**Description** `writetable(T)` writes the table, `T`, to a comma delimited text file. The file name is the workspace variable name of the table, appended with the extension `.txt`. If `writetable` cannot construct the file name from the input table name, then it writes to the file `table.txt`.

Each column of each variable in `T` becomes a column in the output file. The variable names of `T` become column headings in the first line of the file.

`writetable(T,filename)` writes table `T` to a file with the name and extension specified by `filename`.

`writetable` determines the file format based on the specified extension. The extension must be one of the following:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls` or `.xlsx` for Excel spreadsheet files

`writetable( __ ,Name,Value)` writes the table to a file with additional options specified by one or more `Name,Value` pair arguments and can include any of the input arguments in previous syntaxes.

For example, you can specify whether to write the variable names as column headings in the output file.

## Input Arguments

**T - Input table**  
`table`

Input table, specified as a table.

**filename - Name of file to write**

string

Name of file to write, specified as a string. If `filename` includes the file's extension, then `writetable` determines the file format from the extension. Otherwise, `writetable` creates a comma separated text file and appends the extension `.txt`. Alternatively, you can specify `filename` without the file's extension, and then include the `'FileType'` name-value pair arguments to indicate the type of file.

If `filename` does not exist in your current folder, then `writetable` creates the file. `writetable` overwrites any existing file.

**Example:** `'myData.xls'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'WriteVariableNames',false` indicates that the variable names should not be included as the first row of the output file.

## 'FileType' - Type of file

`'text' | 'spreadsheet'`

Type of file, specified as the comma-separated pair consisting of `'FileType'` and the string `'text'` or `'spreadsheet'`.

The `'FileType'` name-value pair must be used with the `filename` input argument. You do not need to specify the `'FileType'` name-value pair argument if the file type can be determined from an extension in the `filename` input argument.

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls` or `.xlsx` for Excel spreadsheet files

**Example:**

```
writetable(T,'mySpreadsheet','FileType','spreadsheet')
```

## **'WriteVariableNames' - Indicator for writing variable names as column headings**

true (default) | false | 1 | 0

Indicator for writing variable names as column headings, specified as the comma-separated pair consisting of 'WriteVariableNames' and either true, false, 1, or 0.

true writetable includes variable names as the column headings of the output file. This is the default behavior.

If both the 'WriteVariablesNames' and 'WriteRowNames' logical indicators are true, then writetable uses the first dimension name from the property T.Properties.DimensionNames as the column heading for the first column of the file.

false writetable does not include variable names in the output file.

## **'WriteRowNames' - Indicator for writing row names in first column**

false (default) | true | 0 | 1

Indicator for writing row names in first column, specified as the comma-separated pair consisting of 'WriteRowNames' and either false, true, 0, or 1.

<code>true</code>	<code>writetable</code> includes the row names from <code>T</code> as the first column of the output file.  If both the <code>'WriteVariablesNames'</code> and <code>'WriteRowNames'</code> logical indicators are <code>true</code> , then <code>writetable</code> uses the first dimension name from the property <code>T.Properties.DimensionNames</code> as the column heading for the first column of the file.
<code>false</code>	<code>writetable</code> does not include the row names from <code>T</code> in the output file. This is the default behavior.

## **'Delimiter' - Field delimiter character**

string

Field delimiter character, specified as the comma-separated pair consisting of `'Delimiter'` and one of the following strings:

<code>','</code>	Comma. This is the default behavior.
<code>'comma'</code>	
<code>' '</code>	Space
<code>'space'</code>	
<code>'\t'</code>	Tab
<code>'tab'</code>	
<code>';'</code>	Semicolon
<code>'semi'</code>	
<code>' '</code>	Vertical bar
<code>'bar'</code>	

You can use the `'Delimiter'` name-value pair only for delimited text files.

**Example:** `'Delimiter','space'`

## **'Sheet' - Worksheet to write to**

string containing worksheet name | positive integer indicating worksheet index

Worksheet to write to, specified as the comma-separated pair consisting of 'Sheet' and a string containing the worksheet name or a positive integer indicating the worksheet index. The worksheet name string cannot contain a colon (:). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsinfo(filename)`.

If the sheet does not exist, then `writetable` adds a new sheet at the end of the worksheet collection. If the sheet is an index larger than the number of worksheets, then `writetable` appends empty sheets until the number of worksheets in the workbook equals the sheet index. In either case, `writetable` generates a warning indicating that it has added a new worksheet.

You can use the 'Sheet' name-value pair only with spreadsheet files.

**Example:** 'Sheet',2

## **'Range' - Rectangular portion of worksheet to write to**

string

Rectangular portion of worksheet to write to, specified as the comma-separated pair consisting of 'Range' and a string.

Specify the range using the syntax '*Corner1:Corner2*', where *Corner1* and *Corner2* are two opposing corners that define the region to write. For example, 'D2:H4' represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The 'Range' name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help).

If the range you specify is larger than the size of the input table T, Excel software fills the remainder of the region with #N/A. If the range specified is smaller than the size of the input table T, then `writetable` writes only the subset that fits into the range.

The 'Range' name-value pair can only be used with Excel files.

Example: 'Range', 'D2:H4'

## Examples

### Write Table to Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
        {'NY';'CA';'MA'},[true;false;false])
```

T =

Var1	Var2	Var3	Var4
M	45	45	'NY'
F	41	32	'CA'
M	40	34	'MA'

Write the table, T, to a comma delimited text file.

```
writetable(T)
```

writetable outputs a text file named T.txt.

Display the contents of the file.

```
type 'T.txt'
```

```
Var1,Var2_1,Var2_2,Var3,Var4
M,45,45,NY,1
F,41,32,CA,0
M,40,34,MA,0
```

writetable appends a unique suffix to the variable name, Var2, above the two columns of corresponding data.

### Write Table to Space Delimited Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
        {'NY';'CA';'MA'},[true;false;false])
```

# writetable

---

```
T =  
    Var1      Var2      Var3      Var4  
    _____  _____  _____  _____  
    M         45         45      'NY'      true  
    F         41         32      'CA'      false  
    M         40         34      'MA'      false
```

Write the table, T, to a space delimited text file, called myData.txt.

```
writetable(T,'myData.txt','Delimiter',' ')
```

Display the contents of the file.

```
type 'myData.txt'
```

```
Var1 Var2_1 Var2_2 Var3 Var4  
M 45 45 NY 1  
F 41 32 CA 0  
M 40 34 MA 0
```

writetable appends a unique suffix to the variable name, Var2, above the two columns of corresponding data.

## Write Table to Text File Including Row Names

Create a table.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};  
Age = [38;43;38;40;49];  
Height = [71;69;64;67;64];  
Weight = [176;163;131;133;119];  
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure,...  
         'RowNames',LastName)
```

```
T =  
  
    Age      Height      Weight      BloodPressure  
    _____  _____  _____  _____  
    RowNames1  RowNames1  RowNames1  RowNames1  
    RowNames2  RowNames2  RowNames2  RowNames2  
    RowNames3  RowNames3  RowNames3  RowNames3  
    RowNames4  RowNames4  RowNames4  RowNames4  
    RowNames5  RowNames5  RowNames5  RowNames5
```

Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Write the table, T, to a comma delimited text file, called myPatientData.dat.

```
writetable(T,'myPatientData.dat','WriteRowNames',true)
```

Display the contents of the file.

```
type 'myPatientData.dat'
```

```
Row, Age, Height, Weight, BloodPressure_1, BloodPressure_2
Smith, 38, 71, 176, 124, 93
Johnson, 43, 69, 163, 109, 77
Williams, 38, 64, 131, 125, 83
Jones, 40, 67, 133, 117, 75
Brown, 49, 64, 119, 122, 80
```

The first column, which contains the row names, has the column heading, Row. This is the first dimension name for the table from the property T.Properties.DimensionNames.

### Write Table to Specific Sheet and Range in Spreadsheet

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
        {'NY';'CA';'MA'},[true;false;false])
```

```
T =
```

Var1	Var2	Var3	Var4
_____	_____	_____	_____

# writetable

---

M	45	45	'NY'	true
F	41	32	'CA'	false
M	40	34	'MA'	false

Write the table, `T`, to a spreadsheet, called `myData.xls`. Include the data on the second sheet in the 5-by-5 region with corners at B2 and F6.

```
writetable(T, 'myData.xls', 'Sheet', 2, 'Range', 'B2:F6')
```

Excel fills the row of the spreadsheet from B6 to F6 with #N/A since the range specified is larger than the size of the input table `T`.

## Algorithms

Excel converts Inf values to 65535. MATLAB converts NaN values to empty cells.

## Tips

- In the cases below, `writetable` creates a file that does not represent `T` exactly. Then, if you use `readtable` to read that file and create a new table, the result might not have the same format or contents as the original table. Save `T` as a MAT-file if you need to import it again as a table with the same data and organization.
  - `writetable` outputs numeric variables using long g format, and categorical or character variables as unquoted strings in text files.
  - For variables that have more than one column, `writetable` appends a unique identifier to the variable name to use as the column headings.
  - For output variables that have more than two dimensions, `writetable` outputs these variables as two dimensional where the trailing dimensions are collapsed. For example, `writetable` outputs a 4-by-3-by-2 variable as if its size were 4-by-6.
  - For variables with a `cell` data type, `writetable` outputs the contents of each cell as a single row, in multiple fields. If the contents are other than numeric, logical, character, or categorical, then `writetable` outputs a single empty field.

**See Also**    `table` | `readtable`

# Tiff.write

---

**Purpose** Write entire image

**Syntax** `tiffobj.write(imageData)`  
`tiffobj.write(Y,Cb,Cr)`

**Description** `tiffobj.write(imageData)` writes `imageData` to TIFF file associated with the Tiff object, `tiffobj`. The write method breaks the data into strips or tiles, depending on the value of the `RowsPerStrip` tag, or the `TileLength` and `TileWidth` tags.

`tiffobj.write(Y,Cb,Cr)` writes the YCbCr component data to the TIFF file. Use this syntax only for images with a YCbCr photometric interpretation.

## **Examples** Write Image Data

Write tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a Tiff object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');  
t = Tiff('myfile.tif','w');
```

Set tag values.

```
t.setTag('ImageLength',size(imdata,1));  
t.setTag('ImageWidth',size(imdata,2));  
t.setTag('Photometric',Tiff.Photometric.RGB);  
t.setTag('BitsPerSample',8);  
t.setTag('SamplesPerPixel',size(imdata,3));  
t.setTag('TileWidth',128);  
t.setTag('TileLength',128);  
t.setTag('Compression',Tiff.Compression.JPEG);  
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);  
t.setTag('Software','MATLAB');
```

Write the image data to the TIFF file.

```
t.write(imdata);  
t.close();
```

## See Also

Tiff.writeDirectory

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”

# Tiff.writeDirectory

---

**Purpose** Create new IFD and make it current IFD

**Syntax** `tiffobj.writeDirectory()`

**Description** `tiffobj.writeDirectory()` create a new image file directory (IFD) and makes it the current IFD. Tiff object methods operate on the current IFD. If you are creating a TIFF file that only contains one image, you do not need to use this method. With single-image TIFF files, just close the Tiff object to write data to the file.

**Examples** Open a TIFF file for modification and create a new IFD in the file. `writeDirectory` makes the newly created IFD the current IFD. Replace the name `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');
dnum = t.currentDirectory();
t.writeDirectory();
dnum = t.currentDirectory();
```

**References** This method corresponds to the `TIFFWriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## Purpose

Write data to specified strip

## Syntax

```
tiffobj.writeEncodedStrip(stripNumber,imageData)  
tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)
```

## Description

`tiffobj.writeEncodedStrip(stripNumber,imageData)` writes the data in `imageData` to the strip specified by `stripNumber`. Strip identification numbers are one-based. If `imageData` has fewer bytes than fit into a strip, `writeEncodedStrip` silently pads the strip. If `imageData` has more bytes than fit into a strip, `writeEncodedStrip` issues a warning and truncates the data. To determine the size of a strip, view the value of the `RowsPerStrip` tag.

`tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tag.

## Examples

### Write Image Data to Strips

Open a Tiff object for writing and set tag values.

```
t = Tiff('myfile.tif','w');  
t.setTag('ImageLength',32);  
t.setTag('ImageWidth',32);  
t.setTag('Photometric',Tiff.Photometric.MinIsBlack);  
t.setTag('BitsPerSample',8);  
t.setTag('SamplesPerPixel',1);  
t.setTag('RowsPerStrip',16);  
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write data to the first and second strips.

```
t.writeEncodedStrip(1,ones(16,32,'uint8'));  
t.writeEncodedStrip(2,2*ones(16,32,'uint8'));  
t.close();
```

## References

This method corresponds to the `TIFFWriteEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the

`Tiff.writeEncodedTile`

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose**

Write data to specified tile

**Syntax**

```
tiffobj.writeEncodedTile(tileNumber,imageData)  
tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)
```

**Description**

`tiffobj.writeEncodedTile(tileNumber,imageData)` writes the data in `imageData` to the tile specified by `tileNumber`. Tile identification numbers are one-based. If `imageData` has fewer bytes than fit into a tile, `writeEncodedTile` silently pads the tile. If `imageData` has more bytes than fit into a tile, `writeEncodedTile` issues a warning and truncates the data. To determine the size of a tile, view the value of the `tileLength` and `tileWidth` tags.

`tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tags.

**Examples****Write Image Data to Tiles**

Open a Tiff object for writing and set tag values.

```
t = Tiff('myfile.tif','w');  
t.setTag('ImageLength',32);  
t.setTag('ImageWidth',32);  
t.setTag('Photometric',Tiff.Photometric.MinIsBlack);  
t.setTag('BitsPerSample',8);  
t.setTag('SamplesPerPixel',1);  
t.setTag('TileWidth',16);  
t.setTag('TileLength',16);  
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write data to four tiles.

```
t.writeEncodedTile(1,ones(16,16,'uint8'));  
t.writeEncodedTile(2,2*ones(16,16,'uint8'));  
t.writeEncodedTile(3,3*ones(16,16,'uint8'));  
t.writeEncodedTile(4,4*ones(16,16,'uint8'));  
t.close();
```

# Tiff.writeEncodedTile

- “Reading Image Data and Metadata from TIFF Files”

## Purpose

Write video data to file

## Syntax

```
writeVideo(writerObj,img)
writeVideo(writerObj,images)
writeVideo(writerObj,frame)
writeVideo(writerObj,mov)
```

## Description

`writeVideo(writerObj,img)` writes data from an image to a video file.

`writeVideo(writerObj,images)` writes a sequence of color images to a video file.

`writeVideo(writerObj,frame)` writes a frame to the video file associated with `writerObj`.

`writeVideo(writerObj,mov)` writes a MATLAB movie to a video file. `MOV` is an array of frame structures.

You must call `open(writerObj)` before calling `writeVideo`.

## Input Arguments

### **writerObj**

VideoWriter object created by the `VideoWriter` function.

### **img**

When creating AVI or MPEG-4 files, `img` is an array of `single`, `double`, or `uint8` values representing a grayscale or RGB color image, which `writeVideo` writes as an RGB video frame. Data of type `single` or `double` must be in the range `[0,1]`, except when writing Indexed AVI files.

When creating Motion JPEG 2000 files, `img` is an array of `uint8`, `int8`, `uint16`, or `int16` values representing a monochrome or RGB color image.

For grayscale, monochrome, or indexed data, `img` must be two-dimensional: height-by-width. For color data that is not indexed, `img` is three-dimensional: height-by-width-by-3. The height and width must be consistent for all frames within a file. For more information, see “Image Types”.

# VideoWriter.writeVideo

---

## images

Four-dimensional array of grayscale (height-by-width-by-1-by-frames) or RGB (height-by-width-by-3-by-frames) images.

## frame

Structure typically returned by the `getframe` function that contains two fields: `cdata` and `colormap`. If the `colormap` is not empty, `writeVideo` expects a two-dimensional (height-by-width) array `cdata`. The height and width must be consistent for all frames within a file. `colormap` can contain a maximum of 256 entries.

The profile of `writerObj` and the size of `cdata` determine how the `writeVideo` method uses `frame`.

profile of VideoWriter object	Size of cdata	Behavior of writeVideo
'Indexed AVI' or 'Grayscale AVI'	2-dimensional (height-by-width)	Use frame as provided. For 'Grayscale AVI', colormap should be empty.
	3-dimensional (height-by-width-by-3)	Error
All other profiles	2-dimensional (height-by-width)	Construct RGB image frames using the colormap field
	3-dimensional (height-by-width-by-3)	Colormap field ignored. Construct RGB image frames using the cdata field

## **mov**

1-by-F array of frame structures, where F is the number of images.  
Each frame structure contains fields `cdata` and `colormap`.

## **Examples**

### **AVI File from Animation**

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');  
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);  
axis tight  
set(gca, 'nextplot', 'replacechildren');  
set(gcf, 'Renderer', 'zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20  
    surf(sin(2*pi*k/20)*Z,Z)  
    frame = getframe;  
    writeVideo(writerObj,frame);  
end
```

```
close(writerObj);
```

### **MPG to AVI Conversion**

Convert an example file, `xylophone.mp4`, to an uncompressed AVI file:

# VideoWriter.writeVideo

---

Create objects to read and write the video, and open the AVI file for writing.

```
readerObj = VideoReader('xylophone.mp4');  
writerObj = VideoWriter('transcoded_xylophone.avi', ...  
                        'Uncompressed AVI');
```

```
open(writerObj);
```

Read and write each frame.

```
for k = 1:readerObj.NumberOfFrames  
    img = read(readerObj,k);  
    writeVideo(writerObj,img);  
end
```

```
close(writerObj);
```

**Purpose**

Label x-axis

**Syntax**

```
xlabel(str)
xlabel(str,Name,Value)

xlabel(axes_handle, ___ )

h = xlabel( ___ )
```

**Description**

`xlabel(str)` labels the *x*-axis of the current axes with the string, `str`. Each axes graphics object has one predefined *x*-axis label. Reissuing the `xlabel` command causes the new label to replace the old label. Labels appear beneath the axis in a two-dimensional view and to the side or beneath the axis in a three-dimensional view.

`xlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`xlabel(axes_handle, ___ )` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = xlabel( ___ )` returns the handle to the text object used as the *x*-axis label. The handle is useful when making future modifications to the label.

**Input Arguments****str - Text to display as x-axis label**

string

Text to display as the *x*-axis label, specified as a string or the name of a function that returns a string.

**Example:** 'myLabel'

**axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Color','red','FontSize',12` adds an x-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

### 'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green

RGB Value	Short Name	Long Name
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

**Example:** 'Color',[0 1 0]

**Example:** 'Color','green'

### 'FontAngle' - Character slant

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

**Example:** 'FontAngle','italic'

### 'FontName' - Font name

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName','Courier'

### 'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize',12.5

## 'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $\frac{1}{72}$  inch

---

**Note** When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits', 'inches', 'FontSize', 0.3 in the argument list.

---

## 'FontWeight' - Weight of text characters

'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

**Example:** `'FontWeight','bold'`

### 'Interpreter' - Character interpretation

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** `'Interpreter','latex'`

## Output Arguments

### **h** - Handle to text object used as x-axis label

scalar

Handle to the text object used as the *x*-axis label, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the label.

## Examples

### Label x-axis with String

```
figure
plot((1:10).^2)
xlabel('Population')
```

MATLAB displays Population beneath the *x*-axis.

### Label x-axis with Numeric Input

```
figure
plot((1:10).^2)
xlabel(123)
```

MATLAB displays 123 beneath the *x*-axis.

### Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
plot((1:10).^2)
xlabel({'date'; 'Population'; 'in Years'})
```

### Create Label and Set Font Properties

Use Name, Value pair arguments to set the font size, font weight, and text color properties of the *x*-axis label.

```
figure
plot((1:10).^2)
xlabel('Population', 'FontSize', 12, 'FontWeight', 'bold', 'Color', 'r')
```

'FontSize', 12 displays the label text in 12-point font.

'FontWeight', 'bold' makes the text bold. 'Color', 'r' sets the text color to red.

### Label x-Axis of Specific Axes

Create two subplots and return the handles to the axes objects, *s*(1) and *s*(2).

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Label the  $x$ -axis of the top plot by referring to its axes handle, `s(1)`.

```
xlabel(s(1), 'Population')
```

### **Label $x$ -axis and Return Object Handle**

Label the  $x$ -axis and return the handle to the text object used as the label.

```
figure
plot((1:10).^2)
str = 'Population';
h = xlabel(str);
```

MATLAB returns the object handle in the output variable, `h`.

Set the color of the label to red, using the object handle.

```
set(h, 'Color', 'red')
```

### **Concepts**

- “Adding Axis Labels to Graphs”  
Text Properties

# ylabel

---

## Purpose

Label y-axis

## Syntax

```
ylabel(str)
ylabel(str,Name,Value)

ylabel(axes_handle, ___ )

h = ylabel( ___ )
```

## Description

`ylabel(str)` labels the *y*-axis of the current axes with the string, `str`. Every axes has one predefined *y*-axis label. Reissuing the `ylabel` command causes the new label to replace the old label. Labels appear beside the axis in a two-dimensional view and to the side or in front of the axis in a three-dimensional view.

`ylabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`ylabel(axes_handle, ___ )` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = ylabel( ___ )` returns the handle to the text object used as the *y*-axis label. The handle is useful when making future modifications to the label.

## Input Arguments

### **str - Text to display as y-axis label**

string

Text to display as the *y*-axis label, specified as a string or the name of a function that returns a string.

**Example:** 'myLabel'

### **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Color', 'red', 'FontSize', 12` adds a y-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

#### 'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green

RGB Value	Short Name	Long Name
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

**Example:** 'Color',[0 1 0]

**Example:** 'Color','green'

### **'FontAngle' - Character slant**

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

**Example:** 'FontAngle','italic'

### **'FontName' - Font name**

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName','Courier'

### **'FontSize' - Font size**

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize',12.5

### 'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $1/72$  inch

---

**Note** When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits', 'inches', 'FontSize', 0.3 in the argument list.

---

### 'FontWeight' - Weight of text characters

'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

**Example:** `'FontWeight','bold'`

### 'Interpreter' - Character interpretation

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** `'Interpreter','latex'`

## Output Arguments

### **h** - Handle to text object used as y-axis label

scalar

Handle to the text object used as the *y*-axis label, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the label.

## Examples

### Label y-axis with String

```
figure
plot((1:10).^2)
ylabel('Population')
```

MATLAB displays Population beside the y-axis.

### Label y-axis with Numeric Input

```
figure
plot((1:10).^2)
ylabel(123)
```

MATLAB displays 123 beside the y-axis.

### Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
plot((1:10).^2)
ylabel({'2010'; 'Population'; 'in Years'})
```

### Create Label and Set Font Properties

Use Name, Value pairs to set the font size, font weight, and text color properties of the y-axis label.

```
figure
plot((1:10).^2)
ylabel('Population', 'FontSize', 12, 'FontWeight', 'bold', 'Color', 'r')
```

'FontSize', 12 displays the label text in 12-point font.

'FontWeight', 'bold' makes the text bold. 'Color', 'r' sets the text color to red.

### Label y-Axis of Specific Axes

Create two subplots and return the handles to the axes objects, s(1) and s(2).

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Label the  $y$ -axis of the top plot by referring to its axes handle, `s(1)`.

```
ylabel(s(1), 'Population')
```

## Label $y$ -axis and Return Object Handle

Label the  $y$ -axis and return the handle to the text object used as the label.

```
figure
plot((1:10).^2)
str = 'Population';
h = ylabel(str);
```

MATLAB returns the object handle in the output variable, `h`.

Set the color of the label to red, using the object handle.

```
set(h, 'Color', 'red')
```

## See Also

`strings` | `xlabel` | `zlabel` | `text` | `title`

## Concepts

- “Adding Axis Labels to Graphs”  
Text Properties

## Purpose

Label z-axis

## Syntax

```
zlabel(str)
zlabel(str,Name,Value)

zlabel(axes_handle, ___ )

h = zlabel( ___ )
```

## Description

`zlabel(str)` labels the z-axis of the current axes with the string, `str`. Every axes has one predefined z-axis label. Reissuing the `zlabel` command causes the new label to replace the old label.

`zlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`zlabel(axes_handle, ___ )` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = zlabel( ___ )` returns the handle to the text object used as the z-axis label. The handle is useful when making future modifications to the label.

## Input Arguments

### **str - Text to display as z-axis label**

string

Text to display as the z-axis label, specified as a string or the name of a function that returns a string.

**Example:** 'myLabel'

### **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Color', 'red', 'FontSize', 12` adds an z-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

### 'Color' - Text color

`[0 0 0]` (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
<code>[1 1 0]</code>	y	yellow
<code>[1 0 1]</code>	m	magenta
<code>[0 1 1]</code>	c	cyan
<code>[1 0 0]</code>	r	red
<code>[0 1 0]</code>	g	green
<code>[0 0 1]</code>	b	blue

RGB Value	Short Name	Long Name
[1 1 1]	w	white
[0 0 0]	k	black

**Example:** 'Color',[0 1 0]

**Example:** 'Color','green'

### 'FontAngle' - Character slant

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

**Example:** 'FontAngle','italic'

### 'FontName' - Font name

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName','Courier'

### 'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize',12.5

## 'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $\frac{1}{72}$  inch

---

**Note** When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits', 'inches', 'FontSize', 0.3 in the argument list.

---

## 'FontWeight' - Weight of text characters

'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

**Example:** `'FontWeight','bold'`

### 'Interpreter' - Character interpretation

`'tex' (default) | 'latex' | 'none'`

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** `'Interpreter','latex'`

## Output Arguments

### **h** - Handle to text object used as z-axis label

scalar

Handle to the text object used as the *z*-axis label, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the label.

## Examples

### Label z-axis with String

```
figure
surf(peaks)
zlabel('Height')
```

MATLAB displays Height beside the  $z$ -axis.

### Label z-axis with Numeric Input

```
figure
surf(peaks)
zlabel(123)
```

MATLAB displays 123 beside the  $z$ -axis.

### Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
surf(peaks)
zlabel({'First Line';'Second Line'})
```

### Create Label and Set Font Properties

Use Name, Value pairs to set the font size, font weight, and text color properties of the  $z$ -axis label.

```
figure
surf(peaks)
zlabel('Elevation','FontSize',12,'FontWeight','bold','Color','r');
```

'FontSize',12 displays the label text in 12-point font.

'FontWeight','bold' makes the text bold. 'Color','r' sets the text color to red.

### Label z-Axis of Specific Axes

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
surf(peaks(30))
s(2) = subplot(2,1,2);
surf(peaks(45))
```

Label the *z*-axis of each plot by referring to the axes handles, `s(1)` and `s(2)`.

```
zlabel(s(1), 'Height1')
zlabel(s(2), 'Height2')
```

### **Label *z*-axis and Return Object Handle**

Label the *z*-axis and return the handle to the text object used as the label.

```
figure
surf(peaks)
str = 'Population Change';
h = zlabel(str);
```

MATLAB returns the object handle in the output variable, `h`.

Set the color of the label to red, using the object handle.

```
set(h, 'Color', 'red')
```

### **See Also**

`strings` | `ylabel` | `xlabel` | `text` | `title`

### **Concepts**

- “Adding Axis Labels to Graphs”  
Text Properties

**Purpose** Set or query  $x$ -axis limits

**Syntax**

```
xlim
xlim([xmin xmax])
xlim('mode')
xlim('auto')
xlim('manual')
xlim(axes_handle,...)
```

**Description**

`xlim` with no arguments returns the limits of the current axes.

`xlim([xmin xmax])` sets the axis limits in the current axes to the specified values.

`xlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`xlim('auto')` sets the axis limit mode to `auto`.

`xlim('manual')` sets the axis limit mode to `manual`.

`xlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips**

`xlim` sets or queries values of the axes object `XLim`, and `XLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

## Examples

This example illustrates how to set the  $x$ - and  $y$ -axis limits to match the actual range of the data, rather than the rounded values of  $[-2\ 3]$  for the  $x$ -axis,  $[-2\ 4]$  for the  $y$ -axis and  $[-0.5\ 0.5]$  for  $z$ -axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);  
z = x.*exp(-x.^2-y.^2);  
surf(x,y,z)  
xlim([-1.75 3.25])  
ylim([-1.75 3.25])  
zlim([-0.45 0.45])
```

## Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

## See Also

`ylim` | `zlim` | `axis`

## How To

- `XLim`
- `YLim`

- ZLim
- Understanding Axes Aspect Ratio

**Purpose** Set or query *y*-axis limits

**Syntax**

```
ylim  
ylim([ymin ymax])  
ylim('mode')  
ylim('auto')  
ylim('manual')  
ylim(axes_handle,...)
```

**Description**

`ylim` with no arguments returns the limits of the current axes.

`ylim([ymin ymax])` sets the axis limits in the current axes to the specified values.

`ylim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`ylim('auto')` sets the axis limit mode to `auto`.

`ylim('manual')` sets the axis limit mode to `manual`.

`ylim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips** `ylim` sets or queries values of the axes object `YLim` and `YLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

**Examples**

This example illustrates how to set the  $x$ - and  $y$ -axis limits to match the actual range of the data, rather than the rounded values of  $[-2 \ 3]$  for the  $x$ -axis and  $[-2 \ 4]$  for the  $y$ -axis and  $[-0.5 \ 0.5]$  for  $z$ -axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);  
z = x.*exp(-x.^2-y.^2);  
surf(x,y,z)  
xlim([-1.75 3.25])  
ylim([-1.75 3.25])  
zlim([-0.45 0.45])
```

**Alternatives** To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

# zlim

---

**Purpose** Set or query z-axis limits

**Syntax**

```
zlim
zlim([zmin zmax])
zlim('mode')
zlim('auto')
zlim('manual')
zlim(axes_handle,...)
```

**Description**

`zlim` with no arguments returns the limits of the current axes.

`zlim([zmin zmax])` sets the axis limits in the current axes to the specified values.

`zlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`zlim('auto')` sets the axis limit mode to `auto`.

`zlim('manual')` sets the axis limit mode to `manual`.

`zlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips**

`zlim` sets or queries values of the axes object `ZLim` and `ZLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

## Examples

This example illustrates how to set the  $x$ -,  $y$ -, and  $z$ -axis limits to match the actual range of the data, rather than the rounded values of  $[-2 \ 3]$  for the  $x$ -axis,  $[-2 \ 4]$  for the  $y$ -axis and  $[-0.5 \ 0.5]$  for  $z$ -axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);  
z = x.*exp(-x.^2-y.^2);  
surf(x,y,z)  
xlim([-1.75 3.25])  
ylim([-1.75 3.25])  
zlim([-0.45 0.45])
```

**Alternatives** To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

**See Also** `xlim` | `ylim` | `axis`

**How To**

- `YLim`

- ZLim
- Understanding Axes Aspect Ratio

# xlsfinfo

---

**Purpose** Determine if file contains Microsoft Excel spreadsheet

**Syntax**

```
status = xlsfinfo(filename)
[status,sheets] = xlsfinfo(filename)
[status,sheets,xlFormat] = xlsfinfo(filename)
```

**Description** `status = xlsfinfo(filename)` indicates if `filename` is a file that the `xlsread` function can read.

`[status,sheets] = xlsfinfo(filename)` additionally returns the name of each spreadsheet in the file.

`[status,sheets,xlFormat] = xlsfinfo(filename)` also returns the format description that Excel returns for the file. On systems without Excel for Windows, `xlFormat` is an empty string, `''`.

## Input Arguments

### **filename - Name of file**

string

Name of file, specified as a string.

**Example:** `'myFile.xlsx'`

### **Data Types**

char

## Output Arguments

### **status - Type of file**

string

Type of file, returned as a string.

- If `filename` is a file that `xlsread` can read, then `status` is a descriptive string, such as `'Microsoft Excel Spreadsheet'`.
- If `filename` is not a file that `xlsread` can read, then `status` is an empty string, `''`.
- If MATLAB cannot find the file, then `xlsfinfo` returns an error.

**sheets - Worksheet names**

1-by-n cell array of strings

Worksheet names, returned as a 1-by-n cell array of strings, where n is the number of worksheets in the file. Each cell contains the name of a worksheet. If `xlsread` cannot read a particular worksheet, the corresponding cell contains an error message.

If `xlsinfo` cannot read the file, then `sheets` contains an error message.

**xlFormat - File format description returned by Excel**

string

File format description returned by Excel, returned as a string.

On Windows systems with Excel software, `xlFormat` is a nonempty string, such as one of the following.

'xlOpenXMLWorkbook'	Spreadsheet in XLSX format (Excel 2007 or later)
'xlWorkbookNormal' or 'xlExcel8'	Spreadsheet in XLS format (compatible with Excel 97-2003)
'xlCSV'	File in comma-separated value (CSV) format
'xlHtml' or 'xlWebArchive'	Spreadsheet exported to HTML format

On all other systems, `xlFormat` is an empty string, ''.

**Examples****View Information About Spreadsheet File**

Create a sample Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First', 'Second', 'Third'};
xlswrite('myExample.xlsx', [headers; values]);
```

Call `xlsinfo` to get information about the file.

# xlsfinfo

---

```
[status,sheets,xlFormat] = xlsfinfo('myExample.xlsx')

status =

Microsoft Excel Spreadsheet

sheets =

    'Sheet1'    'Sheet2'    'Sheet3'

xlFormat =

xlOpenXMLWorkbook
```

`status` is a descriptive string indicating that the `xlsread` function can read the sample file.

## Tips

- If `xlsfinfo` warns that it cannot start an ActiveX server, then the COM server, which is part of the typical Excel installation, is unavailable. In this case, consider reinstalling your Excel software. On systems with Excel for Windows, `xlsfinfo` uses the COM server to obtain information.

## Limitations

- `xlsfinfo` supports only 7-bit ASCII characters.

## See Also

`xlsread` | `xlswrite`

**Purpose** Read Microsoft Excel spreadsheet file

**Syntax**

```
num = xlsread(filename)
num = xlsread(filename, sheet)
num = xlsread(filename, xlRange)
num = xlsread(filename, sheet, xlRange)
num = xlsread(filename, sheet, xlRange, 'basic')
[num, txt, raw] = xlsread( ___ )

___ = xlsread(filename, -1)

[num, txt, raw, custom] = xlsread(filename, sheet, xlRange, '',
    functionHandle)
```

**Description** `num = xlsread(filename)` reads data from the first worksheet in the Microsoft Excel spreadsheet file named `filename` and returns the numeric data in array `num`.

On Windows systems with Microsoft Excel software, `xlsread` reads any file format recognized by your version of Excel.

If your system does not have Excel for Windows, `xlsread` operates in basic import mode, and reads only XLS, XLSX, XLSM, XLTX, and XLTM files.

`num = xlsread(filename, sheet)` reads the specified worksheet.

`num = xlsread(filename, xlRange)` reads data from the specified range, `xlRange`, of the first worksheet in the file.

`num = xlsread(filename, sheet, xlRange)` reads from the specified sheet and range, `xlRange`.

`num = xlsread(filename, sheet, xlRange, 'basic')` reads data from the spreadsheet in basic mode, the default on systems without Excel for

# xlsread

---

Windows. If you do not specify all the arguments, use empty strings as placeholders, for example, `num = xlsread(filename, '', '', 'basic')`.

`[num,txt,row] = xlsread( ___ )` additionally returns the text fields in cell array `txt`, and the unprocessed data (numbers and text) in cell array `row` using any of the input arguments in the previous syntaxes. If `xlRange` is specified, leading blank rows and columns in the worksheet that precede rows and columns with data are returned in `row`.

`___ = xlsread(filename, -1)` opens an Excel window to interactively select data. Select the worksheet, drag and drop the mouse over the range you want, and click **OK**. This syntax is supported only on Windows systems with Excel software.

`[num,txt,row,custom] = xlsread(filename, sheet, xlRange, '', functionHandle)` reads from the spreadsheet, executes the function associated with `functionHandle` on the data, and returns the final results as numeric data in array `num`. The `xlsread` function optionally returns the text fields in cell array `txt`, the unprocessed data (numbers and text) in cell array `row`, and the second output from the function associated with `functionHandle` in array `custom`. The `xlsread` function does not change the data stored in the spreadsheet. This syntax is supported only on Windows systems with Excel software.

## Input Arguments

### **filename - Name of file to read**

string

Name of the file to read, specified as a string. If you do not include an extension, `xlsread` searches for a file with the specified name and a supported Excel extension. `xlsread` can read data saved in files that are currently open in Excel for Windows.

**Example:** `'myFile.xlsx'`

### **Data Types**

char

**sheet - Worksheet to read**

string | positive integer

Worksheet to read, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`. For XLS files in `basic` mode, `sheet` is case sensitive.
- Positive integer that indicates the worksheet index. Not supported for XLS files in `basic` mode.

**xlRange - Rectangular portion of the worksheet to read**

string

Rectangular portion of the worksheet to read, specified as a string.

Specify `xlRange` using the syntax '`C1:C2`', where `C1` and `C2` are two opposing corners that define the region to read. For example, '`D2:H4`' represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help).

Range selection is not supported when reading XLS files in `basic` mode. In this case, use '' in place of `xlRange`.

If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as '`D2:D2`'). Otherwise, `xlsread` interprets the input as a worksheet name (such as '`sales`' or '`D2`').

If you specify `sheet`, then `xlRange`:

- Does not need to include a colon and opposite corner to describe a single cell.
- Can refer to a named range that you defined in the Excel file (see the Excel help).

**Data Types**

char

## **'basic' - Flag to request reading in basic mode**

literal string

Flag to request reading in basic mode, specified as the literal string, 'basic'.

basic mode is the default for systems without Excel for Windows. In basic mode, xlsread:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support an x1Range input when reading XLS files. In this case, use '' in place of x1Range.
- Does not support function handle inputs.
- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

## **functionHandle - Handle to a custom function**

function handle

Handle to a custom function, starting with the symbol @. Supported only on Windows systems with Excel software. xlsread reads from the spreadsheet, executes your function on a copy of the data, and returns the final results. xlsread does not change the data stored in the spreadsheet.

When xlsread calls the custom function, it passes a range interface from the Excel application to provide access to the data. The custom function must include this interface both as an input and output argument. (See the Examples.)

**Example:** @myFunctionHandle

## **Output Arguments**

### **num - Numeric data**

matrix

Numeric data, returned as a matrix of double values. The array does not contain any information from header lines, or from outer rows or columns that contain nonnumeric data. Text data in inner spreadsheet rows and columns appear as NaN in the num output.

**txt - Text data**

cell array

Text data, returned as a cell array. Numeric values in inner spreadsheet rows and columns appear as empty strings, '', in txt.

For XLS files in basic import mode, the txt output contains empty strings, '', in place of leading columns of numeric data that precede text data in the spreadsheet. In all other cases, txt does not contain these additional columns.

Undefined values (such as '#N/A') appear in the txt output as '#N/A', except for XLS files in basic mode.

**raw - Unprocessed data**

cell array

Unprocessed data from the worksheet, returned as a cell array. Contains both numeric and text data.

On systems with Excel for Windows, undefined values (such as '#N/A') appear in the raw output as 'ActiveX\_VT\_ERROR:'. For XLSX, XLSM, XLTX, and XLTM files on other systems, undefined values appear as '#N/A'.

**custom - Second output of the function corresponding to functionHandle**

defined by the function

Second output of the function corresponding to functionHandle. The value and data type of custom are determined by the function.

**Examples****Read Data from First Worksheet Into Numeric Array**

Create an Excel file named myExample.xlsx.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};  
headers = {'First', 'Second', 'Third'};  
xlswrite('myExample.xlsx', [headers; values]);
```

Sheet1 of myExample.xlsx contains:

First	Second	Third
1	2	3
4	5	x
7	8	9

Read data from the first worksheet.

```
filename = 'myExample.xlsx';  
A = xlsread(filename)
```

```
A =  
     1     2     3  
     4     5   NaN  
     7     8     9
```

xlsread returns the numeric data in array A.

## Read a Specific Range of Data

Read a specific range of data from the Excel file in the previous example.

```
filename = 'myExample.xlsx';  
sheet = 1;  
xlRange = 'B2:C3';
```

```
subsetA = xlsread(filename, sheet, xlRange)
```

```
subsetA =  
     2     3  
     5   NaN
```

## Read a Column of Data

Read the second column of data from the Excel file in the first example.

```
filename = 'myExample.xlsx';  
  
columnB = xlsread(filename, 'B:B')
```

```
columnB =
     2
     5
     8
```

For better performance, specify the row numbers in the range, as shown in the previous example.

### Request Numeric, Text, and Unprocessed Data

Request the numeric data, text, and a copy of the unprocessed (raw) data from the Excel file in the first example.

```
[ndata, text, alldata] = xlsread('myExample.xlsx')
```

```
ndata =
     1     2     3
     4     5    NaN
     7     8     9

text =
    'First'    'Second'    'Third'
    ''        ''          ''
    ''        ''          'x'

alldata =
    'First'    'Second'    'Third'
    [     1]    [     2]    [     3]
    [     4]    [     5]    'x'
    [     7]    [     8]    [     9]
```

`xlsread` returns numeric data in array `ndata`, text data in cell array `text`, and unprocessed data in cell array `alldata`.

### Execute a Function on a Worksheet and Return Numeric Data

In the Editor, create a function to process data from a worksheet. In this case, set values outside the range `[-3, 3]` to `-3` or `3`.

```
function [Data] = setMinMax(Data)

    minval = -3; maxval = 3;

    for k = 1:Data.Count
        v = Data.Value{k};
        if v > maxval || v < minval
            if v > maxval
                Data.Value{k} = maxval;
            else
                Data.Value{k} = minval;
            end
        end
    end
end
```

In the Command Window, add data to myExample.xlsx.

```
misc = pi*gallery('normaldata',[10,3],1);
xlswrite('myExample.xlsx',misc,'MyData');
```

Worksheet MyData contains the following values, which range from -6.6493 to 3.4845:

2.7156	-6.1744	1.8064
0.2959	-2.3383	-2.7210
-2.6764	-1.7351	-6.6493
2.7442	-2.5752	-3.0300
-1.3761	3.4845	0.6683
-1.3498	-1.9319	1.5014
-3.4643	-0.8000	0.3162
1.2448	-0.8477	0.9344
-3.0314	-5.2527	1.7912
0.5292	-5.8938	-5.1035

Read the data from the worksheet, and reset any values outside the range [-3, 3]. Specify the sheet name, but use '' as placeholders for the xlRange and 'basic' inputs.

```
trim = xlsread('myExample.xlsx','MyData','','',@setMinMax)
```

```
trim =
    2.7156   -3.0000    1.8064
    0.2959   -2.3383   -2.7210
   -2.6764   -1.7351   -3.0000
    2.7442   -2.5752   -3.0000
   -1.3761    3.0000    0.6683
   -1.3498   -1.9319    1.5014
   -3.0000   -0.8000    0.3162
    1.2448   -0.8477    0.9344
   -3.0000   -3.0000    1.7912
    0.5292   -3.0000   -3.0000
```

### Request Custom Output

Execute a function on a worksheet and display the custom index output.

In the Editor, modify the function `setMinMax` from the previous example to return the indices of the changed elements (custom output).

```
function [Data,indices] = setMinMax(Data)

    minval = -3; maxval = 3;
    indices = [];

    for k = 1:Data.Count
        v = Data.Value{k};
        if v > maxval || v < minval
            if v > maxval
                Data.Value{k} = maxval;
            else
                Data.Value{k} = minval;
            end
            indices = [indices k];
        end
    end
end
```

# xlsread

---

Read the data from the worksheet MyData, and request the custom index output, idx.

```
[trim,txt,row,idx] = xlsread('myExample.xlsx','MyData','','',@setMinMax);  
disp(idx)
```

```
7      9      11      15      19      20      23      24      30
```

## Algorithms

- If you do not specify `xlRange`, then `xlsread` ignores leading blank rows and columns in the worksheet that precede your data.
- If you specify `xlRange`, then leading blank rows and columns in the worksheet that precede your data are returned in `row`, but not in `num` or `txt`.
- When the specified `xlRange` overlaps merged cells:
  - On Windows systems with Excel, `xlsread` expands the range to include all merged cells.
  - On systems without Excel for Windows, `xlsread` returns data for the specified range only, with empty or NaN values for merged cells.
- `xlsread` imports formatted dates as strings (such as '10/31/96'), except in basic mode and on systems without Excel for Windows.

## Limitations

- `xlsread` reads only 7-bit ASCII characters.
- `xlsread` does not support non-contiguous ranges.

## See Also

`xlswrite` | `xlsinfo` | `importdata` | `uiimport` | `readtable` | `function_handle`

## Concepts

- “When to Convert Dates from Excel Files”

## Purpose

Write Microsoft Excel spreadsheet file

## Syntax

```
xlswrite(filename,A)
xlswrite(filename,A,sheet)
xlswrite(filename,A,xlRange)
xlswrite(filename,A,sheet,xlRange)
```

```
status = xlswrite( ___ )
[status,message] = xlswrite( ___ )
```

## Description

`xlswrite(filename,A)` writes array `A` to the first worksheet in Excel file, `filename`, starting at cell `A1`.

`xlswrite(filename,A,sheet)` writes to the specified worksheet.

`xlswrite(filename,A,xlRange)` writes to the rectangular region specified by `xlRange` in the first worksheet of the file.

`xlswrite(filename,A,sheet,xlRange)` writes to the specified sheet and range, `xlRange`.

`status = xlswrite( ___ )` returns the status of the write operation, and can include any of the input arguments in previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0.

`[status,message] = xlswrite( ___ )` additionally returns any warning or error message generated by the write operation in structure `message`.

## Input Arguments

**filename - Name of file to write**

string

Name of file to write, specified as a string.

# xlswrite

---

If `filename` does not exist, `xlswrite` creates a file, determining the format based on the specified extension. To create a file compatible with Excel 97-2003 software, specify an extension of `.xls`. To create files in Excel 2007 formats, specify an extension of `.xlsx`, `.xlsb`, or `.xlsm`. If you do not specify an extension, `xlswrite` uses the default, `.xls`.

**Example:** `'myFile.xlsx'`

## **A - Data to write**

`matrix` | `cell array`

Data to write, specified as a two-dimensional numeric or character array, or, if each cell contains a single element, a cell array.

If `A` is a cell array containing something other than a scalar numeric or a string, then `xlswrite` silently leaves the corresponding cell in the spreadsheet empty.

The maximum size of array `A` depends on the associated Excel version. For more information on Excel specifications and limits, see the Excel help.

**Example:** `[10,2,45;-32,478,50]`

**Example:** `{92.0, 'Yes', 45.9, 'No'}`

## **Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell`

## **sheet - Worksheet name**

`string` | `positive integer`

Worksheet name, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsinfo`.
- Positive integer that indicates the worksheet index.

If `sheet` does not exist, `xlswrite` adds a new sheet at the end of the worksheet collection. If `sheet` is an index larger than the number of worksheets, `xlswrite` appends empty sheets until the number of worksheets in the workbook equals `sheet`. In either case, `xlswrite` generates a warning indicating that it has added a new worksheet.

### **xlRange - Rectangular portion of the worksheet to write**

string

Rectangular portion of the worksheet to write, specified as a string.

Specify `xlRange` using the syntax '`C1:C2`', where `C1` and `C2` are two opposing corners that define the region to write. For example, '`D2:H4`' represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help). `xlswrite` does not recognize named ranges.

- If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as '`D2:D2`'). Otherwise, `xlswrite` interprets the input as a worksheet name (such as '`D2`').
- If you specify `sheet`, then `xlRange` can specify only the first cell (such as '`D2`'). `xlswrite` writes input array `A` beginning at this cell.
- If `xlRange` is larger than the size of input array `A`, Excel software fills the remainder of the region with `#N/A`. If `xlRange` is smaller than the size of `A`, then `xlswrite` writes only the subset that fits into `xlRange` to the file.

## **Output Arguments**

### **status - Status of the write operation**

1 | 0

Status of the write operation, returned as either 1 (true) or 0 (false). When the write operation is successful, `status` is 1. Otherwise, `status` is 0.

### **message - Error or warning generated during the write operation**

structure array

Error or warning generated during the write operation, returned as a structure array containing two fields:

`message`      Text of the warning or error message, returned as a string.

`identifier`    Message identifier, returned as a string.

## Examples

### Write Data to a Spreadsheet

Write a 7-element vector to an Excel file, `testdata.xlsx`.

```
filename = 'testdata.xlsx';  
A = [12.7, 5.02, -98, 63.9, 0, -.2, 56];  
xlswrite(filename,A)
```

### Write Data to a Specific Sheet and Range in a Spreadsheet

Write mixed text and numeric data to an Excel file, `testdata.xlsx`, starting at cell E1 of Sheet2.

```
filename = 'testdata.xlsx';  
A = {'Time', 'Temperature'; 12,98; 13,99; 14,97};  
sheet = 2;  
xlRange = 'E1';  
xlswrite(filename,A,sheet,xlRange)
```

## Tips

- If your system has Microsoft Office 2003 software, but you want to create a file in an Excel 2007 format, install the Office 2007 Compatibility Pack.
- Excel and MATLAB can store dates as strings (such as '10/31/96') or serial date numbers (such as 729329). If your array `A` includes serial date numbers, convert the dates to strings using `datestr` before calling `xlswrite`. Alternatively, see [Converting Dates](#).
- To write data to Excel files with custom formats (such as fonts or colors), access the Windows COM server directly using `actxserver`

rather than `xlswrite`. For example, Technical Solution 1-QLD4K uses `actxserver` to establish a connection between MATLAB and Excel, writes data to a worksheet, and specifies the colors of the cells.

## Algorithms

Excel converts `Inf` values to 65535. MATLAB converts `NaN` values to empty cells.

If your system does not have Excel for Windows, or if the COM server (part of the typical installation of Excel) is unavailable, then the `xlswrite` function:

- Writes array `A` to a text file in comma-separated value (CSV) format.
- Ignores the `sheet` and `xlRange` arguments.
- Generates an error when input array `A` is a cell array.

# xmlread

---

<b>Purpose</b>	Read XML document and return Document Object Model node
<b>Syntax</b>	<code>DOMnode = xmlread(filename)</code>
<b>Description</b>	<code>DOMnode = xmlread(filename)</code> reads the specified XML file and returns a Document Object Model node representing the document.
<b>Tips</b>	<p>The display for a properly parsed document is <code>[#document: null]</code>. For example,</p> <pre>xDoc = xmlread('info.xml')</pre> <p>returns</p> <pre>xDoc = [#document: null]</pre>
<b>Input Arguments</b>	<p><b>filename</b></p> <p>String enclosed in single quotation marks that specifies the name of the local file or URL.</p>
<b>Output Arguments</b>	<p><b>DOMnode</b></p> <p>Document Object Model node, as defined by the World Wide Web consortium. For more information, see “What Is an XML Document Object Model (DOM)?”.</p>
<b>Examples</b>	<p>The root element in an XML file sometimes includes an <code>xsi:noNamespaceSchemaLocation</code> attribute. The value of this attribute is the name of the preferred schema file. Call the <code>getAttribute</code> method to get this value:</p> <pre>xDoc = xmlread(fullfile(matlabroot,'toolbox',...                         'matlab','general','info.xml'));  xRoot = xDoc.getDocumentElement; schema = char(xRoot.getAttribute('xsi:noNamespaceSchemaLocation'))</pre>

This code returns:

```
schema =  
http://www.mathworks.com/namespace/info/v1/info.xsd
```

---

Create functions that parse data from an XML file into a MATLAB structure array with fields Name, Attributes, Data, and Children:

```
function theStruct = parseXML(filename)  
% PARSEXML Convert XML file to a MATLAB structure.  
try  
    tree = xmlread(filename);  
catch  
    error('Failed to read XML file %s.',filename);  
end  
  
% Recurse over child nodes. This could run into problems  
% with very deeply nested trees.  
try  
    theStruct = parseChildNodes(tree);  
catch  
    error('Unable to parse XML file %s.',filename);  
end  
  
% ----- Local function PARSECHILDNODES -----  
function children = parseChildNodes(theNode)  
% Recurse over node children.  
children = [];  
if theNode.hasChildNodes  
    childNodes = theNode.getChildNodes;  
    numChildNodes = childNodes.getLength;  
    allocCell = cell(1, numChildNodes);  
  
    children = struct( ...  
        'Name', allocCell, 'Attributes', allocCell, ...
```

```
        'Data', allocCell, 'Children', allocCell);

    for count = 1:numChildNodes
        theChild = childNodes.item(count-1);
        children(count) = makeStructFromNode(theChild);
    end
end

% ----- Local function MAKESTRUCTFROMNODE -----
function nodeStruct = makeStructFromNode(theNode)
% Create structure of node info.

nodeStruct = struct(
    'Name', char(theNode.getNodeName), ...
    'Attributes', parseAttributes(theNode), ...
    'Data', '', ...
    'Children', parseChildNodes(theNode));

if any(strcmp(methods(theNode), 'getData'))
    nodeStruct.Data = char(theNode.getData);
else
    nodeStruct.Data = '';
end

% ----- Local function PARSEATTRIBUTES -----
function attributes = parseAttributes(theNode)
% Create attributes structure.

attributes = [];
if theNode.hasAttributes
    theAttributes = theNode.getAttributes;
    numAttributes = theAttributes.getLength;
    allocCell = cell(1, numAttributes);
    attributes = struct('Name', allocCell, 'Value', ...
        allocCell);

    for count = 1:numAttributes
```

```
        attrib = theAttributes.item(count-1);
        attributes(count).Name = char(attrib.getName);
        attributes(count).Value = char(attrib.getValue);
    end
end
```

# xmlwrite

---

**Purpose** Write XML Document Object Model node

**Syntax** `xmlwrite(filename,DOMnode)`  
`str = xmlwrite(DOMnode)`

**Description** `xmlwrite(filename,DOMnode)` writes the Document Object Model (DOM) node `DOMnode` to the file `filename`.

`str = xmlwrite(DOMnode)` serializes the DOM node to a string.

**Input Arguments**

**filename**

String enclosed in single quotation marks that specifies the name of a local file or a URL.

**DOMnode**

Document Object Model node, as defined by the World Wide Web consortium. For more information, see “What Is an XML Document Object Model (DOM)?”

**Output Arguments**

**str**

String that contains the serialized DOM node as it appears in an XML file.

**Examples**

Create and view an XML document:

```
docNode = com.mathworks.xml.XMLUtils.createDocument...
    ('root_element')
docRootNode = docNode.getDocumentElement;
docRootNode.setAttribute('attr_name','attr_value');
for i=1:20
    thisElement = docNode.createElement('child_node');
    thisElement.appendChild...
        (docNode.createTextNode(sprintf('%i',i)));
    docRootNode.appendChild(thisElement);
end
```

```
docNode.appendChild(docNode.createComment('this is a comment'));

xmlFileName = [tempname, '.xml'];
xmlwrite(xmlFileName, docNode);
type(xmlFileName);
```

# xor

---

**Purpose** Logical exclusive-OR

**Syntax** `C = xor(A, B)`

**Description** `C = xor(A, B)` performs an exclusive OR operation on the corresponding elements of arrays A and B. The resulting element `C(i, j, ...)` is logical true (1) if `A(i, j, ...)` or `B(i, j, ...)`, but not both, is nonzero.

<b>A</b>	<b>B</b>	<b>C</b>
Zero	Zero	0
Zero	Nonzero	1
Nonzero	Zero	1
Nonzero	Nonzero	0

**Examples** Given `A = [0 0 pi eps]` and `B = [0 -2.4 0 1]`, then

```
C = xor(A,B)
C =
     0     1     1     0
```

To see where either A or B has a nonzero element and the other matrix does not,

```
spy(xor(A,B))
```

---

<b>Purpose</b>	Transform XML document using XSLT engine
<b>Syntax</b>	<pre>result = xslt(source, style, dest) [result,style] = xslt( ___ ) xslt( ___ , '-web' )</pre>
<b>Description</b>	<p><code>result = xslt(source, style, dest)</code> transforms an XML document using a stylesheet and returns the resulting document's URL. The function uses these inputs, the first of which is required:</p> <ul style="list-style-type: none"><li>• <code>source</code> is the filename or URL of the source XML file. <code>source</code> can also specify a DOM node.</li><li>• <code>style</code> is the filename or URL of an XSL stylesheet.</li><li>• <code>dest</code> is the filename or URL of the desired output document. If <code>dest</code> is absent or empty, the function uses a temporary filename. If <code>dest</code> is <code>'-tostring'</code>, the function returns the output document as a MATLAB string.</li></ul> <p><code>[result,style] = xslt( ___ )</code> returns a processed stylesheet appropriate for passing to subsequent XSLT calls as <code>style</code>. This prevents costly repeated processing of the stylesheet.</p> <p><code>xslt( ___ , '-web' )</code> displays the resulting document in the Help Browser.</p>
<b>Tips</b>	<p>MATLAB uses the Saxon XSLT processor, version 6.5.5, which supports XSLT 1.0 expressions. For more information, see <a href="http://saxon.sourceforge.net/saxon6.5.5/">http://saxon.sourceforge.net/saxon6.5.5/</a></p> <p>For additional information on writing XSL stylesheets, see the World Wide Web Consortium (W3C®) web site, <a href="http://www.w3.org/Style/XSL/">http://www.w3.org/Style/XSL/</a>.</p>
<b>Examples</b>	<p>This example converts the file <code>info.xml</code> using the stylesheet <code>info.xsl</code>, writing the output to the file <code>info.html</code>. It launches the resulting HTML file in the MATLAB Web Browser.</p>

# xslt

---

```
xslt('info.xml', 'info.xsl', 'info.html', '-web')
```

## See Also

`xmlread` | `xmlwrite`

**Purpose**

Create array of all zeros

**Syntax**

```
X = zeros
X = zeros(n)
X = zeros(sz1,...,szN)
X = zeros(sz)

X = zeros(classname)
X = zeros(n,classname)
X = zeros(sz1,...,szN,classname)
X = zeros(sz,classname)

X = zeros('like',p)
X = zeros(n,'like',p)
X = zeros(sz1,...,szN,'like',p)
X = zeros(sz,'like',p)
```

**Description**

`X = zeros` returns the scalar 0.

`X = zeros(n)` returns an n-by-n matrix of zeros.

`X = zeros(sz1,...,szN)` returns an sz1-by-...-by-szN array of zeros where sz1,...,szN indicates the size of each dimension. For example, `zeros(2,3)` returns a 2-by-3 array of zeros.

`X = zeros(sz)` returns an array of zeros where the size vector, sz, defines `size(X)`. For example, `zeros([2,3])` returns a 2-by-3 array of zeros.

`X = zeros(classname)` returns a scalar 0 where the string, classname, specifies the data type. For example, `zeros('int8')` returns a scalar, 8-bit integer 0.

# zeros

---

`X = zeros(n,classname)` returns an n-by-n array of zeros of data type `classname`.

`X = zeros(sz1,...,szN,classname)` returns an sz1-by-...-by-szN array of zeros of data type `classname`.

`X = zeros(sz,classname)` returns an array of zeros where the size vector, `sz`, defines `size(X)` and `classname` defines `class(X)`.

`X = zeros('like',p)` returns a scalar 0 with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = zeros(n,'like',p)` returns an n-by-n array of zeros like `p`.

`X = zeros(sz1,...,szN,'like',p)` returns an sz1-by-...-by-szN array of zeros like `p`.

`X = zeros(sz,'like',p)` returns an array of zeros like `p` where the size vector, `sz`, defines `size(X)`.

## Input Arguments

### **n - Size of square matrix**

integer value

Size of square matrix, specified as an integer value, defines the output as a square, n-by-n matrix of zeros.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### **sz1,...,szN - Size of each dimension**

two or more integer values

Size of each dimension, specified as two or more integer values, defines X as a sz1-by...-by-szN array.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

#### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

#### sz - Output size

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

**Example:** sz = [2,3,4] defines X as a 2-by-3-by-4 array.

#### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

#### classname - Output class

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

#### Data Types

char

## **p - Prototype**

numeric variable

Prototype, specified as a numeric variable.

## **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**Complex Number Support:** Yes

## **Examples**

### **Square Array of Zeros**

Create a 4-by-4 array of zeros.

```
X = zeros(4)
```

```
X =
```

```
    0    0    0    0
    0    0    0    0
    0    0    0    0
    0    0    0    0
```

### **3-D Array of Zeros**

Create a 2-by-3-by-4 array of zeros.

```
X = zeros(2,3,4);
```

```
size(X)
```

```
ans =
```

```
    2    3    4
```

### **Size Defined by Existing Array**

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)
```

```
sz =
```

```
     3     2
```

Create an array of zeros that is the same size as A

```
X = zeros(sz)
```

```
X =
```

```
     0     0
     0     0
     0     0
```

### **Nondefault Numeric Data Type**

Create a 1-by-3 vector of zeros whose elements are 32-bit unsigned integers.

```
X = zeros(1,3,'uint32'),  
class(X)
```

```
X =
```

```
     0     0     0
```

```
ans =
```

```
uint32
```

### **Complex Zero**

Create a scalar 0 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar 0 that is complex like p.

```
X = zeros('like',p)
```

```
X =
```

```
0.0000 + 0.0000i
```

## **Sparse Array**

Define a 10-by-10 sparse matrix.

```
p = sparse(10,10,pi);
```

Create a 2-by-3 matrix of zeros that is sparse like p.

```
X = zeros(2,3,'like',p)
```

```
X =
```

```
All zero sparse: 2-by-3
```

## **Size and Numeric Data Type Defined by Existing Array**

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of zeros that is the same size and data type as p.

```
X = zeros(size(p),'like',p),  
class(X)
```

```
X =
```

```
0 0 0  
0 0 0
```

```
ans =
```

```
uint8
```

**Concepts**

- “Preallocating Arrays”

**Purpose** Compress files into zip file

**Syntax**

```
zip(zipfile,files)
zip(zipfile,files,rootfolder)
entrynames = zip(zipfile,files,rootfolder)
```

**Description** `zip(zipfile,files)` creates a zip file with the name `zipfile` from the list of files and folders specified in `files`. Folders recursively include all of their content.

`zip(zipfile,files,rootfolder)` specifies the path for files relative to `rootfolder` instead of the current folder.

`entrynames = zip(zipfile,files,rootfolder)` returns a string cell array of the names of the files contained in `zipfile`. Specifying `rootfolder` is optional.

## Input Arguments

### **zipfile**

String that specifies the name of the zip file. If `zipfile` has no extension, MATLAB appends the `.zip` extension.

If `files` includes relative paths, the zip file also contains relative paths. The zip file does not include absolute paths.

### **files**

String or cell array of strings containing the list of files or folders to include in `zipfile`.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

**rootfolder**

String that specifies the root of the paths for the files to zip.

Relative paths in the zip file reflect the relative paths in files, and do not include path information from `rootfolder`.

**Default:** current folder ('.')

**Output Arguments****entrynames**

Cell array of strings that contain the paths to the files in `zipfile`. If `files` includes relative paths, `entrynames` also contains relative paths.

**Examples****Zip a File**

Create a zip file of the file `membrane.m`, which is in the MATLAB general folder. Save the zip file `tmwlogo.zip` in the current folder:

```
file = fullfile(matlabroot,'toolbox','matlab','general','membrane.m');  
zip('tmwlogo',file);
```

**Zip Selected Files**

Suppose that your system has a folder named `d:/myfiles`. Zip the files `membrane.m` and `logo.m`, which are on the MATLAB search path, into a file named `tmwlogo.zip`:

```
myfile = fullfile('d:','myfiles','tmwlogo.zip');  
zip(myfile,{'membrane.m','logo.m'});
```

Zip all `.m` and `.mat` files in the current folder to the file `backup.zip`:

```
zip('backup',{'*.m','*.mat'});
```

**Zip a Folder**

Suppose that your current folder contains a subfolder named `mywork`. Zip the contents of all subfolders of `mywork`, and store the relative paths in the zip file:

# zip

---

```
zip('myfiles.zip','mywork');
```

## Zip Between Folders

Suppose that you have files `thesis.doc` and `defense.ppt` in `d:/PhD`. Zip these files into `thesis.zip`, one level up from the current folder:

```
zip('../thesis.zip',{'thesis.doc','defense.ppt'],'d:/PhD');
```

## Alternatives

To zip files in the Current Folder browser, select the files, right-click to open the context menu, and then select **Create Zip File**.

## See Also

`gzip` | `gunzip` | `tar` | `untar` | `unzip`

**Purpose** Turn zooming on or off or magnify by factor

**Syntax**

```
zoom on
zoom off
zoom out
zoom reset
zoom
zoom xon
zoom yon
zoom(factor)
zoom(fig, option)
h = zoom(figure_handle)
```

**Description** `zoom on` turns on interactive zooming. When interactive zooming is enabled in a figure, pressing a mouse button while your cursor is within an axes zooms into the point or out from the point beneath the mouse. Zooming changes the axes limits. When using zoom mode, you

- Zoom in by positioning the mouse cursor where you want the center of the plot to be and either
  - Press the mouse button or
  - Rotate the mouse scroll wheel away from you (upward).
- Zoom out by positioning the mouse cursor where you want the center of the plot to be and either
  - Simultaneously press **Shift** and the mouse button, or
  - Rotate the mouse scroll wheel toward you (downward).

Each mouse click or scroll wheel click zooms in or out by a factor of 2.

Clicking and dragging over an axes when zooming in is enabled draws a rubberband box. When you release the mouse button, the axes zoom in to the region enclosed by the rubberband box.

Double-clicking over an axes returns the axes to its initial zoom setting in both zoom-in and zoom-out modes.

`zoom off` turns interactive zooming off.

`zoom out` returns the plot to its initial zoom setting.

`zoom reset` remembers the current zoom setting as the initial zoom setting. Later calls to `zoom out`, or double-clicks when interactive zoom mode is enabled, will return to this zoom level.

`zoom` toggles the interactive zoom status between off and on (restoring the most recently used zoom tool).

`zoom xon` and `zoom yon` set `zoom on` for the  $x$ - and  $y$ -axis, respectively.

`zoom(factor)` zooms in or out by the specified zoom factor, without affecting the interactive zoom mode. Values greater than 1 zoom in by that amount, while numbers greater than 0 and less than 1 zoom out by  $1/\text{factor}$ .

`zoom(fig, option)` Any of the preceding options can be specified on a figure other than the current figure using this syntax.

`h = zoom(figure_handle)` returns a *zoom mode object* for the figure `figure_handle` for you to customize the mode's behavior.

## Using Zoom Mode Objects

Access the following properties of zoom mode objects via `get` and modify some of them using `set`.

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *FigureHandle* <handle> — The associated figure handle, a read-only property that cannot be set
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of zooming enabled for the figure
- *Direction* 'in' | 'out' — The direction of the zoom operation
- *RightClickAction* 'InverseZoom' | 'PostContextMenu' — The behavior of a right-click action

A value of 'InverseZoom' causes a right-click to zoom out. A value of 'PostContextMenu' displays a context menu. This setting persists between MATLAB sessions.

- `UIContextMenu <handle>` — Specifies a custom context menu to be displayed during a right-click action

This property is ignored if the `RightClickAction` property has been set to `'on'`.

## Zoom Mode Callbacks

You can program the following callbacks for zoom mode operations.

- `ButtonDownFilter <function_handle>` — Function to intercept `ButtonDown` events

The application can inhibit the zoom operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function [res] = myfunction(obj,event_obj)
% obj          handle to the object that has been clicked on
% event_obj    struct for event data (empty in this release)
% res [output] a logical flag determines whether the zoom
%              operation should take place(for 'res' set to 'false'
%              or the 'ButtonDownFcn' property of the object should
%              take precedence (when 'res' is 'true'))
```

- `ActionPreCallback <function_handle>` — Function to execute before zooming

Set this callback if you want to execute code when a zoom operation starts. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on.
% event_obj    object containing struct of event data
```

The event data has the following field.

Axes	The handle of the axes that is being zoomed
------	---------------------------------------------

- **ActionPostCallback** <function\_handle> — Function to execute after zooming

Set this callback if you want to execute code when a zoom operation finishes. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

## Zoom Mode Utility Functions

The following functions in zoom mode query and set certain of its properties.

- **flags = isAllowAxesZoom(h,axes)** — Function querying permission to zoom axes

Calling the function `isAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a zoom operation is permitted on the axes objects.

- **setAllowAxesZoom(h,axes,flag)** — Function to set permission to zoom axes

Calling the function `setAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a zoom operation on the axes objects.

- **info = getAxesZoomMotion(h,axes)** — Function to get style of zoom operations

Calling the function `getAxesZoomMotion` on the zoom object, `H`, with a vector of axes handles, `axes`, as input returns a character cell array of the same dimension as the axes handle vector, which indicates the type of zoom operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical', or 'both'.

- `setAxesZoomMotion(h,axes,style)` — Function to set style of zoom operations

Calling the function `setAxesZoomMotion` on the zoom object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of zooming on each axes.

## Examples

### Example 1 – Entering Zoom Mode

Plot a graph and turn on Zoom mode:

```
plot(1:10);  
zoom on  
% zoom in on the plot
```

### Example 2 – Constrained Zoom

Create zoom mode object and constrain to *x*-axis zooming:

```
plot(1:10);  
h = zoom;  
set(h,'Motion','horizontal','Enable','on');  
% zoom in on the plot in the horizontal direction.
```

### Example 3 – Constrained Zoom in Subplots

Create four axes as subplots and set zoom style differently for each by setting a different property for each axes handle:

```
ax1 = subplot(2,2,1);  
plot(1:10);  
h = zoom;  
ax2 = subplot(2,2,2);  
plot(rand(3));
```

```
setAllowAxesZoom(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesZoomMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesZoomMotion(h,ax4,'vertical');
% Zoom in on the plots.
```

## Example 4 – Coding a ButtonDown Callback

Create a `ButtonDown` callback for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zooming behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = zoom;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
    flag = true;
else
    flag = false;
end
```

### Example 5 – Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-buttonDown events for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zoom behavior:

```
function demo
% Listen to zoom events
plot(1:10);
h = zoom;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
%
function myprecallback(obj,evd)
disp('A zoom is about to occur.');
```

```
%
function mypostcallback(obj,evd)
newLim = get(evd.Axes,'XLim');
msgbox(sprintf('The new X-Limits are [%.2f %.2f].',newLim));
```

### Example 6 – Creating a Context Menu for Zoom Mode

Coding a context menu that lets the user to switch to Pan mode by right-clicking:

```
figure;plot(magic(10))
hCMZ = uicontextmenu;
hZMenu = uimenu('Parent',hCMZ,'Label','Switch to pan',...
'Callback','pan(gcf,'on')');
hZoom = zoom(gcf);
set(hZoom,'UIContextMenu',hCMZ);
zoom('on')
```

You cannot add items to the built-in zoom context menu, but you can replace it with your own.

# zoom

---

## Tips

zoom changes the axes limits by a factor of 2 (in or out) each time you press the mouse button while the cursor is within an axes. You can also click and drag the mouse to define a zoom area, or double-click to return to the initial zoom level.

You can create a zoom mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure's callbacks, the GUI should somehow keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different zoom behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the Zoom tools  on the figure toolbar to zoom in or zoom out on a plot, or select **Zoom In** or **Zoom Out** from the figure's **Tools** menu. For details, see “Zooming in Graphs”.

.NET  
    summary of functions 1-4014  
netcdf  
    summary of capabilities 1-4129  
netcdf.abort  
    revert recent netCDF file definitions 1-4070  
netcdf.close  
    close netCDF file 1-4072  
netcdf.copyAtt  
    copy attribute to new location 1-4073  
netcdf.create  
    create netCDF file 1-4075  
netcdf.defDim  
    create dimension in netCDF file 1-4077  
netcdf.defVar  
    define variable in netCDF dataset 1-4079  
netcdf.delAtt  
    delete netCDF attribute 1-4088  
netcdf.endDef  
    takes a netCDF file out of define mode 1-4090  
netcdf.getAtt  
    return data from netCDF attribute 1-4092  
netcdf.getConstant  
    get numeric value of netCDF constant 1-4095  
netcdf.getConstantNames  
    get list of netCDF constants 1-4096  
netcdf.getVar  
    return data from netCDF variable 1-4097  
netcdf.inq  
    return information about netCDF file 1-4100  
netcdf.inqAtt  
    return information about a netCDF  
        attribute 1-4121  
netcdf.inqAttID  
    return identifier of netCDF attribute 1-4123  
netcdf.inqAttName  
    return name of netCDF attribute 1-4124  
netcdf.inqDim  
    return information about netCDF  
        dimension 1-4126  
netcdf.inqDimID  
    return dimension ID for netCDF file 1-4127  
netcdf.inqLibVers  
    return version of netCDF library 1-4128  
netcdf.inqVarID  
    return netCDF variable identifier 1-4131  
netcdf.open  
    open an existing netCDF file 1-4132  
netcdf.putAtt  
    write a netCDF attribute 1-4134  
netcdf.putVar  
    write data to netCDF variable 1-4136  
netcdf.reDef  
    put netCDF file into define mode 1-4139  
netcdf.renameAtt  
    netCDF function to change the name of an  
        attribute 1-4140  
netcdf.renameDim  
    netCDF function to change the name of a  
        dimension 1-4142  
netcdf.renameVar  
    change the name of a netCDF  
        variable 1-4143  
netcdf.setDefaultFormat  
    change the default netCDF file format 1-4147  
netcdf.setFill  
    set netCDF fill behavior 1-4148  
netcdf.sync  
    synchronize netCDF dataset to disk 1-4149  
newplot 1-4150
